Sun Performance Library[tm] Reference Manual

Sun [tm] ONE Studio 8

This reference manual is the Sun Performance Library section 3P man pages, available in HTML and PDF formats. For additional information, see the *Sun Performance Library User's Guide*, available on `docs.sun.com`, or the *LAPACK Users' Guide*, available from the Society for Industrial and Applied Mathematics (SIAM).

[available_threads](#) - available_threads - returns information about current thread usage

[blas_dpermute](#) - blas_dpermute - permutes a real (double precision) array in terms of the permutation vector P, output by dsortv

[blas_dsort](#) - blas_dsort - sorts a real (double precision) vector X in increasing or decreasing order using quick sort algorithm

[blas_dsortv](#) - blas_dsortv - sorts a real (double precision) vector X in increasing or decreasing order using quick sort algorithm and overwrite P with the permutation vector

[blas_ipermute](#) - blas_ipermute - permutes an integer array in terms of the permutation vector P, output by dsortv

[blas_isort](#) - blas_isort - sorts an integer vector X in increasing or decreasing order using quick sort algorithm

[blas_isortv](#) - blas_isortv - sorts a real vector X in increasing or decreasing order using quick sort algorithm and overwrite P with the permutation vector

[blas_spermute](#) - blas_spermute - permutes a real array in terms of the permutation vector P, output by dsortv

[blas_ssort](#) - blas_ssort - sorts a real vector X in increasing or decreasing order using quick sort algorithm

[blas_ssortv](#) - blas_ssortv - sorts a real vector X in increasing or decreasing order using quick sort algorithm and overwrite P with the permutation vector

[caxpy](#) - caxpy - compute $y := \alpha * x + y$

[caxpyi](#) - caxpyi - Compute $y := \alpha * x + y$

[cbcomm](#) - cbcomm - block coordinate matrix-matrix multiply

[cbdimm](#) - cbdimm - block diagonal format matrix-matrix multiply

[cbdism](#) - cbdism - block diagonal format triangular solve

[cbdsqr](#) - cbdsqr - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B.

[cbelmm](#) - cbelmm - block Ellpack format matrix-matrix multiply

[cbelsm](#) - cbelsm - block Ellpack format triangular solve

[cbscmm](#) - cbscmm - block sparse column matrix-matrix multiply

[cbscsm](#) - cbscsm - block sparse column format triangular solve

[cbsrmm](#) - cbsrmm - block sparse row format matrix-matrix multiply

[cbsrsm](#) - cbsrsm - block sparse row format triangular solve

[cnvcor](#) - cnvcor - compute the convolution or correlation of complex vectors

[cnvcor2](#) - cnvcor2 - compute the convolution or correlation of complex matrices

[ccoomm](#) - ccoomm - coordinate matrix-matrix multiply

[ccopy](#) - ccopy - Copy x to y

[ccscmm](#) - ccscmm - compressed sparse column format matrix-matrix multiply

[ccscsm](#) - ccscsm - compressed sparse column format triangular solve

[ccsrmm](#) - ccsrmm - compressed sparse row format matrix-matrix multiply

[ccsrsm](#) - ccsrsm - compressed sparse row format triangular solve

[cdiamm](#) - cdiamm - diagonal format matrix-matrix multiply

[cdiasm](#) - cdiasm - diagonal format triangular solve

[cdotc](#) - cdotc - compute the dot product of two vectors $\text{conjg}(x)$ and y .

[cdotci](#) - cdotci - Compute the complex conjugated indexed dot product.

[cdotu](#) - cdotu - compute the dot product of two vectors x and y .

[cdotui](#) - cdotui - Compute the complex conjugated indexed dot product.

[cellmm](#) - cellmm - Ellpack format matrix-matrix multiply

[cellsm](#) - cellsm - Ellpack format triangular solve

[cfft2b](#) - cfft2b - compute a periodic sequence from its Fourier coefficients. The xFFT operations are unnormalized, so a call of xFFT2F followed by a call of xFFT2B will multiply the input sequence by $M*N$.

[cfft2f](#) - cfft2f - compute the Fourier coefficients of a periodic sequence. The xFFT operations are unnormalized, so a call of xFFT2F followed by a call of xFFT2B will multiply the input sequence by $M*N$.

[cfft2i](#) - cfft2i - initialize the array WSAVE, which is used in both the forward and backward transforms.

[cfft3b](#) - cfft3b - compute a periodic sequence from its Fourier coefficients. The FFT operations are unnormalized, so a call of CFFT3F followed by a call of CFFT3B will multiply the input sequence by $M*N*K$.

[cfft3f](#) - cfft3f - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of CFFT3F followed by a call of CFFT3B will multiply the input sequence by $M*N*K$.

[cfft3i](#) - cfft3i - initialize the array WSAVE, which is used in both CFFT3F and CFFT3B.

[cftfb](#) - cftfb - compute a periodic sequence from its Fourier coefficients. The FFT operations are unnormalized, so a call of CFFTF followed by a call of CFFTB will multiply the input sequence by N .

[cftfc](#) - cftfc - initialize the trigonometric weight and factor tables or compute the Fast Fourier transform (forward or inverse) of a complex sequence.

[cftfc2](#) - cftfc2 - initialize the trigonometric weight and factor tables or compute the two-dimensional Fast Fourier Transform (forward or inverse) of a two-dimensional complex array.

[cftfc3](#) - cftfc3 - initialize the trigonometric weight and factor tables or compute the three-dimensional Fast Fourier Transform (forward or inverse) of a three-dimensional complex array.

[cftfcm](#) - cftfcm - initialize the trigonometric weight and factor tables or compute the one-dimensional Fast Fourier Transform (forward or inverse) of a set of data sequences stored in a two-dimensional complex array.

[cftff](#) - cftff - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of CFFTF followed by a call of CFFTB will multiply the input sequence by N .

[cftfi](#) - cftfi - initialize the array WSAVE, which is used in both CFFTF and CFFTB.

[cftfpt](#) - cftfpt - compute the length of the closest fast FFT

[cftfs](#) - cftfs - initialize the trigonometric weight and factor tables or compute the inverse Fast Fourier Transform of a complex sequence as follows.

[cftfs2](#) - cftfs2 - initialize the trigonometric weight and factor tables or compute the two-dimensional inverse Fast Fourier Transform of a two-dimensional complex array.

[cftfs3](#) - cftfs3 - initialize the trigonometric weight and factor tables or compute the three-dimensional inverse Fast Fourier Transform of a three-dimensional complex array.

[cftfsm](#) - cftfsm - initialize the trigonometric weight and factor tables or compute the one-dimensional inverse Fast Fourier Transform of a set of complex data sequences stored in a two-dimensional array.

[cgbbird](#) - cgbbird - reduce a complex general m -by- n band matrix A to real upper bidiagonal form B by a unitary transformation

[cgbson](#) - cgbson - estimate the reciprocal of the condition number of a complex general band matrix A, in either the 1-norm or the infinity-norm,

[cgbequ](#) - cgbequ - compute row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number

[cgbmvm](#) - cgbmvm - perform one of the matrix-vector operations $y := \alpha * A * x + \beta * y$, or $y := \alpha * A' * x + \beta * y$, or $y := \alpha * \text{conjg}(A') * x + \beta * y$

[cgbrfs](#) - cgbrfs - improve the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution

[cgbsv](#) - cgbsv - compute the solution to a complex system of linear equations $A * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices

[cgbsvx](#) - cgbsvx - use the LU factorization to compute the solution to a complex system of linear equations $A * X = B$, $A ** T * X = B$, or $A ** H * X = B$,

[cgbtf2](#) - cgbtf2 - compute an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges

[cgbtrf](#) - cgbtrf - compute an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges

[cgbtrs](#) - cgbtrs - solve a system of linear equations $A * X = B$, $A ** T * X = B$, or $A ** H * X = B$ with a general band matrix A using the LU factorization computed by CGBTRF

[cgebak](#) - cgebak - form the right or left eigenvectors of a complex general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by CGEBAL

[cgebal](#) - cgebal - balance a general complex matrix A

[cgebrd](#) - cgebrd - reduce a general complex M-by-N matrix A to upper or lower bidiagonal form B by a unitary transformation

[cgecon](#) - cgecon - estimate the reciprocal of the condition number of a general complex matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by CGETRF

[cgeequ](#) - cgeequ - compute row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number

[cgees](#) - cgees - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z

[cgeesx](#) - cgeesx - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z

[cgeev](#) - cgeev - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

[cgeevx](#) - cgeevx - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

[cgegs](#) - cgegs - routine is deprecated and has been replaced by routine CGGES

[cgegv](#) - cgegv - routine is deprecated and has been replaced by routine CGGEV

[cgehrd](#) - cgehrd - reduce a complex general matrix A to upper Hessenberg form H by a unitary similarity transformation

[cgelqf](#) - cgelqf - compute an LQ factorization of a complex M-by-N matrix A

[cgels](#) - cgels - solve overdetermined or underdetermined complex linear systems involving an M-by-N matrix A, or its conjugate-transpose, using a QR or LQ factorization of A

[cgelsd](#) - cgelsd - compute the minimum-norm solution to a real linear least squares problem

[cgelss](#) - cgelss - compute the minimum norm solution to a complex linear least squares problem

[cgelsx](#) - cgelsx - routine is deprecated and has been replaced by routine CGELSY

[cgelsy](#) - cgelsy - compute the minimum-norm solution to a complex linear least squares problem

[cgemm](#) - cgemm - perform one of the matrix-matrix operations $C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C$

[cgemv](#) - cgemv - perform one of the matrix-vector operations $y := \alpha * A * x + \beta * y$, or $y := \alpha * A' * x + \beta * y$, or $y := \alpha * \text{conjg}(A') * x + \beta * y$

[cgeqlf](#) - cgeqlf - compute a QL factorization of a complex M-by-N matrix A

[cgeqp3](#) - cgeqp3 - compute a QR factorization with column pivoting of a matrix A

[cgeqpf](#) - cgeqpf - routine is deprecated and has been replaced by routine CGEQP3

[cgeqrf](#) - cgeqrf - compute a QR factorization of a complex M-by-N matrix A

[cgerc](#) - cgerc - perform the rank 1 operation $A := \alpha * x * \text{conjg}(y') + A$

[cgerfs](#) - cgerfs - improve the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution

[cgerqf](#) - cgerqf - compute an RQ factorization of a complex M-by-N matrix A

[cgeru](#) - cgeru - perform the rank 1 operation $A := \alpha * x * y' + A$

[cgesdd](#) - cgesdd - compute the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors, by using divide-and-conquer method

[cgesv](#) - cgesv - compute the solution to a complex system of linear equations $A * X = B$,

[cgesvd](#) - cgesvd - compute the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors

[cgesvx](#) - cgesvx - use the LU factorization to compute the solution to a complex system of linear equations $A * X = B$,

[cgetf2](#) - cgetf2 - compute an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges

[cgetrf](#) - cgetrf - compute an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges

[cgetri](#) - cgetri - compute the inverse of a matrix using the LU factorization computed by CGETRF

[cgetrs](#) - cgetrs - solve a system of linear equations $A * X = B$, $A ** T * X = B$, or $A ** H * X = B$ with a general N-by-N matrix A using the LU factorization computed by CGETRF

[cggbak](#) - cggbak - form the right or left eigenvectors of a complex generalized eigenvalue problem $A * x = \lambda * B * x$, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by CGGBAL

[cggbal](#) - cggbal - balance a pair of general complex matrices (A,B)

[cgges](#) - cgges - compute for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized complex Schur form (S, T), and optionally left and/or right Schur vectors (VSL and VSR)

[cggesx](#) - cggesx - compute for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the complex Schur form (S,T),

[cggev](#) - cggev - compute for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors

[cggevz](#) - cggevz - compute for a pair of N-by-N complex nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors

[cgglm](#) - cgglm - solve a general Gauss-Markov linear model (GLM) problem

[cgghrd](#) - cgghrd - reduce a pair of complex matrices (A,B) to generalized upper Hessenberg form using unitary transformations, where A is a general matrix and B is upper triangular

[cgglse](#) - cgglse - solve the linear equality-constrained least squares (LSE) problem

[cggrqf](#) - cggrqf - compute a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B.

[cggrqf](#) - cggrqf - compute a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B

[cggsvd](#) - cggsvd - compute the generalized singular value decomposition (GSVD) of an M-by-N complex matrix A and P-by-N complex matrix B

[cggsvp](#) - cggsvp - compute unitary matrices U, V and Q such that $N-K-L \begin{matrix} K & L \\ U^* & A^* & Q \end{matrix} = K \begin{pmatrix} 0 & A_{12} & A_{13} \end{pmatrix}$ if $M-K-L \geq 0$

[cgssco](#) - cgssco - General sparse solver condition number estimate.

[cgssda](#) - cgssda - Deallocate working storage for the general sparse solver.

[cgssfa](#) - cgssfa - General sparse solver numeric factorization.

[cgssfs](#) - cgssfs - General sparse solver one call interface.

[cgssin](#) - cgssin - Initialize the general sparse solver.

[cgssor](#) - cgssor - General sparse solver ordering and symbolic factorization.

[cgssps](#) - cgssps - Print general sparse solver statics.

[cgssrp](#) - cgssrp - Return permutation used by the general sparse solver.

[cgsssl](#) - cgsssl - Solve routine for the general sparse solver.

[cgssuo](#) - cgssuo - User supplied permutation for ordering used in the general sparse solver.

[cgtrcon](#) - cgtrcon - estimate the reciprocal of the condition number of a complex tridiagonal matrix A using the LU factorization as computed by CGTTRF

[cgthr](#) - cgthr - Gathers specified elements from y into x.

[cgthrz](#) - cgthrz - Gather and zero.

[cgtrfs](#) - cgtrfs - improve the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution

[cgtsv](#) - cgtsv - solve the equation $A^*X = B$,

[cgtsvx](#) - cgtsvx - use the LU factorization to compute the solution to a complex system of linear equations $A^*X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$,

[cgtrf](#) - cgtrf - compute an LU factorization of a complex tridiagonal matrix A using elimination with partial pivoting and row interchanges

[cgtrrs](#) - cgtrrs - solve one of the systems of equations $A^*X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$,

[chbev](#) - chbev - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A

[chbevd](#) - chbevd - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A

[chbevz](#) - chbevz - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A

[chbgst](#) - chbgst - reduce a complex Hermitian-definite banded generalized eigenproblem $A^*x = \lambda B^*x$ to standard form $C^*y = \lambda y$,

[chbgv](#) - chbgv - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A^*x = (\lambda B)^*x$

[chbgvd](#) - chbgvd - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A^*x = (\lambda B)^*x$

[chbgvx](#) - chbgvx - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A^*x = (\lambda B)^*x$

[chbmV](#) - chbmV - perform the matrix-vector operation $y := \alpha A^*x + \beta y$

[chbtrd](#) - chbtrd - reduce a complex Hermitian band matrix A to real symmetric tridiagonal form T by a unitary similarity transformation

[checon](#) - checon - estimate the reciprocal of the condition number of a complex Hermitian matrix A using the factorization $A = U^*D^*U^{**H}$ or $A = L^*D^*L^{**H}$ computed by CHETRF

[cheev](#) - cheev - compute all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A

[cheevd](#) - cheevd - compute all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A

[cheevr](#) - cheevr - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian tridiagonal matrix T

[cheevx](#) - cheevx - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A

[chegs2](#) - chesg2 - reduce a complex Hermitian-definite generalized eigenproblem to standard form

[chgst](#) - chgst - reduce a complex Hermitian-definite generalized eigenproblem to standard form

[chegv](#) - chegv - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$

[chegvd](#) - chegvd - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$

[chegvx](#) - chegvx - compute selected eigenvalues, and optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$

[chemm](#) - chemm - perform one of the matrix-matrix operations $C := \alpha*A*B + \beta*C$ or $C := \alpha*B*A + \beta*C$

[chemv](#) - chemv - perform the matrix-vector operation $y := \alpha*A*x + \beta*y$

[cher](#) - cher - perform the hermitian rank 1 operation $A := \alpha*x*conjg(x') + A$

[cher2](#) - cher2 - perform the hermitian rank 2 operation $A := \alpha*x*conjg(y') + conjg(\alpha)*y*conjg(x') + A$

[cher2k](#) - cher2k - perform one of the Hermitian rank 2k operations $C := \alpha*A*conjg(B') + conjg(\alpha)*B*conjg(A')$ + $\beta*C$ or $C := \alpha*conjg(A')*B + conjg(\alpha)*conjg(B')*A + \beta*C$

[cherfs](#) - cherfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite, and provides error bounds and backward error estimates for the solution

[cherk](#) - cherk - perform one of the Hermitian rank k operations $C := \alpha*A*conjg(A') + \beta*C$ or $C := \alpha*conjg(A')*A + \beta*C$

[chesv](#) - chesv - compute the solution to a complex system of linear equations $A * X = B$,

[chesvx](#) - chesvx - use the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A * X = B$,

[chetf2](#) - chetf2 - compute the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method

[chetrd](#) - chetrd - reduce a complex Hermitian matrix A to real symmetric tridiagonal form T by a unitary similarity transformation

[chetrf](#) - chetrf - compute the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method

[chetri](#) - chetri - compute the inverse of a complex Hermitian indefinite matrix A using the factorization $A = U*D*U**H$ or $A = L*D*L**H$ computed by CHETRF

[chetrs](#) - chetrs - solve a system of linear equations $A*X = B$ with a complex Hermitian matrix A using the factorization $A = U*D*U**H$ or $A = L*D*L**H$ computed by CHETRF

[chgeqz](#) - chgeqz - implement a single-shift version of the QZ method for finding the generalized eigenvalues $w(i)=\text{ALPHA}(i)/\text{BETA}(i)$ of the equation $\det(A-w(i) B) = 0$ If JOB='S', then the pair (A,B) is simultaneously reduced to Schur form (i.e., A and B are both upper triangular) by applying one unitary transformation (usually called Q) on the left and another (usually called Z) on the right

[chpcon](#) - chpcon - estimate the reciprocal of the condition number of a complex Hermitian packed matrix A using the factorization $A = U*D*U**H$ or $A = L*D*L**H$ computed by CHPTRF

[chpev](#) - chpev - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix in packed storage

[chpevd](#) - chpevd - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage

[chpevx](#) - chpevx - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage

[chpgst](#) - chpgst - reduce a complex Hermitian-definite generalized eigenproblem to standard form, using packed storage

[chpgv](#) - chpgv - compute all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$

[chpgvd](#) - chpgvd - compute all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$

[chpgvx](#) - chpgvx - compute selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$

[chpmv](#) - chpmv - perform the matrix-vector operation $y := \alpha*A*x + \beta*y$

[chpr](#) - chpr - perform the hermitian rank 1 operation $A := \alpha*x*\text{conjg}(x') + A$

[chpr2](#) - chpr2 - perform the Hermitian rank 2 operation $A := \alpha*x*\text{conjg}(y') + \text{conjg}(\alpha)*y*\text{conjg}(x') + A$

[chprfs](#) - chprfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite and packed, and provides error bounds and backward error estimates for the solution

[chpsv](#) - chpsv - compute the solution to a complex system of linear equations $A * X = B$,

[chpsvx](#) - chpsvx - use the diagonal pivoting factorization $A = U*D*U**H$ or $A = L*D*L**H$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N Hermitian matrix stored in packed format and X and B are N-by-NRHS matrices

[chptrd](#) - chptrd - reduce a complex Hermitian matrix A stored in packed form to real symmetric tridiagonal form T by a unitary similarity transformation

[chptrf](#) - chptrf - compute the factorization of a complex Hermitian packed matrix A using the Bunch-Kaufman diagonal pivoting method

[chptri](#) - chptri - compute the inverse of a complex Hermitian indefinite matrix A in packed storage using the factorization $A = U*D*U**H$ or $A = L*D*L**H$ computed by CHPTRF

[chptrs](#) - chptrs - solve a system of linear equations $A*X = B$ with a complex Hermitian matrix A stored in packed format using the factorization $A = U*D*U**H$ or $A = L*D*L**H$ computed by CHPTRF

[chsein](#) - chsein - use inverse iteration to find specified right and/or left eigenvectors of a complex upper Hessenberg matrix H

[chseqr](#) - chseqr - compute the eigenvalues of a complex upper Hessenberg matrix H, and, optionally, the matrices T and Z from the Schur decomposition $H = Z T Z**H$, where T is an upper triangular matrix (the Schur form), and Z is the unitary matrix of Schur vectors

[cjadmm](#) - cjadmm - Jagged diagonal matrix-matrix multiply (modified Ellpack)

[cjadrp](#) - cjadrp - right permutation of a jagged diagonal matrix

[cjadsm](#) - cjadsm - Jagged-diagonal format triangular solve

[clarz](#) - clarz - apply a complex elementary reflector H to a complex M-by-N matrix C, from either the left or the right

[clarzb](#) - clarzb - apply a complex block reflector H or its transpose $H**H$ to a complex distributed M-by-N C from the left or the right

[clarzt](#) - clarzt - form the triangular factor T of a complex block reflector H of order > n, which is defined as a product of k elementary reflectors

[clatzm](#) - clatzm - routine is deprecated and has been replaced by routine CUNMRZ

[cosqb](#) - cosqb - synthesize a Fourier sequence from its representation in terms of a cosine series with odd wave numbers. The COSQ operations are unnormalized inverses of themselves, so a call to COSQF followed by a call to COSQB will multiply the input sequence by $4 * N$.

[cosqf](#) - cosqf - compute the Fourier coefficients in a cosine series representation with only odd wave numbers. The COSQ operations are unnormalized inverses of themselves, so a call to COSQF followed by a call to COSQB will multiply the input sequence by $4 * N$.

[cosqi](#) - cosqi - initialize the array WSAVE, which is used in both COSQF and COSQB.

[cost](#) - cost - compute the discrete Fourier cosine transform of an even sequence. The COST transforms are

unnormalized inverses of themselves, so a call of COST followed by another call of COST will multiply the input sequence by $2 * (N-1)$.

[costi](#) - costi - initialize the array WSAVE, which is used in COST.

[cpbcon](#) - cpbcon - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite band matrix using the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$ computed by CPBTRF

[cpbequ](#) - cpbequ - compute row and column scalings intended to equilibrate a Hermitian positive definite band matrix A and reduce its condition number (with respect to the two-norm)

[cpbrfs](#) - cpbrfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and banded, and provides error bounds and backward error estimates for the solution

[cpbstf](#) - cpbstf - compute a split Cholesky factorization of a complex Hermitian positive definite band matrix A

[cpbsv](#) - cpbsv - compute the solution to a complex system of linear equations $A * X = B$,

[cpbsvx](#) - cpbsvx - use the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$ to compute the solution to a complex system of linear equations $A * X = B$,

[cpbtf2](#) - cpbtf2 - compute the Cholesky factorization of a complex Hermitian positive definite band matrix A

[cpbtrf](#) - cpbtrf - compute the Cholesky factorization of a complex Hermitian positive definite band matrix A

[cpbtrs](#) - cpbtrs - solve a system of linear equations $A * X = B$ with a Hermitian positive definite band matrix A using the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$ computed by CPBTRF

[cpocon](#) - cpocon - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite matrix using the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$ computed by CPOTRF

[cpoequ](#) - cpoequ - compute row and column scalings intended to equilibrate a Hermitian positive definite matrix A and reduce its condition number (with respect to the two-norm)

[cporfs](#) - cporfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite,

[cposv](#) - cposv - compute the solution to a complex system of linear equations $A * X = B$,

[cposvx](#) - cposvx - use the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$ to compute the solution to a complex system of linear equations $A * X = B$,

[cpotf2](#) - cpotf2 - compute the Cholesky factorization of a complex Hermitian positive definite matrix A

[cpotrf](#) - cpotrf - compute the Cholesky factorization of a complex Hermitian positive definite matrix A

[cpotri](#) - cpotri - compute the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$ computed by CPOTRF

[cpotrs](#) - cpotrs - solve a system of linear equations $A * X = B$ with a Hermitian positive definite matrix A using the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$ computed by CPOTRF

[cppcon](#) - cppcon - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite packed matrix using the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$ computed by CPPTRF

[cppequ](#) - cppequ - compute row and column scalings intended to equilibrate a Hermitian positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm)

[cpprfs](#) - cpprfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and packed, and provides error bounds and backward error estimates for the solution

[cppsv](#) - cppsv - compute the solution to a complex system of linear equations $A * X = B$,

[cppsvx](#) - cppsvx - use the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$ to compute the solution to a complex system of linear equations $A * X = B$,

[cpptrf](#) - cpptrf - compute the Cholesky factorization of a complex Hermitian positive definite matrix A stored in packed format

[cpptri](#) - cpptri - compute the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$ computed by CPPTRF

[cpptrs](#) - cpptrs - solve a system of linear equations $A * X = B$ with a Hermitian positive definite matrix A in packed

storage using the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^{**}H$ computed by CPPTRF

[cptcon](#) - cptcon - compute the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite tridiagonal matrix using the factorization $A = L^*D^*L^{**}H$ or $A = U^*H^*D^*U$ computed by CPTTRF

[cpteqr](#) - cpteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF and then calling CBDSQR to compute the singular values of the bidiagonal factor

[cptrfs](#) - cptrfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution

[cptsv](#) - cptsv - compute the solution to a complex system of linear equations $A^*X = B$, where A is an N-by-N Hermitian positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

[cptsvx](#) - cptsvx - use the factorization $A = L^*D^*L^{**}H$ to compute the solution to a complex system of linear equations $A^*X = B$, where A is an N-by-N Hermitian positive definite tridiagonal matrix and X and B are N-by-NRHS matrices

[cpttrf](#) - cpttrf - compute the L^*D^*L' factorization of a complex Hermitian positive definite tridiagonal matrix A

[cpttrs](#) - cpttrs - solve a tridiagonal system of the form $A^*X = B$ using the factorization $A = U^*D^*U$ or $A = L^*D^*L'$ computed by CPTTRF

[cptts2](#) - cptts2 - solve a tridiagonal system of the form $A^*X = B$ using the factorization $A = U^*D^*U$ or $A = L^*D^*L'$ computed by CPTTRF

[crot](#) - crot - apply a plane rotation, where the cos (C) is real and the sin (S) is complex, and the vectors X and Y are complex

[crotg](#) - crotg - Construct a Given's plane rotation

[cscal](#) - cscal - Compute $y := \alpha * y$

[csctr](#) - csctr - Scatters elements from x into y .

[cskymm](#) - cskymm - Skyline format matrix-matrix multiply

[cskysm](#) - cskysm - Skyline format triangular solve

[cspcon](#) - cspcon - estimate the reciprocal of the condition number (in the 1-norm) of a complex symmetric packed matrix A using the factorization $A = U^*D^*U^{**}T$ or $A = L^*D^*L^{**}T$ computed by CSPTRF

[csprfs](#) - csprfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution

[cspsv](#) - cspsv - compute the solution to a complex system of linear equations $A^*X = B$,

[cspsvx](#) - cspsvx - use the diagonal pivoting factorization $A = U^*D^*U^{**}T$ or $A = L^*D^*L^{**}T$ to compute the solution to a complex system of linear equations $A^*X = B$, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices

[csptrf](#) - csptrf - compute the factorization of a complex symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method

[csptri](#) - csptri - compute the inverse of a complex symmetric indefinite matrix A in packed storage using the factorization $A = U^*D^*U^{**}T$ or $A = L^*D^*L^{**}T$ computed by CSPTRF

[csptrs](#) - csptrs - solve a system of linear equations $A^*X = B$ with a complex symmetric matrix A stored in packed format using the factorization $A = U^*D^*U^{**}T$ or $A = L^*D^*L^{**}T$ computed by CSPTRF

[csrot](#) - csrot - Apply a plane rotation.

[csscal](#) - csscal - Compute $y := \alpha * y$

[cstedc](#) - cstedc - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method

[cstegr](#) - cstegr - Compute $T\text{-sigma}_i = L_i D_i L_i^*T$, such that $L_i D_i L_i^*T$ is a relatively robust representation

[cstein](#) - cstein - compute the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration

[csteqr](#) - csteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the

implicit QL or QR method

[cstsv](#) - cstsv - compute the solution to a complex system of linear equations $A * X = B$ where A is a Hermitian tridiagonal matrix

[csttrf](#) - csttrf - compute the factorization of a complex Hermitian tridiagonal matrix A

[csttrs](#) - csttrs - computes the solution to a complex system of linear equations $A * X = B$

[cswap](#) - cswap - Exchange vectors x and y.

[csycon](#) - csycon - estimate the reciprocal of the condition number (in the 1-norm) of a complex symmetric matrix A using the factorization $A = U * D * U ** T$ or $A = L * D * L ** T$ computed by CSYTRF

[csymm](#) - csymm - perform one of the matrix-matrix operations $C := \alpha * A * B + \beta * C$ or $C := \alpha * B * A + \beta * C$

[csyr2k](#) - csyr2k - perform one of the symmetric rank 2k operations $C := \alpha * A * B' + \alpha * B * A' + \beta * C$ or $C := \alpha * A * B + \alpha * B' * A + \beta * C$

[csyrfs](#) - csyrfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution

[csyrk](#) - csyrk - perform one of the symmetric rank k operations $C := \alpha * A * A' + \beta * C$ or $C := \alpha * A' * A + \beta * C$

[csysv](#) - csysv - compute the solution to a complex system of linear equations $A * X = B$,

[csysvx](#) - csysvx - use the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A * X = B$,

[csytf2](#) - csytf2 - compute the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

[csytrf](#) - csytrf - compute the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

[csytri](#) - csytri - compute the inverse of a complex symmetric indefinite matrix A using the factorization $A = U * D * U ** T$ or $A = L * D * L ** T$ computed by CSYTRF

[csytrs](#) - csytrs - solve a system of linear equations $A * X = B$ with a complex symmetric matrix A using the factorization $A = U * D * U ** T$ or $A = L * D * L ** T$ computed by CSYTRF

[ctbcon](#) - ctbcon - estimate the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm

[ctbmV](#) - ctbmv - perform one of the matrix-vector operations $x := A * x$, or $x := A' * x$, or $x := \text{conjg}(A') * x$

[ctbrfs](#) - ctbrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix

[ctbsv](#) - ctbsv - solve one of the systems of equations $A * x = b$, or $A' * x = b$, or $\text{conjg}(A') * x = b$

[ctbtrs](#) - ctbtrs - solve a triangular system of the form $A * X = B$, $A ** T * X = B$, or $A ** H * X = B$,

[ctgevc](#) - ctgevc - compute some or all of the right and/or left generalized eigenvectors of a pair of complex upper triangular matrices (A,B)

[ctgexc](#) - ctgexc - reorder the generalized Schur decomposition of a complex matrix pair (A,B), using an unitary equivalence transformation $(A, B) := Q * (A, B) * Z'$, so that the diagonal block of (A, B) with row index IFST is moved to row ILST

[ctgsen](#) - ctgsen - reorder the generalized Schur decomposition of a complex matrix pair (A, B) (in terms of an unitary equivalence transformation $Q' * (A, B) * Z$), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the pair (A,B)

[ctgsja](#) - ctgsja - compute the generalized singular value decomposition (GSVD) of two complex upper triangular (or trapezoidal) matrices A and B

[ctgsna](#) - ctgsna - estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B)

[ctgsyl](#) - ctgsyl - solve the generalized Sylvester equation

[ctpcon](#) - ctpcon - estimate the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm

[ctpmv](#) - ctpmv - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$

[ctprfs](#) - ctpfrs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix

[ctpsv](#) - ctpsv - solve one of the systems of equations $A*x = b$, or $A'*x = b$, or $\text{conjg}(A')*x = b$

[ctptri](#) - ctptri - compute the inverse of a complex upper or lower triangular matrix A stored in packed format

[ctptrs](#) - ctptrs - solve a triangular system of the form $A * X = B$, $A**T * X = B$, or $A**H * X = B$,

[ctrans](#) - ctrans - transpose and scale source matrix

[ctrcon](#) - ctrcon - estimate the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm

[ctrevc](#) - ctrevc - compute some or all of the right and/or left eigenvectors of a complex upper triangular matrix T

[ctrexc](#) - ctrexc - reorder the Schur factorization of a complex matrix $A = Q*T*Q**H$, so that the diagonal element of T with row index IFST is moved to row ILST

[ctrrm](#) - ctrrm - perform one of the matrix-matrix operations $B := \alpha*\text{op}(A)*B$, or $B := \alpha*B*\text{op}(A)$ where alpha is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and $\text{op}(A)$ is one of $\text{op}(A) = A$ or $\text{op}(A) = A'$ or $\text{op}(A) = \text{conjg}(A')$

[ctrmv](#) - ctrmv - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$

[ctrfs](#) - ctrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix

[ctrsen](#) - ctrsen - reorder the Schur factorization of a complex matrix $A = Q*T*Q**H$, so that a selected cluster of eigenvalues appears in the leading positions on the diagonal of the upper triangular matrix T, and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace

[ctrsm](#) - ctrsm - solve one of the matrix equations $\text{op}(A)*X = \alpha*B$, or $X*\text{op}(A) = \alpha*B$

[ctrzna](#) - ctrzna - estimate reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a complex upper triangular matrix T (or of any matrix $Q*T*Q**H$ with Q unitary)

[ctrsv](#) - ctrsv - solve one of the systems of equations $A*x = b$, or $A'*x = b$, or $\text{conjg}(A')*x = b$

[ctrsyl](#) - ctrsyl - solve the complex Sylvester matrix equation

[crti2](#) - crt2i - compute the inverse of a complex upper or lower triangular matrix

[ctrtri](#) - ctrtri - compute the inverse of a complex upper or lower triangular matrix A

[ctrtrs](#) - ctrtrs - solve a triangular system of the form $A * X = B$, $A**T * X = B$, or $A**H * X = B$,

[ctzrqf](#) - ctzrqf - routine is deprecated and has been replaced by routine CTZRZF

[ctzrzf](#) - ctzrzf - reduce the M-by-N ($M \leq N$) complex upper trapezoidal matrix A to upper triangular form by means of unitary transformations

[cung2l](#) - cung2l - generate an m by n complex matrix Q with orthonormal columns,

[cung2r](#) - cung2r - generate an m by n complex matrix Q with orthonormal columns,

[cungbr](#) - cungbr - generate one of the complex unitary matrices Q or $P**H$ determined by CGEBRD when reducing a complex matrix A to bidiagonal form

[cunghr](#) - cunghr - generate a complex unitary matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by CGEHRD

[cungl2](#) - cungl2 - generate an m-by-n complex matrix Q with orthonormal rows,

[cunglq](#) - cunglq - generate an M-by-N complex matrix Q with orthonormal rows,

[cungql](#) - cungql - generate an M-by-N complex matrix Q with orthonormal columns,

[cungqr](#) - cungqr - generate an M-by-N complex matrix Q with orthonormal columns,

[cungr2](#) - cungr2 - generate an m by n complex matrix Q with orthonormal rows,

[cungrq](#) - cungrq - generate an M-by-N complex matrix Q with orthonormal rows,

[cungr](#) - cungr - generate a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by CHETRD

[cunmbr](#) - cunmbr - VECT = 'Q', CUNMBR overwrites the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[cunmhr](#) - cunmhr - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[cunml2](#) - cunml2 - overwrite the general complex m-by-n matrix C with $Q * C$ if SIDE = 'L' and TRANS = 'N', or $Q^* * C$ if SIDE = 'L' and TRANS = 'C', or $C * Q$ if SIDE = 'R' and TRANS = 'N', or $C * Q^*$ if SIDE = 'R' and TRANS = 'C',

[cunmlq](#) - cunmlq - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[cunmq1](#) - cunmq1 - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[cunmqr](#) - cunmqr - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[cunmr2](#) - cunmr2 - overwrite the general complex m-by-n matrix C with $Q * C$ if SIDE = 'L' and TRANS = 'N', or $Q^* * C$ if SIDE = 'L' and TRANS = 'C', or $C * Q$ if SIDE = 'R' and TRANS = 'N', or $C * Q^*$ if SIDE = 'R' and TRANS = 'C',

[cunmrq](#) - cunmrq - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[cunmrz](#) - cunmrz - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[cunmtr](#) - cunmtr - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[cupgtr](#) - cupgtr - generate a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors H(i) of order n, as returned by CHPTRD using packed storage

[cupmtr](#) - cupmtr - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[cvbrmm](#) - cvbrmm - variable block sparse row format matrix-matrix multiply

[cvbrsm](#) - cvbrsm - variable block sparse row format triangular solve

[cvmul](#) - cvmul - compute the scaled product of complex vectors

[dasum](#) - dasum - Return the sum of the absolute values of a vector x.

[daxpy](#) - daxpy - compute $y := \alpha * x + y$

[daxpyi](#) - daxpyi - Compute $y := \alpha * x + y$

[dbcomm](#) - dbcomm - block coordinate matrix-matrix multiply

[dbdimm](#) - dbdimm - block diagonal format matrix-matrix multiply

[dbdism](#) - dbdism - block diagonal format triangular solve

[dbdsdc](#) - dbdsdc - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B

[dbdsqr](#) - dbdsqr - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B.

[dbelmm](#) - dbelmm - block Ellpack format matrix-matrix multiply

[dbelsm](#) - dbelsm - block Ellpack format triangular solve

[dbscmm](#) - dbscmm - block sparse column matrix-matrix multiply

[dbscsm](#) - dbscsm - block sparse column format triangular solve

[dbsrmm](#) - dbsrmm - block sparse row format matrix-matrix multiply

[dbsrsm](#) - dbsrsm - block sparse row format triangular solve

[dcnvcor](#) - dcnvcor - compute the convolution or correlation of real vectors

[dcnvcor2](#) - dcnvcor2 - compute the convolution or correlation of real matrices

[dcoomm](#) - dcoomm - coordinate matrix-matrix multiply

[dcopy](#) - dcopy - Copy x to y

[dcosqb](#) - dcosqb - synthesize a Fourier sequence from its representation in terms of a cosine series with odd wave numbers. The COSQ operations are unnormalized inverses of themselves, so a call to COSQF followed by a call to COSQB will multiply the input sequence by $4 * N$.

[dcosqf](#) - dcosqf - compute the Fourier coefficients in a cosine series representation with only odd wave numbers. The COSQ operations are unnormalized inverses of themselves, so a call to COSQF followed by a call to COSQB will multiply the input sequence by $4 * N$.

[dcosqi](#) - dcosqi - initialize the array WSAVE, which is used in both COSQF and COSQB.

[dcost](#) - dcost - compute the discrete Fourier cosine transform of an even sequence. The COST transforms are unnormalized inverses of themselves, so a call of COST followed by another call of COST will multiply the input sequence by $2 * (N-1)$.

[dcosti](#) - dcosti - initialize the array WSAVE, which is used in COST.

[dcscomm](#) - dcscomm - compressed sparse column format matrix-matrix multiply

[dcscsm](#) - dcscsm - compressed sparse column format triangular solve

[dcrrmm](#) - dcrrmm - compressed sparse row format matrix-matrix multiply

[dcrrsm](#) - dcrrsm - compressed sparse row format triangular solve

[ddiamm](#) - ddiamm - diagonal format matrix-matrix multiply

[ddiasm](#) - ddiasm - diagonal format triangular solve

[ddisna](#) - ddisna - compute the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m-by-n matrix

[ddot](#) - ddot - compute the dot product of two vectors x and y.

[ddoti](#) - ddoti - Compute the indexed dot product.

[dellmm](#) - dellmm - Ellpack format matrix-matrix multiply

[dellsm](#) - dellsm - Ellpack format triangular solve

[dezftb](#) - dezftb - computes a periodic sequence from its Fourier coefficients. DEZFTB is a simplified but slower version of DFFTB.

[dezftf](#) - dezftf - computes the Fourier coefficients of a periodic sequence. DEZFTF is a simplified but slower version of DFFTF.

[dezfti](#) - dezfti - initializes the array WSAVE, which is used in both DEZFTF and DEZFTB.

[dfft2b](#) - dfft2b - compute a periodic sequence from its Fourier coefficients. The DFFT operations are unnormalized, so a call of DFFT2F followed by a call of DFFT2B will multiply the input sequence by $M*N$.

[dfft2f](#) - dfft2f - compute the Fourier coefficients of a periodic sequence. The DFFT operations are unnormalized, so a call of DFFT2F followed by a call of DFFT2B will multiply the input sequence by $M*N$.

[dfft2i](#) - dfft2i - initialize the array WSAVE, which is used in both the forward and backward transforms.

[dfft3b](#) - dfft3b - compute a periodic sequence from its Fourier coefficients. The DFFT operations are unnormalized, so a call of DFFT3F followed by a call of DFFT3B will multiply the input sequence by $M*N*K$.

[dfft3f](#) - dfft3f - compute the Fourier coefficients of a real periodic sequence. The DFFT operations are unnormalized, so a call of DFFT3F followed by a call of DFFT3B will multiply the input sequence by $M*N*K$.

[dfft3i](#) - dfft3i - initialize the array WSAVE, which is used in both DFFT3F and DFFT3B.

[dftfb](#) - dftfb - compute a periodic sequence from its Fourier coefficients. The DFFT operations are unnormalized, so a call of DFFTF followed by a call of DFFTB will multiply the input sequence by N .

[dftff](#) - dftff - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of

DFFTF followed by a call of DFFTB will multiply the input sequence by N.

[dfft](#) - dfft - initialize the array WSAVE, which is used in both DFFTF and DFFTB.

[dfftopt](#) - dfftopt - compute the length of the closest fast FFT

[dfftz](#) - dfftz - initialize the trigonometric weight and factor tables or compute the forward Fast Fourier Transform of a double precision sequence.

[dfftz2](#) - dfftz2 - initialize the trigonometric weight and factor tables or compute the two-dimensional forward Fast Fourier Transform of a two-dimensional double precision array.

[dfftz3](#) - dfftz3 - initialize the trigonometric weight and factor tables or compute the three-dimensional forward Fast Fourier Transform of a three-dimensional double complex array.

[dfftzm](#) - dfftzm - initialize the trigonometric weight and factor tables or compute the one-dimensional forward Fast Fourier Transform of a set of double precision data sequences stored in a two-dimensional array.

[dgbbrd](#) - dgbbrd - reduce a real general m-by-n band matrix A to upper bidiagonal form B by an orthogonal transformation

[dgbcon](#) - dgbcon - estimate the reciprocal of the condition number of a real general band matrix A, in either the 1-norm or the infinity-norm,

[dgbegu](#) - dgbegu - compute row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number

[dgbmv](#) - dgbmv - perform one of the matrix-vector operations $y := \alpha * A * x + \beta * y$ or $y := \alpha * A^T * x + \beta * y$

[dgbfrs](#) - dgbfrs - improve the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution

[dgbsv](#) - dgbsv - compute the solution to a real system of linear equations $A * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices

[dgbsvx](#) - dgbsvx - use the LU factorization to compute the solution to a real system of linear equations $A * X = B$, $A^T * X = B$, or $A^H * X = B$,

[dgbtf2](#) - dgbtf2 - compute an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges

[dgbtrf](#) - dgbtrf - compute an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges

[dgbtrs](#) - dgbtrs - solve a system of linear equations $A * X = B$ or $A^T * X = B$ with a general band matrix A using the LU factorization computed by SGBTRF

[dgebak](#) - dgebak - form the right or left eigenvectors of a real general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by SGEBAL

[dgebal](#) - dgebal - balance a general real matrix A

[dgebrd](#) - dgebrd - reduce a general real M-by-N matrix A to upper or lower bidiagonal form B by an orthogonal transformation

[dgecon](#) - dgecon - estimate the reciprocal of the condition number of a general real matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by SGETRF

[dgeequ](#) - dgeequ - compute row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number

[dgees](#) - dgees - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z

[dgeesx](#) - dgeesx - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z

[dgeev](#) - dgeev - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

[dgeevx](#) - dgeevx - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

[dgegs](#) - dgegs - routine is deprecated and has been replaced by routine SGGES

[dgeg](#) - dgeg - routine is deprecated and has been replaced by routine SGGEV

[dgehrd](#) - dgehrd - reduce a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation

[dgelqf](#) - dgelqf - compute an LQ factorization of a real M-by-N matrix A

[dgels](#) - dgels - solve overdetermined or underdetermined real linear systems involving an M-by-N matrix A, or its transpose, using a QR or LQ factorization of A

[dgelsd](#) - dgelsd - compute the minimum-norm solution to a real linear least squares problem

[dgels](#) - dgels - compute the minimum norm solution to a real linear least squares problem

[dgelsx](#) - dgelsx - routine is deprecated and has been replaced by routine SGELSY

[dgelsy](#) - dgelsy - compute the minimum-norm solution to a real linear least squares problem

[dgemm](#) - dgemm - perform one of the matrix-matrix operations $C := \alpha * op(A) * op(B) + \beta * C$

[dgemv](#) - dgemv - perform one of the matrix-vector operations $y := \alpha * A * x + \beta * y$ or $y := \alpha * A' * x + \beta * y$

[dgeqlf](#) - dgeqlf - compute a QL factorization of a real M-by-N matrix A

[dgeqp3](#) - dgeqp3 - compute a QR factorization with column pivoting of a matrix A

[dgeqpf](#) - dgeqpf - routine is deprecated and has been replaced by routine SGEQP3

[dgeqrf](#) - dgeqrf - compute a QR factorization of a real M-by-N matrix A

[dger](#) - dger - perform the rank 1 operation $A := \alpha * x * y' + A$

[dgerfs](#) - dgerfs - improve the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution

[dgerqf](#) - dgerqf - compute an RQ factorization of a real M-by-N matrix A

[dgesdd](#) - dgesdd - compute the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and right singular vectors

[dgesv](#) - dgesv - compute the solution to a real system of linear equations $A * X = B$,

[dgesvd](#) - dgesvd - compute the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and/or right singular vectors

[dgesvx](#) - dgesvx - use the LU factorization to compute the solution to a real system of linear equations $A * X = B$,

[dgetf2](#) - dgetf2 - compute an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges

[dgetrf](#) - dgetrf - compute an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges

[dgetri](#) - dgetri - compute the inverse of a matrix using the LU factorization computed by SGETRF

[dgets](#) - dgets - solve a system of linear equations $A * X = B$ or $A' * X = B$ with a general N-by-N matrix A using the LU factorization computed by SGETRF

[dggbak](#) - dggbak - form the right or left eigenvectors of a real generalized eigenvalue problem $A * x = \lambda * B * x$, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by SGGBAL

[dggbal](#) - dggbal - balance a pair of general real matrices (A,B)

[dgges](#) - dgges - compute for a pair of N-by-N real nonsymmetric matrices (A,B),

[dggsex](#) - dggsex - compute for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the real Schur form (S,T), and,

[dggev](#) - dggev - compute for a pair of N-by-N real nonsymmetric matrices (A,B)

[dggevx](#) - dggevx - compute for a pair of N-by-N real nonsymmetric matrices (A,B)

[dggglm](#) - dggglm - solve a general Gauss-Markov linear model (GLM) problem

[dgghrd](#) - dgghrd - reduce a pair of real matrices (A,B) to generalized upper Hessenberg form using orthogonal transformations, where A is a general matrix and B is upper triangular

[dgglse](#) - dgglse - solve the linear equality-constrained least squares (LSE) problem

[dggqrf](#) - dggqrf - compute a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B.

[dggqrq](#) - dggqrq - compute a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B

[dggsvd](#) - dggsvd - compute the generalized singular value decomposition (GSVD) of an M-by-N real matrix A and P-by-N real matrix B

[dggsvp](#) - dggsvp - compute orthogonal matrices U, V and Q such that $N \times K \times L \times U^* \times A \times Q = K \begin{pmatrix} 0 & A_{12} & A_{13} \end{pmatrix}$ if $M \times K \times L \geq 0$

[dgssco](#) - dgssco - General sparse solver condition number estimate.

[dgssda](#) - dgssda - Deallocate working storage for the general sparse solver.

[dgssfa](#) - dgssfa - General sparse solver numeric factorization.

[dgssfs](#) - dgssfs - General sparse solver one call interface.

[dgssin](#) - dgssin - Initialize the general sparse solver.

[dgssor](#) - dgssor - General sparse solver ordering and symbolic factorization.

[dgssps](#) - dgssps - Print general sparse solver statics.

[dgssrp](#) - dgssrp - Return permutation used by the general sparse solver.

[dgsssl](#) - dgsssl - Solve routine for the general sparse solver.

[dgssuo](#) - dgssuo - User supplied permutation for ordering used in the general sparse solver.

[dgtcon](#) - dgtcon - estimate the reciprocal of the condition number of a real tridiagonal matrix A using the LU factorization as computed by SGTTRF

[dgthr](#) - dgthr - Gathers specified elements from y into x.

[dgthrz](#) - dgthrz - Gather and zero.

[dgtfrs](#) - dgtfrs - improve the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution

[dgtsv](#) - dgtsv - solve the equation $A * X = B$,

[dgtsvx](#) - dgtsvx - use the LU factorization to compute the solution to a real system of linear equations $A * X = B$ or $A^{**T} * X = B$,

[dgttrf](#) - dgttrf - compute an LU factorization of a real tridiagonal matrix A using elimination with partial pivoting and row interchanges

[dgttrs](#) - dgttrs - solve one of the systems of equations $A * X = B$ or $A^* * X = B$,

[dhgeqz](#) - dhgeqz - implement a single-/double-shift version of the QZ method for finding the generalized eigenvalues $w(j) = (\text{ALPHAR}(j) + i * \text{ALPHAI}(j)) / \text{BETAR}(j)$ of the equation $\det(A - w(i) B) = 0$ In addition, the pair A,B may be reduced to generalized Schur form

[dhsein](#) - dhsein - use inverse iteration to find specified right and/or left eigenvectors of a real upper Hessenberg matrix H

[dhseqr](#) - dhseqr - compute the eigenvalues of a real upper Hessenberg matrix H and, optionally, the matrices T and Z from the Schur decomposition $H = Z T Z^{**T}$, where T is an upper quasi-triangular matrix (the Schur form), and Z is the orthogonal matrix of Schur vectors

[djadmm](#) - djadmm - Jagged diagonal matrix-matrix multiply (modified Ellpack)

[djadrp](#) - djadrp - right permutation of a jagged diagonal matrix

[djadsm](#) - djadsm - Jagged-diagonal format triangular solve

[dlagtf](#) - dlagtf - factorize the matrix $(T-\lambda I)$, where T is an n by n tridiagonal matrix and λ is a scalar, as $T-\lambda I = PLU$

[dlamrg](#) - dlamrg - will create a permutation list which will merge the elements of A (which is composed of two independently sorted sets) into a single set which is sorted in ascending order

[dlarz](#) - dlarz - applies a real elementary reflector H to a real M-by-N matrix C, from either the left or the right

[dlarzb](#) - dlarzb - applies a real block reflector H or its transpose H^*T to a real distributed M-by-N C from the left or the right

[dlarzt](#) - dlarzt - form the triangular factor T of a real block reflector H of order $> n$, which is defined as a product of k elementary reflectors

[dlasrt](#) - dlasrt - the numbers in D in increasing order (if ID = 'I') or in decreasing order (if ID = 'D')

[dlatzm](#) - dlatzm - routine is deprecated and has been replaced by routine SORMRZ

[dnrm2](#) - dnrm2 - Return the Euclidian norm of a vector.

[dopgtr](#) - dopgtr - generate a real orthogonal matrix Q which is defined as the product of n-1 elementary reflectors H(i) of order n, as returned by SSPTD using packed storage

[dopmtr](#) - dopmtr - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[dorg2l](#) - dorg2l - generate an m by n real matrix Q with orthonormal columns,

[dorg2r](#) - dorg2r - generate an m by n real matrix Q with orthonormal columns,

[dorgbr](#) - dorgbr - generate one of the real orthogonal matrices Q or P^*T determined by SGBRD when reducing a real matrix A to bidiagonal form

[dorghr](#) - dorghr - generate a real orthogonal matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by SGEHRD

[dorgl2](#) - dorgl2 - generate an m by n real matrix Q with orthonormal rows,

[dorglq](#) - dorglq - generate an M-by-N real matrix Q with orthonormal rows,

[dorgql](#) - dorgql - generate an M-by-N real matrix Q with orthonormal columns,

[dorgqr](#) - dorgqr - generate an M-by-N real matrix Q with orthonormal columns,

[dorgr2](#) - dorgr2 - generate an m by n real matrix Q with orthonormal rows,

[dorgrq](#) - dorgrq - generate an M-by-N real matrix Q with orthonormal rows,

[dorgtr](#) - dorgtr - generate a real orthogonal matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by SSYTRD

[dormbr](#) - dormbr - VECT = 'Q', SORMBR overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[dormhr](#) - dormhr - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[dormlq](#) - dormlq - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[dormql](#) - dormql - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[dormqr](#) - dormqr - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[dormrq](#) - dormrq - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[dormrz](#) - dormrz - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[dormtr](#) - dormtr - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[dpbcon](#) - dpbcon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite band matrix using the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^*T$ computed by SPBTRF

[dpbequ](#) - dpbequ - compute row and column scalings intended to equilibrate a symmetric positive definite band matrix A and reduce its condition number (with respect to the two-norm)

[dpbrfs](#) - dpbrfs - improve the computed solution to a system of linear equations when the coefficient matrix is

symmetric positive definite and banded, and provides error bounds and backward error estimates for the solution

[dpbstf](#) - dpbstf - compute a split Cholesky factorization of a real symmetric positive definite band matrix A

[dpbsv](#) - dpbsv - compute the solution to a real system of linear equations $A * X = B$,

[dpbsvx](#) - dpbsvx - use the Cholesky factorization $A = U^{**T} * U$ or $A = L * L^{**T}$ to compute the solution to a real system of linear equations $A * X = B$,

[dpbtf2](#) - dpbtf2 - compute the Cholesky factorization of a real symmetric positive definite band matrix A

[dpbtrf](#) - dpbtrf - compute the Cholesky factorization of a real symmetric positive definite band matrix A

[dpbtrs](#) - dpbtrs - solve a system of linear equations $A * X = B$ with a symmetric positive definite band matrix A using the Cholesky factorization $A = U^{**T} * U$ or $A = L * L^{**T}$ computed by SPBTRF

[dpocon](#) - dpocon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite matrix using the Cholesky factorization $A = U^{**T} * U$ or $A = L * L^{**T}$ computed by SPOTRF

[dpoequ](#) - dpoequ - compute row and column scalings intended to equilibrate a symmetric positive definite matrix A and reduce its condition number (with respect to the two-norm)

[dporfs](#) - dporfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite,

[dposv](#) - dposv - compute the solution to a real system of linear equations $A * X = B$,

[dposvx](#) - dposvx - use the Cholesky factorization $A = U^{**T} * U$ or $A = L * L^{**T}$ to compute the solution to a real system of linear equations $A * X = B$,

[dpotf2](#) - dpotf2 - compute the Cholesky factorization of a real symmetric positive definite matrix A

[dpotrf](#) - dpotrf - compute the Cholesky factorization of a real symmetric positive definite matrix A

[dpotri](#) - dpotri - compute the inverse of a real symmetric positive definite matrix A using the Cholesky factorization $A = U^{**T} * U$ or $A = L * L^{**T}$ computed by SPOTRF

[dpotrs](#) - dpotrs - solve a system of linear equations $A * X = B$ with a symmetric positive definite matrix A using the Cholesky factorization $A = U^{**T} * U$ or $A = L * L^{**T}$ computed by SPOTRF

[dppcon](#) - dppcon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite packed matrix using the Cholesky factorization $A = U^{**T} * U$ or $A = L * L^{**T}$ computed by SPPTRF

[dppequ](#) - dppequ - compute row and column scalings intended to equilibrate a symmetric positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm)

[dpprfs](#) - dpprfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and packed, and provides error bounds and backward error estimates for the solution

[dppsv](#) - dppsv - compute the solution to a real system of linear equations $A * X = B$,

[dppsvx](#) - dppsvx - use the Cholesky factorization $A = U^{**T} * U$ or $A = L * L^{**T}$ to compute the solution to a real system of linear equations $A * X = B$,

[dpptrf](#) - dpptrf - compute the Cholesky factorization of a real symmetric positive definite matrix A stored in packed format

[dpptri](#) - dpptri - compute the inverse of a real symmetric positive definite matrix A using the Cholesky factorization $A = U^{**T} * U$ or $A = L * L^{**T}$ computed by SPPTRF

[dpptrs](#) - dpptrs - solve a system of linear equations $A * X = B$ with a symmetric positive definite matrix A in packed storage using the Cholesky factorization $A = U^{**T} * U$ or $A = L * L^{**T}$ computed by SPPTRF

[dptcon](#) - dptcon - compute the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite tridiagonal matrix using the factorization $A = L * D * L^{**T}$ or $A = U^{**T} * D * U$ computed by SPTTRF

[dpteqr](#) - dpteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF, and then calling SBDSQR to compute the singular values of the bidiagonal factor

[dptrfs](#) - dptrfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution

[dptsv](#) - dptsv - compute the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

[dptsvx](#) - dptsvx - use the factorization $A = L * D * L' * T$ to compute the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric positive definite tridiagonal matrix and X and B are N-by-NRHS matrices

[dpttrf](#) - dpttrf - compute the $L * D * L'$ factorization of a real symmetric positive definite tridiagonal matrix A

[dpttrs](#) - dpttrs - solve a tridiagonal system of the form $A * X = B$ using the $L * D * L'$ factorization of A computed by SPTTRF

[dptts2](#) - dptts2 - solve a tridiagonal system of the form $A * X = B$ using the $L * D * L'$ factorization of A computed by SPTTRF

[dqdota](#) - dqdota - compute a double precision constant plus an extended precision constant plus the extended precision dot product of two double precision vectors x and y.

[dqdoti](#) - dqdoti - compute a constant plus the extended precision dot product of two double precision vectors x and y.

[drot](#) - drot - Apply a Given's rotation constructed by SROTG.

[drotg](#) - drotg - Construct a Given's plane rotation

[droti](#) - droti - Apply an indexed Givens rotation.

[drotm](#) - drotm - Apply a Gentleman's modified Given's rotation constructed by SROTMG.

[drotmg](#) - drotmg - Construct a Gentleman's modified Given's plane rotation

[dsbev](#) - dsbev - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

[dsbevd](#) - dsbevd - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

[dsbevz](#) - dsbevz - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

[dsbgst](#) - dsbgst - reduce a real symmetric-definite banded generalized eigenproblem $A * x = \lambda * B * x$ to standard form $C * y = \lambda * y$,

[dsbgv](#) - dsbgv - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A * x = (\lambda * B) * x$

[dsbgvd](#) - dsbgvd - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A * x = (\lambda * B) * x$

[dsbgvx](#) - dsbgvx - compute selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A * x = (\lambda * B) * x$

[dsbmv](#) - dsbmv - perform the matrix-vector operation $y := \alpha * A * x + \beta * y$

[dsbtrd](#) - dsbtrd - reduce a real symmetric band matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation

[dscal](#) - dscal - Compute $y := \alpha * y$

[dsctr](#) - dsctr - Scatters elements from x into y.

[dsdot](#) - dsdot - compute the double precision dot product of two single precision vectors x and y.

[dsecnd](#) - dsecnd - return the user time for a process in seconds

[dsinqb](#) - dsinqb - synthesize a Fourier sequence from its representation in terms of a sine series with odd wave numbers. The SING operations are unnormalized inverses of themselves, so a call to SINGF followed by a call to SINGB will multiply the input sequence by $4 * N$.

[dsinqf](#) - dsinqf - compute the Fourier coefficients in a sine series representation with only odd wave numbers. The SING operations are unnormalized inverses of themselves, so a call to SINGF followed by a call to SINGB will multiply the input sequence by $4 * N$.

[dsinqi](#) - dsinqi - initialize the array xWSAVE, which is used in both SINGF and SINGB.

[dsint](#) - dsint - compute the discrete Fourier sine transform of an odd sequence. The SINT transforms are unnormalized inverses of themselves, so a call of SINT followed by another call of SINT will multiply the input sequence by $2 * (N+1)$.

[dsinti](#) - dsinti - initialize the array WSAVE, which is used in subroutine SINT.

[dskymm](#) - dskymm - Skyline format matrix-matrix multiply

[dskysm](#) - dskysm - Skyline format triangular solve

[dspcon](#) - dspcon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric packed matrix A using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by SSPTRF

[dspev](#) - dspev - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

[dspevd](#) - dspevd - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

[dspevx](#) - dspevx - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

[dspgst](#) - dspgst - reduce a real symmetric-definite generalized eigenproblem to standard form, using packed storage

[dspgv](#) - dspgv - compute all the eigenvalues and, optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A^*x=(\lambda)*B^*x$, $A^*Bx=(\lambda)*x$, or $B^*A^*x=(\lambda)*x$

[dspgvd](#) - dspgvd - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A^*x=(\lambda)*B^*x$, $A^*Bx=(\lambda)*x$, or $B^*A^*x=(\lambda)*x$

[dspgvx](#) - dspgvx - compute selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A^*x=(\lambda)*B^*x$, $A^*Bx=(\lambda)*x$, or $B^*A^*x=(\lambda)*x$

[dspmv](#) - dspmv - perform the matrix-vector operation $y := \alpha^*A^*x + \beta^*y$

[dspr](#) - dspr - perform the symmetric rank 1 operation $A := \alpha^*x^*x' + A$

[dspr2](#) - dspr2 - perform the symmetric rank 2 operation $A := \alpha^*x^*y' + \alpha^*y^*x' + A$

[dsprfs](#) - dsprfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution

[dspsv](#) - dspsv - compute the solution to a real system of linear equations $A * X = B$,

[dspsvx](#) - dspsvx - use the diagonal pivoting factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ to compute the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices

[dsptrd](#) - dsptrd - reduce a real symmetric matrix A stored in packed form to symmetric tridiagonal form T by an orthogonal similarity transformation

[dsptrf](#) - dsptrf - compute the factorization of a real symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method

[dsptri](#) - dsptri - compute the inverse of a real symmetric indefinite matrix A in packed storage using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by SSPTRF

[dsptrs](#) - dsptrs - solve a system of linear equations $A^*X = B$ with a real symmetric matrix A stored in packed format using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by SSPTRF

[dstebz](#) - dstebz - compute the eigenvalues of a symmetric tridiagonal matrix T

[dstedc](#) - dstedc - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method

[dstegr](#) - dstegr - (a) Compute $T\text{-}\sigma_i = L_i D_i L_i^T$, such that $L_i D_i L_i^T$ is a relatively robust representation

[dstein](#) - dstein - compute the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration

[dsteqr](#) - dsteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method

[dsterf](#) - dsterf - compute all eigenvalues of a symmetric tridiagonal matrix using the Pal-Walker-Kahan variant of the QL or QR algorithm

[dstev](#) - dstev - compute all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A

[dstevd](#) - dstevd - compute all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A

[dstevr](#) - dstevr - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T

[dstevx](#) - dstevx - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A

[dstsv](#) - dstsv - compute the solution to a system of linear equations $A * X = B$ where A is a symmetric tridiagonal matrix

[dsttrf](#) - dsttrf - compute the factorization of a symmetric tridiagonal matrix A

[dsttrs](#) - dsttrs - computes the solution to a real system of linear equations $A * X = B$

[dswap](#) - dswap - Exchange vectors x and y.

[dsycon](#) - dsycon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric matrix A using the factorization $A = U * D * U^{**T}$ or $A = L * D * L^{**T}$ computed by SSYTRF

[dsyev](#) - dsyev - compute all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

[dsyevd](#) - dsyevd - compute all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

[dsyevr](#) - dsyevr - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T

[dsyevx](#) - dsyevx - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

[dsygs2](#) - dsygs2 - reduce a real symmetric-definite generalized eigenproblem to standard form

[dsygst](#) - dsygst - reduce a real symmetric-definite generalized eigenproblem to standard form

[dsygv](#) - dsygv - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A * x = (\text{lambda}) * B * x$, $A * Bx = (\text{lambda}) * x$, or $B * A * x = (\text{lambda}) * x$

[dsygvd](#) - dsygvd - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A * x = (\text{lambda}) * B * x$, $A * Bx = (\text{lambda}) * x$, or $B * A * x = (\text{lambda}) * x$

[dsygvx](#) - dsygvx - compute selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A * x = (\text{lambda}) * B * x$, $A * Bx = (\text{lambda}) * x$, or $B * A * x = (\text{lambda}) * x$

[dsymm](#) - dsymm - perform one of the matrix-matrix operations $C := \text{alpha} * A * B + \text{beta} * C$ or $C := \text{alpha} * B * A + \text{beta} * C$

[dsymv](#) - dsymv - perform the matrix-vector operation $y := \text{alpha} * A * x + \text{beta} * y$

[dsyr](#) - dsyr - perform the symmetric rank 1 operation $A := \text{alpha} * x * x' + A$

[dsyr2](#) - dsyr2 - perform the symmetric rank 2 operation $A := \text{alpha} * x * y' + \text{alpha} * y * x' + A$

[dsyr2k](#) - dsyr2k - perform one of the symmetric rank 2k operations $C := \text{alpha} * A * B' + \text{alpha} * B * A' + \text{beta} * C$ or $C := \text{alpha} * A' * B + \text{alpha} * B' * A + \text{beta} * C$

[dsyrfs](#) - dsyrfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution

[dsyrk](#) - dsyrk - perform one of the symmetric rank k operations $C := \text{alpha} * A * A' + \text{beta} * C$ or $C := \text{alpha} * A' * A + \text{beta} * C$

[dsysv](#) - dsysv - compute the solution to a real system of linear equations $A * X = B$,

[dsysvx](#) - dsysvx - use the diagonal pivoting factorization to compute the solution to a real system of linear equations $A * X = B$,

[dsytd2](#) - dsytd2 - reduce a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation

[dsytf2](#) - dsytf2 - compute the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

[dsytrd](#) - dsytrd - reduce a real symmetric matrix A to real symmetric tridiagonal form T by an orthogonal similarity transformation

[dsytrf](#) - dsytrf - compute the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting

method

[dsytri](#) - dsytri - compute the inverse of a real symmetric indefinite matrix A using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by SSYTRF

[dsytrs](#) - dsytrs - solve a system of linear equations $A^*X = B$ with a real symmetric matrix A using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by SSYTRF

[dtbcon](#) - dtbcon - estimate the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm

[dtbmv](#) - dtbmv - perform one of the matrix-vector operations $x := A^*x$, or $x := A'^*x$

[dtbrfs](#) - dtbrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix

[dtbsv](#) - dtbsv - solve one of the systems of equations $A^*x = b$, or $A'^*x = b$

[dtbtrs](#) - dtbtrs - solve a triangular system of the form $A^*X = B$ or $A^{**T}^*X = B$,

[dtgevc](#) - dtgevc - compute some or all of the right and/or left generalized eigenvectors of a pair of real upper triangular matrices (A,B)

[dtgexc](#) - dtgexc - reorder the generalized real Schur decomposition of a real matrix pair (A,B) using an orthogonal equivalence transformation $(A, B) = Q^* (A, B) ^* Z'$,

[dtgsen](#) - dtgsen - reorder the generalized real Schur decomposition of a real matrix pair (A, B) (in terms of an orthonormal equivalence transformation $Q'^* (A, B) ^* Z$), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix A and the upper triangular B

[dtgsja](#) - dtgsja - compute the generalized singular value decomposition (GSVD) of two real upper triangular (or trapezoidal) matrices A and B

[dtgsna](#) - dtgsna - estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) in generalized real Schur canonical form (or of any matrix pair (Q^*A^*Z', Q^*B^*Z') with orthogonal matrices Q and Z, where Z' denotes the transpose of Z

[dtgsyl](#) - dtgsyl - solve the generalized Sylvester equation

[dtpcon](#) - dtpcon - estimate the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm

[dtpmv](#) - dtpmv - perform one of the matrix-vector operations $x := A^*x$, or $x := A'^*x$

[dtpfrs](#) - dtpfrs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix

[dtpsv](#) - dtpsv - solve one of the systems of equations $A^*x = b$, or $A'^*x = b$

[dtptri](#) - dtptri - compute the inverse of a real upper or lower triangular matrix A stored in packed format

[dtptrs](#) - dtptrs - solve a triangular system of the form $A^*X = B$ or $A^{**T}^*X = B$,

[dtrans](#) - dtrans - transpose and scale source matrix

[dtrcon](#) - dtrcon - estimate the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm

[dtrevc](#) - dtrevc - compute some or all of the right and/or left eigenvectors of a real upper quasi-triangular matrix T

[dtrexc](#) - dtrexc - reorder the real Schur factorization of a real matrix $A = Q^*T^*Q^{**T}$, so that the diagonal block of T with row index IFST is moved to row ILST

[dtrmm](#) - dtrmm - perform one of the matrix-matrix operations $B := \alpha^*op(A)^*B$, or $B := \alpha^*B^*op(A)$

[dtrmv](#) - dtrmv - perform one of the matrix-vector operations $x := A^*x$, or $x := A'^*x$

[dtrrfs](#) - dtrrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix

[dtrsen](#) - dtrsen - reorder the real Schur factorization of a real matrix $A = Q^*T^*Q^{**T}$, so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix T,

[dtrsm](#) - dtrsm - solve one of the matrix equations $\text{op}(A) * X = \alpha * B$, or $X * \text{op}(A) = \alpha * B$

[dtrsna](#) - dtrsna - estimate reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a real upper quasi-triangular matrix T (or of any matrix $Q * T * Q ** T$ with Q orthogonal)

[dtrsv](#) - dtrsv - solve one of the systems of equations $A * x = b$, or $A' * x = b$

[dtrsyl](#) - dtrsyl - solve the real Sylvester matrix equation

[dtrti2](#) - dtrti2 - compute the inverse of a real upper or lower triangular matrix

[dtrtri](#) - dtrtri - compute the inverse of a real upper or lower triangular matrix A

[dtrtrs](#) - dtrtrs - solve a triangular system of the form $A * X = B$ or $A ** T * X = B$,

[dtzrqf](#) - dtzrqf - routine is deprecated and has been replaced by routine STZRZF

[dtzrzf](#) - dtzrzf - reduce the M-by-N ($M \leq N$) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations

[dvbrmm](#) - dvbrmm - variable block sparse row format matrix-matrix multiply

[dvbrsm](#) - dvbrsm - variable block sparse row format triangular solve

[dwiener](#) - dwiener - perform Wiener deconvolution of two signals

[dzasum](#) - dzasum - Return the sum of the absolute values of a vector x.

[dznrm2](#) - dznrm2 - Return the Euclidian norm of a vector.

[ezffb](#) - ezffb - computes a periodic sequence from its Fourier coefficients. EZFFTB is a simplified but slower version of RFFTB.

[ezfff](#) - ezfff - computes the Fourier coefficients of a periodic sequence. EZFFTF is a simplified but slower version of RFFTF.

[ezffti](#) - ezffti - initializes the array WSAVE, which is used in both EZFFTF and EZFFTB.

[fft](#) - Overview of Fast Fourier Transform subroutines

[icamax](#) - icamax - return the index of the element with largest absolute value.

[idamax](#) - idamax - return the index of the element with largest absolute value.

[ilaenv](#) - The name of the calling subroutine, in either upper case or lower case.

[isamax](#) - isamax - return the index of the element with largest absolute value.

[izamax](#) - izamax - return the index of the element with largest absolute value.

[lsame](#) - lsame - returns .TRUE. if CA is the same letter as CB regardless of case

[rfft2b](#) - rfft2b - compute a periodic sequence from its Fourier coefficients. The RFFT operations are unnormalized, so a call of RFFT2F followed by a call of RFFT2B will multiply the input sequence by $M * N$.

[rfft2f](#) - rfft2f - compute the Fourier coefficients of a periodic sequence. The RFFT operations are unnormalized, so a call of RFFT2F followed by a call of RFFT2B will multiply the input sequence by $M * N$.

[rfft2i](#) - rfft2i - initialize the array WSAVE, which is used in both the forward and backward transforms.

[rfft3b](#) - rfft3b - compute a periodic sequence from its Fourier coefficients. The RFFT operations are unnormalized, so a call of RFFT3F followed by a call of RFFT3B will multiply the input sequence by $M * N * K$.

[rfft3f](#) - rfft3f - compute the Fourier coefficients of a real periodic sequence. The RFFT operations are unnormalized, so a call of RFFT3F followed by a call of RFFT3B will multiply the input sequence by $M * N * K$.

[rfft3i](#) - rfft3i - initialize the array WSAVE, which is used in both RFFT3F and RFFT3B.

[rfftb](#) - rfftb - compute a periodic sequence from its Fourier coefficients. The RFFT operations are unnormalized, so a call of RFFTF followed by a call of RFFTB will multiply the input sequence by N.

[rfftf](#) - rfftf - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of RFFTF followed by a call of RFFTB will multiply the input sequence by N.

[rffti](#) - rffti - initialize the array WSAVE, which is used in both RFFTF and RFFTB.

[rfftopt](#) - rfftopt - compute the length of the closest fast FFT

[sasum](#) - sasum - Return the sum of the absolute values of a vector x.

[saxpy](#) - saxpy - compute $y := \alpha * x + y$

[saxpyi](#) - saxpyi - Compute $y := \alpha * x + y$

[sbcomm](#) - sbcomm - block coordinate matrix-matrix multiply

[sbdimm](#) - sbdimm - block diagonal format matrix-matrix multiply

[sbdism](#) - sbdism - block diagonal format triangular solve

[sbdsc](#) - sbdsc - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B

[sbdscr](#) - sbdscr - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B.

[sbelmm](#) - sbelmm - block Ellpack format matrix-matrix multiply

[sbelsm](#) - sbelsm - block Ellpack format triangular solve

[sbscmm](#) - sbscmm - block sparse column matrix-matrix multiply

[sbscsm](#) - sbscsm - block sparse column format triangular solve

[sbsrmm](#) - sbsrmm - block sparse row format matrix-matrix multiply

[sbsrsm](#) - sbsrsm - block sparse row format triangular solve

[scasum](#) - scasum - Return the sum of the absolute values of a vector x.

[scnrm2](#) - scnrm2 - Return the Euclidian norm of a vector.

[scnvcor](#) - scnvcor - compute the convolution or correlation of real vectors

[scnvcor2](#) - scnvcor2 - compute the convolution or correlation of real matrices

[scoomm](#) - scoomm - coordinate matrix-matrix multiply

[scopy](#) - scopy - Copy x to y

[scscmm](#) - scscmm - compressed sparse column format matrix-matrix multiply

[scscsm](#) - scscsm - compressed sparse column format triangular solve

[scsrmm](#) - scsrmm - compressed sparse row format matrix-matrix multiply

[scsrsm](#) - scsrsm - compressed sparse row format triangular solve

[sdiamm](#) - sdiamm - diagonal format matrix-matrix multiply

[sdiasm](#) - sdiasm - diagonal format triangular solve

[sdisna](#) - sdisna - compute the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m-by-n matrix

[sdot](#) - sdot - compute the dot product of two vectors x and y.

[sdoti](#) - sdoti - Compute the indexed dot product.

[sdsdot](#) - sdsdot - compute a constant plus the double precision dot product of two single precision vectors x and y

[second](#) - second - return the user time for a process in seconds

[sellmm](#) - sellmm - Ellpack format matrix-matrix multiply

[sellsm](#) - sellsm - Ellpack format triangular solve

[sfftc](#) - sfftc - initialize the trigonometric weight and factor tables or compute the forward Fast Fourier Transform of a real sequence.

[sfft2](#) - sfft2 - initialize the trigonometric weight and factor tables or compute the two-dimensional forward Fast Fourier Transform of a two-dimensional real array.

[sfft3](#) - sfft3 - initialize the trigonometric weight and factor tables or compute the three-dimensional forward Fast Fourier Transform of a three-dimensional complex array.

[sfftc](#) - sfftc - initialize the trigonometric weight and factor tables or compute the one-dimensional forward Fast Fourier Transform of a set of real data sequences stored in a two-dimensional array.

[sgbbrd](#) - sgbbrd - reduce a real general m-by-n band matrix A to upper bidiagonal form B by an orthogonal transformation

[sgbcon](#) - sgbcon - estimate the reciprocal of the condition number of a real general band matrix A, in either the 1-norm or the infinity-norm,

[sgbequ](#) - sgbequ - compute row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number

[sgbmv](#) - sgbmv - perform one of the matrix-vector operations $y := \alpha * A * x + \beta * y$ or $y := \alpha * A' * x + \beta * y$

[sgbrfs](#) - sgbrfs - improve the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution

[sgbsv](#) - sgbsv - compute the solution to a real system of linear equations $A * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices

[sgbsvx](#) - sgbsvx - use the LU factorization to compute the solution to a real system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$,

[sgbtf2](#) - sgbtf2 - compute an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges

[sgbtrf](#) - sgbtrf - compute an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges

[sgbtrs](#) - sgbtrs - solve a system of linear equations $A * X = B$ or $A' * X = B$ with a general band matrix A using the LU factorization computed by SGBTRF

[sgebak](#) - sgebak - form the right or left eigenvectors of a real general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by SGEBAL

[sgebal](#) - sgebal - balance a general real matrix A

[sgebrd](#) - sgebrd - reduce a general real M-by-N matrix A to upper or lower bidiagonal form B by an orthogonal transformation

[sgecon](#) - sgecon - estimate the reciprocal of the condition number of a general real matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by SGETRF

[sgeequ](#) - sgeequ - compute row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number

[sgees](#) - sgees - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z

[sgeesx](#) - sgeesx - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z

[sgeev](#) - sgeev - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

[sgeevx](#) - sgeevx - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

[sgegs](#) - sgegs - routine is deprecated and has been replaced by routine SGGES

[sgegv](#) - sgegv - routine is deprecated and has been replaced by routine SGGEV

[sgehrd](#) - sgehrd - reduce a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation

[sgelqf](#) - sgelqf - compute an LQ factorization of a real M-by-N matrix A

[sgels](#) - sgels - solve overdetermined or underdetermined real linear systems involving an M-by-N matrix A, or its transpose, using a QR or LQ factorization of A

[sgelsd](#) - sgelsd - compute the minimum-norm solution to a real linear least squares problem

[sgelss](#) - sgelss - compute the minimum norm solution to a real linear least squares problem

[sgelsx](#) - sgelsx - routine is deprecated and has been replaced by routine SGELSY

[sgelsy](#) - sgelsy - compute the minimum-norm solution to a real linear least squares problem

[sgemm](#) - sgemm - perform one of the matrix-matrix operations $C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C$

[sgemv](#) - sgemv - perform one of the matrix-vector operations $y := \alpha * A * x + \beta * y$ or $y := \alpha * A' * x + \beta * y$

[sgeqlf](#) - sgeqlf - compute a QL factorization of a real M-by-N matrix A

[sgeqp3](#) - sgeqp3 - compute a QR factorization with column pivoting of a matrix A

[sgeqpf](#) - sgeqpf - routine is deprecated and has been replaced by routine SGEQP3

[sgeqrf](#) - sgeqrf - compute a QR factorization of a real M-by-N matrix A

[sger](#) - sger - perform the rank 1 operation $A := \alpha * x * y' + A$

[sgerfs](#) - sgerfs - improve the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution

[sgerqf](#) - sgerqf - compute an RQ factorization of a real M-by-N matrix A

[sgesdd](#) - sgesdd - compute the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and right singular vectors

[sgesv](#) - sgesv - compute the solution to a real system of linear equations $A * X = B$,

[sgesvd](#) - sgesvd - compute the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and/or right singular vectors

[sgesvx](#) - sgesvx - use the LU factorization to compute the solution to a real system of linear equations $A * X = B$,

[sgetf2](#) - sgetf2 - compute an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges

[sgetrf](#) - sgetrf - compute an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges

[sgetri](#) - sgetri - compute the inverse of a matrix using the LU factorization computed by SGETRF

[sgetrs](#) - sgetrs - solve a system of linear equations $A * X = B$ or $A' * X = B$ with a general N-by-N matrix A using the LU factorization computed by SGETRF

[sggbak](#) - sggbak - form the right or left eigenvectors of a real generalized eigenvalue problem $A * x = \lambda * B * x$, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by SGGBAL

[sggbal](#) - sggbal - balance a pair of general real matrices (A,B)

[sgges](#) - sgges - compute for a pair of N-by-N real nonsymmetric matrices (A,B),

[sggesx](#) - sggesx - compute for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the real Schur form (S,T), and,

[sggev](#) - sggev - compute for a pair of N-by-N real nonsymmetric matrices (A,B)

[sggevz](#) - sggevz - compute for a pair of N-by-N real nonsymmetric matrices (A,B)

[sgglm](#) - sgglm - solve a general Gauss-Markov linear model (GLM) problem

[sgghrd](#) - sgghrd - reduce a pair of real matrices (A,B) to generalized upper Hessenberg form using orthogonal transformations, where A is a general matrix and B is upper triangular

[sgglse](#) - sgglse - solve the linear equality-constrained least squares (LSE) problem

[sggqrf](#) - sggqrf - compute a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B.

[sggrqf](#) - sggrqf - compute a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B

[sggsvd](#) - sggsvd - compute the generalized singular value decomposition (GSVD) of an M-by-N real matrix A and P-by-N real matrix B

[sggsvp](#) - sggsvp - compute orthogonal matrices U, V and Q such that $N-K-L \begin{matrix} K & L \\ U^* & A^* & Q \end{matrix} = K \begin{pmatrix} 0 & A_{12} & A_{13} \end{pmatrix}$ if $M-K-L \geq 0$

[sgssco](#) - sgssco - General sparse solver condition number estimate.

[sgssda](#) - sgssda - Deallocate working storage for the general sparse solver.

[sgssfa](#) - sgssfa - General sparse solver numeric factorization.

[sgssfs](#) - sgssfs - General sparse solver one call interface.

[sgssin](#) - sgssin - Initialize the general sparse solver.

[sgssor](#) - sgssor - General sparse solver ordering and symbolic factorization.

[sgssps](#) - sgssps - Print general sparse solver statics.

[sgssrp](#) - sgssrp - Return permutation used by the general sparse solver.

[sgsssl](#) - sgsssl - Solve routine for the general sparse solver.

[sgssuo](#) - sgssuo - User supplied permutation for ordering used in the general sparse solver.

[sgtcon](#) - sgtcon - estimate the reciprocal of the condition number of a real tridiagonal matrix A using the LU factorization as computed by SGTTRF

[sgthr](#) - sgthr - Gathers specified elements from y into x.

[sgthrz](#) - sgthrz - Gather and zero.

[sgtrfs](#) - sgtrfs - improve the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution

[sgtsv](#) - sgtsv - solve the equation $A^*X = B$,

[sgtsvx](#) - sgtsvx - use the LU factorization to compute the solution to a real system of linear equations $A^*X = B$ or $A^{**T} * X = B$,

[sgttrf](#) - sgttrf - compute an LU factorization of a real tridiagonal matrix A using elimination with partial pivoting and row interchanges

[sgttrs](#) - sgttrs - solve one of the systems of equations $A^*X = B$ or $A^{**T}X = B$,

[shgeqz](#) - shgeqz - implement a single-/double-shift version of the QZ method for finding the generalized eigenvalues $w(j) = (\text{ALPHAR}(j) + i * \text{ALPHAI}(j)) / \text{BETAR}(j)$ of the equation $\det(A - w(i) B) = 0$ In addition, the pair A,B may be reduced to generalized Schur form

[shsein](#) - shsein - use inverse iteration to find specified right and/or left eigenvectors of a real upper Hessenberg matrix H

[shseqr](#) - shseqr - compute the eigenvalues of a real upper Hessenberg matrix H and, optionally, the matrices T and Z from the Schur decomposition $H = Z T Z^{**T}$, where T is an upper quasi-triangular matrix (the Schur form), and Z is the orthogonal matrix of Schur vectors

[sinqb](#) - sinqb - synthesize a Fourier sequence from its representation in terms of a sine series with odd wave numbers. The SINQ operations are unnormalized inverses of themselves, so a call to SINQF followed by a call to SINQB will multiply the input sequence by $4 * N$.

[sinqf](#) - sinqf - compute the Fourier coefficients in a sine series representation with only odd wave numbers. The SINQ operations are unnormalized inverses of themselves, so a call to SINQF followed by a call to SINQB will multiply the input sequence by $4 * N$.

[sinqi](#) - sinqi - initialize the array xWSAVE, which is used in both SINQF and SINQB.

[sint](#) - sint - compute the discrete Fourier sine transform of an odd sequence. The SINT transforms are unnormalized inverses of themselves, so a call of SINT followed by another call of SINT will multiply the input sequence by $2 *$

(N+1).

[sinti](#) - sinti - initialize the array WSAVE, which is used in subroutine SINT.

[sjadmm](#) - sjadmm - Jagged diagonal matrix-matrix multiply (modified Ellpack)

[sjadrp](#) - sjadrp - right permutation of a jagged diagonal matrix

[sjadsm](#) - sjadsm - Jagged-diagonal format triangular solve

[slagtf](#) - slagtf - factorize the matrix $(T-\lambda I)$, where T is an n by n tridiagonal matrix and λ is a scalar, as $T-\lambda I = PLU$

[slamrg](#) - slamrg - will create a permutation list which will merge the elements of A (which is composed of two independently sorted sets) into a single set which is sorted in ascending order

[slarz](#) - slarz - applies a real elementary reflector H to a real M-by-N matrix C, from either the left or the right

[slarzb](#) - slarzb - applies a real block reflector H or its transpose H^*T to a real distributed M-by-N C from the left or the right

[slarzt](#) - slarzt - form the triangular factor T of a real block reflector H of order $> n$, which is defined as a product of k elementary reflectors

[slasrt](#) - slasrt - the numbers in D in increasing order (if ID = 'I') or in decreasing order (if ID = 'D')

[slatzm](#) - slatzm - routine is deprecated and has been replaced by routine SORMRZ

[snrm2](#) - snrm2 - Return the Euclidian norm of a vector.

[sopgtr](#) - sopgtr - generate a real orthogonal matrix Q which is defined as the product of n-1 elementary reflectors H(i) of order n, as returned by SSPTRD using packed storage

[sopmtr](#) - sopmtr - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[sorg2l](#) - sorg2l - generate an m by n real matrix Q with orthonormal columns,

[sorg2r](#) - sorg2r - generate an m by n real matrix Q with orthonormal columns,

[sorgbr](#) - sorgbr - generate one of the real orthogonal matrices Q or P^*T determined by SGEBRD when reducing a real matrix A to bidiagonal form

[sorghr](#) - sorghr - generate a real orthogonal matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by SGEHRD

[sorgl2](#) - sorgl2 - generate an m by n real matrix Q with orthonormal rows,

[sorglq](#) - sorglq - generate an M-by-N real matrix Q with orthonormal rows,

[sorgql](#) - sorgql - generate an M-by-N real matrix Q with orthonormal columns,

[sorgqr](#) - sorgqr - generate an M-by-N real matrix Q with orthonormal columns,

[sorgr2](#) - sorgr2 - generate an m by n real matrix Q with orthonormal rows,

[sorgrq](#) - sorgrq - generate an M-by-N real matrix Q with orthonormal rows,

[sorgtr](#) - sorgtr - generate a real orthogonal matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by SSYTRD

[sormbr](#) - sormbr - VECT = 'Q', SORMBR overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[sormhr](#) - sormhr - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[sormlq](#) - sormlq - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[sormql](#) - sormql - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[sormqr](#) - sormqr - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[sormrq](#) - sormrq - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[sormrz](#) - sormrz - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[sormtr](#) - sormtr - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[spbcon](#) - spbcon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite band matrix using the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ computed by SPBTRF

[spbequ](#) - spbequ - compute row and column scalings intended to equilibrate a symmetric positive definite band matrix A and reduce its condition number (with respect to the two-norm)

[spbrfs](#) - spbrfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and banded, and provides error bounds and backward error estimates for the solution

[spbtf](#) - spbstf - compute a split Cholesky factorization of a real symmetric positive definite band matrix A

[spbsv](#) - spbsv - compute the solution to a real system of linear equations $A * X = B$,

[spbsvx](#) - spbsvx - use the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ to compute the solution to a real system of linear equations $A * X = B$,

[spbt2](#) - spbt2 - compute the Cholesky factorization of a real symmetric positive definite band matrix A

[spbtrf](#) - spbtrf - compute the Cholesky factorization of a real symmetric positive definite band matrix A

[spbtrs](#) - spbtrs - solve a system of linear equations $A * X = B$ with a symmetric positive definite band matrix A using the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ computed by SPBTRF

[spocon](#) - spocon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite matrix using the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ computed by SPOTRF

[spoequ](#) - spoequ - compute row and column scalings intended to equilibrate a symmetric positive definite matrix A and reduce its condition number (with respect to the two-norm)

[sporfs](#) - sporfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite,

[sposv](#) - sposv - compute the solution to a real system of linear equations $A * X = B$,

[sposvx](#) - sposvx - use the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ to compute the solution to a real system of linear equations $A * X = B$,

[spot2](#) - spot2 - compute the Cholesky factorization of a real symmetric positive definite matrix A

[spotrf](#) - spotrf - compute the Cholesky factorization of a real symmetric positive definite matrix A

[spotri](#) - spotri - compute the inverse of a real symmetric positive definite matrix A using the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ computed by SPOTRF

[spots](#) - spots - solve a system of linear equations $A * X = B$ with a symmetric positive definite matrix A using the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ computed by SPOTRF

[sppcon](#) - sppcon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite packed matrix using the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ computed by SPPTRF

[sppequ](#) - sppequ - compute row and column scalings intended to equilibrate a symmetric positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm)

[spprfs](#) - spprfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and packed, and provides error bounds and backward error estimates for the solution

[sppsv](#) - sppsv - compute the solution to a real system of linear equations $A * X = B$,

[sppsvx](#) - sppsvx - use the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ to compute the solution to a real system of linear equations $A * X = B$,

[spptrf](#) - spptrf - compute the Cholesky factorization of a real symmetric positive definite matrix A stored in packed format

[spptri](#) - spptri - compute the inverse of a real symmetric positive definite matrix A using the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ computed by SPPTRF

[spptrs](#) - spptrs - solve a system of linear equations $A * X = B$ with a symmetric positive definite matrix A in packed storage using the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ computed by SPPTRF

[sptcon](#) - sptcon - compute the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite tridiagonal matrix using the factorization $A = L^*D^*L^{**T}$ or $A = U^{**T}D^*U$ computed by SPTTRF

[spteqr](#) - spteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF, and then calling SBDSQR to compute the singular values of the bidiagonal factor

[sptfrs](#) - sptfrs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution

[sptsv](#) - sptsv - compute the solution to a real system of linear equations $A^*X = B$, where A is an N-by-N symmetric positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

[sptsvx](#) - sptsvx - use the factorization $A = L^*D^*L^{**T}$ to compute the solution to a real system of linear equations $A^*X = B$, where A is an N-by-N symmetric positive definite tridiagonal matrix and X and B are N-by-NRHS matrices

[spttrf](#) - spttrf - compute the L^*D^*L' factorization of a real symmetric positive definite tridiagonal matrix A

[spttrs](#) - spttrs - solve a tridiagonal system of the form $A^*X = B$ using the L^*D^*L' factorization of A computed by SPTTRF

[sptts2](#) - sptts2 - solve a tridiagonal system of the form $A^*X = B$ using the L^*D^*L' factorization of A computed by SPTTRF

[srot](#) - srot - Apply a Given's rotation constructed by SROTG.

[srotg](#) - srotg - Construct a Given's plane rotation

[sroti](#) - sroti - Apply an indexed Givens rotation.

[srotm](#) - srotm - Apply a Gentleman's modified Given's rotation constructed by SROTMG.

[srotmg](#) - srotmg - Construct a Gentleman's modified Given's plane rotation

[ssbev](#) - ssbev - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

[ssbevd](#) - ssbevd - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

[ssbevz](#) - ssbevz - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

[ssbgst](#) - ssbgst - reduce a real symmetric-definite banded generalized eigenproblem $A^*x = \lambda B^*x$ to standard form $C^*y = \lambda y$,

[ssbgv](#) - ssbgv - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A^*x = (\lambda B)^*x$

[ssbgvd](#) - ssbgvd - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A^*x = (\lambda B)^*x$

[ssbgvx](#) - ssbgvx - compute selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A^*x = (\lambda B)^*x$

[ssbmV](#) - ssbmV - perform the matrix-vector operation $y := \alpha^*A^*x + \beta^*y$

[ssbtrd](#) - ssbtrd - reduce a real symmetric band matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation

[sscal](#) - sscal - Compute $y := \alpha^*y$

[ssctr](#) - ssctr - Scatters elements from x into y.

[sskymm](#) - sskymm - Skyline format matrix-matrix multiply

[sskysm](#) - sskysm - Skyline format triangular solve

[sspcon](#) - sspcon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric packed matrix A using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by SSPTRF

[sspev](#) - sspev - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

[sspevd](#) - sspevd - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

[sspevx](#) - sspevx - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

[sspgst](#) - sspgst - reduce a real symmetric-definite generalized eigenproblem to standard form, using packed storage

[sspgv](#) - sspgv - compute all the eigenvalues and, optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A^*x=(\lambda)B^*x$, $A^*Bx=(\lambda)x$, or $B^*A^*x=(\lambda)x$

[sspgvd](#) - sspgvd - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A^*x=(\lambda)B^*x$, $A^*Bx=(\lambda)x$, or $B^*A^*x=(\lambda)x$

[sspgvx](#) - sspgvx - compute selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A^*x=(\lambda)B^*x$, $A^*Bx=(\lambda)x$, or $B^*A^*x=(\lambda)x$

[sspmv](#) - sspmv - perform the matrix-vector operation $y := \alpha A^*x + \beta y$

[sspr](#) - sspr - perform the symmetric rank 1 operation $A := \alpha x x^T + A$

[sspr2](#) - sspr2 - perform the symmetric rank 2 operation $A := \alpha x x^T + \alpha y y^T + A$

[ssprfs](#) - ssprfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution

[sspsv](#) - sspsv - compute the solution to a real system of linear equations $A * X = B$,

[sspsvx](#) - sspsvx - use the diagonal pivoting factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ to compute the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices

[ssptrd](#) - ssptrd - reduce a real symmetric matrix A stored in packed form to symmetric tridiagonal form T by an orthogonal similarity transformation

[ssptf](#) - ssptrf - compute the factorization of a real symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method

[ssptri](#) - ssptri - compute the inverse of a real symmetric indefinite matrix A in packed storage using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by SSPTRF

[ssptrs](#) - ssptrs - solve a system of linear equations $A^*X = B$ with a real symmetric matrix A stored in packed format using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by SSPTRF

[sstebz](#) - sstebz - compute the eigenvalues of a symmetric tridiagonal matrix T

[sstedc](#) - sstedc - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method

[sstegr](#) - sstegr - (a) Compute $T\text{-}\sigma_i = L_i D_i L_i^T$, such that $L_i D_i L_i^T$ is a relatively robust representation

[sstein](#) - sstein - compute the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration

[ssteqr](#) - ssteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method

[sstfrf](#) - sstfrf - compute all eigenvalues of a symmetric tridiagonal matrix using the Pal-Walker-Kahan variant of the QL or QR algorithm

[sstev](#) - sstev - compute all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A

[sstevd](#) - sstevd - compute all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix

[sstevr](#) - sstevr - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T

[sstevx](#) - sstevx - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A

[sstsv](#) - sstsv - compute the solution to a system of linear equations $A * X = B$ where A is a symmetric tridiagonal matrix

[ssttrf](#) - ssttrf - compute the factorization of a symmetric tridiagonal matrix A

[ssttrs](#) - ssttrs - computes the solution to a real system of linear equations $A * X = B$

[sswap](#) - sswap - Exchange vectors x and y.

[ssycon](#) - ssycon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric matrix A using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by SSYTRF

[ssyev](#) - ssyev - compute all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

[ssyevd](#) - ssyevd - compute all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

[ssyevr](#) - ssyevr - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T

[ssyevx](#) - ssyevx - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

[ssygs2](#) - ssygs2 - reduce a real symmetric-definite generalized eigenproblem to standard form

[ssygst](#) - ssygst - reduce a real symmetric-definite generalized eigenproblem to standard form

[ssygv](#) - ssygv - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A^*x=(\lambda)^*B^*x$, $A^*Bx=(\lambda)^*x$, or $B^*A^*x=(\lambda)^*x$

[ssygvd](#) - ssygvd - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A^*x=(\lambda)^*B^*x$, $A^*Bx=(\lambda)^*x$, or $B^*A^*x=(\lambda)^*x$

[ssygvx](#) - ssygvx - compute selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A^*x=(\lambda)^*B^*x$, $A^*Bx=(\lambda)^*x$, or $B^*A^*x=(\lambda)^*x$

[ssymm](#) - ssymm - perform one of the matrix-matrix operations $C := \alpha^*A^*B + \beta^*C$ or $C := \alpha^*B^*A + \beta^*C$

[ssymv](#) - ssymv - perform the matrix-vector operation $y := \alpha^*A^*x + \beta^*y$

[ssyr](#) - ssyr - perform the symmetric rank 1 operation $A := \alpha^*x^*x' + A$

[ssyr2](#) - ssyr2 - perform the symmetric rank 2 operation $A := \alpha^*x^*y' + \alpha^*y^*x' + A$

[ssyr2k](#) - ssyr2k - perform one of the symmetric rank 2k operations $C := \alpha^*A^*B' + \alpha^*B^*A' + \beta^*C$ or $C := \alpha^*A^*B + \alpha^*B^*A + \beta^*C$

[ssyrfs](#) - ssyrfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution

[ssyrk](#) - ssyrk - perform one of the symmetric rank k operations $C := \alpha^*A^*A' + \beta^*C$ or $C := \alpha^*A^*A + \beta^*C$

[ssysv](#) - ssysv - compute the solution to a real system of linear equations $A^*X = B$,

[ssysvx](#) - ssysvx - use the diagonal pivoting factorization to compute the solution to a real system of linear equations $A^*X = B$,

[ssytd2](#) - ssytd2 - reduce a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation

[ssytf2](#) - ssytf2 - compute the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

[ssytrd](#) - ssytrd - reduce a real symmetric matrix A to real symmetric tridiagonal form T by an orthogonal similarity transformation

[ssytrf](#) - ssytrf - compute the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

[ssytri](#) - ssytri - compute the inverse of a real symmetric indefinite matrix A using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by SSYTRF

[ssytrs](#) - ssytrs - solve a system of linear equations $A^*X = B$ with a real symmetric matrix A using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by SSYTRF

[stbcon](#) - stbcon - estimate the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm

[stbmV](#) - stbmV - perform one of the matrix-vector operations $x := A^*x$, or $x := A^*x$

[stbrfs](#) - stbrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix

[stbsv](#) - stbsv - solve one of the systems of equations $A^*x = b$, or $A^*x = b$

[stbtrs](#) - stbtrs - solve a triangular system of the form $A * X = B$ or $A^{**T} * X = B$,

[stgevc](#) - stgevc - compute some or all of the right and/or left generalized eigenvectors of a pair of real upper triangular matrices (A,B)

[stgexc](#) - stgexc - reorder the generalized real Schur decomposition of a real matrix pair (A,B) using an orthogonal equivalence transformation $(A, B) = Q * (A, B) * Z'$,

[stgsen](#) - stgsen - reorder the generalized real Schur decomposition of a real matrix pair (A, B) (in terms of an orthonormal equivalence transformation $Q' * (A, B) * Z$), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix A and the upper triangular B

[stgsja](#) - stgsja - compute the generalized singular value decomposition (GSVD) of two real upper triangular (or trapezoidal) matrices A and B

[stgsna](#) - stgsna - estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) in generalized real Schur canonical form (or of any matrix pair $(Q * A * Z', Q * B * Z')$ with orthogonal matrices Q and Z, where Z' denotes the transpose of Z)

[stgsyl](#) - stgsyl - solve the generalized Sylvester equation

[stpcon](#) - stpcon - estimate the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm

[stpmv](#) - stpmv - perform one of the matrix-vector operations $x := A * x$, or $x := A' * x$

[stprfs](#) - stprfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix

[stpsv](#) - stpsv - solve one of the systems of equations $A * x = b$, or $A' * x = b$

[stptri](#) - stptri - compute the inverse of a real upper or lower triangular matrix A stored in packed format

[stptrs](#) - stptrs - solve a triangular system of the form $A * X = B$ or $A^{**T} * X = B$,

[strans](#) - strans - transpose and scale source matrix

[strcon](#) - strcon - estimate the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm

[strevc](#) - strevc - compute some or all of the right and/or left eigenvectors of a real upper quasi-triangular matrix T

[strex](#) - strex - reorder the real Schur factorization of a real matrix $A = Q * T * Q^{**T}$, so that the diagonal block of T with row index IFST is moved to row ILST

[strmm](#) - strmm - perform one of the matrix-matrix operations $B := \alpha * \text{op}(A) * B$, or $B := \alpha * B * \text{op}(A)$

[strmv](#) - strmv - perform one of the matrix-vector operations $x := A * x$, or $x := A' * x$

[strrfs](#) - strrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix

[strsen](#) - strsen - reorder the real Schur factorization of a real matrix $A = Q * T * Q^{**T}$, so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix T,

[strsm](#) - strsm - solve one of the matrix equations $\text{op}(A) * X = \alpha * B$, or $X * \text{op}(A) = \alpha * B$

[strsna](#) - strsna - estimate reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a real upper quasi-triangular matrix T (or of any matrix $Q * T * Q^{**T}$ with Q orthogonal)

[strsv](#) - strsv - solve one of the systems of equations $A * x = b$, or $A' * x = b$

[strsyl](#) - strsyl - solve the real Sylvester matrix equation

[strti2](#) - strti2 - compute the inverse of a real upper or lower triangular matrix

[strtri](#) - strtri - compute the inverse of a real upper or lower triangular matrix A

[strtrs](#) - strtrs - solve a triangular system of the form $A * X = B$ or $A^{**T} * X = B$,

[stzrqf](#) - stzrqf - routine is deprecated and has been replaced by routine STZRZF

[stzrzf](#) - stzrzf - reduce the M-by-N ($M \leq N$) real upper trapezoidal matrix A to upper triangular form by means of

orthogonal transformations

[sunperf_version](#) - sunperf_version - gets library information .HP 1i SUBROUTINE SUNPERF_VERSION(VERSION, PATCH, UPDATE) .HP 1i INTEGER VERSION, PATCH, UPDATE .HP 1i

[svbrmm](#) - svbrmm - variable block sparse row format matrix-matrix multiply

[svbrsm](#) - svbrsm - variable block sparse row format triangular solve

[swiener](#) - swiener - perform Wiener deconvolution of two signals

[use_threads](#) - use_threads - set the upper bound on the number of threads that the calling thread wants used

[using_threads](#) - using_threads - returns the current Use number set by the USE_THREADS subroutine

[vcfftb](#) - vcfftb - compute a periodic sequence from its Fourier coefficients. The VCFFT operations are normalized, so a call of VCFFTF followed by a call of VCFFTB will return the original sequence.

[vcfftf](#) - vcfftf - compute the Fourier coefficients of a periodic sequence. The VCFFT operations are normalized, so a call of VCFFTF followed by a call of VCFFTB will return the original sequence.

[vcffti](#) - vcffti - initialize the array WSAVE, which is used in both VCFFTF and VCFFTB.

[vcosqb](#) - vcosqb - synthesize a Fourier sequence from its representation in terms of a cosine series with odd wave numbers. The VCOSQ operations are normalized, so a call of VCOSQF followed by a call of VCOSQB will return the original sequence.

[vcosqf](#) - vcosqf - compute the Fourier coefficients in a cosine series representation with only odd wave numbers. The VCOSQ operations are normalized, so a call of VCOSQF followed by a call of VCOSQB will return the original sequence.

[vcosqi](#) - vcosqi - initialize the array WSAVE, which is used in both VCOSQF and VCOSQB.

[vcost](#) - vcost - compute the discrete Fourier cosine transform of an even sequence. The VCOST transform is normalized, so a call of VCOST followed by a call of VCOST will return the original sequence.

[vcosti](#) - vcosti - initialize the array WSAVE, which is used in VCOST.

[vdcosqb](#) - vdcosqb - synthesize a Fourier sequence from its representation in terms of a cosine series with odd wave numbers. The VCOSQ operations are normalized, so a call of VCOSQF followed by a call of VCOSQB will return the original sequence.

[vdcosqf](#) - vdcosqf - compute the Fourier coefficients in a cosine series representation with only odd wave numbers. The VCOSQ operations are normalized, so a call of VCOSQF followed by a call of VCOSQB will return the original sequence.

[vdcosqi](#) - vdcosqi - initialize the array WSAVE, which is used in both VCOSQF and VCOSQB.

[vdcost](#) - vdcost - compute the discrete Fourier cosine transform of an even sequence. The VCOST transform is normalized, so a call of VCOST followed by a call of VCOST will return the original sequence.

[vdcosti](#) - vdcosti - initialize the array WSAVE, which is used in VCOST.

[vdrfftb](#) - vdrfftb - compute a periodic sequence from its Fourier coefficients. The VRFFT operations are normalized, so a call of VRFFTF followed by a call of VRFFTB will return the original sequence.

[vdrfftf](#) - vdrfftf - compute the Fourier coefficients of a periodic sequence. The VRFFT operations are normalized, so a call of VRFFTF followed by a call of VRFFTB will return the original sequence.

[vdrffti](#) - vdrffti - initialize the array WSAVE, which is used in both VRFFTF and VRFFTB.

[vdsinqb](#) - vdsinqb - synthesize a Fourier sequence from its representation in terms of a sine series with odd wave numbers. The VSINQ operations are normalized, so a call of VSINQF followed by a call of VSINQB will return the original sequence.

[vdsinqf](#) - vdsinqf - compute the Fourier coefficients in a sine series representation with only odd wave numbers. The VSINQ operations are normalized, so a call of VSINQF followed by a call of VSINQB will return the original sequence.

[vdsinqi](#) - vdsinqi - initialize the array WSAVE, which is used in both VSINQF and VSINQB.

[vdsint](#) - vdsint - compute the discrete Fourier sine transform of an odd sequence. The VSINT transforms are

unnormalized inverses of themselves, so a call of VSINT followed by another call of VSINT will multiply the input sequence by $2 * (N+1)$. The VSINT transforms are normalized, so a call of VSINT followed by a call of VSINT will return the original sequence.

[vdsinti](#) - vdsinti - initialize the array WSAVE, which is used in subroutine VSINT.

[vrfftb](#) - vrfftb - compute a periodic sequence from its Fourier coefficients. The VRFFT operations are normalized, so a call of VRFFTF followed by a call of VRFFTB will return the original sequence.

[vrfft](#) - vrfft - compute the Fourier coefficients of a periodic sequence. The VRFFT operations are normalized, so a call of VRFFTF followed by a call of VRFFTB will return the original sequence.

[vrffti](#) - vrffti - initialize the array WSAVE, which is used in both VRFFTF and VRFFTB.

[vsinqb](#) - vsinqb - synthesize a Fourier sequence from its representation in terms of a sine series with odd wave numbers. The VSINQ operations are normalized, so a call of VSINQF followed by a call of VSINQB will return the original sequence.

[vsinqf](#) - vsinqf - compute the Fourier coefficients in a sine series representation with only odd wave numbers. The VSINQ operations are normalized, so a call of VSINQF followed by a call of VSINQB will return the original sequence.

[vsinqi](#) - vsinqi - initialize the array WSAVE, which is used in both VSINQF and VSINQB.

[vsint](#) - vsint - compute the discrete Fourier sine transform of an odd sequence. The VSINT transforms are unnormalized inverses of themselves, so a call of VSINT followed by another call of VSINT will multiply the input sequence by $2 * (N+1)$. The VSINT transforms are normalized, so a call of VSINT followed by a call of VSINT will return the original sequence.

[vsinti](#) - vsinti - initialize the array WSAVE, which is used in subroutine VSINT.

[vzfftb](#) - vzfftb - compute a periodic sequence from its Fourier coefficients. The VZFFT operations are normalized, so a call of VZFFTF followed by a call of VZFFTB will return the original sequence.

[vzfft](#) - vzfft - compute the Fourier coefficients of a periodic sequence. The VZFFT operations are normalized, so a call of VZFFTF followed by a call of VZFFTB will return the original sequence.

[vzffti](#) - vzffti - initialize the array WSAVE, which is used in both VZFFTF and VZFFTB.

[zaxpy](#) - zaxpy - compute $y := \alpha * x + y$

[zaxpyi](#) - zaxpyi - Compute $y := \alpha * x + y$

[zbcmm](#) - zbcmm - block coordinate matrix-matrix multiply

[zbdimm](#) - zbdimm - block diagonal format matrix-matrix multiply

[zbdism](#) - zbdism - block diagonal format triangular solve

[zbdsm](#) - zbdsm - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B.

[zbelmm](#) - zbelmm - block Ellpack format matrix-matrix multiply

[zbelsm](#) - zbelsm - block Ellpack format triangular solve

[zbscmm](#) - zbscmm - block sparse column matrix-matrix multiply

[zbscsm](#) - zbscsm - block sparse column format triangular solve

[zbsrmm](#) - zbsrmm - block sparse row format matrix-matrix multiply

[zbsrsm](#) - zbsrsm - block sparse row format triangular solve

[zcnvcor](#) - zcnvcor - compute the convolution or correlation of complex vectors

[zcnvcor2](#) - zcnvcor2 - compute the convolution or correlation of complex matrices

[zcoomm](#) - zcoomm - coordinate matrix-matrix multiply

[zcopy](#) - zcopy - Copy x to y

[zscmm](#) - zscmm - compressed sparse column format matrix-matrix multiply

[zscscsm](#) - zscscsm - compressed sparse column format triangular solve

[zcsrmm](#) - zcsrmm - compressed sparse row format matrix-matrix multiply

[zcsrsm](#) - zcsrsm - compressed sparse row format triangular solve

[zdiamm](#) - zdiamm - diagonal format matrix-matrix multiply

[zdiasm](#) - zdiasm - diagonal format triangular solve

[zdotc](#) - zdotc - compute the dot product of two vectors conjg(x) and y.

[zdotci](#) - zdotci - Compute the complex conjugated indexed dot product.

[zdotu](#) - zdotu - compute the dot product of two vectors x and y.

[zdotui](#) - zdotui - Compute the complex unconjugated indexed dot product.

[zdrot](#) - zdrot - Apply a plane rotation.

[zdscal](#) - zdscal - Compute $y := \alpha * y$

[zellmm](#) - zellmm - Ellpack format matrix-matrix multiply

[zellsn](#) - zellsn - Ellpack format triangular solve

[zfft2b](#) - zfft2b - compute a periodic sequence from its Fourier coefficients. The FFT operations are unnormalized, so a call of ZFFT2F followed by a call of ZFFT2B will multiply the input sequence by $M*N$.

[zfft2f](#) - zfft2f - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of ZFFT2F followed by a call of ZFFT2B will multiply the input sequence by $M*N$.

[zfft2i](#) - zfft2i - initialize the array WSAVE, which is used in both the forward and backward transforms.

[zfft3b](#) - zfft3b - compute a periodic sequence from its Fourier coefficients. The FFT operations are unnormalized, so a call of ZFFT3F followed by a call of ZFFT3B will multiply the input sequence by $M*N*K$.

[zfft3f](#) - zfft3f - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of ZFFT3F followed by a call of ZFFT3B will multiply the input sequence by $M*N*K$.

[zfft3i](#) - zfft3i - initialize the array WSAVE, which is used in both ZFFT3F and ZFFT3B.

[zfftb](#) - zfftb - compute a periodic sequence from its Fourier coefficients. The FFT operations are unnormalized, so a call of ZFFTF followed by a call of ZFFTB will multiply the input sequence by N .

[zfftd](#) - zfftd - initialize the trigonometric weight and factor tables or compute the inverse Fast Fourier Transform of a double complex sequence.

[zfftd2](#) - zfftd2 - initialize the trigonometric weight and factor tables or compute the two-dimensional inverse Fast Fourier Transform of a two-dimensional double complex array.

[zfftd3](#) - zfftd3 - initialize the trigonometric weight and factor tables or compute the three-dimensional inverse Fast Fourier Transform of a three-dimensional double complex array.

[zfftdm](#) - zfftdm - initialize the trigonometric weight and factor tables or compute the one-dimensional inverse Fast Fourier Transform of a set of double complex data sequences stored in a two-dimensional array.

[zfftf](#) - zfftf - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of ZFFTF followed by a call of ZFFTB will multiply the input sequence by N .

[zffti](#) - zffti - initialize the array WSAVE, which is used in both ZFFTF and ZFFTB.

[zfftpt](#) - zfftpt - compute the length of the closest fast FFT

[zfftz](#) - zfftz - initialize the trigonometric weight and factor tables or compute the Fast Fourier transform (forward or inverse) of a double complex sequence.

[zfftz2](#) - zfftz2 - initialize the trigonometric weight and factor tables or compute the two-dimensional Fast Fourier Transform (forward or inverse) of a two-dimensional double complex array.

[zfftz3](#) - zfftz3 - initialize the trigonometric weight and factor tables or compute the three-dimensional Fast Fourier Transform (forward or inverse) of a three-dimensional double complex array.

[zfftzm](#) - zfftzm - initialize the trigonometric weight and factor tables or compute the one-dimensional Fast Fourier Transform (forward or inverse) of a set of data sequences stored in a two-dimensional double complex array.

[zgbbrd](#) - zgbbrd - reduce a complex general m-by-n band matrix A to real upper bidiagonal form B by a unitary transformation

[zgbcon](#) - zgbcon - estimate the reciprocal of the condition number of a complex general band matrix A, in either the 1-norm or the infinity-norm,

[zgbegu](#) - zgbegu - compute row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number

[zgbmv](#) - zgbmv - perform one of the matrix-vector operations $y := \alpha * A * x + \beta * y$, or $y := \alpha * A' * x + \beta * y$, or $y := \alpha * \text{conjg}(A') * x + \beta * y$

[zgbfrs](#) - zgbfrs - improve the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution

[zgbsv](#) - zgbsv - compute the solution to a complex system of linear equations $A * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices

[zgbsvx](#) - zgbsvx - use the LU factorization to compute the solution to a complex system of linear equations $A * X = B$, $A ** T * X = B$, or $A ** H * X = B$,

[zgbtf2](#) - zgbtf2 - compute an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges

[zgbtrf](#) - zgbtrf - compute an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges

[zgbtrs](#) - zgbtrs - solve a system of linear equations $A * X = B$, $A ** T * X = B$, or $A ** H * X = B$ with a general band matrix A using the LU factorization computed by CGBTRF

[zgebak](#) - zgebak - form the right or left eigenvectors of a complex general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by CGEBAL

[zgebal](#) - zgebal - balance a general complex matrix A

[zgebrd](#) - zgebrd - reduce a general complex M-by-N matrix A to upper or lower bidiagonal form B by a unitary transformation

[zgecon](#) - zgecon - estimate the reciprocal of the condition number of a general complex matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by CGETRF

[zgeequ](#) - zgeequ - compute row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number

[zgees](#) - zgees - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z

[zgeesx](#) - zgeesx - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z

[zgeev](#) - zgeev - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

[zgeevx](#) - zgeevx - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

[zgegs](#) - zgegs - routine is deprecated and has been replaced by routine CGGES

[zgeg](#) - zgeg - routine is deprecated and has been replaced by routine CGGEV

[zgehrd](#) - zgehrd - reduce a complex general matrix A to upper Hessenberg form H by a unitary similarity transformation

[zgelqf](#) - zgelqf - compute an LQ factorization of a complex M-by-N matrix A

[zgels](#) - zgels - solve overdetermined or underdetermined complex linear systems involving an M-by-N matrix A, or its conjugate-transpose, using a QR or LQ factorization of A

[zgel](#) - zgel - compute the minimum-norm solution to a real linear least squares problem

[zgels](#) - zgels - compute the minimum norm solution to a complex linear least squares problem

[zgelsx](#) - zgelsx - routine is deprecated and has been replaced by routine CGELSY

[zgelsy](#) - zgelsy - compute the minimum-norm solution to a complex linear least squares problem

[zgemm](#) - zgemm - perform one of the matrix-matrix operations $C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C$

[zgemv](#) - zgemv - perform one of the matrix-vector operations $y := \alpha * A * x + \beta * y$, or $y := \alpha * A' * x + \beta * y$, or $y := \alpha * \text{conjg}(A') * x + \beta * y$

[zgeqlf](#) - zgeqlf - compute a QL factorization of a complex M-by-N matrix A

[zgeqp3](#) - zgeqp3 - compute a QR factorization with column pivoting of a matrix A

[zgeqpf](#) - zgeqpf - routine is deprecated and has been replaced by routine CGEQP3

[zgeqrf](#) - zgeqrf - compute a QR factorization of a complex M-by-N matrix A

[zgerc](#) - zgerc - perform the rank 1 operation $A := \alpha * x * \text{conjg}(y') + A$

[zgerfs](#) - zgerfs - improve the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution

[zgerqf](#) - zgerqf - compute an RQ factorization of a complex M-by-N matrix A

[zgeru](#) - zgeru - perform the rank 1 operation $A := \alpha * x * y' + A$

[zgesdd](#) - zgesdd - compute the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors, by using divide-and-conquer method

[zgesv](#) - zgesv - compute the solution to a complex system of linear equations $A * X = B$,

[zgesvd](#) - zgesvd - compute the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors

[zgesvx](#) - zgesvx - use the LU factorization to compute the solution to a complex system of linear equations $A * X = B$,

[zgetf2](#) - zgetf2 - compute an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges

[zgetrf](#) - zgetrf - compute an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges

[zgetri](#) - zgetri - compute the inverse of a matrix using the LU factorization computed by CGETRF

[zgetrs](#) - zgetrs - solve a system of linear equations $A * X = B$, $A ** T * X = B$, or $A ** H * X = B$ with a general N-by-N matrix A using the LU factorization computed by CGETRF

[zggbak](#) - zggbak - form the right or left eigenvectors of a complex generalized eigenvalue problem $A * x = \lambda * B * x$, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by CGGBAL

[zggbal](#) - zggbal - balance a pair of general complex matrices (A,B)

[zggcs](#) - zggcs - compute for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized complex Schur form (S, T), and optionally left and/or right Schur vectors (VSL and VSR)

[zggcsx](#) - zggcsx - compute for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the complex Schur form (S,T),

[zggeev](#) - zggeev - compute for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors

[zggevx](#) - zggevx - compute for a pair of N-by-N complex nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors

[zggglm](#) - zggglm - solve a general Gauss-Markov linear model (GLM) problem

[zggghrd](#) - zggghrd - reduce a pair of complex matrices (A,B) to generalized upper Hessenberg form using unitary transformations, where A is a general matrix and B is upper triangular

[zggls](#) - zggls - solve the linear equality-constrained least squares (LSE) problem

[zggqrf](#) - zggqrf - compute a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B.

[zggqrqf](#) - zggqrqf - compute a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B

[zggsvd](#) - zggsvd - compute the generalized singular value decomposition (GSVD) of an M-by-N complex matrix A and P-by-N complex matrix B

[zggsvp](#) - zggsvp - compute unitary matrices U, V and Q such that $N-K-L \begin{matrix} K & L \\ U^* & A^* & Q \end{matrix} = K \begin{pmatrix} 0 & A_{12} & A_{13} \end{pmatrix}$ if $M-K-L \geq 0$

[zgssco](#) - zgssco - General sparse solver condition number estimate.

[zgssda](#) - zgssda - Deallocate working storage for the general sparse solver.

[zgssfa](#) - zgssfa - General sparse solver numeric factorization.

[zgssfs](#) - zgssfs - General sparse solver one call interface.

[zgssin](#) - zgssin - Initialize the general sparse solver.

[zgssor](#) - zgssor - General sparse solver ordering and symbolic factorization.

[zgssps](#) - zgssps - Print general sparse solver statics.

[zgssrp](#) - zgssrp - Return permutation used by the general sparse solver.

[zgsssl](#) - zgsssl - Solve routine for the general sparse solver.

[zgssuo](#) - zgssuo - User supplied permutation for ordering used in the general sparse solver.

[zgtcon](#) - zgtcon - estimate the reciprocal of the condition number of a complex tridiagonal matrix A using the LU factorization as computed by CGTTRF

[zgthr](#) - zgthr - Gathers specified elements from y into x.

[zgthrz](#) - zgthrz - Gather and zero.

[zgtfrs](#) - zgtfrs - improve the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution

[zgtsv](#) - zgtsv - solve the equation $A^*X = B$,

[zgtsvx](#) - zgtsvx - use the LU factorization to compute the solution to a complex system of linear equations $A^*X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$,

[zgttrf](#) - zgttrf - compute an LU factorization of a complex tridiagonal matrix A using elimination with partial pivoting and row interchanges

[zgttrs](#) - zgttrs - solve one of the systems of equations $A^*X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$,

[zhbev](#) - zhbev - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A

[zhbevd](#) - zhbevd - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A

[zhbevz](#) - zhbevz - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A

[zhbgst](#) - zhbgst - reduce a complex Hermitian-definite banded generalized eigenproblem $A^*x = \lambda B^*x$ to standard form $C^*y = \lambda y$,

[zhbgv](#) - zhbgv - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A^*x = (\lambda B^*x$

[zhbgvd](#) - zhbgvd - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A^*x = (\lambda B^*x$

[zhbgvx](#) - zhbgvx - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A^*x = (\lambda B^*x$

[zhbmvs](#) - zhbmvs - perform the matrix-vector operation $y := \alpha A^*x + \beta y$

[zhhbtrd](#) - zhhbtrd - reduce a complex Hermitian band matrix A to real symmetric tridiagonal form T by a unitary similarity transformation

[zhecon](#) - zhecon - estimate the reciprocal of the condition number of a complex Hermitian matrix A using the

factorization $A = U^*D^*U^{**H}$ or $A = L^*D^*L^{**H}$ computed by CHETRF

[zheev](#) - zheev - compute all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A

[zheevd](#) - zheevd - compute all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A

[zheevr](#) - zheevr - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian tridiagonal matrix T

[zheevx](#) - zheevx - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A

[zhegs2](#) - zhegs2 - reduce a complex Hermitian-definite generalized eigenproblem to standard form

[zhegst](#) - zhegst - reduce a complex Hermitian-definite generalized eigenproblem to standard form

[zhegv](#) - zhegv - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A^*x=(\lambda)^*B^*x$, $A^*Bx=(\lambda)^*x$, or $B^*A^*x=(\lambda)^*x$

[zhegvd](#) - zhegvd - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A^*x=(\lambda)^*B^*x$, $A^*Bx=(\lambda)^*x$, or $B^*A^*x=(\lambda)^*x$

[zhegvx](#) - zhegvx - compute selected eigenvalues, and optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A^*x=(\lambda)^*B^*x$, $A^*Bx=(\lambda)^*x$, or $B^*A^*x=(\lambda)^*x$

[zhemm](#) - zhemm - perform one of the matrix-matrix operations $C := \alpha^*A^*B + \beta^*C$ or $C := \alpha^*B^*A + \beta^*C$

[zhemv](#) - zhmv - perform the matrix-vector operation $y := \alpha^*A^*x + \beta^*y$

[zher](#) - zher - perform the hermitian rank 1 operation $A := \alpha^*x^*\text{conjg}(x') + A$

[zher2](#) - zher2 - perform the hermitian rank 2 operation $A := \alpha^*x^*\text{conjg}(y') + \text{conjg}(\alpha)^*y^*\text{conjg}(x') + A$

[zher2k](#) - zher2k - perform one of the Hermitian rank 2k operations $C := \alpha^*A^*\text{conjg}(B') + \text{conjg}(\alpha)^*B^*\text{conjg}(A')$ + β^*C or $C := \alpha^*\text{conjg}(A')^*B + \text{conjg}(\alpha)^*\text{conjg}(B')^*A + \beta^*C$

[zherfs](#) - zherfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite, and provides error bounds and backward error estimates for the solution

[zherk](#) - zherk - perform one of the Hermitian rank k operations $C := \alpha^*A^*\text{conjg}(A') + \beta^*C$ or $C := \alpha^*\text{conjg}(A')^*A + \beta^*C$

[zhesv](#) - zhesv - compute the solution to a complex system of linear equations $A^*X = B$,

[zhesvx](#) - zhesvx - use the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A^*X = B$,

[zhetf2](#) - zhetf2 - compute the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method

[zhetrd](#) - zhetrd - reduce a complex Hermitian matrix A to real symmetric tridiagonal form T by a unitary similarity transformation

[zhetrf](#) - zhetrf - compute the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method

[zhetri](#) - zhetri - compute the inverse of a complex Hermitian indefinite matrix A using the factorization $A = U^*D^*U^{**H}$ or $A = L^*D^*L^{**H}$ computed by CHETRF

[zhetrs](#) - zhetrs - solve a system of linear equations $A^*X = B$ with a complex Hermitian matrix A using the factorization $A = U^*D^*U^{**H}$ or $A = L^*D^*L^{**H}$ computed by CHETRF

[zhgeqz](#) - zhgeqz - implement a single-shift version of the QZ method for finding the generalized eigenvalues $w(i)=\text{ALPHA}(i)/\text{BETA}(i)$ of the equation $\det(A-w(i)B) = 0$ If JOB='S', then the pair (A,B) is simultaneously reduced to Schur form (i.e., A and B are both upper triangular) by applying one unitary transformation (usually called Q) on the left and another (usually called Z) on the right

[zhpcon](#) - zhpcon - estimate the reciprocal of the condition number of a complex Hermitian packed matrix A using the factorization $A = U^*D^*U^{**H}$ or $A = L^*D^*L^{**H}$ computed by CHPTRF

[zhpev](#) - zhpev - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix in packed storage

[zhpevd](#) - zhpevd - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in

packed storage

[zhpevx](#) - zhpevx - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage

[zhpgst](#) - zhpgst - reduce a complex Hermitian-definite generalized eigenproblem to standard form, using packed storage

[zhpgv](#) - zhpgv - compute all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$

[zhpgvd](#) - zhpgvd - compute all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$

[zhpgvx](#) - zhpgvx - compute selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$

[zhpmv](#) - zhpmv - perform the matrix-vector operation $y := \alpha*A*x + \beta*y$

[zhpr](#) - zhpr - perform the hermitian rank 1 operation $A := \alpha*x*\text{conjg}(x') + A$

[zhpr2](#) - zhpr2 - perform the Hermitian rank 2 operation $A := \alpha*x*\text{conjg}(y') + \text{conjg}(\alpha)*y*\text{conjg}(x') + A$

[zhprfs](#) - zhprfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite and packed, and provides error bounds and backward error estimates for the solution

[zhpsv](#) - zhpsv - compute the solution to a complex system of linear equations $A * X = B$,

[zhpsvx](#) - zhpsvx - use the diagonal pivoting factorization $A = U*D*U**H$ or $A = L*D*L**H$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N Hermitian matrix stored in packed format and X and B are N-by-NRHS matrices

[zhptrd](#) - zhptrd - reduce a complex Hermitian matrix A stored in packed form to real symmetric tridiagonal form T by a unitary similarity transformation

[zhptrf](#) - zhptrf - compute the factorization of a complex Hermitian packed matrix A using the Bunch-Kaufman diagonal pivoting method

[zhptri](#) - zhptri - compute the inverse of a complex Hermitian indefinite matrix A in packed storage using the factorization $A = U*D*U**H$ or $A = L*D*L**H$ computed by CHPTRF

[zhptrs](#) - zhptrs - solve a system of linear equations $A*X = B$ with a complex Hermitian matrix A stored in packed format using the factorization $A = U*D*U**H$ or $A = L*D*L**H$ computed by CHPTRF

[zhsein](#) - zhsein - use inverse iteration to find specified right and/or left eigenvectors of a complex upper Hessenberg matrix H

[zhseqr](#) - zhseqr - compute the eigenvalues of a complex upper Hessenberg matrix H, and, optionally, the matrices T and Z from the Schur decomposition $H = Z T Z**H$, where T is an upper triangular matrix (the Schur form), and Z is the unitary matrix of Schur vectors

[zjadmm](#) - zjadmm - Jagged diagonal matrix-matrix multiply (modified Ellpack)

[zjadrp](#) - zjadrp - right permutation of a jagged diagonal matrix

[zjadsm](#) - zjadsm - Jagged-diagonal format triangular solve

[zlarz](#) - zlarz - apply a complex elementary reflector H to a complex M-by-N matrix C, from either the left or the right

[zlarzb](#) - zlarzb - apply a complex block reflector H or its transpose $H**H$ to a complex distributed M-by-N C from the left or the right

[zlarzt](#) - zlarzt - form the triangular factor T of a complex block reflector H of order $> n$, which is defined as a product of k elementary reflectors

[zlatzm](#) - zlatzm - routine is deprecated and has been replaced by routine CUNMRZ

[zpbcon](#) - zpbcon - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite band matrix using the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ computed by CPBTRF

[zpbegu](#) - zpbegu - compute row and column scalings intended to equilibrate a Hermitian positive definite band matrix A and reduce its condition number (with respect to the two-norm)

[zpbfrs](#) - zpbfrs - improve the computed solution to a system of linear equations when the coefficient matrix is

Hermitian positive definite and banded, and provides error bounds and backward error estimates for the solution

[zpbstf](#) - zpbstf - compute a split Cholesky factorization of a complex Hermitian positive definite band matrix A

[zpbsv](#) - zpbsv - compute the solution to a complex system of linear equations $A * X = B$,

[zpbsvx](#) - zpbsvx - use the Cholesky factorization $A = U^{**}H*U$ or $A = L*L^{**}H$ to compute the solution to a complex system of linear equations $A * X = B$,

[zpbtf2](#) - zpbtf2 - compute the Cholesky factorization of a complex Hermitian positive definite band matrix A

[zpbtrf](#) - zpbtrf - compute the Cholesky factorization of a complex Hermitian positive definite band matrix A

[zpbtrs](#) - zpbtrs - solve a system of linear equations $A*X = B$ with a Hermitian positive definite band matrix A using the Cholesky factorization $A = U^{**}H*U$ or $A = L*L^{**}H$ computed by CPBTRF

[zpocon](#) - zpocon - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite matrix using the Cholesky factorization $A = U^{**}H*U$ or $A = L*L^{**}H$ computed by CPOTRF

[zpoequ](#) - zpoequ - compute row and column scalings intended to equilibrate a Hermitian positive definite matrix A and reduce its condition number (with respect to the two-norm)

[zporfs](#) - zporfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite,

[zposv](#) - zposv - compute the solution to a complex system of linear equations $A * X = B$,

[zposvx](#) - zposvx - use the Cholesky factorization $A = U^{**}H*U$ or $A = L*L^{**}H$ to compute the solution to a complex system of linear equations $A * X = B$,

[zpotf2](#) - zpotf2 - compute the Cholesky factorization of a complex Hermitian positive definite matrix A

[zpotrf](#) - zpotrf - compute the Cholesky factorization of a complex Hermitian positive definite matrix A

[zpotri](#) - zpotri - compute the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization $A = U^{**}H*U$ or $A = L*L^{**}H$ computed by CPOTRF

[zpotrs](#) - zpotrs - solve a system of linear equations $A*X = B$ with a Hermitian positive definite matrix A using the Cholesky factorization $A = U^{**}H*U$ or $A = L*L^{**}H$ computed by CPOTRF

[zppcon](#) - zppcon - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite packed matrix using the Cholesky factorization $A = U^{**}H*U$ or $A = L*L^{**}H$ computed by CPPTRF

[zppequ](#) - zppequ - compute row and column scalings intended to equilibrate a Hermitian positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm)

[zpprfs](#) - zpprfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and packed, and provides error bounds and backward error estimates for the solution

[zppsv](#) - zppsv - compute the solution to a complex system of linear equations $A * X = B$,

[zppsvx](#) - zppsvx - use the Cholesky factorization $A = U^{**}H*U$ or $A = L*L^{**}H$ to compute the solution to a complex system of linear equations $A * X = B$,

[zpptrf](#) - zpptrf - compute the Cholesky factorization of a complex Hermitian positive definite matrix A stored in packed format

[zpptri](#) - zpptri - compute the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization $A = U^{**}H*U$ or $A = L*L^{**}H$ computed by CPPTRF

[zpptrs](#) - zpptrs - solve a system of linear equations $A*X = B$ with a Hermitian positive definite matrix A in packed storage using the Cholesky factorization $A = U^{**}H*U$ or $A = L*L^{**}H$ computed by CPPTRF

[zptcon](#) - zptcon - compute the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite tridiagonal matrix using the factorization $A = L*D*L^{**}H$ or $A = U^{**}H*D*U$ computed by CPTTRF

[zpteqr](#) - zpteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF and then calling CBDSQR to compute the singular values of the bidiagonal factor

[zptrfs](#) - zptrfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution

[zptsv](#) - zptsv - compute the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N Hermitian positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

[zptsvx](#) - zptsvx - use the factorization $A = L * D * L ** H$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N Hermitian positive definite tridiagonal matrix and X and B are N-by-NRHS matrices

[zpttrf](#) - zpttrf - compute the $L * D * L'$ factorization of a complex Hermitian positive definite tridiagonal matrix A

[zpttrs](#) - zpttrs - solve a tridiagonal system of the form $A * X = B$ using the factorization $A = U' * D * U$ or $A = L * D * L'$ computed by CPTTRF

[zptts2](#) - zptts2 - solve a tridiagonal system of the form $A * X = B$ using the factorization $A = U' * D * U$ or $A = L * D * L'$ computed by CPTTRF

[zrot](#) - zrot - apply a plane rotation, where the cos (C) is real and the sin (S) is complex, and the vectors X and Y are complex

[zrotg](#) - zrotg - Construct a Given's plane rotation

[zscal](#) - zscal - Compute $y := \alpha * y$

[zsctr](#) - zsctr - Scatters elements from x into y.

[zskymm](#) - zskymm - Skyline format matrix-matrix multiply

[zskysm](#) - zskysm - Skyline format triangular solve

[zspcon](#) - zspcon - estimate the reciprocal of the condition number (in the 1-norm) of a complex symmetric packed matrix A using the factorization $A = U * D * U ** T$ or $A = L * D * L ** T$ computed by CSPTRF

[zsprfs](#) - zsprfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution

[zpsv](#) - zpsv - compute the solution to a complex system of linear equations $A * X = B$,

[zpsvx](#) - zpsvx - use the diagonal pivoting factorization $A = U * D * U ** T$ or $A = L * D * L ** T$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices

[zsptf](#) - zsptf - compute the factorization of a complex symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method

[zsptri](#) - zsptri - compute the inverse of a complex symmetric indefinite matrix A in packed storage using the factorization $A = U * D * U ** T$ or $A = L * D * L ** T$ computed by CSPTRF

[zsptrs](#) - zsptrs - solve a system of linear equations $A * X = B$ with a complex symmetric matrix A stored in packed format using the factorization $A = U * D * U ** T$ or $A = L * D * L ** T$ computed by CSPTRF

[zstedc](#) - zstedc - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method

[zstegr](#) - zstegr - Compute $T - \sigma_i = L_i D_i L_i^T$, such that $L_i D_i L_i^T$ is a relatively robust representation

[zstein](#) - zstein - compute the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration

[zsteqr](#) - zsteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method

[zstsv](#) - zstsv - compute the solution to a complex system of linear equations $A * X = B$ where A is a Hermitian tridiagonal matrix

[zsttrf](#) - zsttrf - compute the factorization of a complex Hermitian tridiagonal matrix A

[zsttrs](#) - zsttrs - computes the solution to a complex system of linear equations $A * X = B$

[zswap](#) - zswap - Exchange vectors x and y.

[zsycon](#) - zsycon - estimate the reciprocal of the condition number (in the 1-norm) of a complex symmetric matrix A using the factorization $A = U * D * U ** T$ or $A = L * D * L ** T$ computed by CSYTRF

[zsymm](#) - zsymm - perform one of the matrix-matrix operations $C := \alpha * A * B + \beta * C$ or $C := \alpha * B * A + \beta * C$

[zsy2k](#) - zsy2k - perform one of the symmetric rank 2k operations $C := \alpha * A * B' + \alpha * B * A' + \beta * C$ or $C := \alpha * A' * B + \alpha * B' * A + \beta * C$

[zsyfs](#) - zsyfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution

[zsyk](#) - zsyk - perform one of the symmetric rank k operations $C := \alpha * A * A' + \beta * C$ or $C := \alpha * A' * A + \beta * C$

[zsysv](#) - zsysv - compute the solution to a complex system of linear equations $A * X = B$,

[zsysvx](#) - zsysvx - use the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A * X = B$,

[zsytf2](#) - zsytf2 - compute the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

[zsytrf](#) - zsytrf - compute the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

[zsytri](#) - zsytri - compute the inverse of a complex symmetric indefinite matrix A using the factorization $A = U * D * U' * T$ or $A = L * D * L' * T$ computed by CSYTRF

[zsytrs](#) - zsytrs - solve a system of linear equations $A * X = B$ with a complex symmetric matrix A using the factorization $A = U * D * U' * T$ or $A = L * D * L' * T$ computed by CSYTRF

[ztbcon](#) - ztbcon - estimate the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm

[ztbmV](#) - ztbmv - perform one of the matrix-vector operations $x := A * x$, or $x := A' * x$, or $x := \text{conjg}(A') * x$

[ztbrfs](#) - ztbrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix

[ztbsv](#) - ztbsv - solve one of the systems of equations $A * x = b$, or $A' * x = b$, or $\text{conjg}(A') * x = b$

[ztbtrs](#) - ztbtrs - solve a triangular system of the form $A * X = B$, $A' * X = B$, or $A' * H * X = B$,

[ztgevc](#) - ztgevc - compute some or all of the right and/or left generalized eigenvectors of a pair of complex upper triangular matrices (A,B)

[ztgexc](#) - ztgexc - reorder the generalized Schur decomposition of a complex matrix pair (A,B), using an unitary equivalence transformation $(A, B) := Q * (A, B) * Z'$, so that the diagonal block of (A, B) with row index IFST is moved to row ILST

[ztgsen](#) - ztgsen - reorder the generalized Schur decomposition of a complex matrix pair (A, B) (in terms of an unitary equivalence transformation $Q' * (A, B) * Z$), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the pair (A,B)

[ztgsja](#) - ztgsja - compute the generalized singular value decomposition (GSVD) of two complex upper triangular (or trapezoidal) matrices A and B

[ztgsna](#) - ztgsna - estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B)

[ztgsyl](#) - ztgsyl - solve the generalized Sylvester equation

[ztpcon](#) - ztpcon - estimate the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm

[ztpmv](#) - ztpmv - perform one of the matrix-vector operations $x := A * x$, or $x := A' * x$, or $x := \text{conjg}(A') * x$

[ztpfrs](#) - ztpfrs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix

[ztpsv](#) - ztpsv - solve one of the systems of equations $A * x = b$, or $A' * x = b$, or $\text{conjg}(A') * x = b$

[ztptri](#) - ztptri - compute the inverse of a complex upper or lower triangular matrix A stored in packed format

[ztptrs](#) - ztptrs - solve a triangular system of the form $A * X = B$, $A' * X = B$, or $A' * H * X = B$,

[ztrans](#) - ztrans - transpose and scale source matrix

[ztrcon](#) - ztrcon - estimate the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm

[ztrevc](#) - ztrevc - compute some or all of the right and/or left eigenvectors of a complex upper triangular matrix T

[ztrexc](#) - ztrexc - reorder the Schur factorization of a complex matrix $A = Q^*T^*Q^{**}H$, so that the diagonal element of T with row index IFST is moved to row ILST

[ztrmm](#) - ztrmm - perform one of the matrix-matrix operations $B := \alpha * \text{op}(A) * B$, or $B := \alpha * B * \text{op}(A)$ where alpha is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and op(A) is one of $\text{op}(A) = A$ or $\text{op}(A) = A'$ or $\text{op}(A) = \text{conjg}(A')$

[ztrmv](#) - ztrmv - perform one of the matrix-vector operations $x := A * x$, or $x := A' * x$, or $x := \text{conjg}(A') * x$

[ztrrfs](#) - ztrrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix

[ztrsen](#) - ztrsen - reorder the Schur factorization of a complex matrix $A = Q^*T^*Q^{**}H$, so that a selected cluster of eigenvalues appears in the leading positions on the diagonal of the upper triangular matrix T, and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace

[ztrsm](#) - ztrsm - solve one of the matrix equations $\text{op}(A) * X = \alpha * B$, or $X * \text{op}(A) = \alpha * B$

[ztrsna](#) - ztrsna - estimate reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a complex upper triangular matrix T (or of any matrix $Q^*T^*Q^{**}H$ with Q unitary)

[ztrsv](#) - ztrsv - solve one of the systems of equations $A * x = b$, or $A' * x = b$, or $\text{conjg}(A') * x = b$

[ztrsyl](#) - ztrsyl - solve the complex Sylvester matrix equation

[ztrti2](#) - ztrti2 - compute the inverse of a complex upper or lower triangular matrix

[ztrtri](#) - ztrtri - compute the inverse of a complex upper or lower triangular matrix A

[ztrtrs](#) - ztrtrs - solve a triangular system of the form $A * X = B$, $A^{**}T * X = B$, or $A^{**}H * X = B$,

[ztrzrf](#) - ztrzrf - routine is deprecated and has been replaced by routine CTZRZF

[ztrzrf](#) - ztrzrf - reduce the M-by-N ($M \leq N$) complex upper trapezoidal matrix A to upper triangular form by means of unitary transformations

[zung2l](#) - zung2l - generate an m by n complex matrix Q with orthonormal columns,

[zung2r](#) - zung2r - generate an m by n complex matrix Q with orthonormal columns,

[zungbr](#) - zungbr - generate one of the complex unitary matrices Q or $P^{**}H$ determined by CGEBRD when reducing a complex matrix A to bidiagonal form

[zunghr](#) - zunghr - generate a complex unitary matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by CGEHRD

[zungl2](#) - zungl2 - generate an m-by-n complex matrix Q with orthonormal rows,

[zunglq](#) - zunglq - generate an M-by-N complex matrix Q with orthonormal rows,

[zungql](#) - zungql - generate an M-by-N complex matrix Q with orthonormal columns,

[zungqr](#) - zungqr - generate an M-by-N complex matrix Q with orthonormal columns,

[zungr2](#) - zungr2 - generate an m by n complex matrix Q with orthonormal rows,

[zungrq](#) - zungrq - generate an M-by-N complex matrix Q with orthonormal rows,

[zungtr](#) - zungtr - generate a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by CHETRD

[zunmbr](#) - zunmbr - VECT = 'Q', CUNMBR overwrites the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[zunmhr](#) - zunmhr - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[zunml2](#) - zunml2 - overwrite the general complex m-by-n matrix C with $Q * C$ if SIDE = 'L' and TRANS = 'N', or $Q' * C$ if SIDE = 'L' and TRANS = 'C', or $C * Q$ if SIDE = 'R' and TRANS = 'N', or $C * Q'$ if SIDE = 'R' and TRANS = 'C',

[zunmlq](#) - zunmlq - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[zunmql](#) - zunmql - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[zunmqr](#) - zunmqr - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[zunmr2](#) - zunmr2 - overwrite the general complex m-by-n matrix C with $Q * C$ if SIDE = 'L' and TRANS = 'N', or $Q^* C$ if SIDE = 'L' and TRANS = 'C', or $C * Q$ if SIDE = 'R' and TRANS = 'N', or $C * Q^*$ if SIDE = 'R' and TRANS = 'C',

[zunmrq](#) - zunmrq - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[zunmrz](#) - zunmrz - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[zunmtr](#) - zunmtr - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[zupgtr](#) - zupgtr - generate a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors H(i) of order n, as returned by CHPTRD using packed storage

[zupmtr](#) - zupmtr - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[zvbrmm](#) - zvbrmm - variable block sparse row format matrix-matrix multiply

[zvbrsm](#) - zvbrsm - variable block sparse row format triangular solve

[zvmul](#) - zvmul - compute the scaled product of complex vectors

NAME

`available_threads` - returns information about current thread usage

SYNOPSIS

```
SUBROUTINE AVAILABLE_THREADS(NTOTAL, NUSING)

INTEGER NTOTAL, NUSING

SUBROUTINE AVAILABLE_THREADS_64(NTOTAL, NUSING)

INTEGER*8 NTOTAL, NUSING
```

F95 INTERFACE

```
SUBROUTINE AVAILABLE_THREADS(NTOTAL, NUSING)

INTEGER :: NTOTAL, NUSING

SUBROUTINE AVAILABLE_THREADS_64(NTOTAL, NUSING)

INTEGER(8) :: NTOTAL, NUSING
```

C INTERFACE

```
#include <sunperf.h>

void available_threads(int *ntotal, int *nusing);

void available_threads_64(long *ntotal, long *nusing);
```

PURPOSE

`available_threads` returns `NTOTAL`, which is the total number of CPUs available to the job (generally the number of CPUs presently on-line in the partition), and `NUSING`, which is the sum of the current Use numbers for all threads specified in `USE_THREADS`. If `NTOTAL < NUSING` then the system is potentially overcommitted.

ARGUMENTS

NTOTAL (output)
Total number of CPUs available.

NUSING (output)
Sum of current Use numbers for all threads specified in USE_THREADS.

NAME

blas_dpermute - permutes a real (double precision) array in terms of the permutation vector P, output by dsortv

SYNOPSIS

```
SUBROUTINE BLAS_DPERMUTE (N, P, INCP, X, INCX)
```

```
INTEGER N  
INTEGER P(*)  
INTEGER INCP  
REAL*8 X(*)  
INTEGER INCX
```

```
SUBROUTINE BLAS_DPERMUTE_64 (N, P, INCP, X, INCX)
```

```
INTEGER*8 N  
INTEGER*8 P(*)  
INTEGER*8 INCP  
REAL*8 X(*)  
INTEGER*8 INCX
```

F95 INTERFACE

```
SUBROUTINE PERMUTE (X, P)
```

```
USE SUNPERF
```

```
SUBROUTINE PERMUTE_64 (X, P)
```

```
USE SUNPERF
```

ARGUMENTS

N (input) INTEGER, the number of elements to be permuted in X
If $N \leq 1$, the subroutine returns without trying to permute X.

P (input) INTEGER((N-1)*|INCP|+1), the permutation (index) vector defined follows the same conventions as that for DTYPE SORTV. It records the details of the interchanges of the elements of X during sorting. That is $X = P*X$. In current implementation, P contains the index of sorted X.

INCP (input) INTEGER, increment for P
 INCP must not be zero. INCP could be negative. If
 INCP < 0, the permutation is applied in the oppo-
 site direction. That is
 If INCP > 0,
 if INCX > 0,
 sorted X((i-1)*INCX+1) = X(P((i-1)*INCP+1)),
 if INCX < 0,
 sorted X((N-i)*|INCX|+1) = X(P((i-1)*INCP+1));
 If INCP < 0,
 if INCX > 0,
 sorted X((i-1)*INCX+1) = X(P((N-i)*|INCP|+1)).
 if INCX < 0,
 sorted X((N-i)*|INCX|+1)
 = X(P((N-i)*|INCP|+1)).

X (input/output) REAL*8(KIND)((N-1)*|INCX|+1), the array to
 be permuted. Minimum size (N-1)*|INCX|+1 is
 required

INCX (input) INTEGER, increment for X
 INCX must not be zero. INCX could be negative. If
 INCX < 0, X will be permuted in a reverse way (see
 the description for INCP above).

SUBROUTINE SORT (X [, SORT])
```

```
USE SUNPERF
```

```
SUBROUTINE SORT_64 (X [, SORT])
```

```
USE SUNPERF
```

The functionality of SORT is covered by SORTV

ARGUMENTS

SORT (input) INTEGER, indicating sort directions
SORT = 0, descending
SORT = 1, ascending
SORT = other value, error
SORT is default to 1 for F95 INTERFACE

N (input) INTEGER, the number of elements to be sorted in X
If N <= 1, the subroutine returns without trying to sort X.

X (input/output) REAL*8((N-1)*|INCX|+1), the array to be

sorted
Minimum size $(N-1)*|INCX|+1$ is required

INCX (input) INTEGER, increment for X
INCX must not be zero. INCX could be negative. If
INCX < 0, change the sorting direction defined by
SORT. That is
If SORT = 0, let SORT = 1, INCX = $|INCX|$;
If SORT = 1, let SORT = 0, INCX = $|INCX|$.

SORTV covers the functionality of SORT
```

ARGUMENTS

SORT (input) INTEGER, indicating sort directions
SORT = 0, descending
SORT = 1, ascending
SORT = other value, error
SORT is default to 1 for F95 INTERFACE

N (input) INTEGER, the number of elements to be sorted in X
If $N \leq 1$, the subroutine returns without trying to sort X.

X (input/output) INTEGER($(N-1)*|INCX|+1$), the array to be sorted
Minimum size $(N-1)*|INCX|+1$ is required

INCX (input) INTEGER, increment for X
INCX must not be zero. INCX could be negative. If $INCX < 0$, change the sorting direction defined by SORT. That is
If $SORT = 0$, let $SORT = 1$, $INCX = |INCX|$;
If $SORT = 1$, let $SORT = 0$, $INCX = |INCX|$.

P (output) INTEGER($(N-1)*|INCP|+1$), the permutation (index) vector recording the details of the interchanges of the elements of X during sorting. That is $X = P*X$. In this implementation, P contains the index of sorted X.

INCP (input) INTEGER, increment for P
INCP must not be zero. INCP could be negative. If $INCP < 0$, store P(i) in reverse order. That is
If $INCP > 0$,
if $INCX > 0$,
sorted $X((i-1)*INCX+1) = X(P((i-1)*INCP+1))$,
if $INCX < 0$,
sorted $X((N-i)*|INCX|+1) = X(P((i-1)*INCP+1))$;
If $INCP < 0$,
if $INCX > 0$,
sorted $X((i-1)*INCX+1) = X(P((N-i)*|INCP|+1))$,
if $INCX < 0$,
sorted $X((N-i)*|INCX|+1)$
= $X(P((N-i)*|INCP|+1))$.

NAME

blas_spermute - permutes a real array in terms of the permutation vector P, output by dsortv

SYNOPSIS

```
SUBROUTINE BLAS_SPERMUTE (N, P, INCP, X, INCX)
```

```
INTEGER N  
INTEGER P(*)  
INTEGER INCP  
REAL X(*)  
INTEGER INCX
```

```
SUBROUTINE BLAS_SPERMUTE_64 (N, P, INCP, X, INCX)
```

```
INTEGER*8 N  
INTEGER*8 P(*)  
INTEGER*8 INCP  
REAL X(*)  
INTEGER*8 INCX
```

F95 INTERFACE

```
SUBROUTINE PERMUTE (X, P)
```

```
USE SUNPERF
```

```
SUBROUTINE PERMUTE_64 (X, P)
```

```
USE SUNPERF
```

ARGUMENTS

N (input) INTEGER, the number of elements to be permuted in X
If $N \leq 1$, the subroutine returns without trying to permute X.

P (input) INTEGER((N-1)*|INCP|+1), the permutation (index) vector defined follows the same conventions as that for DTYPE SORTV. It records the details of the interchanges of the elements of X during sorting. That is $X = P*X$. In current implementation, P contains the index of sorted X.

INCP (input) INTEGER, increment for P
 INCP must not be zero. INCP could be negative. If
 INCP < 0, the permutation is applied in the oppo-
 site direction. That is
 If INCP > 0,
 if INCX > 0,
 sorted X((i-1)*INCX+1) = X(P((i-1)*INCP+1)),
 if INCX < 0,
 sorted X((N-i)*|INCX|+1) = X(P((i-1)*INCP+1));
 If INCP < 0,
 if INCX > 0,
 sorted X((i-1)*INCX+1) = X(P((N-i)*|INCP|+1)).
 if INCX < 0,
 sorted X((N-i)*|INCX|+1)
 = X(P((N-i)*|INCP|+1)).

X (input/output) REAL(KIND)((N-1)*|INCX|+1), the array to be
 permuted. Minimum size (N-1)*|INCX|+1 is required

INCX (input) INTEGER, increment for X
 INCX must not be zero. INCX could be negative. If
 INCX < 0, X will be permuted in a reverse way (see
 the description for INCP above).

NAME

caxpy - compute $y := \alpha * x + y$

SYNOPSIS

```
SUBROUTINE CAXPY(N, ALPHA, X, INCX, Y, INCY)
```

```
COMPLEX ALPHA  
COMPLEX X(*), Y(*)  
INTEGER N, INCX, INCY
```

```
SUBROUTINE CAXPY_64(N, ALPHA, X, INCX, Y, INCY)
```

```
COMPLEX ALPHA  
COMPLEX X(*), Y(*)  
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE AXPY([N], ALPHA, X, [INCX], Y, [INCY])
```

```
COMPLEX :: ALPHA  
COMPLEX, DIMENSION(:) :: X, Y  
INTEGER :: N, INCX, INCY
```

```
SUBROUTINE AXPY_64([N], ALPHA, X, [INCX], Y, [INCY])
```

```
COMPLEX :: ALPHA  
COMPLEX, DIMENSION(:) :: X, Y  
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void caxpy(int n, complex *alpha, complex *x, int incx, complex *y, int incy);
```

```
void caxpy_64(long n, complex *alpha, complex *x, long incx, complex *y, long incy);
```

PURPOSE

caxpy compute $y := \text{alpha} * x + y$ where alpha is a scalar and x and y are n-vectors.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)

array of DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input/output)

array of DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{INCY}))$. On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

caxpyi - Compute $y := \alpha * x + y$

SYNOPSIS

```
SUBROUTINE CAXPYI(NZ, A, X, INDX, Y)

COMPLEX A
COMPLEX X(*), Y(*)
INTEGER NZ
INTEGER INDX(*)

SUBROUTINE CAXPYI_64(NZ, A, X, INDX, Y)

COMPLEX A
COMPLEX X(*), Y(*)
INTEGER*8 NZ
INTEGER*8 INDX(*)

F95 INTERFACE
SUBROUTINE AXPYI([NZ], [A], X, INDX, Y)

COMPLEX :: A
COMPLEX, DIMENSION(:) :: X, Y
INTEGER :: NZ
INTEGER, DIMENSION(:) :: INDX

SUBROUTINE AXPYI_64([NZ], [A], X, INDX, Y)

COMPLEX :: A
COMPLEX, DIMENSION(:) :: X, Y
INTEGER(8) :: NZ
INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

CAXPYI Compute $y := \alpha * x + y$ where α is a scalar, x is a sparse vector, and y is a vector in full storage form

```
do i = 1, n
  y(indx(i)) = alpha * x(i) + y(indx(i))
enddo
```

ARGUMENTS

NZ (input) - INTEGER
Number of elements in the compressed form.
Unchanged on exit.

A (input)
On entry, A(LPHA) specifies the scaling value.
Unchanged on exit. A is defaulted to (1.0E0, 0.0E0)
for F95 INTERFACE.

X (input)
Vector containing the values of the compressed form.
Unchanged on exit.

INDX (input) - INTEGER
Vector containing the indices of the compressed
form. It is assumed that the elements in INDX are
distinct and greater than zero. Unchanged on exit.

Y (output)
Vector on input which contains the vector Y in full
storage form. On exit, only the elements
corresponding to the indices in INDX have been
modified.

INTEGER*8, DIMENSION(:) :: DESCRA, BINDX, BJNDX
COMPLEX          ALPHA, BETA
COMPLEX, DIMENSION(:) :: VAL
COMPLEX, DIMENSION(:, :) :: B, C
```

DESCRIPTION

```
C <- alpha op(A) B + beta C
```

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in block coordinate format and
op(A) is one of

```
op( A ) = A    or    op( A ) = A'    or    op( A ) = conjg( A' ).  
                ( ' indicates matrix transpose)
```

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if the matrix is real.
MB	Number of block rows in matrix A
N	Number of columns in matrix C
KB	Number of block columns in matrix A
ALPHA	Scalar parameter
DESCRA()	Descriptor argument. Five element integer array DESCRA(1) matrix structure 0 : general 1 : symmetric (A=A') 2 : Hermitian (A= CONJG(A')) 3 : Triangular 4 : Skew(Anti)-Symmetric (A=-A') 5 : Diagonal 6 : Skew-Hermitian (A= -CONJG(A')) DESCRA(2) upper/lower triangular indicator 1 : lower 2 : upper DESCRA(3) main diagonal type 0 : non-unit 1 : unit DESCRA(4) Array base (NOT IMPLEMENTED) 0 : C/C++ compatible 1 : Fortran compatible DESCRA(5) repeated indices? (NOT IMPLEMENTED) 0 : unknown 1 : no repeated indices
VAL()	scalar array of length LB*LB*BNNZ consisting of the non-zero block entries of A, in any order. Each block is stored in standard column-major form.
BINDX()	integer array of length BNNZ consisting of the block row indices of the block entries of A.
BJNDX()	integer array of length BNNZ consisting of the block column indices of the block entries of A.
BNNZ	number of block entries

LB	dimension of dense blocks composing A.
B() LDB	rectangular array with first dimension LDB. leading dimension of B
BETA	Scalar parameter
C() LDC	rectangular array with first dimension LDC. leading dimension of C
WORK()	scratch array of length LWORK. WORK is not referenced in the current version.
LWORK	length of WORK array. LWORK is not referenced in the current version.

COMPLEX, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
C <- alpha op(A) B + beta C
```

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in block diagonal format and
op(A) is one of

```
op( A ) = A    or    op( A ) = A'    or    op( A ) = conjg( A' ).  
                ( ' indicates matrix transpose)
```

ARGUMENTS

TRANSA Indicates how to operate with the sparse matrix
 0 : operate with matrix
 1 : operate with transpose matrix
 2 : operate with the conjugate transpose of matrix.
 2 is equivalent to 1 if matrix is real.

MB Number of block rows in matrix A

N Number of columns in matrix C

KB Number of block columns in matrix A

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array
DESCRA(1) matrix structure
 0 : general
 1 : symmetric (A=A')
 2 : Hermitian (A= CONJG(A'))
 3 : Triangular
 4 : Skew(Anti)-Symmetric (A=-A')
 5 : Diagonal
 6 : Skew-Hermitian (A= -CONJG(A'))
DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper
DESCRA(3) main diagonal type
 0 : non-unit
 1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL() two-dimensional LB*LB*BLDA-by-NBDIAG scalar array
 consisting of the NBDIAG nonzero block diagonal in
 any order. Each dense block is stored in standard
 column-major form.

BLDA leading block dimension of VAL().

IBDIAG() integer array of length NBDIAG consisting of the
 corresponding diagonal offsets of the non-zero
 block diagonals of A in VAL. Lower triangular
 block diagonals have negative offsets, the main
 block diagonal has offset 0, and upper triangular

block diagonals have positive offset.

NBDIAG the number of non-zero block diagonals in A.
LB dimension of dense blocks composing A.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK. WORK is not
referenced in the current version.

LWORK length of WORK array. LWORK is not referenced
in the current version.

DESCRIPTION

```
C <- ALPHA op(A) B + BETA C      C <- ALPHA D op(A) B + BETA C
C <- ALPHA op(A) D B + BETA C
```

where ALPHA and BETA are scalar, C and B are m by n dense matrices, D is a block diagonal matrix, A is a unit, or non-unit, upper or lower triangular matrix represented in block diagonal format and op(A) is one of
op(A) = inv(A) or op(A) = inv(A') or op(A) =inv(conjg(A'))
(inv denotes matrix inverse, ' indicates matrix transpose)

ARGUMENTS

TRANSA Indicates how to operate with the sparse matrix
 0 : operate with matrix
 1 : operate with transpose matrix
 2 : operate with the conjugate transpose of matrix.
 2 is equivalent to 1 if matrix is real.

MB Number of block rows in matrix A

N Number of columns in matrix C

UNITD Type of scaling:
 1 : Identity matrix (argument DV[] is ignored)
 2 : Scale on left (row scaling)
 3 : Scale on right (column scaling)

DV() Array of length MB*LB*LB containing the elements of the diagonal blocks of the matrix D. The size of each square block is LB-by-LB and each block is stored in standard column-major form.

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array
DESCRA(1) matrix structure
 0 : general
 1 : symmetric (A=A')
 2 : Hermitian (A= CONJG(A'))
 3 : Triangular
 4 : Skew(Anti)-Symmetric (A=-A')
 5 : Diagonal
 6 : Skew-Hermitian (A= -CONJG(A'))
Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper

DESCRA(3) main diagonal type
 0 : non-identity blocks on the main diagonal
 1 : identity diagonal blocks
 2 : diagonal blocks are dense matrices

DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL() Two-dimensional LB*LB*BLDA-by-NBDIAG scalar array

consisting of the NBDIAG non-zero block diagonal.
Each dense block is stored in standard column-major form.

BLDA Leading block dimension of VAL(). Should be greater than or equal to MB.

IBDIAG() integer array of length NBDIAG consisting of the corresponding diagonal offsets of the non-zero block diagonals of A in VAL. Lower triangular block diagonals have negative offsets, the main block diagonal has offset 0, and upper triangular block diagonals have positive offset. Elements of IBDIAG MUST be sorted in increasing order.

NBDIAG The number of non-zero block diagonals in A.

LB Dimension of dense blocks composing A.

B() Rectangular array with first dimension LDB.

LDB Leading dimension of B.

BETA Scalar parameter.

C() Rectangular array with first dimension LDC.

LDC Leading dimension of C.

WORK() scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK length of WORK array. LWORK should be at least MB*LB.

For good performance, LWORK should generally be larger.
For optimum performance on multiple processors, LWORK \geq MB*LB*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If *DESCRA*(3)=0, the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).

3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the BDI representation of a sparse matrix. They are not used anyway.

4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine.

WORK(1)=0 on return if the factorization for all diagonal blocks has been completed successfully, otherwise *WORK*(1) = -i where i is the block number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

*info);

```

PURPOSE

cbdsqr computes the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B: $B = Q * S * P'$ (P' denotes the transpose of P), where S is a diagonal matrix with non-negative diagonal elements (the singular values of B), and Q and P are orthogonal matrices.

The routine computes S, and optionally computes $U * Q$, $P' * VT$, or $Q' * C$, for given complex input matrices U, VT, and C.

See "Computing Small Singular Values of Bidiagonal Matrices With Guaranteed High Relative Accuracy," by J. Demmel and W. Kahan, LAPACK Working Note #3 (or SIAM J. Sci. Statist. Comput. vol. 11, no. 5, pp. 873-912, Sept 1990) and "Accurate singular values and differential qd algorithms," by B. Parlett and V. Fernando, Technical Report CPAM-554, Mathematics Department, University of California at Berkeley, July 1992 for a detailed description of the algorithm.

ARGUMENTS

UPLO (input)

= 'U': B is upper bidiagonal;
 = 'L': B is lower bidiagonal.

N (input) The order of the matrix B. $N \geq 0$.

NCVT (input)

The number of columns of the matrix VT. $NCVT \geq 0$.

NRU (input)

The number of rows of the matrix U. $NRU \geq 0$.

NCC (input)

The number of columns of the matrix C. $NCC \geq 0$.

D (input/output)

On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if $INFO=0$, the singular values of B in decreasing order.

E (input/output)

On entry, the elements of E contain the offdiagonal elements of the bidiagonal matrix whose SVD is desired. On normal exit ($INFO = 0$), E is destroyed. If the algorithm does not converge ($INFO > 0$), D and E will contain the diagonal and superdiagonal elements of a bidiagonal matrix orthogonally equivalent to the one given as input. $E(N)$ is used for workspace.

VT (input/output)

On entry, an N-by-NCVT matrix VT. On exit, VT is overwritten by $P' * VT$. VT is not referenced if NCVT = 0.

LDVT (input)

The leading dimension of the array VT. LDVT \geq max(1,N) if NCVT > 0; LDVT \geq 1 if NCVT = 0.

U (input/output)

On entry, an NRU-by-N matrix U. On exit, U is overwritten by $U * Q$. U is not referenced if NRU = 0.

LDU (input)

The leading dimension of the array U. LDU \geq max(1,NRU).

C (input/output)

On entry, an N-by-NCC matrix C. On exit, C is overwritten by $Q' * C$. C is not referenced if NCC = 0.

LDC (input)

The leading dimension of the array C. LDC \geq max(1,N) if NCC > 0; LDC \geq 1 if NCC = 0.

WORK (workspace)

dimension (4*N)

INFO (output)

= 0: successful exit
< 0: If INFO = -i, the i-th argument had an illegal value
> 0: the algorithm did not converge; D and E contain the elements of a bidiagonal matrix which is orthogonally similar to the input matrix B; if INFO = i, i elements of E have not converged to zero.

INTEGER*8, DIMENSION(:) :: DESCRA, BINDX
COMPLEX         ALPHA, BETA
COMPLEX, DIMENSION(:) :: VAL
COMPLEX, DIMENSION(:, :) :: B, C
```

DESCRIPTION

```
C <- alpha op(A) B + beta C
```

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in block Ellpack format and
op(A) is one of

```
op( A ) = A    or    op( A ) = A'    or    op( A ) = conjg( A' ).  
                ( ' indicates matrix transpose)
```

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real.
MB	Number of block rows in matrix A
N	Number of columns in matrix C
KB	Number of block columns in matrix A
ALPHA	Scalar parameter
DESCRA()	Descriptor argument. Five element integer array DESCRA(1) matrix structure 0 : general 1 : symmetric (A=A') 2 : Hermitian (A= CONJG(A')) 3 : Triangular 4 : Skew(Anti)-Symmetric (A=-A') 5 : Diagonal 6 : Skew-Hermitian (A= -CONJG(A')) DESCRA(2) upper/lower triangular indicator 1 : lower 2 : upper DESCRA(3) main diagonal type 0 : non-unit 1 : unit DESCRA(4) Array base (NOT IMPLEMENTED) 0 : C/C++ compatible 1 : Fortran compatible DESCRA(5) repeated indices? (NOT IMPLEMENTED) 0 : unknown 1 : no repeated indices
VAL()	scalar array of length LB*LB*BLDA*MAXBNZ containing matrix entries, stored column-major within each dense block.
BINDX()	two-dimensional integer BLDA-by-MAXBNZ array such BINDX(i,:) consists of the block column indices of the nonzero blocks in block row i, padded by the integer value i if the number of nonzero blocks is less than MAXBNZ.
BLDA	leading dimension of BINDX(:,:).

MAXBNZ	max number of nonzeros blocks per row.
LB	row and column dimension of the dense blocks composing VAL.
B()	rectangular array with first dimension LDB.
LDB	leading dimension of B
BETA	Scalar parameter
C()	rectangular array with first dimension LDC.
LDC	leading dimension of C
WORK()	scratch array of length LWORK. WORK is not referenced in the current version.
LWORK	length of WORK array. LWORK is not referenced in the current version.

```

DESCRIPTION

```
C <- ALPHA op(A) B + BETA C      C <- ALPHA D op(A) B + BETA C
C <- ALPHA op(A) D B + BETA C
```

where ALPHA and BETA are scalar, C and B are m by n dense matrices, D is a block diagonal matrix, A is a unit, or non-unit, upper or lower triangular matrix represented in block Ellpack format and op(A) is one of
op(A) = inv(A) or op(A) = inv(A') or op(A) =inv(conjg(A'))
(inv denotes matrix inverse, ' indicates matrix transpose)

ARGUMENTS

TRANSA Indicates how to operate with the sparse matrix
 0 : operate with matrix
 1 : operate with transpose matrix
 2 : operate with the conjugate transpose of matrix.
 2 is equivalent to 1 if matrix is real.

MB Number of block rows in matrix A

N Number of columns in matrix C

UNITD Type of scaling:
 1 : Identity matrix (argument DV[] is ignored)
 2 : Scale on left (row scaling)
 3 : Scale on right (column scaling)

DV() Array of the length MB*LB*LB consisting of the block
 entries of block diagonal matrix D where each
 block is stored in standard column-major form.

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array
DESCRA(1) matrix structure
 0 : general
 1 : symmetric (A=A')
 2 : Hermitian (A= CONJG(A'))
 3 : Triangular
 4 : Skew(Anti)-Symmetric (A=-A')
 5 : Diagonal
 6 : Skew-Hermitian (A= -CONJG(A'))
Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper

DESCRA(3) main diagonal type
 0 : non-identity blocks on the main diagonal
 1 : identity diagonal blocks
 2 : diagonal blocks are dense matrices

DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL() scalar array of length LB*LB*BLDA*MAXBNZ containing
 matrix entries, stored column-major within each dense

block.

BINDX() two-dimensional integer BLDA-by-MAXBNZ array such
 BINDX(i,:) consists of the block column indices of the
 nonzero blocks in block row i, padded by the integer
 value i if the number of nonzero blocks is less than
 MAXBNZ. The block column indices MUST be sorted
 in increasing order for each block row.

BLDA leading dimension of BINDX(:,:).

MAXBNZ max number of nonzeros blocks per row.

LB row and column dimension of the dense blocks composing A.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK.
 On exit, if LWORK= -1, WORK(1) returns the minimum
 size of LWORK.

LWORK length of WORK array. LWORK should be at least
 MB*LB.

For good performance, LWORK should generally be larger.
 For optimum performance on multiple processors, LWORK
 >=MB*LB*N_CPUS where N_CPUS is the maximum number of
 processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the
 routine only calculates the optimum size of the WORK
 array, returns this value as the first entry of the WORK
 array, and no error message related to LWORK is issued
 by XERBLA.

NOTES/BUGS

1. No test for singularity or near-singularity is included
 in this routine. Such tests must be performed before calling
 this routine.
2. If DESCRA(3)=0, the lower or upper triangular part of each

diagonal block is used by the routine depending on *DESCRA(2)*.

3. If *DESCRA(3)=1*, the unit diagonal blocks might or might not be referenced in the BEL representation of a sparse matrix. They are not used anyway.

4. If *DESCRA(3)=2*, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. *WORK(1)=0* on return if the factorization for all diagonal blocks has been completed successfully, otherwise *WORK(1) = -i* where *i* is the block number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix *A* is used. However *DESCRA(1)* must be equal to 3 in this case.

DESCRIPTION

```
C <- alpha op(A) B + beta C
```

where ALPHA and BETA are scalar, C and B are dense matrices, A is a matrix represented in block sparse column format and op(A) is one of
op(A) = A or op(A) = A' or op(A) = conjg(A').
(' indicates matrix transpose)

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real.
MB	Number of block rows in matrix A
N	Number of columns in matrix C
KB	Number of block columns in matrix A
ALPHA	Scalar parameter
DESCRA()	Descriptor argument. Five element integer array DESCRA(1) matrix structure 0 : general 1 : symmetric (A=A') 2 : Hermitian (A= CONJG(A')) 3 : Triangular 4 : Skew(Anti)-Symmetric (A=-A') 5 : Diagonal 6 : Skew-Hermitian (A= -CONJG(A')) DESCRA(2) upper/lower triangular indicator 1 : lower 2 : upper DESCRA(3) main diagonal type 0 : non-unit 1 : unit DESCRA(4) Array base (NOT IMPLEMENTED) 0 : C/C++ compatible 1 : Fortran compatible DESCRA(5) repeated indices? (NOT IMPLEMENTED) 0 : unknown 1 : no repeated indices
VAL()	scalar array of length LB*LB*BNNZ consisting of the block entries stored column-major within each dense block.
BINDX()	integer array of length BNNZ consisting of the block row indices of the block entries of A.
BPNTRB()	integer array of length KB such that BPNTRB(J)-BPNTRB(1)+1 points to location in BINDX of the first block entry of the J-th block column of A.
BPNTRE()	integer array of length KB such that BPNTRE(J)-BPNTRB(1) points to location in BINDX

of the last block entry of the J-th block column of A.

LB dimension of dense blocks composing A.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK. WORK is not referenced in the current version.

LWORK length of WORK array. LWORK is not referenced in the current version.

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

It is known that there exists another representation of the block sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block column in the arrays VAL and BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of block sparse column format the following calling sequence should be used

```
CALL SBSCMM( TRANSA, MB, N, KB, ALPHA, DESCRA,
*           VAL, BINDX, IA, IA(2), LB,
*           B, LDB, BETA, C, LDC, WORK, LWORK )
```

COMPLEX, DIMENSION(:, :) :: B, C  
  
SUBROUTINE BSCSM_64(TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA, VAL, BINDX,  
*                BPNTRB, BPNTRE, LB, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])  
INTEGER*8        TRANSA, MB, N, UNITD, LB  
INTEGER*8, DIMENSION(:) :: DESCRA, BINDX, BPNTRB, BPNTRE  
COMPLEX          ALPHA, BETA  
COMPLEX, DIMENSION(:) :: VAL, DV  
COMPLEX, DIMENSION(:, :) :: B, C
```

DESCRIPTION

```
C <- ALPHA op(A) B + BETA C      C <- ALPHA D op(A) B + BETA C
C <- ALPHA op(A) D B + BETA C
```

where ALPHA and BETA are scalar, C and B are m by n dense matrices, D is a block diagonal matrix, A is a unit, or non-unit, upper or lower triangular matrix represented in block sparse column format and op(A) is one of
op(A) = inv(A) or op(A) = inv(A') or op(A) =inv(conjg(A'))
(inv denotes matrix inverse, ' indicates matrix transpose)

ARGUMENTS

TRANSA Indicates how to operate with the sparse matrix
0 : operate with matrix
1 : operate with transpose matrix
2 : operate with the conjugate transpose of matrix.
2 is equivalent to 1 if matrix is real.

MB Number of block rows in matrix A

N Number of columns in matrix C

UNITD Type of scaling:
1 : Identity matrix (argument DV[] is ignored)
2 : Scale on left (row block scaling)
3 : Scale on right (column block scaling)

DV() Array of the length MB*LB*LB consisting of the block entries of block diagonal matrix D where each block is stored in standard column-major form.

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array
DESCRA(1) matrix structure
0 : general
1 : symmetric (A=A')
2 : Hermitian (A= CONJG(A'))
3 : Triangular
4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))

Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator

1 : lower

2 : upper

DESCRA(3) main diagonal type

0 : non-identity blocks on the main diagonal

1 : identity diagonal blocks

2 : diagonal blocks are dense matrices

DESCRA(4) Array base (NOT IMPLEMENTED)

0 : C/C++ compatible

1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)

0 : unknown

1 : no repeated indices

VAL() scalar array of length LB*LB*BNNZ consisting of the block

entries stored column-major within each dense block.

BINDX() integer array of length BNNZ consisting of the block row indices of the block entries of A. The block row indices MUST be sorted in increasing order for each block column.

BPNTRB() integer array of length MB such that BPNTRB(J)-BPNTRB(1)+1 points to location in BINDX of the first block entry of the J-th block column of A.

BPNTRE() integer array of length MB such that BPNTRE(J)-BPNTRB(1) points to location in BINDX of the last block entry of the J-th block column of A.

LB dimension of dense blocks composing A.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK. On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK length of WORK array. LWORK should be at least MB*LB.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=MB*LB*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

NIST FORTRAN Sparse Blas User's Guide available at:
<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If *DESCRA*(3)=0, the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).

3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the BSC representation of a sparse matrix. They are not used anyway.

4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. *WORK*(1)=0 on return if the factorization for all diagonal blocks has been completed successfully, otherwise *WORK*(1) = -i where i is the block number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

6. It is known that there exists another representation of the block sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block column in the arrays VAL and BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of block sparse column format the following calling sequence should be used

```
CALL SBSCSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,  
*           VAL, BINDX, IA, IA(2), LB,  
*           B, LDB, BETA, C, LDC, WORK, LWORK )
```

```

PURPOSE

ccnvcor computes the convolution or correlation of complex vectors.

ARGUMENTS

CNVCOR (input)
CHARACTER
'V' or 'v' if convolution is desired, 'R' or 'r'
if correlation is desired.

FOUR (input)
CHARACTER
'T' or 't' if the Fourier transform method is to
be used, 'D' or 'd' if the computation should be
done directly from the definition. The Fourier
transform method is generally faster, but it may
introduce noticeable errors into certain results,
notably when both the real and imaginary parts of
the filter and data vectors consist entirely of
integers or vectors where elements of either the
filter vector or a given data vector differ signi-
ficantly in magnitude from the 1-norm of the vec-
tor.

NX (input)
Length of the filter vector. NX >= 0. CCNVCOR
will return immediately if NX = 0.

X (input) dimension(*)
Filter vector.

IFX (input)
Index of the first element of X. NX >= IFX >= 1.

INCX (input)
Stride between elements of the filter vector in X.
INCX > 0.

NY (input)
Length of the input vectors. NY >= 0. CCNVCOR
will return immediately if NY = 0.

NPRES (input)
The number of implicit zeros prepended to the Y
vectors. NPRES >= 0.

M (input)
Number of input vectors. M >= 0. CCNVCOR will
return immediately if M = 0.

Y (input) dimension(*)
Input vectors.

IFY (input)
Index of the first element of Y. $NY \geq IFY \geq 1$.

INC1Y (input)
Stride between elements of the input vectors in Y.
 $INC1Y > 0$.

INC2Y (input)
Stride between the input vectors in Y. $INC2Y > 0$.

NZ (input)
Length of the output vectors. $NZ \geq 0$. CCNVCOR
will return immediately if $NZ = 0$. See the Notes
section below for information about how this argu-
ment interacts with NX and NY to control circular
versus end-off shifting.

K (input)
Number of Z vectors. $K \geq 0$. If $K = 0$ then
CCNVCOR will return immediately. If $K < M$ then
only the first K input vectors will be processed.
If $K > M$ then M input vectors will be processed.

Z (output)
dimension(*)
Result vectors.

IFZ (input)
Index of the first element of Z. $NZ \geq IFZ \geq 1$.

INC1Z (input)
Stride between elements of the output vectors in
Z. $INC1Z > 0$.

INC2Z (input)
Stride between the output vectors in Z. $INC2Z >$
0.

WORK (input/output)
(input/scratch) dimension(LWORK)
Scratch space. Before the first call to CCNVCOR
with particular values of the integer arguments
the first element of WORK must be set to zero. If
WORK is written between calls to CCNVCOR or if
CCNVCOR is called with different values of the
integer arguments then the first element of WORK
must again be set to zero before each call. If
WORK has not been written and the same values of
the integer arguments are used then the first ele-
ment of WORK to zero. This can avoid certain ini-
tializations that store their results into WORK,
and avoiding the initialization can make CCNVCOR
run faster.

LWORK (input)
Length of WORK. $LWORK \geq 2*MAX(NX,NY+NPRES,NZ)+8$.

  mz, long nz, complex *z, long ldz, complex *work,
  long lwork);
```

PURPOSE

ccncor2 computes the convolution or correlation of complex matrices.

ARGUMENTS

CNVCOR (input)

'V' or 'v' to compute convolution, 'R' or 'r' to compute correlation.

METHOD (input)

'T' or 't' if the Fourier transform method is to be used, 'D' or 'd' to compute directly from the definition.

TRANSX (input)

'N' or 'n' if X is the filter matrix, 'T' or 't' if transpose(X) is the filter matrix.

SCRATCHX (input)

'N' or 'n' if X must be preserved, 'S' or 's' if X can be used as scratch space. The contents of X are undefined after returning from a call in which X is allowed to be used for scratch.

TRANSY (input)

'N' or 'n' if Y is the input matrix, 'T' or 't' if transpose(Y) is the input matrix.

SCRATCHY (input)

'N' or 'n' if Y must be preserved, 'S' or 's' if Y can be used as scratch space. The contents of Y are undefined after returning from a call in which Y is allowed to be used for scratch.

MX (input)

Number of rows in the filter matrix. MX >= 0.

NX (input)

Number of columns in the filter matrix. $NX \geq 0$.

X (input)
On entry, the filter matrix. Unchanged on exit if SCRATCHX is 'N' or 'n', undefined on exit if SCRATCHX is 'S' or 's'.

LDX (input)
Leading dimension of the array that contains the filter matrix.

MY (input)
Number of rows in the input matrix. $MY \geq 0$.

NY (input)
Number of columns in the input matrix. $NY \geq 0$.

MPRE (input)
Number of implicit zeros to prepend to each row of the input matrix. $MPRE \geq 0$.

NPRE (input)
Number of implicit zeros to prepend to each column of the input matrix. $NPRE \geq 0$.

Y (input)
Input matrix. Unchanged on exit if SCRATCHY is 'N' or 'n', undefined on exit if SCRATCHY is 'S' or 's'.

LDY (input)
Leading dimension of the array that contains the input matrix.

MZ (input)
Number of rows in the output matrix. $MZ \geq 0$.
CCNVCOR2 will return immediately if $MZ = 0$.

NZ (input)
Number of columns in the output matrix. $NZ \geq 0$.
CCNVCOR2 will return immediately if $NZ = 0$.

Z (output)
dimension(LDZ,*)
Result matrix.

LDZ (input)
Leading dimension of the array that contains the result matrix. $LDZ \geq \text{MAX}(1, MZ)$.

WORK (input/output)
(input/scratch) dimension(LWORK)
On entry for the first call to CCNVCOR2, WORK(1) must contain CMLPX(0.0,0.0). After the first call, WORK(1) must be set to CMLPX(0.0,0.0) iff WORK has been altered since the last call to this subroutine or if the sizes of the arrays have changed.

LWORK (input)
Length of the work vector. The upper bound of the workspace length requirement is $2 * (\text{MYC} + \text{NYC}) + 15$, where $\text{MYC} = \text{MAX}(\text{MAX}(\text{MX}, \text{NX}), \text{MAX}(\text{MY}, \text{NY}) + \text{NPRES})$ and $\text{NYC} = \text{MAX}(\text{MAX}(\text{MX}, \text{NX}), \text{MAX}(\text{MY}, \text{NY}) + \text{MPRES})$. If LWORK indicates a workspace that is too small, the

routine will allocate its own workspace. If the FFT is not used, the value of LWORK is unimportant.

COMPLEX, DIMENSION(:, :) :: B, C
```

DESCRIPTION

```
C <- alpha op(A) B + beta C
```

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in coordinate format and
op(A) is one of
op(A) = A or op(A) = A' or op(A) = conjg(A').
(' indicates matrix transpose)

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real.
M	Number of rows in matrix A
N	Number of columns in matrix C
K	Number of columns in matrix A
ALPHA	Scalar parameter
DESCRA()	Descriptor argument. Five element integer array DESCRA(1) matrix structure 0 : general 1 : symmetric (A=A') 2 : Hermitian (A= CONJG(A')) 3 : Triangular 4 : Skew(Anti)-Symmetric (A=-A') 5 : Diagonal 6 : Skew-Hermitian (A= -CONJG(A')) DESCRA(2) upper/lower triangular indicator 1 : lower 2 : upper DESCRA(3) main diagonal type 0 : non-unit 1 : unit DESCRA(4) Array base (NOT IMPLEMENTED) 0 : C/C++ compatible 1 : Fortran compatible DESCRA(5) repeated indices? (NOT IMPLEMENTED) 0 : unknown 1 : no repeated indices
VAL()	scalar array of length NNZ consisting of the non-zero entries of A, in any order.
INDX()	integer array of length NNZ consisting of the corresponding row indices of the entries of A.
JNDX()	integer array of length NNZ consisting of the corresponding column indices of the entries of A.
NNZ	number of non-zero elements in A.
B()	rectangular array with first dimension LDB.
LDB	leading dimension of B

BETA	Scalar parameter
C()	rectangular array with first dimension LDC.
LDC	leading dimension of C
WORK()	scratch array of length LWORK. WORK is not referenced in the current version.
LWORK	length of WORK array. LWORK is not referenced in the current version.

incy);
```

```
void ccopy_64(long n, complex *x, long incx, complex *y,  
long incy);
```

PURPOSE

ccopy Copy x to y where x and y are n-vectors.

ARGUMENTS

- N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.
- X (input)
of DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the vector x. Unchanged on exit.
- INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.
- Y (output)
of DIMENSION at least $(1 + (m - 1) * \text{abs}(\text{INCY}))$. On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the vector x.
- INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NOTES/BUGS

It is known that there exists another representation of the compressed sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each column in the arrays VAL and INDX is used instead of two arrays PNTRB and PNTRE. To use the routine with this kind of sparse column format the following calling sequence should be used

```

SUBROUTINE SCSCMM( TRANSA, M, N, K, ALPHA, DESCRA,
*                VAL, INDX, IA, IA(2), B, LDB, BETA,
*                C, LDC, WORK, LWORK )

```

COMPLEX          ALPHA, BETA
COMPLEX          DV(M), VAL(NNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
```

where NNZ = PNTRE(M)-PNTRB(1)

F95 INTERFACE

```
SUBROUTINE CSCSM( TRANSA, M, [N], UNITD, DV, ALPHA, DESCRA, VAL, INDX,
* PNTRB, PNTRE, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
INTEGER TRANSA, M, UNITD
INTEGER, DIMENSION(:) :: DESCRA, INDX, PNTRB, PNTRE
COMPLEX ALPHA, BETA
COMPLEX, DIMENSION(:) :: VAL, DV
COMPLEX, DIMENSION(:, :) :: B, C
```

```
SUBROUTINE CSCSM_64(TRANSA, M, [N], UNITD, DV, ALPHA, DESCRA, VAL, INDX,
* PNTRB, PNTRE, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
INTEGER*8 TRANSA, M, UNITD
INTEGER*8, DIMENSION(:) :: DESCRA, INDX, PNTRB, PNTRE
COMPLEX ALPHA, BETA
COMPLEX, DIMENSION(:) :: VAL, DV
COMPLEX, DIMENSION(:, :) :: B, C
```

DESCRIPTION

```
C <- ALPHA op(A) B + BETA C      C <- ALPHA D op(A) B + BETA C
C <- ALPHA op(A) D B + BETA C
```

where ALPHA and BETA are scalar, C and B are m by n dense matrices, D is a diagonal scaling matrix, A is a unit, or non-unit, upper or lower triangular matrix represented in compressed sparse column format and op(A) is one of
op(A) = inv(A) or op(A) = inv(A') or op(A) = inv(conjg(A'))
(inv denotes matrix inverse, ' indicates matrix transpose)

ARGUMENTS

TRANSA Indicates how to operate with the sparse matrix
 0 : operate with matrix
 1 : operate with transpose matrix
 2 : operate with the conjugate transpose of matrix.
 2 is equivalent to 1 if matrix is real.

M Number of rows in matrix A

N Number of columns in matrix C

UNITD Type of scaling:
 1 : Identity matrix (argument DV[] is ignored)
 2 : Scale on left (row scaling)
 3 : Scale on right (column scaling)
 4 : Automatic column scaling (see section NOTES for
 further details)

DV() Array of length M containing the diagonal entries of the
 scaling diagonal matrix D.

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array
DESCRA(1) matrix structure
 0 : general
 1 : symmetric (A=A')
 2 : Hermitian (A= CONJG(A'))
 3 : Triangular
 4 : Skew(Anti)-Symmetric (A=-A')
 5 : Diagonal
 6 : Skew-Hermitian (A= -CONJG(A'))

Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper

DESCRA(3) main diagonal type
 0 : non-unit
 1 : unit

DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL() scalar array of length NNZ consisting of nonzero entries

of A.

INDX() integer array of length NNZ consisting of the row indices of nonzero entries of A. (Row indices MUST be sorted in increasing order for each column).

PNTRB() integer array of length M such that PNTRB(J)-PNTRB(1)+1 points to location in VAL of the first nonzero element in column J.

PNTRE() integer array of length M such that PNTRE(J)-PNTRB(1) points to location in VAL of the last nonzero element in column J.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK.

On exit, if LWORK = -1, WORK(1) returns the optimum LWORK.

LWORK length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK $\geq M \cdot N_{\text{CPUS}}$ where N_{CPUS} is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If UNITD =4, the routine scales the columns of A such that their 2-norms are one. The scaling may improve the

accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the columns have been scaled. UNITD=3 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise WORK(1) = -i where i is the column number which 2-norm is exactly zero.

3. If DESCRA(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the CSC representation of a sparse matrix. They are not used anyway in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the CSC representation.

4. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However DESCRA(1) must be equal to 3 in this case.

5. It is known that there exists another representation of the compressed sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each column in the arrays VAL and INDX is used instead of two arrays PNTRB and PNTRE. To use the routine with this kind of sparse column format the following calling sequence should be used

```
      SUBROUTINE SCSCSM( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,  
*                   VAL, INDX, IA, IA(2), B, LDB, BETA,  
*                   C, LDC, WORK, LWORK )
```

INTEGER*8 TRANSA, M, UNITD
INTEGER*8, DIMENSION(:) :: DESCRA, INDX, PNTRB, PNTRE
COMPLEX ALPHA, BETA
COMPLEX, DIMENSION(:) :: VAL, DV
COMPLEX, DIMENSION(:, :) :: B, C
```

DESCRIPTION

```
C <- ALPHA op(A) B + BETA C      C <- ALPHA D op(A) B + BETA C
C <- ALPHA op(A) D B + BETA C
```

where ALPHA and BETA are scalar, C and B are m by n dense matrices, D is a diagonal scaling matrix, A is a unit, or non-unit, upper or lower triangular matrix represented in compressed sparse row format and op(A) is one of
op(A) = inv(A) or op(A) = inv(A') or op(A) =inv(conjg(A'))
(inv denotes matrix inverse, ' indicates matrix transpose)

ARGUMENTS

TRANSA Indicates how to operate with the sparse matrix
 0 : operate with matrix
 1 : operate with transpose matrix
 2 : operate with the conjugate transpose of matrix.
 2 is equivalent to 1 if matrix is real.

M Number of rows in matrix A

N Number of columns in matrix C

UNITD Type of scaling:
 1 : Identity matrix (argument DV[] is ignored)
 2 : Scale on left (row scaling)
 3 : Scale on right (column scaling)
 4 : Automatic row scaling (see section NOTES for
 further details)

DV() Array of length M containing the diagonal entries of
 the scaling diagonal matrix D.

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array
DESCRA(1) matrix structure
 0 : general
 1 : symmetric (A=A')
 2 : Hermitian (A= CONJG(A'))
 3 : Triangular
 4 : Skew(Anti)-Symmetric (A=-A')
 5 : Diagonal
 6 : Skew-Hermitian (A= -CONJG(A'))

Note: For the routine, only DESCRA(1)=3 is supported.

DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper

DESCRA(3) main diagonal type
 0 : non-unit
 1 : unit

DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL() scalar array of length NNZ consisting of nonzero entries

of A.

INDX() integer array of length NNZ consisting of the column indices of nonzero entries of A (column indices MUST be sorted in increasing order for each row)

PNTRB() integer array of length M such that PNTRB(J)-PNTRB(1)+1 points to location in VAL of the first nonzero element in row J.

PNTRE() integer array of length M such that PNTRE(J)-PNTRB(1) points to location in VAL of the last nonzero element in row J.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK.

On exit, if LWORK = -1, WORK(1) returns the optimum LWORK.

LWORK length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK $\geq M \cdot N_{\text{CPUS}}$ where N_{CPUS} is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

```

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real.
M	Number of rows in matrix A
N	Number of columns in matrix C
UNITD	Type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) 4 : Automatic row scaling (see section NOTES for further details)
DV()	Array of length M containing the diagonal entries of the scaling diagonal matrix D.
ALPHA	Scalar parameter
DESCRA()	Descriptor argument. Five element integer array DESCRA(1) matrix structure 0 : general 1 : symmetric (A=A') 2 : Hermitian (A= CONJG(A')) 3 : Triangular 4 : Skew(Anti)-Symmetric (A=-A') 5 : Diagonal 6 : Skew-Hermitian (A= -CONJG(A')) Note: For the routine, only DESCRA(1)=3 is supported. DESCRA(2) upper/lower triangular indicator 1 : lower 2 : upper DESCRA(3) main diagonal type 0 : non-unit 1 : unit DESCRA(4) Array base (NOT IMPLEMENTED) 0 : C/C++ compatible 1 : Fortran compatible DESCRA(5) repeated indices? (NOT IMPLEMENTED) 0 : unknown 1 : no repeated indices
VAL()	two-dimensional LDA-by-NDIAG array such that VAL(:,I)

consists of non-zero elements on diagonal IDIAG(I) of A. Diagonals in the lower triangular part of A are padded from the top, and those in the upper triangular part are padded from the bottom.

LDA leading dimension of VAL, must be .GE. MIN(M,K)

IDIAG() integer array of length NDIAG consisting of the corresponding diagonal offsets of the non-zero diagonals of A in VAL. Lower triangular diagonals have negative offsets, the main diagonal has offset 0, and upper triangular diagonals have positive offset. Elements of IDIAG of MUST be sorted in increasing order.

NDIAG number of non-zero diagonals in A.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK.
On exit, if LWORK = -1, WORK(1) returns the optimum LWORK.

LWORK length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK $\geq M \cdot N_{\text{CPUS}}$ where N_{CPUS} is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

```
COMPLEX X(*), Y(*)  
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
COMPLEX FUNCTION DOTC([N], X, [INCX], Y, [INCY])
```

```
COMPLEX, DIMENSION(:) :: X, Y  
INTEGER :: N, INCX, INCY
```

```
COMPLEX FUNCTION DOTC_64([N], X, [INCX], Y, [INCY])
```

```
COMPLEX, DIMENSION(:) :: X, Y  
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
complex cdotc(int n, complex *x, int incx, complex *y, int  
incy);
```

```
complex cdotc_64(long n, complex *x, long incx, complex *y,  
long incy);
```

PURPOSE

cdotc compute the dot product of $\text{conjg}(x)$ and y where x and y are n -vectors.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. If N is not positive then the function returns the value 0.0. Unchanged on exit.

X (input)

of DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{INCX}))$. On entry, the incremented array X must contain the vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X . INCX must not be zero. Unchanged on exit.

Y (input)

of DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{INCY}))$. On entry, the incremented array Y must contain the vector y . Unchanged on exit.

INCY (input)

On entry, INCY specifies the increment for the elements of Y . INCY must not be zero. Unchanged on exit.

NAME

cdotci - Compute the complex conjugated indexed dot product.

SYNOPSIS

```
COMPLEX FUNCTION CDOTCI(NZ, X, INDX, Y)
```

```
COMPLEX X(*), Y(*)  
INTEGER NZ  
INTEGER INDX(*)
```

```
COMPLEX FUNCTION CDOTCI_64(NZ, X, INDX, Y)
```

```
COMPLEX X(*), Y(*)  
INTEGER*8 NZ  
INTEGER*8 INDX(*)
```

```
F95 INTERFACE
```

```
COMPLEX FUNCTION DOTCI([NZ], X, INDX, Y)
```

```
COMPLEX, DIMENSION(:) :: X, Y  
INTEGER :: NZ  
INTEGER, DIMENSION(:) :: INDX
```

```
COMPLEX FUNCTION DOTCI_64([NZ], X, INDX, Y)
```

```
COMPLEX, DIMENSION(:) :: X, Y  
INTEGER(8) :: NZ  
INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

CDOTCI Compute the complex conjugated indexed dot product of a complex sparse vector x stored in compressed form with a complex vector y in full storage form.

```
dot = 0  
do i = 1, n  
  dot = dot + conjg(x(i)) * y(indx(i))  
enddo
```

ARGUMENTS

NZ (input)

Number of elements in the compressed form.
Unchanged on exit.

X (input)

Vector in compressed form. Unchanged on exit.

INDX (input)

Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

Y (input)

Vector in full storage form. Only the elements corresponding to the indices in INDX will be accessed.

COMPLEX          ALPHA, BETA  
COMPLEX          VAL(LDA,MAXNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
```

F95 INTERFACE

```
SUBROUTINE ELLMM( TRANSA, M, [N], K, ALPHA, DESCRA, VAL, INDX,  
*               [LDA], MAXNZ, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])  
INTEGER        TRANSA, M, K, MAXNZ  
INTEGER, DIMENSION(:) :: DESCRA  
INTEGER, DIMENSION(:, :) :: INDX  
COMPLEX        ALPHA, BETA  
COMPLEX, DIMENSION(:, :) :: VAL, B, C
```

```
SUBROUTINE ELLMM_64( TRANSA, M, [N], K, ALPHA, DESCRA, VAL, INDX,  
*                   [LDA], MAXNZ, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])  
INTEGER*8      TRANSA, M, K, MAXNZ  
INTEGER*8, DIMENSION(:) :: DESCRA  
INTEGER*8, DIMENSION(:, :) :: INDX  
COMPLEX        ALPHA, BETA  
COMPLEX, DIMENSION(:, :) :: VAL, B, C
```

DESCRIPTION

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in Ellpack format format and
op(A) is one of

op(A) = A or op(A) = A' or op(A) = conjg(A').
(' indicates matrix transpose)

ARGUMENTS

TRANSA Indicates how to operate with the sparse matrix
0 : operate with matrix
1 : operate with transpose matrix
2 : operate with the conjugate transpose of matrix.
2 is equivalent to 1 if matrix is real.

M Number of rows in matrix A

N Number of columns in matrix C

K Number of columns in matrix A

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array
DESCRA(1) matrix structure
0 : general
1 : symmetric (A=A')
2 : Hermitian (A= CONJG(A'))
3 : Triangular
4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper
DESCRA(3) main diagonal type
0 : non-unit
1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL() two-dimensional LDA-by-MAXNZ array such that VAL(I,:) consists of non-zero elements in row I of A, padded by zero values if the row contains less than MAXNZ.

INDX() two-dimensional integer LDA-by-MAXNZ array such INDX(I,:) consists of the column indices of the nonzero elements in row I, padded by the integer value I if the number of nonzeros is less than MAXNZ.

LDA leading dimension of VAL and INDX.

MAXNZ max number of nonzeros elements per row.

B() rectangular array with first dimension LDB.

LDB	leading dimension of B
BETA	Scalar parameter
C()	rectangular array with first dimension LDC.
LDC	leading dimension of C
WORK()	scratch array of length LWORK. WORK is not referenced in the current version.
LWORK	length of WORK array. LWORK is not referenced in the current version.

INTEGER          INDX(LDA,MAXNZ)
COMPLEX          ALPHA, BETA
COMPLEX          DV(M), VAL(LDA,MAXNZ), B(LDB,*), C(LDC,*), WORK(LWORK)

SUBROUTINE CELLSM_64( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,
*                    VAL, INDX, LDA, MAXNZ,
*                    B, LDB, BETA, C, LDC, WORK, LWORK )
INTEGER*8        TRANSA, M, N, UNITD, DESCRA(5), LDA, MAXNZ,
*                    LDB, LDC, LWORK
INTEGER*8        INDX(LDA,MAXNZ)
COMPLEX          ALPHA, BETA
COMPLEX          DV(M), VAL(LDA,MAXNZ), B(LDB,*), C(LDC,*), WORK(LWORK)

```

F95 INTERFACE

```

SUBROUTINE ELLSM( TRANSA, M, [N], UNITD, DV, ALPHA, DESCRA, VAL,
*               INDX, [LDA], MAXNZ, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
INTEGER          TRANSA, M, MAXNZ
INTEGER, DIMENSION(:) :: DESCRA
INTEGER, DIMENSION(:,:) :: INDX
COMPLEX          ALPHA, BETA
COMPLEX, DIMENSION(:) :: DV
COMPLEX, DIMENSION(:,:) :: VAL, B, C

SUBROUTINE ELLSM_64( TRANSA, M, [N], UNITD, DV, ALPHA, DESCRA, VAL,
*                  INDX, [LDA], MAXNZ, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
INTEGER*8        TRANSA, M, MAXNZ
INTEGER*8, DIMENSION(:) :: DESCRA
INTEGER*8, DIMENSION(:,:) :: INDX
COMPLEX          ALPHA, BETA
COMPLEX, DIMENSION(:) :: DV
COMPLEX, DIMENSION(:,:) :: VAL, B, C

```

DESCRIPTION

```
C <- ALPHA op(A) B + BETA C      C <- ALPHA D op(A) B + BETA C
C <- ALPHA op(A) D B + BETA C
```

where ALPHA and BETA are scalar, C and B are m by n dense matrices, D is a diagonal scaling matrix, A is a unit, or non-unit, upper or lower triangular matrix represented in Ellpack format and op(A) is one of

```
op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))
(inv denotes matrix inverse, ' indicates matrix transpose)
```

ARGUMENTS

TRANSA Indicates how to operate with the sparse matrix
 0 : operate with matrix
 1 : operate with transpose matrix
 2 : operate with the conjugate transpose of matrix.
 2 is equivalent to 1 if matrix is real.

M Number of rows in matrix A

N Number of columns in matrix C

UNITD Type of scaling:
 1 : Identity matrix (argument DV[] is ignored)
 2 : Scale on left (row scaling)
 3 : Scale on right (column scaling)
 4 : Automatic row scaling (see section NOTES for
 further details)

DV() Array of length M containing the diagonal entries of the
 scaling diagonal matrix D.

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array
DESCRA(1) matrix structure
 0 : general
 1 : symmetric (A=A')
 2 : Hermitian (A= CONJG(A'))
 3 : Triangular
 4 : Skew(Anti)-Symmetric (A=-A')
 5 : Diagonal
 6 : Skew-Hermitian (A= -CONJG(A'))

Note: For the routine, only DESCRA(1)=3 is supported.

DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper

DESCRA(3) main diagonal type
 0 : non-unit
 1 : unit

DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL() two-dimensional LDA-by-MAXNZ array such that VAL(I,:)

consists of non-zero elements in row I of A, padded by zero values if the row contains less than MAXNZ.

INDX() two-dimensional integer LDA-by-MAXNZ array such INDX(I,:) consists of the column indices of the nonzero elements in row I, padded by the integer value I if the number of nonzeros is less than MAXNZ. The column indices MUST be sorted in increasing order for each row.

LDA leading dimension of VAL and INDX.

MAXNZ max number of nonzeros elements per row.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK.

On exit, if LWORK = -1, WORK(1) returns the optimum LWORK.

LWORK length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If UNITD =4, the routine scales the rows of A such that their 2-norms are one. The scaling may improve the accuracy

of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise WORK(1) = -i where i is the row number which 2-norm is exactly zero.

3. If DESCRA(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the ELL representation of a sparse matrix. They are not used anyway in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the ELL representation.

4. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However DESCRA(1) must be equal to 3 in this case.

COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, LDA, LWORK  
REAL, DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cfft2b(int m, int n, complex *a, int lda, float *work,  
           int lwork);
```

```
void cfft2b_64(long m, long n, complex *a, long lda, float  
              *work, long lwork);
```

ARGUMENTS

M (input) Number of rows to be transformed. These subroutines are most efficient when M is a product of small primes. $M \geq 0$.

N (input) Number of columns to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

A (input/output)
On entry, a two-dimensional array A(M,N) that contains the sequences to be transformed.

LDA (input)
Leading dimension of the array containing the data to be transformed. $LDA \geq M$.

WORK (input)
On input, workspace WORK must have been initialized by CFFT2I.

LWORK (input)
The dimension of the array WORK. $LWORK \geq (4 * (M + N) + 30)$

 - [F95 INTERFACE](#)
 - [C INTERFACE](#)
- [ARGUMENTS](#)

NAME

cffft2i - initialize the array WSAVE, which is used in both the forward and backward transforms.

SYNOPSIS

```
SUBROUTINE CFFT2I(M, N, WORK)
```

```
INTEGER M, N  
REAL WORK(*)
```

```
SUBROUTINE CFFT2I_64(M, N, WORK)
```

```
INTEGER*8 M, N  
REAL WORK(*)
```

F95 INTERFACE

```
SUBROUTINE CFFT2I(M, N, WORK)
```

```
INTEGER :: M, N  
REAL, DIMENSION(:) :: WORK
```

```
SUBROUTINE CFFT2I_64(M, N, WORK)
```

```
INTEGER(8) :: M, N  
REAL, DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cffft2i(int m, int n, float *work);
```

```
void cffft2i_64(long m, long n, float *work);
```

ARGUMENTS

M (input) Number of rows to be transformed. M >= 0.

N (input) Number of columns to be transformed. N >= 0.

WORK (input/output)

On entry, an array of dimension (4 * (M + N) + 30) or greater. CFFT2I needs to be called only once

to initialize array WORK before calling CFFT2F and/or CFFT2B if M, N and WORK remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

```

```
void cfft3b_64(long m, long n, long k, complex *a, long lda,
              long ld2a, float *work, long lwork);
```

ARGUMENTS

- M (input) Number of rows to be transformed. These subroutines are most efficient when M is a product of small primes. $M \geq 0$.
- N (input) Number of columns to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.
- K (input) Number of planes to be transformed. These subroutines are most efficient when K is a product of small primes. $K \geq 0$.
- A (input/output)
On entry, a three-dimensional array $A(LDA,LD2A,K)$ that contains the sequences to be transformed.
- LDA (input)
Leading dimension of the array containing the data to be transformed. $LDA \geq M$.
- LD2A (input)
Second dimension of the array containing the data to be transformed. $LD2A \geq N$.
- WORK (input)
On input, workspace WORK must have been initialized by CFFT3I.
- LWORK (input)
The dimension of the array WORK. $LWORK \geq (4*(M + N + K) + 45)$.

NAME

cffft3f - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of CFFFT3F followed by a call of CFFFT3B will multiply the input sequence by $M*N*K$.

SYNOPSIS

```
SUBROUTINE CFFFT3F(M, N, K, A, LDA, LD2A, WORK, LWORK)
```

```
COMPLEX A(LDA,LD2A,*)  
INTEGER M, N, K, LDA, LD2A, LWORK  
REAL WORK(*)
```

```
SUBROUTINE CFFFT3F_64(M, N, K, A, LDA, LD2A, WORK, LWORK)
```

```
COMPLEX A(LDA,LD2A,*)  
INTEGER*8 M, N, K, LDA, LD2A, LWORK  
REAL WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT3F([M], [N], [K], A, [LDA], LD2A, WORK, LWORK)
```

```
COMPLEX, DIMENSION(:, :, :) :: A  
INTEGER :: M, N, K, LDA, LD2A, LWORK  
REAL, DIMENSION(:) :: WORK
```

```
SUBROUTINE FFT3F_64([M], [N], [K], A, [LDA], LD2A, WORK, LWORK)
```

```
COMPLEX, DIMENSION(:, :, :) :: A  
INTEGER(8) :: M, N, K, LDA, LD2A, LWORK  
REAL, DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cffft3f(int m, int n, int k, complex *a, int lda, int  
            ld2a, float *work, int lwork);
```

```
void cffft3f_64(long m, long n, long k, complex *a, long lda,  
               long ld2a, float *work, long lwork);
```

ARGUMENTS

- M (input) Number of rows to be transformed. These subroutines are most efficient when M is a product of small primes. $M \geq 0$.
- N (input) Number of columns to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.
- K (input) Number of planes to be transformed. These subroutines are most efficient when K is a product of small primes. $K \geq 0$.
- A (input/output)
On entry, a three-dimensional array A(M,N,K) that contains the sequences to be transformed.
- LDA (input)
Leading dimension of the array containing the data to be transformed. $LDA \geq M$.

NAME

cffft3i - initialize the array WSAVE, which is used in both CFFT3F and CFFT3B.

SYNOPSIS

```
SUBROUTINE CFFT3I(M, N, K, WORK)
```

```
INTEGER M, N, K  
REAL WORK(*)
```

```
SUBROUTINE CFFT3I_64(M, N, K, WORK)
```

```
INTEGER*8 M, N, K  
REAL WORK(*)
```

F95 INTERFACE

```
SUBROUTINE CFFT3I(M, N, K, WORK)
```

```
INTEGER :: M, N, K  
REAL, DIMENSION(:) :: WORK
```

```
SUBROUTINE CFFT3I_64(M, N, K, WORK)
```

```
INTEGER(8) :: M, N, K  
REAL, DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cffft3i(int m, int n, int k, float *work);
```

```
void cffft3i_64(long m, long n, long k, float *work);
```

ARGUMENTS

M (input) Number of rows to be transformed. M >= 0.

N (input) Number of columns to be transformed. N >= 0.

K (input) Number of planes to be transformed. K >= 0.

WORK (input/output)

On entry, an array of dimension $(4*(M + N + K) + 45)$ or greater. CFFT3I needs to be called only once to initialize array WORK before calling CFFT3F and/or CFFT3B if M, N, K and WORK remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

cfftb - compute a periodic sequence from its Fourier coefficients. The FFT operations are unnormalized, so a call of CFFTF followed by a call of CFFTB will multiply the input sequence by N.

SYNOPSIS

```
SUBROUTINE CFFTB(N, X, WSAVE)
```

```
COMPLEX X(*)
INTEGER N
REAL WSAVE(*)
```

```
SUBROUTINE CFFTB_64(N, X, WSAVE)
```

```
COMPLEX X(*)
INTEGER*8 N
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE FFTB([N], X, WSAVE)
```

```
COMPLEX, DIMENSION(:) :: X
INTEGER :: N
REAL, DIMENSION(:) :: WSAVE
```

```
SUBROUTINE FFTB_64([N], X, WSAVE)
```

```
COMPLEX, DIMENSION(:) :: X
INTEGER(8) :: N
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cfftb(int n, complex *x, float *wsave);
```

```
void cfftb_64(long n, complex *x, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

X (input) On entry, an array of length N containing the sequence to be transformed.

WSAVE (input/output)

On entry, WSAVE must be an array of dimension $(4 * N + 15)$ or greater and must have been initialized by CFFTI.

```

```
INTEGER*4, INTENT(IN) :: IOPT  
INTEGER*4, INTENT(IN), OPTIONAL :: N, LWORK  
REAL, INTENT(IN), OPTIONAL :: SCALE  
COMPLEX, INTENT(IN), DIMENSION(:) :: X  
COMPLEX, INTENT(OUT), DIMENSION(:) :: Y  
REAL, INTENT(INOUT), DIMENSION(:) :: TRIGS  
INTEGER*4, INTENT(INOUT), DIMENSION(:) :: IFAC  
REAL, INTENT(OUT), DIMENSION(:) :: WORK  
INTEGER*4, INTENT(OUT) :: IERR
```

```
SUBROUTINE FFT_64(IOPT, [N], [SCALE], X, Y, TRIGS, IFAC, WORK, [LWORK], IERR)
```

```
INTEGER(8), INTENT(IN) :: IOPT  
INTEGER(8), INTENT(IN), OPTIONAL :: N, LWORK  
REAL, INTENT(IN), OPTIONAL :: SCALE  
COMPLEX, INTENT(IN), DIMENSION(:) :: X  
COMPLEX, INTENT(OUT), DIMENSION(:) :: Y  
REAL, INTENT(INOUT), DIMENSION(:) :: TRIGS  
INTEGER(8), INTENT(INOUT), DIMENSION(:) :: IFAC  
REAL, INTENT(OUT), DIMENSION(:) :: WORK  
INTEGER(8), INTENT(OUT) :: IERR
```

C INTERFACE

```
#include <sunperf.h>

void cfftc_ (int *iopt, int *n, float *scale, complex *x,
            complex *y, float *trigs, int *ifac, float *work,
            int *lwork, int *ierr);

void cfftc_64_ (long *iopt, long *n, float *scale, complex
               *x, complex *y, float *trigs, long *ifac, float
               *work, long *lwork, long *ierr);
```

PURPOSE

cfftc initializes the trigonometric weight and factor tables or computes the Fast Fourier transform (forward or inverse) of a complex sequence as follows:

$$Y(k) = \text{scale} * \sum_{j=0}^{N-1} W^i X(j)$$

where

k ranges from 0 to N-1

i = sqrt(-1)

isign = 1 for inverse transform or -1 for forward transform

W = exp(isign*i*j*k*2*pi/N)

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = -1 computes forward FFT
IOPT = +1 computes inverse FFT

N (input)

Integer specifying length of the input sequence X. N is most efficient when it is a product of small primes. N >= 0. Unchanged on exit.

SCALE (input)

Real scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0 for F95 INTERFACE.

X (input) On entry, X is a complex array of dimension at least N that contains the sequence to be transformed.

Y (output)

Complex array of dimension at least N that contains the transform results. X and Y may be the same array starting at the same memory location. Otherwise, it is assumed that there is no overlap between X and Y in memory.

TRIGS (input/output)

Real array of length 2*N that contains the tri-

gonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

IFAC (input/output)

Integer array of dimension at least 128 that contains the factors of N. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls where IOPT = 1 or IOPT = -1. Unchanged on exit.

WORK (workspace)

Real array of dimension at least $2*N$. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)

Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)

On exit, integer IERR has one of the following values:

0 = normal return

-1 = IOPT is not 0, 1 or -1

-2 = $N < 0$

-3 = (LWORK is not 0) and (LWORK is less than $2*N$)

-4 = memory allocation for workspace failed

*scale, complex *x, long *ldx, complex *y, long
```

```
*ldy, float *trigs, long *ifac, float *work, long
*lwork, long *ierr);
```

PURPOSE

cfftc2 initializes the trigonometric weight and factor tables or computes the two-dimensional Fast Fourier Transform (forward or inverse) of a two-dimensional complex array. In computing the two-dimensional FFT, one-dimensional FFTs are computed along the columns of the input array. One-dimensional FFTs are then computed along the rows of the intermediate results.

$$Y(k_1, k_2) = \text{scale} * \sum_{j_2=0}^{N_2-1} \sum_{j_1=0}^{N_1-1} W_2 * W_1 * X(j_1, j_2)$$

where

k_1 ranges from 0 to N_1-1 and k_2 ranges from 0 to N_2-1

$i = \sqrt{-1}$

isign = 1 for inverse transform or -1 for forward transform

$W_1 = \exp(\text{isign} * i * j_1 * k_1 * 2 * \pi / N_1)$

$W_2 = \exp(\text{isign} * i * j_2 * k_2 * 2 * \pi / N_2)$

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = -1 computes forward FFT
IOPT = +1 computes inverse FFT

N1 (input)

Integer specifying length of the transform in the first dimension. N1 is most efficient when it is a product of small primes. N1 >= 0. Unchanged on exit.

N2 (input)

Integer specifying length of the transform in the second dimension. N2 is most efficient when it is a product of small primes. N2 >= 0. Unchanged on exit.

SCALE (input)

Real scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0 for F95 INTERFACE.

X (input) X is a complex array of dimensions (LDX, N2) that contains input data to be transformed.

LDX (input)

Leading dimension of X. LDX >= N1 Unchanged on exit.

Y (output)

Y is a complex array of dimensions (LDY, N2) that contains the transform results. X and Y can be the same array starting at the same memory location, in which case the input data are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY (input)

Leading dimension of Y. If X and Y are the same array, LDY = LDX Else LDY >= N1 Unchanged on exit.

TRIGS (input/output)

Real array of length $2 * (N_1 + N_2)$ that contains the trigonometric weights. The weights are computed

when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

IFAC (input/output)

Integer array of dimension at least 2*128 that contains the factors of N1 and N2. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

WORK (workspace)

Real array of dimension at least 2*MAX(N1,N2)*NCPUS where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)

Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)

On exit, integer IERR has one of the following values:

- 0 = normal return
- 1 = IOPT is not 0, 1 or -1
- 2 = N1 < 0
- 3 = N2 < 0
- 4 = (LDX < N1)
- 5 = (LDY < N1) or (LDY not equal LDX when X and Y are same array)
- 6 = (LWORK not equal 0) and (LWORK < 2*MAX(N1,N2)*NCPUS)
- 7 = memory allocation failed

SEE ALSO

fft

CAUTIONS

On exit, entire output array Y(1:LDY, 1:N2) is overwritten.

PURPOSE

cfftc3 initializes the trigonometric weight and factor tables or computes the three-dimensional Fast Fourier Transform (forward or inverse) of a three-dimensional complex array.

$$Y(k_1, k_2, k_3) = \text{scale} * \sum_{j_3=0}^{N_3-1} \sum_{j_2=0}^{N_2-1} \sum_{j_1=0}^{N_1-1} W_3 * W_2 * W_1 * X(j_1, j_2, j_3)$$

where

k_1 ranges from 0 to N_1-1 ; k_2 ranges from 0 to N_2-1 and k_3 ranges from 0 to N_3-1

$i = \sqrt{-1}$

$\text{isign} = 1$ for inverse transform or -1 for forward transform

$W_1 = \exp(\text{isign} * i * j_1 * k_1 * 2 * \pi / N_1)$

$W_2 = \exp(\text{isign} * i * j_2 * k_2 * 2 * \pi / N_2)$

$W_3 = \exp(\text{isign} * i * j_3 * k_3 * 2 * \pi / N_3)$

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:
 IOPT = 0 computes the trigonometric weight table and factor table
 IOPT = -1 computes forward FFT
 IOPT = +1 computes inverse FFT

N1 (input)

Integer specifying length of the transform in the first dimension. N1 is most efficient when it is a product of small primes. $N_1 \geq 0$. Unchanged on exit.

N2 (input)

Integer specifying length of the transform in the second dimension. N2 is most efficient when it is a product of small primes. $N_2 \geq 0$. Unchanged on exit.

N3 (input)

Integer specifying length of the transform in the third dimension. N3 is most efficient when it is a product of small primes. $N_3 \geq 0$. Unchanged on exit.

SCALE (input)

Real scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0 for F95 INTERFACE.

X (input) X is a complex array of dimensions (LDX1, LDX2, N3) that contains input data to be transformed.

LDX1 (input)

first dimension of X. $LDX_1 \geq N_1$ Unchanged on exit.

LDX2 (input)

second dimension of X. $LDX_2 \geq N_2$ Unchanged on exit.

Y (output)

Y is a complex array of dimensions (LDY1, LDY2, N3) that contains the transform results. X and Y can be the same array starting at the same memory location, in which case the input data are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY1 (input)

first dimension of Y. If X and Y are the same

array, LDY1 = LDX1 Else LDY1 >= N1 Unchanged on exit.

LDY2 (input)
second dimension of Y. If X and Y are the same array, LDY2 = LDX2 Else LDY2 >= N2 Unchanged on exit.

TRIGS (input/output)
Real array of length $2*(N1+N2+N3)$ that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

IFAC (input/output)
Integer array of dimension at least $3*128$ that contains the factors of N1, N2 and N3. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

WORK (workspace)
Real array of dimension at least $(2*MAX(N,N2,N3) + 32*N3) * NCPUS$ where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
On exit, integer IERR has one of the following values:
0 = normal return
-1 = IOPT is not 0, 1 or -1
-2 = N1 < 0
-3 = N2 < 0
-4 = N3 < 0
-5 = (LDX1 < N1)
-6 = (LDX2 < N2)
-7 = (LDY1 < N1) or (LDY1 not equal LDX1 when X and Y are same array)
-8 = (LDY2 < N2) or (LDY2 not equal LDX2 when X and Y are same array)
-9 = (LWORK not equal 0) and (LWORK < $(2*MAX(N,N2,N3) + 16*N3) * NCPUS$)
-10 = memory allocation failed

fft

CAUTIONS

This routine uses $Y(N1+1:LDY1, :, :)$ as scratch space. Therefore, the original contents of this subarray will be lost upon returning from routine while subarray $Y(1:N1, 1:N2, 1:N3)$ contains the transform results.

C INTERFACE

```
#include <sunperf.h>  
void cffftcm_ (int *iopt, int *n1, int *n2, float *scale,  
complex *x, int *ldx, complex *y, int *ldy, float  
*trigs, int *ifac, float *work, int *lwork, int  
*ierr);
```

```
void cffftcm_64_ (long *iopt, long *n1, long *n2, float  
*scale, complex *x, long *ldx, complex *y, long
```

```
*ldy, float *trigs, long *ifac, float *work, long
*lwork, long *ierr);
```

PURPOSE

cffctm initializes the trigonometric weight and factor tables or computes the one-dimensional Fast Fourier Transform (forward or inverse) of a set of data sequences stored in a two-dimensional complex array:

$$Y(k,l) = \sum_{j=0}^{N1-1} W * X(j,l)$$

where

k ranges from 0 to N1-1 and l ranges from 0 to N2-1
i = sqrt(-1)
isign = 1 for inverse transform or -1 for forward transform
W = exp(isign*i*j*k*2*pi/N1)

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = -1 computes forward FFT
IOPT = +1 computes inverse FFT

N1 (input)

Integer specifying length of the input sequences. N1 is most efficient when it is a product of small primes. N1 >= 0. Unchanged on exit.

N2 (input)

Integer specifying number of input sequences. N2 >= 0. Unchanged on exit.

SCALE (input)

Real scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0 for F95 INTERFACE.

X (input) X is a complex array of dimensions (LDX, N2) that contains the sequences to be transformed stored in its columns.

LDX (input)

Leading dimension of X. LDX >= N1 Unchanged on exit.

Y (output)

Y is a complex array of dimensions (LDY, N2) that contains the transform results of the input sequences. X and Y can be the same array starting at the same memory location, in which case the input sequences are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY (input)

Leading dimension of Y. If X and Y are the same array, LDY = LDX Else LDY >= N1 Unchanged on exit.

TRIGS (input/output)

Real array of length 2*N1 that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

IFAC (input/output)

Integer array of dimension at least 128 that contains the factors of N1. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

WORK (workspace)

Real array of dimension at least $2*N1*NCPUS$ where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)

Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)

On exit, integer IERR has one of the following values:

- 0 = normal return
- 1 = IOPT is not 0, 1 or -1
- 2 = $N1 < 0$
- 3 = $N2 < 0$
- 4 = $(LDX < N1)$
- 5 = $(LDY < N1)$ or (LDY not equal LDX when X and Y are same array)
- 6 = (LWORK not equal 0) and $(LWORK < 2*N1*NCPUS)$
- 7 = memory allocation failed

NAME

cfftf - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of CFFTF followed by a call of CFFTB will multiply the input sequence by N.

SYNOPSIS

```
SUBROUTINE CFFTF(N, X, WSAVE)
```

```
COMPLEX X(*)  
INTEGER N  
REAL WSAVE(*)
```

```
SUBROUTINE CFFTF_64(N, X, WSAVE)
```

```
COMPLEX X(*)  
INTEGER*8 N  
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE FFTF([N], X, WSAVE)
```

```
COMPLEX, DIMENSION(:) :: X  
INTEGER :: N  
REAL, DIMENSION(:) :: WSAVE
```

```
SUBROUTINE FFTF_64([N], X, WSAVE)
```

```
COMPLEX, DIMENSION(:) :: X  
INTEGER(8) :: N  
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cfftf(int n, complex *x, float *wsave);
```

```
void cfftf_64(long n, complex *x, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

X (input) On entry, an array of length N containing the sequence to be transformed.

WSAVE (input)
On entry, WSAVE must be an array of dimension $(4 * N + 15)$ or greater and must have been initialized by CFFTI.

Contents

 - [C INTERFACE](#)
- [ARGUMENTS](#)

NAME

`cffti` - initialize the array `WSAVE`, which is used in both `CFFTF` and `CFFTB`.

SYNOPSIS

```
SUBROUTINE CFFTI(N, WSAVE)
```

```
INTEGER N  
REAL WSAVE(*)
```

```
SUBROUTINE CFFTI_64(N, WSAVE)
```

```
INTEGER*8 N  
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE CFFTI(N, WSAVE)
```

```
INTEGER :: N  
REAL, DIMENSION(:) :: WSAVE
```

```
SUBROUTINE CFFTI_64(N, WSAVE)
```

```
INTEGER(8) :: N  
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cffti(int n, float *wsave);
```

```
void cffti_64(long n, float *wsave);
```

ARGUMENTS

`N` (input) Length of the sequence to be transformed. `N` \geq 0.

`WSAVE` (input/output)

On entry, an array of dimension $(4 * N + 15)$ or greater. `CFFTI` needs to be called only once to initialize array `WORK` before calling `CFFTF` and/or `CFFTB` if `N` and `WSAVE` remain unchanged between

these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

`cfftopt` - compute the length of the closest fast FFT

SYNOPSIS

```
INTEGER FUNCTION CFFTOPT(LEN)
```

```
INTEGER LEN
```

```
INTEGER*8 FUNCTION CFFTOPT_64(LEN)
```

```
INTEGER*8 LEN
```

F95 INTERFACE

```
INTEGER FUNCTION CFFTOPT(LEN)
```

```
INTEGER :: LEN
```

```
INTEGER(8) FUNCTION CFFTOPT_64(LEN)
```

```
INTEGER(8) :: LEN
```

C INTERFACE

```
#include <sunperf.h>
```

```
int cfftopt(int len);
```

```
long cfftopt_64(long len);
```

PURPOSE

`cfftopt` computes the length of the closest fast FFT. Fast Fourier transform algorithms, including those used in Performance Library, work best with vector lengths that are products of small primes. For example, an FFT of length $32=2*5$ will run faster than an FFT of prime length 31 because 32 is a product of small primes and 31 is not. If your application is such that you can taper or zero pad your vector to a larger length then this function may help you select a better length and run your FFT faster.

`CFFTOPT` will return an integer no smaller than the input argument `N` that is the closest number that is the product of

small primes. CFFTOPT will return 16 for an input of $N=16$ and return $18=2*3*3$ for an input of $N=17$.

Note that the length computed here is not guaranteed to be optimal, only to be a product of small primes. Also, the value returned may change as the underlying FFTs become capable of handling larger primes. For example, passing in $N=51$ today will return $52=2*2*13$ rather than $51=3*17$ because the FFTs in Performance Library do not have fast radix 17 code. In the future, radix 17 code may be added and then $N=51$ will return 51.

```

F95 INTERFACE

```
SUBROUTINE FFT(IOPT, N, [SCALE], X, Y, TRIGS, IFAC, WORK, [LWORK], IERR)
```

```
INTEGER*4, INTENT(IN) :: IOPT, N  
INTEGER*4, INTENT(IN), OPTIONAL :: LWORK  
REAL, INTENT(IN), OPTIONAL :: SCALE  
COMPLEX, INTENT(IN), DIMENSION(:) :: X  
REAL, INTENT(OUT), DIMENSION(:) :: Y  
REAL, INTENT(INOUT), DIMENSION(:) :: TRIGS  
INTEGER*4, INTENT(INOUT), DIMENSION(:) :: IFAC  
REAL, INTENT(OUT), DIMENSION(:) :: WORK  
INTEGER*4, INTENT(OUT) :: IERR
```

```
SUBROUTINE FFT_64(IOPT, N, [SCALE], X, Y, TRIGS, IFAC, WORK, [LWORK], IERR)
```

```
INTEGER(8), INTENT(IN) :: IOPT, N  
INTEGER(8), INTENT(IN), OPTIONAL :: LWORK  
REAL, INTENT(IN), OPTIONAL :: SCALE  
COMPLEX, INTENT(IN), DIMENSION(:) :: X  
REAL, INTENT(OUT), DIMENSION(:) :: Y  
REAL, INTENT(INOUT), DIMENSION(:) :: TRIGS  
INTEGER(8), INTENT(INOUT), DIMENSION(:) :: IFAC  
REAL, INTENT(OUT), DIMENSION(:) :: WORK  
INTEGER(8), INTENT(OUT) :: IERR
```

C INTERFACE

```
#include <sunperf.h>

void cffts_ (int *iopt, int *n, float *scale, complex *x,
            float *y, float *trigs, int *ifac, float *work,
            int *lwork, int *ierr);

void cffts_64_ (long *iopt, long *n, float *scale, complex
               *x, float *y, float *trigs, long *ifac, float
               *work, long *lwork, long *ierr);
```

PURPOSE

cffts initializes the trigonometric weight and factor tables or computes the inverse Fast Fourier Transform of a complex sequence as follows:

$$Y(k) = \text{scale} * \sum_{j=0}^{N-1} W^j X(j)$$

where

k ranges from 0 to N-1

i = sqrt(-1)

isign = 1 for inverse transform or -1 for forward transform

$W = \exp(isign * i * j * k * 2 * \pi / N)$

In complex-to-real transform of length N, the (N/2+1) complex input data points stored are the positive-frequency half of the spectrum of the Discrete Fourier Transform. The other half can be obtained through complex conjugation and therefore is not stored. Furthermore, due to symmetries the imaginary of the component of X(0) and X(N/2) (if N is even in the latter) is assumed to be zero and is not referenced.

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = 1 computes inverse FFT

N (input)

Integer specifying length of the input sequence X. N is most efficient when it is a product of small primes. N >= 0. Unchanged on exit.

SCALE (input)

Real scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0 for F95 INTERFACE.

X (input) On entry, X is a complex array whose first (N/2+1) elements are the input sequence to be transformed.

Y (output)

Real array of dimension at least N that contains the transform results. X and Y may be the same array starting at the same memory location. Otherwise, it is assumed that there is no overlap

between X and Y in memory.

TRIGS (input/output)

Real array of length $2*N$ that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

IFAC (input/output)

Integer array of dimension at least 128 that contains the factors of N. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls where IOPT = 1. Unchanged on exit.

WORK (workspace)

Real array of dimension at least N. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)

Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)

On exit, integer IERR has one of the following values:

- 0 = normal return
- 1 = IOPT is not 0 or 1
- 2 = $N < 0$
- 3 = (LWORK is not 0) and (LWORK is less than N)
- 4 = memory allocation for workspace failed

```
#include <sunperf.h>  
void cffts2_(int *iopt, int *n1, int *n2, float *scale,  
            complex *x, int *ldx, float *y, int *ldy, float  
            *trigs, int *ifac, float *work, int *lwork, int  
            *ierr);
```

```

void cffts2_64_ (long *iopt, long *n1, long *n2, float
    *scale, complex *x, long *ldx, float *y, long
    *ldy, float *trigs, long *ifac, float *work, long
    *lwork, long *ierr);

```

PURPOSE

cffts2 initializes the trigonometric weight and factor tables or computes the two-dimensional inverse Fast Fourier Transform of a two-dimensional complex array. In computing the two-dimensional FFT, one-dimensional FFTs are computed along the rows of the input array. One-dimensional FFTs are then computed along the columns of the intermediate results.

$$Y(k_1, k_2) = \text{scale} * \sum_{j_1=0}^{N_1-1} \sum_{j_2=0}^{N_2-1} W_2 * W_1 * X(j_1, j_2)$$

where

k_1 ranges from 0 to N_1-1 and k_2 ranges from 0 to N_2-1

$i = \sqrt{-1}$

isign = 1 for inverse transform

$W_1 = \exp(\text{isign} * i * j_1 * k_1 * 2 * \pi / N_1)$

$W_2 = \exp(\text{isign} * i * j_2 * k_2 * 2 * \pi / N_2)$

In complex-to-real transform of length N_1 , the $(N_1/2+1)$ complex input data points stored are the positive-frequency half of the spectrum of the Discrete Fourier Transform. The other half can be obtained through complex conjugation and therefore is not stored.

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:
 IOPT = 0 computes the trigonometric weight table and factor table
 IOPT = 1 computes inverse FFT

N1 (input)

Integer specifying length of the transform in the first dimension. N1 is most efficient when it is a product of small primes. $N_1 \geq 0$. Unchanged on exit.

N2 (input)

Integer specifying length of the transform in the second dimension. N2 is most efficient when it is a product of small primes. $N_2 \geq 0$. Unchanged on exit.

SCALE (input)

Real scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0 for F95 INTERFACE.

X (input) X is a complex array of dimensions (LDX, N2) that contains input data to be transformed.

LDX (input)

Leading dimension of X. $LDX \geq (N_1/2 + 1)$ Unchanged on exit.

Y (output)

Y is a real array of dimensions (LDY, N2) that contains the transform results. X and Y can be the same array starting at the same memory location, in which case the input data are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY (input)
 Leading dimension of Y. If X and Y are the same array, LDY = 2*LDX Else LDY >= 2*LDX and LDY must be even. Unchanged on exit.

TRIGS (input/output)
 Real array of length 2*(N1+N2) that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

IFAC (input/output)
 Integer array of dimension at least 2*128 that contains the factors of N1 and N2. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

WORK (workspace)
 Real array of dimension at least MAX(N1,2*N2)*NCPUS, where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
 Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
 On exit, integer IERR has one of the following values:
 0 = normal return
 -1 = IOPT is not 0, 1
 -2 = N1 < 0
 -3 = N2 < 0
 -4 = (LDX < N1/2+1)
 -5 = LDY not equal 2*LDX when X and Y are same array
 -6 = (LDY < 2*LDX or LDY odd) when X and Y are same array
 -7 = (LWORK not equal 0) and (LWORK < MAX(N1,2*N2)*NCPUS)
 -8 = memory allocation failed

SEE ALSO

fft

CAUTIONS

Y(N1+1:LDY,:) is used as scratch space. Upon returning, the original contents of Y(N1+1:LDY,:) will be lost, whereas Y(1:N1,1:N2) contains the transform results.

float *work, int *lwork, int *ierr);
```

```
void cffts3_64_ (long *iopt, long *n1, long *n2, long *n3,  
float *scale, complex *x, long *ldx1, long *ldx2,  
float *y, long *ldy1, long *ldy2, float *trigs,
```

```
long *ifac, float *work, long *lwork, long *ierr);
```

PURPOSE

cffts3 initializes the trigonometric weight and factor tables or computes the three-dimensional inverse Fast Fourier Transform of a three-dimensional complex array.

$$Y(k_1, k_2, k_3) = \text{scale} * \sum_{j_3=0}^{N_3-1} \sum_{j_2=0}^{N_2-1} \sum_{j_1=0}^{N_1-1} W_3 * W_2 * W_1 * X(j_1, j_2, j_3)$$

where

k_1 ranges from 0 to N_1-1 ; k_2 ranges from 0 to N_2-1 and k_3 ranges from 0 to N_3-1

$i = \sqrt{-1}$

isign = 1 for inverse transform

$W_1 = \exp(\text{isign} * i * j_1 * k_1 * 2 * \pi / N_1)$

$W_2 = \exp(\text{isign} * i * j_2 * k_2 * 2 * \pi / N_2)$

$W_3 = \exp(\text{isign} * i * j_3 * k_3 * 2 * \pi / N_3)$

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = +1 computes inverse FFT

N1 (input)

Integer specifying length of the transform in the first dimension. N1 is most efficient when it is a product of small primes. $N_1 \geq 0$. Unchanged on exit.

N2 (input)

Integer specifying length of the transform in the second dimension. N2 is most efficient when it is a product of small primes. $N_2 \geq 0$. Unchanged on exit.

N3 (input)

Integer specifying length of the transform in the third dimension. N3 is most efficient when it is a product of small primes. $N_3 \geq 0$. Unchanged on exit.

SCALE (input)

Real scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0 for F95 INTERFACE.

X (input) X is a complex array of dimensions (LDX1, LDX2, N3) that contains input data to be transformed.

LDX1 (input)

first dimension of X. $LDX_1 \geq N_1/2+1$ Unchanged on exit.

LDX2 (input)

second dimension of X. $LDX_2 \geq N_2$ Unchanged on exit.

Y (output)

Y is a complex array of dimensions (LDY1, LDY2, N3) that contains the transform results. X and Y can be the same array starting at the same memory location, in which case the input data are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY1 (input)

first dimension of Y. If X and Y are the same array, $LDY_1 = 2 * LDX_1$ Else $LDY_1 \geq 2 * LDX_1$ and LDY1 is even Unchanged on exit.

LDY2 (input)

second dimension of Y. If X and Y are the same

array, LDY2 = LDX2 Else LDY2 >= N2 Unchanged on exit.

TRIGS (input/output)
 Real array of length $2*(N1+N2+N3)$ that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

IFAC (input/output)
 Integer array of dimension at least $3*128$ that contains the factors of N1, N2 and N3. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

WORK (workspace)
 Real array of dimension at least $(MAX(N,2*N2,2*N3) + 16*N3) * NCPUS$ where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
 Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
 On exit, integer IERR has one of the following values:
 0 = normal return
 -1 = IOPT is not 0 or 1
 -2 = N1 < 0
 -3 = N2 < 0
 -4 = N3 < 0
 -5 = (LDX1 < N1/2+1)
 -6 = (LDX2 < N2)
 -7 = LDY1 not equal $2*LDX1$ when X and Y are same array
 -8 = (LDY1 < $2*LDX1$) or (LDY1 is odd) when X and Y are not same array
 -9 = (LDY2 < N2) or (LDY2 not equal LDX2) when X and Y are same array
 -10 = (LWORK not equal 0) and $((LWORK < MAX(N,2*N2,2*N3) + 16*N3)*NCPUS)$
 -11 = memory allocation failed

SEE ALSO

fft

CAUTIONS

This routine uses $Y(N1+1:LDY1, :, :)$ as scratch space. Therefore, the original contents of this subarray will be lost upon returning from routine while subarray $Y(1:N1, 1:N2, 1:N3)$ contains the transform results.

```

*scale, complex *x, long *ldx, float *y, long
*ldy, float *trigs, long *ifac, float *work, long
*lwork, long *ierr);

```

PURPOSE

cfftsm initializes the trigonometric weight and factor tables or computes the one-dimensional inverse Fast Fourier Transform of a set of complex data sequences stored in a two-dimensional array:

$$Y(k,l) = \text{scale} * \sum_{j=0}^{N1-1} W * X(j,l)$$

where

k ranges from 0 to N1-1 and l ranges from 0 to N2-1

i = sqrt(-1)

isign = 1 for inverse transform

W = exp(isign*i*j*k*2*pi/N1)

In complex-to-real transform of length N1, the (N1/2+1) complex input data points stored are the positive-frequency half of the spectrum of the Discrete Fourier Transform. The other half can be obtained through complex conjugation and therefore is not stored. Furthermore, due to symmetries the imaginary of the component of X(0,0:N2-1) and X(N1/2,0:N2-1) (if N1 is even in the latter) is assumed to be zero and is not referenced.

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:
 IOPT = 0 computes the trigonometric weight table and factor table
 IOPT = 1 computes inverse FFT

N1 (input)

Integer specifying length of the input sequences. N1 is most efficient when it is a product of small primes. N1 >= 0. Unchanged on exit.

N2 (input)

Integer specifying number of input sequences. N2 >= 0. Unchanged on exit.

SCALE (input)

Real scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0 for F95 INTERFACE.

X (input) X is a complex array of dimensions (LDX, N2) that contains the sequences to be transformed stored in its columns in X(0:N1/2, 0:N2-1).

LDX (input)

Leading dimension of X. LDX >= (N1/2+1) Unchanged on exit.

Y (output)

Y is a real array of dimensions (LDY, N2) that contains the transform results of the input sequences in Y(0:N1-1,0:N2-1). X and Y can be the same array starting at the same memory location, in which case the input sequences are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY (input)

Leading dimension of Y. If X and Y are the same array, LDY = 2*LDX Else LDY >= N1 Unchanged on

exit.

TRIGS (input/output)

Real array of length $2*N1$ that contains the trigonometric weights. The weights are computed when the routine is called with $IOPT = 0$ and they are used in subsequent calls when $IOPT = 1$. Unchanged on exit.

IFAC (input/output)

Integer array of dimension at least 128 that contains the factors of $N1$. The factors are computed when the routine is called with $IOPT = 0$ and they are used in subsequent calls when $IOPT = 1$. Unchanged on exit.

WORK (workspace)

Real array of dimension at least $N1$. The user can also choose to have the routine allocate its own workspace (see `LWORK`).

LWORK (input)

Integer specifying workspace size. If $LWORK = 0$, the routine will allocate its own workspace.

IERR (output)

On exit, integer IERR has one of the following values:

- 0 = normal return
- 1 = IOPT is not 0 or 1
- 2 = $N1 < 0$
- 3 = $N2 < 0$
- 4 = ($LDX < N1/2+1$)
- 5 = ($LDY < N1$) or (LDY not equal $2*LDX$ when X and Y are same array)
- 6 = ($LWORK$ not equal 0) and ($LWORK < N1$)
- 7 = memory allocation failed

              complex *c, long ldc, long *info);

```

PURPOSE

cgbbrd reduces a complex general m-by-n band matrix A to real upper bidiagonal form B by a unitary transformation: $Q' * A * P = B$.

The routine computes B, and optionally forms Q or P', or computes $Q'*C$ for a given matrix C.

ARGUMENTS

VECT (input)

Specifies whether or not the matrices Q and P' are to be formed. = 'N': do not form Q or P'; = 'Q': form Q only; = 'P': form P' only; = 'B': form both.

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

NCC (input)

The number of columns of the matrix C. $NCC \geq 0$.

KL (input)

The number of subdiagonals of the matrix A. $KL \geq 0$.

KU (input)

The number of superdiagonals of the matrix A. $KU \geq 0$.

AB (input/output)

On entry, the m-by-n band matrix A, stored in rows 1 to $KL+KU+1$. The j-th column of A is stored in the j-th column of the array AB as follows: $AB(ku+1+i-j, j) = A(i, j)$ for $\max(1, j-ku) \leq i \leq \min(m, j+kl)$. On exit, A is overwritten by values generated during the reduction.

LDAB (input)

The leading dimension of the array A. $LDAB \geq KL+KU+1$.

D (output)

The diagonal elements of the bidiagonal matrix B.

E (output)

The superdiagonal elements of the bidiagonal matrix B.

Q (output)
If VECT = 'Q' or 'B', the m-by-m unitary matrix Q.
If VECT = 'N' or 'P', the array Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= max(1,M) if VECT = 'Q' or 'B'; LDQ >= 1 otherwise.

PT (output)
If VECT = 'P' or 'B', the n-by-n unitary matrix P'. If VECT = 'N' or 'Q', the array PT is not referenced.

LDPT (input)
The leading dimension of the array PT. LDPT >= max(1,N) if VECT = 'P' or 'B'; LDPT >= 1 otherwise.

C (input/output)
On entry, an m-by-ncc matrix C. On exit, C is overwritten by Q*C. C is not referenced if NCC = 0.

LDC (input)
The leading dimension of the array C. LDC >= max(1,M) if NCC > 0; LDC >= 1 if NCC = 0.

WORK (workspace)
dimension(MAX(M,N))

RWORK (workspace)
dimension(MAX(M,N))

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: WORK2
C INTERFACE
#include <sunperf.h>

void cgbcon(char norm, int n, int nsub, int nsuper, complex
            *a, int lda, int *ipivot, float anorm, float
            *rcond, int *info);

void cgbcon_64(char norm, long n, long nsub, long nsuper,
               complex *a, long lda, long *ipivot, float anorm,
               float *rcond, long *info);

```

PURPOSE

cgbcon estimates the reciprocal of the condition number of a complex general band matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by CGBTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A)))$$

ARGUMENTS

NORM (input)
 Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
 = '1' or 'O': 1-norm;
 = 'I': Infinity-norm.

N (input) The order of the matrix A. $N \geq 0$.

NSUB (input)
 The number of subdiagonals within the band of A.
 $\text{NSUB} \geq 0$.

NSUPER (input)
 The number of superdiagonals within the band of A.
 $\text{NSUPER} \geq 0$.

A (input) Details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with $\text{NSUB} + \text{NSUPER}$ superdiagonals in rows 1 to $\text{NSUB} + \text{NSUPER} + 1$, and the multipliers used during the factorization are stored in rows $\text{NSUB} + \text{NSUPER} + 2$ to $2 * \text{NSUB} + \text{NSUPER} + 1$.

LDA (input)
 The leading dimension of the array A. $\text{LDA} \geq 2 * \text{NSUB} + \text{NSUPER} + 1$.

IPIVOT (input)
 The pivot indices; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

ANORM (input)

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND (output)

The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

WORK (workspace)

dimension(2*N)

WORK2 (workspace)

dimension (N)

```

```

        int  lda,   float *rowsc, float *colsc, float
        *rowcnd, float *colcnd, float *amax, int *info);
void cgbequ_64(long m, long n, long nsub, long nsuper, com-
        plex *a, long lda, float *rowsc, float *colsc,
        float *rowcnd, float *colcnd, float *amax, long
        *info);

```

PURPOSE

cgbequ computes row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements $B(i,j)=R(i)*A(i,j)*C(j)$ have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

NSUB (input)

The number of subdiagonals within the band of A.
NSUB ≥ 0 .

NSUPER (input)

The number of superdiagonals within the band of A.
NSUPER ≥ 0 .

A (input) The band matrix A, stored in rows 1 to NSUB+NSUPER+1. The j-th column of A is stored in the j-th column of the array A as follows:
 $A(ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(m,j+kl)$.

LDA (input)

The leading dimension of the array A. LDA \geq NSUB+NSUPER+1.

ROWSC (output)

If INFO = 0, or INFO > M, ROWSC contains the row scale factors for A.

COLSC (output)

If INFO = 0, COLSC contains the column scale factors for A.

ROWCND (output)

If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest ROWSC(i) to the largest ROWSC(i). If ROWCND ≥ 0.1 and AMAX is neither too large nor too small, it is not worth scaling by ROWSC.

COLCND (output)

If INFO = 0, COLCND contains the ratio of the smallest COLSC(i) to the largest COLSC(i). If COLCND >= 0.1, it is not worth scaling by COLSC.

AMAX (output)

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

cgbmw - perform one of the matrix-vector operations $y := \alpha A^T x + \beta y$, or $y := \alpha A^H x + \beta y$, or $y := \alpha \text{conjg}(A^T)x + \beta y$

SYNOPSIS

```
SUBROUTINE CGBMV(TRANSA, M, N, NSUB, NSUPER, ALPHA, A, LDA, X, INCX,
                 BETA, Y, INCY)
```

```
CHARACTER * 1 TRANSA
COMPLEX ALPHA, BETA
COMPLEX A(LDA,*), X(*), Y(*)
INTEGER M, N, NSUB, NSUPER, LDA, INCX, INCY
```

```
SUBROUTINE CGBMV_64(TRANSA, M, N, NSUB, NSUPER, ALPHA, A, LDA, X,
                   INCX, BETA, Y, INCY)
```

```
CHARACTER * 1 TRANSA
COMPLEX ALPHA, BETA
COMPLEX A(LDA,*), X(*), Y(*)
INTEGER*8 M, N, NSUB, NSUPER, LDA, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE GBMV([TRANSA], [M], [N], NSUB, NSUPER, ALPHA, A, [LDA], X,
                [INCX], BETA, Y, [INCY])
```

```
CHARACTER(LEN=1) :: TRANSA
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:) :: X, Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: M, N, NSUB, NSUPER, LDA, INCX, INCY
```

```
SUBROUTINE GBMV_64([TRANSA], [M], [N], NSUB, NSUPER, ALPHA, A, [LDA],
                  X, [INCX], BETA, Y, [INCY])
```

```
CHARACTER(LEN=1) :: TRANSA
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:) :: X, Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: M, N, NSUB, NSUPER, LDA, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```

void cgbmv(char transa, int m, int n, int nsub, int nsuper,
           complex *alpha, complex *a, int lda, complex *x,
           int incx, complex *beta, complex *y, int incy);
void cgbmv_64(char transa, long m, long n, long nsub, long
              nsuper, complex *alpha, complex *a, long lda, com-
              plex *x, long incx, complex *beta, complex *y,
              long incy);

```

PURPOSE

cgbmv performs one of the matrix-vector operations $y := \alpha A x + \beta y$, or $y := \alpha A' x + \beta y$, or $y := \alpha \text{conjg}(A') x + \beta y$ where α and β are scalars, x and y are vectors and A is an m by n band matrix, with $nsub$ sub-diagonals and $nsuper$ super-diagonals.

ARGUMENTS

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $y := \alpha A x + \beta y$.

TRANSA = 'T' or 't' $y := \alpha A' x + \beta y$.

TRANSA = 'C' or 'c' $y := \alpha \text{conjg}(A') x + \beta y$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input)

On entry, M specifies the number of rows of the matrix A. M must be at least zero. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix A. N must be at least zero. Unchanged on exit.

NSUB (input)

On entry, NSUB specifies the number of sub-diagonals of the matrix A. NSUB must satisfy $0 \leq NSUB$. Unchanged on exit.

NSUPER (input)

On entry, NSUPER specifies the number of super-diagonals of the matrix A. NSUPER must satisfy $0 \leq NSUPER$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

A (input)

Before entry, the leading $(nsub + nsuper + 1)$ by n part of the array A must contain the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row $(nsuper + 1)$ of the array, the first super-diagonal starting at position 2 in row $nsuper$, the first sub-

diagonal starting at position 1 in row (nsuper + 2), and so on. Elements in the array A that do not correspond to elements in the band matrix (such as the top left nsuper by nsuper triangle) are not referenced. The following program segment will transfer a band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        K = NSUPER + 1 - J
        DO 10, I = MAX( 1, J - NSUPER ), MIN( M, J +
NSUB )
          A( K + I, J ) = matrix( I, J )
10      CONTINUE
20     CONTINUE
```

Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (nsub + nsuper + 1). Unchanged on exit.

X (input)

(1 + (n - 1) * abs(INCX)) when TRANSA = 'N' or 'n' and at least (1 + (m - 1) * abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)

(1 + (m - 1) * abs(INCY)) when TRANSA = 'N' or 'n' and at least (1 + (n - 1) * abs(INCY)) otherwise. Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

```

PURPOSE

cgbrfs improves the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

TRANSA (input)
 Specifies the form of the system of equations:
 = 'N': $A * X = B$ (No transpose)
 = 'T': $A^{**T} * X = B$ (Transpose)
 = 'C': $A^{**H} * X = B$ (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

NSUB (input)
 The number of subdiagonals within the band of A.
 $NSUB \geq 0$.

NSUPER (input)
 The number of superdiagonals within the band of A.
 $NSUPER \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The original band matrix A, stored in rows 1 to $NSUB+NSUPER+1$. The j-th column of A is stored in the j-th column of the array A as follows:
 $A(ku+1+i-j, j) = A(i, j)$ for $\max(1, j-ku) \leq i \leq \min(n, j+kl)$.

LDA (input)
 The leading dimension of the array A. $LDA \geq NSUB+NSUPER+1$.

AF (input)
Details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with NSUB+NSUPER superdiagonals in rows 1 to NSUB+NSUPER+1, and the multipliers used during the factorization are stored in rows NSUB+NSUPER+2 to 2*NSUB+NSUPER+1.

LDAF (input)
The leading dimension of the array AF. LDAF >= 2*NSUB*NSUPER+1.

IPIVOT (input)
The pivot indices from CGBTRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIVOT(i).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by CGBTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgbsv(int n, int nsub, int nsuper, int nrhs, complex
*a, int lda, int *ipivot, complex *b, int ldb, int
*info);
```

```
void cgbsv_64(long n, long nsub, long nsuper, long nrhs,
             complex *a, long lda, long *ipivot, complex *b,
             long ldb, long *info);
```

PURPOSE

cgbsv computes the solution to a complex system of linear equations $A * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as $A = L * U$, where L is a product of permutation and unit lower triangular matrices with KL subdiagonals, and U is upper triangular with KL+KU superdiagonals. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NSUB (input)
The number of subdiagonals within the band of A. $NSUB \geq 0$.

NSUPER (input)
The number of superdiagonals within the band of A. $NSUPER \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input/output)
On entry, the matrix A in band storage, in rows NSUB+1 to $2*NSUB+NSUPER+1$; rows 1 to NSUB of the array need not be set. The j-th column of A is stored in the j-th column of the array A as follows: $A(NSUB+NSUPER+1+i-j, j) = A(i, j)$ for $\max(1, j-NSUPER) \leq i \leq \min(N, j+NSUB)$ On exit, details of the factorization: U is stored as an upper triangular band matrix with NSUB+NSUPER superdiagonals in rows 1 to NSUB+NSUPER+1, and the multipliers used during the factorization are stored in rows NSUB+NSUPER+2 to $2*NSUB+NSUPER+1$. See below for further details.

LDA (input)
The leading dimension of the array A. $LDA \geq 2*NSUB+NSUPER+1$.

IPIVOT (output)
The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIVOT(i).

B (input/output)

On entry, the N-by-NRHS right hand side matrix B.
 On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and the solution has not been computed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when M = N = 6, NSUB = 2, NSUPER = 1:

On entry:

On exit:

	*	*	*	+	+	+		*	*	*	u14	u25	
u36	*	*	+	+	+	+		*	*		u13	u24	u35
u46	*	a12	a23	a34	a45	a56		*	u12	u23	u34	u45	
u56	a11	a22	a33	a44	a55	a66		u11	u22	u33	u44	u55	
u66	a21	a32	a43	a54	a65	*		m21	m32	m43	m54	m65	
*	a31	a42	a53	a64	*	*		m31	m42	m53	m64	*	
*													

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U because of fill-in resulting from the row interchanges.

    float *rowsc, float *colsc, complex *b, long ldb,  
    complex *x, long ldx, float *rcond, float *ferr,  
    float *berr, long *info);
```

PURPOSE

cgbsvx uses the LU factorization to compute the solution to a complex system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed by this subroutine:

1. If FACT = 'E', real scaling factors are computed to equilibrate the system:

```
TRANS = 'N': diag(R)*A*diag(C) *inv(diag(C))*X =  
diag(R)*B  
TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X =  
diag(C)*B  
TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X =  
diag(C)*B
```

Whether or not the system will be equilibrated depends on the

scaling of the matrix A, but if equilibration is used, A is

overwritten by $\text{diag}(R)*A*\text{diag}(C)$ and B by $\text{diag}(R)*B$ (if TRANS='N')

or $\text{diag}(C)*B$ (if TRANS = 'T' or 'C').

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the

matrix A (after equilibration if FACT = 'E') as

$A = L * U$,

where L is a product of permutation and unit lower triangular matrices with KL subdiagonals, and U is upper triangular with KL+KU superdiagonals.

3. If some $U(i,i)=0$, so that U is exactly singular, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
4. The system of equations is solved for X using the factored form of A.
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so that it solves the original system before equilibration.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIVOT contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by ROWSC and COLSC. A, AF, and IPIVOT are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

TRANSA (input)

Specifies the form of the system of equations. = 'N': $A * X = B$ (No transpose)
= 'T': $A^{**T} * X = B$ (Transpose)
= 'COLSC': $A^{**H} * X = B$ (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NSUB (input)

The number of subdiagonals within the band of A.

NSUB >= 0.

NSUPER (input)

The number of superdiagonals within the band of A.
NSUPER >= 0.

NRHS (input)

The number of right hand sides, i.e., the number
of columns of the matrices B and X. NRHS >= 0.

A (input/output)

On entry, the matrix A in band storage, in rows 1
to NSUB+NSUPER+1. The j-th column of A is stored
in the j-th column of the array A as follows:
A(NSUPER+1+i-j,j) = A(i,j) for max(1,j-
NSUPER)<=i<=min(N,j+kl)

If FACT = 'F' and EQUED is not 'N', then A must
have been equilibrated by the scaling factors in
ROWSC and/or COLSC. A is not modified if FACT =
'F' or 'N', or if FACT = 'E' and EQUED = 'N' on
exit.

On exit, if EQUED .ne. 'N', A is scaled as fol-
lows: EQUED = 'ROWSC': A := diag(ROWSC) * A
EQUED = 'COLSC': A := A * diag(COLSC)
EQUED = 'B': A := diag(ROWSC) * A * diag(COLSC).

LDA (input)

The leading dimension of the array A. LDA >=
NSUB+NSUPER+1.

AF (input/output)

If FACT = 'F', then AF is an input argument and on
entry contains details of the LU factorization of
the band matrix A, as computed by CGBTRF. U is
stored as an upper triangular band matrix with
NSUB+NSUPER superdiagonals in rows 1 to
NSUB+NSUPER+1, and the multipliers used during the
factorization are stored in rows NSUB+NSUPER+2 to
2*NSUB+NSUPER+1. If EQUED .ne. 'N', then AF is
the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and
on exit returns details of the LU factorization of
A.

If FACT = 'E', then AF is an output argument and
on exit returns details of the LU factorization of
the equilibrated matrix A (see the description of
A for the form of the equilibrated matrix).

LDAF (input)

The leading dimension of the array AF. LDAF >=
2*NSUB+NSUPER+1.

IPIVOT (input)

If FACT = 'F', then IPIVOT is an input argument
and on entry contains the pivot indices from the
factorization A = L*U as computed by CGBTRF; row i
of the matrix was interchanged with row IPIVOT(i).

If FACT = 'N', then IPIVOT is an output argument
and on exit contains the pivot indices from the
factorization A = L*U of the original matrix A.

If FACT = 'E', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = L*U$ of the equilibrated matrix A.

EQUED (input)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'ROWSC': Row equilibration, i.e., A has been premultiplied by diag(ROWSC). = 'COLSC': Column equilibration, i.e., A has been postmultiplied by diag(COLSC). = 'B': Both row and column equilibration, i.e., A has been replaced by $\text{diag}(\text{ROWSC}) * A * \text{diag}(\text{COLSC})$. EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

ROWSC (input/output)

The row scale factors for A. If EQUED = 'ROWSC' or 'B', A is multiplied on the left by diag(ROWSC); if EQUED = 'N' or 'COLSC', ROWSC is not accessed. ROWSC is an input argument if FACT = 'F'; otherwise, ROWSC is an output argument. If FACT = 'F' and EQUED = 'ROWSC' or 'B', each element of ROWSC must be positive.

COLSC (input/output)

The column scale factors for A. If EQUED = 'COLSC' or 'B', A is multiplied on the right by diag(COLSC); if EQUED = 'N' or 'ROWSC', COLSC is not accessed. COLSC is an input argument if FACT = 'F'; otherwise, COLSC is an output argument. If FACT = 'F' and EQUED = 'COLSC' or 'B', each element of COLSC must be positive.

B (input/output)

On entry, the right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANSA = 'N' and EQUED = 'ROWSC' or 'B', B is overwritten by $\text{diag}(\text{ROWSC}) * B$; if TRANSA = 'T' or 'COLSC' and EQUED = 'COLSC' or 'B', B is overwritten by $\text{diag}(\text{COLSC}) * B$.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,N).

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED \neq 'N', and the solution to the equilibrated system is $\text{inv}(\text{diag}(\text{COLSC})) * X$ if TRANSA = 'N' and EQUED = 'COLSC' or 'B', or $\text{inv}(\text{diag}(\text{ROWSC})) * X$ if TRANSA = 'T' or 'COLSC' and EQUED = 'ROWSC' or 'B'.

LDX (input)

The leading dimension of the array X. LDX \geq max(1,N).

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If

RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

dimension(2*N)

WORK2 (workspace)

dimension(N) On exit, WORK2(1) contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If WORK2(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with 0 < INFO <= N, then WORK2(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned.
= N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

NAME

cgbtbf2 - compute an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges

SYNOPSIS

```
SUBROUTINE CGBTf2(M, N, KL, KU, AB, LDAB, IPIV, INFO)
```

```
COMPLEX AB(LDAB,*)  
INTEGER M, N, KL, KU, LDAB, INFO  
INTEGER IPIV(*)
```

```
SUBROUTINE CGBTf2_64(M, N, KL, KU, AB, LDAB, IPIV, INFO)
```

```
COMPLEX AB(LDAB,*)  
INTEGER*8 M, N, KL, KU, LDAB, INFO  
INTEGER*8 IPIV(*)
```

F95 INTERFACE

```
SUBROUTINE GBTf2([M], [N], KL, KU, AB, [LDAB], IPIV, [INFO])
```

```
COMPLEX, DIMENSION(:, :) :: AB  
INTEGER :: M, N, KL, KU, LDAB, INFO  
INTEGER, DIMENSION(:) :: IPIV
```

```
SUBROUTINE GBTf2_64([M], [N], KL, KU, AB, [LDAB], IPIV, [INFO])
```

```
COMPLEX, DIMENSION(:, :) :: AB  
INTEGER(8) :: M, N, KL, KU, LDAB, INFO  
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgbtf2(int m, int n, int kl, int ku, complex *ab, int  
          ldab, int *ipiv, int *info);
```

```
void cgbtf2_64(long m, long n, long kl, long ku, complex  
             *ab, long ldab, long *ipiv, long *info);
```

PURPOSE

cgbtbf2 computes an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

KL (input)
The number of subdiagonals within the band of A.
 $KL \geq 0$.

KU (input)
The number of superdiagonals within the band of A.
 $KU \geq 0$.

AB (input/output)
On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows:
$$AB(kl+ku+1+i-j,j) = A(i,j) \quad \text{for } \max(1,j-ku) \leq i \leq \min(m,j+kl)$$

On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB (input)
The leading dimension of the array AB. $LDAB \geq 2*KL+KU+1$.

IPIV (output)
The pivot indices; for $1 \leq i \leq \min(M,N)$, row i of the matrix was interchanged with row IPIV(i).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = +i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when $M = N = 6$, $KL = 2$, $KU = 1$:

On entry:

On exit:

	*	*	*	+	+	+		*	*	*	u14	u25	
u36	*	*	+	+	+	+		*	*		u13	u24	u35
u46	*	a12	a23	a34	a45	a56		*	u12	u23	u34	u45	
u56	a11	a22	a33	a44	a55	a66		u11	u22	u33	u44	u55	
u66	a21	a32	a43	a54	a65	*		m21	m32	m43	m54	m65	
*	a31	a42	a53	a64	*	*		m31	m42	m53	m64	*	
*													

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U, because of fill-in resulting from the row interchanges.

           int lda, int *ipivot, int *info);
```

```
void cgbtrf_64(long m, long n, long nsub, long nsuper, com-  
              plex *a, long lda, long *ipivot, long *info);
```

PURPOSE

cgbtrf computes an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

NSUB (input)
The number of subdiagonals within the band of A.
 $NSUB \geq 0$.

NSUPER (input)
The number of superdiagonals within the band of A.
 $NSUPER \geq 0$.

A (input/output)
On entry, the matrix A in band storage, in rows NSUB+1 to $2*NSUB+NSUPER+1$; rows 1 to NSUB of the array need not be set. The j-th column of A is stored in the j-th column of the array A as follows: $A(kl+ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(m,j+kl)$

On exit, details of the factorization: U is stored as an upper triangular band matrix with NSUB+NSUPER superdiagonals in rows 1 to NSUB+NSUPER+1, and the multipliers used during the factorization are stored in rows NSUB+NSUPER+2 to $2*NSUB+NSUPER+1$. See below for further details.

LDA (input)
The leading dimension of the array A. $LDA \geq 2*NSUB+NSUPER+1$.

IPIVOT (output)
The pivot indices; for $1 \leq i \leq \min(M,N)$, row i of the matrix was interchanged with row IPIVOT(i).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = +i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when $M = N = 6$, $NSUB = 2$, $NSUPER = 1$:

On entry:

On exit:

	*	*	*	+	+	+		*	*	*	u14	u25
u36								*	*			
	*	*	+	+	+	+		*	*	u13	u24	u35
u46												
	*	a12	a23	a34	a45	a56		*	u12	u23	u34	u45
u56												
	a11	a22	a33	a44	a55	a66		u11	u22	u33	u44	u55
u66												
	a21	a32	a43	a54	a65	*		m21	m32	m43	m54	m65
*												
	a31	a42	a53	a64	*	*		m31	m42	m53	m64	*
*												

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U because of fill-in resulting from the row interchanges.

  IPIVOT, B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: TRANSA
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER :: N, NSUB, NSUPER, NRHS, LDA, LDB, INFO
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE GBTRS_64([TRANSA], [N], NSUB, NSUPER, [NRHS], A, [LDA],
  IPIVOT, B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: TRANSA
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER(8) :: N, NSUB, NSUPER, NRHS, LDA, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgbtrs(char transa, int n, int nsub, int nsuper, int
```

```

        nrhs, complex *a, int lda, int *ipivot, complex
        *b, int ldb, int *info);
void cgbtrs_64(char transa, long n, long nsub, long nsuper,
              long nrhs, complex *a, long lda, long *ipivot,
              complex *b, long ldb, long *info);

```

PURPOSE

cgbtrs solves a system of linear equations
 $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$ with a general band matrix A using the LU factorization computed by CGBTRF.

ARGUMENTS

TRANSA (input)
 Specifies the form of the system of equations. =
 'N': $A * X = B$ (No transpose)
 = 'T': $A^{**T} * X = B$ (Transpose)
 = 'C': $A^{**H} * X = B$ (Conjugate transpose)
 TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

NSUB (input)
 The number of subdiagonals within the band of A.
 $NSUB \geq 0$.

NSUPER (input)
 The number of superdiagonals within the band of A.
 $NSUPER \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input) Details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with $NSUB+NSUPER$ superdiagonals in rows 1 to $NSUB+NSUPER+1$, and the multipliers used during the factorization are stored in rows $NSUB+NSUPER+2$ to $2*NSUB+NSUPER+1$.

LDA (input)
 The leading dimension of the array A. $LDA \geq 2*NSUB+NSUPER+1$.

IPIVOT (input)
 The pivot indices; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

B (input/output)
 On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB (input)
 The leading dimension of the array B. $LDB \geq \max(1,N)$.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

cgebak - form the right or left eigenvectors of a complex general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by CGEBAL

SYNOPSIS

```
SUBROUTINE CGEBAK(JOB, SIDE, N, ILO, IHI, SCALE, M, V, LDV, INFO)
```

```
CHARACTER * 1 JOB, SIDE  
COMPLEX V(LDV,*)  
INTEGER N, ILO, IHI, M, LDV, INFO  
REAL SCALE(*)
```

```
SUBROUTINE CGEBAK_64(JOB, SIDE, N, ILO, IHI, SCALE, M, V, LDV, INFO)
```

```
CHARACTER * 1 JOB, SIDE  
COMPLEX V(LDV,*)  
INTEGER*8 N, ILO, IHI, M, LDV, INFO  
REAL SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE GEBAK(JOB, SIDE, [N], ILO, IHI, SCALE, [M], V, [LDV],  
[INFO])
```

```
CHARACTER(LEN=1) :: JOB, SIDE  
COMPLEX, DIMENSION(:, :) :: V  
INTEGER :: N, ILO, IHI, M, LDV, INFO  
REAL, DIMENSION(:) :: SCALE
```

```
SUBROUTINE GEBAK_64(JOB, SIDE, [N], ILO, IHI, SCALE, [M], V, [LDV],  
[INFO])
```

```
CHARACTER(LEN=1) :: JOB, SIDE  
COMPLEX, DIMENSION(:, :) :: V  
INTEGER(8) :: N, ILO, IHI, M, LDV, INFO  
REAL, DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgebak(char job, char side, int n, int ilo, int ihi,  
float *scale, int m, complex *v, int ldv, int  
*info);
```

```
void cgebak_64(char job, char side, long n, long ilo, long
             ihi, float *scale, long m, complex *v, long ldv,
             long *info);
```

PURPOSE

cgebak forms the right or left eigenvectors of a complex general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by CGEBAL.

ARGUMENTS

JOB (input)

Specifies the type of backward transformation required: = 'N', do nothing, return immediately; = 'P', do backward transformation for permutation only; = 'S', do backward transformation for scaling only; = 'B', do backward transformations for both permutation and scaling. JOB must be the same as the argument JOB supplied to CGEBAL.

SIDE (input)

= 'R': V contains right eigenvectors;
= 'L': V contains left eigenvectors.

N (input) The number of rows of the matrix V. N >= 0.

ILO (input)

The integer ILO determined by CGEBAL. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

IHI (input)

The integer IHI determined by CGEBAL. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

SCALE (input)

Details of the permutation and scaling factors, as returned by CGEBAL.

M (input) The number of columns of the matrix V. M >= 0.

V (input/output)

On entry, the matrix of right or left eigenvectors to be transformed, as returned by CHSEIN or CTREVC. On exit, V is overwritten by the transformed eigenvectors.

LDV (input)

The leading dimension of the array V. LDV >= max(1,N).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

NAME

cgebal - balance a general complex matrix A

SYNOPSIS

```
SUBROUTINE CGEBAL(JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
```

```
CHARACTER * 1 JOB  
COMPLEX A(LDA,*)  
INTEGER N, LDA, ILO, IHI, INFO  
REAL SCALE(*)
```

```
SUBROUTINE CGEBAL_64(JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
```

```
CHARACTER * 1 JOB  
COMPLEX A(LDA,*)  
INTEGER*8 N, LDA, ILO, IHI, INFO  
REAL SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE GEBAL(JOB, [N], A, [LDA], ILO, IHI, SCALE, [INFO])
```

```
CHARACTER(LEN=1) :: JOB  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER :: N, LDA, ILO, IHI, INFO  
REAL, DIMENSION(:) :: SCALE
```

```
SUBROUTINE GEBAL_64(JOB, [N], A, [LDA], ILO, IHI, SCALE, [INFO])
```

```
CHARACTER(LEN=1) :: JOB  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: N, LDA, ILO, IHI, INFO  
REAL, DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgebal(char job, int n, complex *a, int lda, int *ilo,  
            int *ihi, float *scale, int *info);
```

```
void cgebal_64(char job, long n, complex *a, long lda, long  
               *ilo, long *ihi, float *scale, long *info);
```

PURPOSE

cgebal balances a general complex matrix A. This involves, first, permuting A by a similarity transformation to isolate eigenvalues in the first 1 to ILO-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

ARGUMENTS

JOB (input)

Specifies the operations to be performed on A:
= 'N': none: simply set ILO = 1, IHI = N,
SCALE(I) = 1.0 for i = 1,...,N; = 'P': permute
only;
= 'S': scale only;
= 'B': both permute and scale.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the input matrix A. On exit, A is
overwritten by the balanced matrix. If JOB = 'N',
A is not referenced. See Further Details.

LDA (input)

The leading dimension of the array A. $LDA \geq$
 $\max(1, N)$.

ILO (output)

ILO and IHI are set to integers such that on exit
 $A(i, j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i =$
 $IHI+1, \dots, N$. If JOB = 'N' or 'S', ILO = 1 and IHI
= N.

IHI (output)

ILO and IHI are set to integers such that on exit
 $A(i, j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i =$
 $IHI+1, \dots, N$. If JOB = 'N' or 'S', ILO = 1 and IHI
= N.

SCALE (output)

Details of the permutations and scaling factors
applied to A. If P(j) is the index of the row and
column interchanged with row and column j and D(j)
is the scaling factor applied to row and column j,
then $SCALE(j) = P(j)$ for $j = 1, \dots, ILO-1 = D(j)$
for $j = ILO, \dots, IHI = P(j)$ for $j = IHI+1, \dots, N$.
The order in which the interchanges are made is N
to IHI+1, then 1 to ILO-1.

INFO (output)

= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The permutations consist of row and column interchanges which put the matrix in the form

$$P A P = \begin{pmatrix} T1 & X & Y \\ 0 & B & Z \\ 0 & 0 & T2 \end{pmatrix}$$

where T1 and T2 are upper triangular matrices whose eigenvalues lie along the diagonal. The column indices ILO and IHI mark the starting and ending columns of the submatrix B. Balancing consists of applying a diagonal similarity transformation $\text{inv}(D) * B * D$ to make the 1-norms of each row of B and its corresponding column nearly equal. The output matrix is

$$\begin{pmatrix} T1 & X*D & Y \\ 0 & \text{inv}(D)*B*D & \text{inv}(D)*Z \\ 0 & 0 & T2 \end{pmatrix}.$$

Information about the permutations P and the diagonal matrix D is returned in the vector SCALE.

This subroutine is based on the EISPACK routine CBAL.

```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgebrd(int m, int n, complex *a, int lda, float *d,  
float *e, complex *tauq, complex *taup, int  
*info);
```

```
void cgebrd_64(long m, long n, complex *a, long lda, float
              *d, float *e, complex *tauq, complex *taup, long
              *info);
```

PURPOSE

cgebrd reduces a general complex M-by-N matrix A to upper or lower bidiagonal form B by a unitary transformation: $Q^{*H} * A * P = B$.

If $m \geq n$, B is upper bidiagonal; if $m < n$, B is lower bidiagonal.

ARGUMENTS

M (input) The number of rows in the matrix A. $M \geq 0$.

N (input) The number of columns in the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N general matrix to be reduced. On exit, if $m \geq n$, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array TAUP, represent the unitary matrix P as a product of elementary reflectors; if $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array TAUP, represent the unitary matrix P as a product of elementary reflectors. See Further Details.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

D (output)

The diagonal elements of the bidiagonal matrix B: $D(i) = A(i, i)$.

E (output)

The off-diagonal elements of the bidiagonal matrix B: if $m \geq n$, $E(i) = A(i, i+1)$ for $i = 1, 2, \dots, n-1$; if $m < n$, $E(i) = A(i+1, i)$ for $i = 1, 2, \dots, m-1$.

TAUQ (output)

The scalar factors of the elementary reflectors which represent the unitary matrix Q. See Further Details.

TAUP (output)

The scalar factors of the elementary reflectors which represent the unitary matrix P. See Further Details.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The length of the array WORK. LWORK \geq max(1,M,N). For optimum performance LWORK \geq (M+N)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrices Q and P are represented as products of elementary reflectors:

If $m \geq n$,

$$Q = H(1) H(2) \dots H(n) \quad \text{and} \quad P = G(1) G(2) \dots G(n-1)$$

Each H(i) and G(i) has the form:

$$H(i) = I - \tau_{uq} * v * v' \quad \text{and} \quad G(i) = I - \tau_{up} * u * u'$$

where τ_{uq} and τ_{up} are complex scalars, and v and u are complex vectors; $v(1:i-1) = 0$, $v(i) = 1$, and $v(i+1:m)$ is stored on exit in $A(i+1:m,i)$; $u(1:i) = 0$, $u(i+1) = 1$, and $u(i+2:n)$ is stored on exit in $A(i,i+2:n)$; τ_{uq} is stored in $TAUQ(i)$ and τ_{up} in $TAUP(i)$.

If $m < n$,

$$Q = H(1) H(2) \dots H(m-1) \quad \text{and} \quad P = G(1) G(2) \dots G(m)$$

Each H(i) and G(i) has the form:

$$H(i) = I - \tau_{uq} * v * v' \quad \text{and} \quad G(i) = I - \tau_{up} * u * u'$$

where τ_{uq} and τ_{up} are complex scalars, and v and u are complex vectors; $v(1:i) = 0$, $v(i+1) = 1$, and $v(i+2:m)$ is stored on exit in $A(i+2:m,i)$; $u(1:i-1) = 0$, $u(i) = 1$, and $u(i+1:n)$ is stored on exit in $A(i,i+1:n)$; τ_{uq} is stored in $TAUQ(i)$ and τ_{up} in $TAUP(i)$.

The contents of A on exit are illustrated by the following examples:

$m = 6$ and $n = 5$ ($m > n$):

```
( d  e  u1 u1 u1 )  
u1 )  
( v1 d  e  u2 u2 )  
u2 )  
( v1 v2 d  e  u3 )
```

$m = 5$ and $n = 6$ ($m < n$):

```
( d  u1  u1  u1  u1  
e  d  u2  u2  u2  
v1 e  d  u3  u3
```

$$\begin{array}{l}
 u_3 \) \\
 (\ v_1 \ v_2 \ v_3 \ d \ e \) \qquad (\ v_1 \ v_2 \ e \ d \ u_4 \\
 u_4 \) \\
 (\ v_1 \ v_2 \ v_3 \ v_4 \ d \) \qquad (\ v_1 \ v_2 \ v_3 \ e \ d \\
 u_5 \) \\
 (\ v_1 \ v_2 \ v_3 \ v_4 \ v_5 \)
 \end{array}$$

where d and e denote diagonal and off-diagonal elements of B , v_i denotes an element of the vector defining $H(i)$, and u_i an element of the vector defining $G(i)$.

```
CHARACTER(LEN=1) :: NORM  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: N, LDA, INFO  
REAL :: ANORM, RCOND  
REAL, DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
void cgecon(char norm, int n, complex *a, int lda, float
            anorm, float *rcond, int *info);

void cgecon_64(char norm, long n, complex *a, long lda,
              float anorm, float *rcond, long *info);
```

PURPOSE

cgecon estimates the reciprocal of the condition number of a general complex matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by CGETRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))) .$$

ARGUMENTS

NORM (input)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I': Infinity-norm.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The factors L and U from the factorization $A = P * L * U$ as computed by CGETRF.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

ANORM (input)

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND (output)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

WORK (workspace)

dimension(2*N)

WORK2 (workspace)

dimension(2*N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

INTEGER(8) :: M, N, LDA, INFO
REAL :: ROWCND, COLCND, AMAX
REAL, DIMENSION(:) :: ROWSC, COLSC
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cggequ(int m, int n, complex *a, int lda, float *rowsc,
           float *colsc, float *rowcnd, float *colcnd, float
```

```

    *amax, int *info);

void cgeequ_64(long m, long n, complex *a, long lda, float
    *rowsc, float *colsc, float *rowcnd, float
    *colcnd, float *amax, long *info);

```

PURPOSE

cgeequ computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements $B(i,j)=R(i)*A(i,j)*C(j)$ have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input) The M-by-N matrix whose equilibration factors are to be computed.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1,M)$.

ROWSC (output)
If INFO = 0 or INFO > M, ROWSC contains the row scale factors for A.

COLSC (output)
If INFO = 0, COLSC contains the column scale factors for A.

ROWCND (output)
If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest ROWSC(i) to the largest ROWSC(i). If ROWCND ≥ 0.1 and AMAX is neither too large nor too small, it is not worth scaling by ROWSC.

COLCND (output)
If INFO = 0, COLCND contains the ratio of the smallest COLSC(i) to the largest COLSC(i). If COLCND ≥ 0.1 , it is not worth scaling by COLSC.

AMAX (output)
Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-

```
gal value
> 0:  if INFO = i,  and i is
<= M:  the i-th row of A is exactly zero
>  M:  the (i-M)-th column of A is exactly zero
```

C INTERFACE

```
#include <sunperf.h>

void cgees(char jobz, char sortev, int(*select)(complex),
           int n, complex *a, int lda, int *nout, complex *w,
           complex *z, int ldz, int *info);

void cgees_64(char jobz, char sortev,
              long(*select)(complex), long n, complex *a, long
              lda, long *nout, complex *w, complex *z, long ldz,
              long *info);
```

PURPOSE

cgees computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization $A = Z^*T^*(Z^{**}H)$.

Optionally, it also orders the eigenvalues on the diagonal of the Schur form so that selected eigenvalues are at the top left. The leading columns of Z then form an orthonormal basis for the invariant subspace corresponding to the selected eigenvalues.

A complex matrix is in Schur form if it is upper triangular.

ARGUMENTS

JOBZ (input)
= 'N': Schur vectors are not computed;
= 'V': Schur vectors are computed.

SORTEV (input)
Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. = 'N': Eigenvalues are not ordered:
= 'S': Eigenvalues are ordered (see SELECT).

SELECT (input)
SELECT must be declared EXTERNAL in the calling subroutine. If SORTEV = 'S', SELECT is used to select eigenvalues to order to the top left of the Schur form. If SORTEV = 'N', SELECT is not referenced. The eigenvalue W(j) is selected if SELECT(W(j)) is true.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
On entry, the N-by-N matrix A. On exit, A has been overwritten by its Schur form T.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, N)$.

NOUT (output)
 If SORTEV = 'N', NOUT = 0. If SORTEV = 'S', NOUT = number of eigenvalues for which SELECT is true.

W (output)
 W contains the computed eigenvalues, in the same order that they appear on the diagonal of the output Schur form T.

Z (output)
 If JOBZ = 'V', Z contains the unitary matrix Z of Schur vectors. If JOBZ = 'N', Z is not referenced.

LDZ (input)
 The leading dimension of the array Z. LDZ >= 1; if JOBZ = 'V', LDZ >= N.

WORK (workspace)
 On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
 The dimension of the array WORK. LDWORK >= max(1,2*N). For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
 dimension(N)

WORK3 (workspace)
 dimension(N) Not referenced if SORTEV = 'N'.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value.
 > 0: if INFO = i, and i is
 <= N: the QR algorithm failed to compute all the eigenvalues; elements 1:ILO-1 and i+1:N of W contain those eigenvalues which have converged; if JOBZ = 'V', Z contains the matrix which reduces A to its partially converged Schur form. = N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned); = N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT = .TRUE.. This could also be caused by underflow due to scaling.

```

PURPOSE

cgeesx computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization $A = Z^*T^*(Z^*H)$.

Optionally, it also orders the eigenvalues on the diagonal of the Schur form so that selected eigenvalues are at the top left; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right invariant subspace corresponding to the selected eigenvalues (RCONDV). The leading columns of Z form an orthonormal basis for this invariant subspace.

For further explanation of the reciprocal condition numbers RCONDE and RCONDV, see Section 4.10 of the LAPACK Users' Guide (where these quantities are called s and sep respectively).

A complex matrix is in Schur form if it is upper triangular.

ARGUMENTS

JOBZ (input)
= 'N': Schur vectors are not computed;
= 'V': Schur vectors are computed.
SORTEV (input)
Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. = 'N': Eigenvalues are not ordered;
= 'S': Eigenvalues are ordered (see SELECT).

SELECT (input)
 SELECT must be declared EXTERNAL in the calling subroutine. If SORTEV = 'S', SELECT is used to select eigenvalues to order to the top left of the Schur form. If SORTEV = 'N', SELECT is not referenced. An eigenvalue W(j) is selected if SELECT(W(j)) is true.

SENSE (input)
 Determines which reciprocal condition numbers are computed. = 'N': None are computed;
 = 'E': Computed for average of selected eigenvalues only;
 = 'V': Computed for selected right invariant subspace only;
 = 'B': Computed for both. If SENSE = 'E', 'V' or 'B', SORTEV must equal 'S'.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
 On entry, the N-by-N matrix A. On exit, A is overwritten by its Schur form T.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1, N)$.

NOUT (output)
 If SORTEV = 'N', NOUT = 0. If SORTEV = 'S', NOUT = number of eigenvalues for which SELECT is true.

W (output)
 W contains the computed eigenvalues, in the same order that they appear on the diagonal of the output Schur form T.

Z (output)
 If JOBZ = 'V', Z contains the unitary matrix Z of Schur vectors. If JOBZ = 'N', Z is not referenced.

LDZ (input)
 The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq N$.

RCONE (output)
 If SENSE = 'E' or 'B', RCONE contains the reciprocal condition number for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

RCONV (output)
 If SENSE = 'V' or 'B', RCONV contains the reciprocal condition number for the selected right invariant subspace. Not referenced if SENSE = 'N' or 'E'.

WORK (workspace)
 dimension(LDWORK) On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
 The dimension of the array WORK. $LDWORK \geq$

max(1,2*N). Also, if SENSE = 'E' or 'V' or 'B', LDWORK >= 2*NOUT*(N-NOUT), where NOUT is the number of selected eigenvalues computed by this routine. Note that 2*NOUT*(N-NOUT) <= N*N/2. For good performance, LDWORK must generally be larger.

WORK2 (workspace)
dimension(N)

BWORK3 (workspace)
dimension(N) Not referenced if SORTEV = 'N'.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, and i is
<= N: the QR algorithm failed to compute all the eigenvalues; elements 1:ILO-1 and i+1:N of W contain those eigenvalues which have converged; if JOBZ = 'V', Z contains the transformation which reduces A to its partially converged Schur form.
= N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned);
= N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT=.TRUE. This could also be caused by underflow due to scaling.

              plex *vr, long ldvr, long *info);

```

PURPOSE

cgeev computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

The right eigenvector $v(j)$ of A satisfies

$$A * v(j) = \text{lambda}(j) * v(j)$$

where $\text{lambda}(j)$ is its eigenvalue.

The left eigenvector $u(j)$ of A satisfies

$$u(j)**H * A = \text{lambda}(j) * u(j)**H$$

where $u(j)**H$ denotes the conjugate transpose of $u(j)$.

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

ARGUMENTS

JOBVL (input)

= 'N': left eigenvectors of A are not computed;
 = 'V': left eigenvectors of are computed.

JOBVR (input)

= 'N': right eigenvectors of A are not computed;
 = 'V': right eigenvectors of A are computed.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the N-by-N matrix A. On exit, A has been overwritten.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

W (output)

W contains the computed eigenvalues.

VL (input)

If JOBVL = 'V', the left eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. If JOBVL = 'N', VL is not referenced. $u(j) = VL(:, j)$, the j-th column of VL.

LDVL (input)

The leading dimension of the array VL. $LDVL \geq 1$; if JOBVL = 'V', $LDVL \geq N$.

VR (input)

If JOBVR = 'V', the right eigenvectors $v(j)$ are

stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. $v(j) = VR(:,j)$, the j-th column of VR.

LDVR (input)

The leading dimension of the array VR. LDVR ≥ 1 ; if JOBVR = 'V', LDVR $\geq N$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK $\geq \max(1, 2*N)$. For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)

dimension(2*N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors have been computed; elements and i+1:N of W contain eigenvalues which have converged.

```

PURPOSE

cgeevx computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, SCALE, and ABNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

The right eigenvector $v(j)$ of A satisfies

$$A * v(j) = \lambda(j) * v(j)$$
where $\lambda(j)$ is its eigenvalue.

The left eigenvector $u(j)$ of A satisfies

$$u(j)**H * A = \lambda(j) * u(j)**H$$
where $u(j)**H$ denotes the conjugate transpose of $u(j)$.

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation $D * A * D^{(-1)}$, where D is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.10.2 of the LAPACK Users' Guide.

ARGUMENTS

BALANC (input)

Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues. = 'N': Do not diagonally scale or permute;
= 'P': Perform permutations to make the matrix

more nearly upper triangular. Do not diagonally scale; = 'S': Diagonally scale the matrix, ie. replace A by $D*A*D^{*(-1)}$, where D is a diagonal matrix chosen to make the rows and columns of A more equal in norm. Do not permute; = 'B': Both diagonally scale and permute A.

Computed reciprocal condition numbers will be for the matrix after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL (input)

= 'N': left eigenvectors of A are not computed;
= 'V': left eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVL must = 'V'.

JOBVR (input)

= 'N': right eigenvectors of A are not computed;
= 'V': right eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVR must = 'V'.

SENSE (input)

Determines which reciprocal condition numbers are computed. = 'N': None are computed;
= 'E': Computed for eigenvalues only;
= 'V': Computed for right eigenvectors only;
= 'B': Computed for eigenvalues and right eigenvectors.

If SENSE = 'E' or 'B', both left and right eigenvectors must also be computed (JOBVL = 'V' and JOBVR = 'V').

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the N-by-N matrix A. On exit, A has been overwritten. If JOBVL = 'V' or JOBVR = 'V', A contains the Schur form of the balanced version of the matrix A.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,N)$.

W (output)

W contains the computed eigenvalues.

VL (input)

If JOBVL = 'V', the left eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. If JOBVL = 'N', VL is not referenced. $u(j) = VL(:,j)$, the j-th column of VL.

LDVL (input)

The leading dimension of the array VL. $LDVL \geq 1$; if JOBVL = 'V', $LDVL \geq N$.

VR (input)

If JOBVR = 'V', the right eigenvectors $v(j)$ are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. $v(j) = VR(:,j)$, the

j-th column of VR.

LDVR (input)

The leading dimension of the array VR. LDVR ≥ 1 ;
if JOBVR = 'V', LDVR $\geq N$.

ILO (output)

ILO and IHI are integer values determined when A
was balanced. The balanced $A(i,j) = 0$ if $I > J$
and $J = 1, \dots, ILO-1$ or $I = IHI+1, \dots, N$.

IHI (output)

ILO and IHI are integer values determined when A
was balanced. The balanced $A(i,j) = 0$ if $I > J$
and $J = 1, \dots, ILO-1$ or $I = IHI+1, \dots, N$.

SCALE (output)

Details of the permutations and scaling factors
applied when balancing A. If $P(j)$ is the index of
the row and column interchanged with row and
column j , and $D(j)$ is the scaling factor applied
to row and column j , then $SCALE(J) = P(J)$,
for $J = 1, \dots, ILO-1 = D(J)$, for $J = ILO, \dots, IHI =$
 $P(J)$ for $J = IHI+1, \dots, N$. The order in which
the interchanges are made is N to $IHI+1$, then 1 to
 $ILO-1$.

ABNRM (output)

The one-norm of the balanced matrix (the maximum
of the sum of absolute values of elements of any
column).

RCONE (output)

RCONE(j) is the reciprocal condition number of the
 j -th eigenvalue.

RCONV (output)

RCONV(j) is the reciprocal condition number of the
 j -th right eigenvector.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal
LDWORK.

LDWORK (output)

The dimension of the array WORK. If SENSE = 'N'
or 'E', LDWORK $\geq \max(1, 2*N)$, and if SENSE = 'V'
or 'B', LDWORK $\geq N*N+2*N$. For good performance,
LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed;
the routine only calculates the optimal size of
the WORK array, returns this value as the first
entry of the WORK array, and no error message
related to LDWORK is issued by XERBLA.

WORK2 (workspace)

dimension($2*N$)

INFO (output)

= 0: successful exit
< 0: if INFO = - i , the i -th argument had an ille-
gal value.
> 0: if INFO = i , the QR algorithm failed to com-

pute all the eigenvalues, and no eigenvectors or condition numbers have been computed; elements 1:ILO-1 and i+1:N of W contain eigenvalues which have converged.

```

PURPOSE

cgegs routine is deprecated and has been replaced by routine CGGES.

CGEGS computes for a pair of N-by-N complex nonsymmetric matrices A, B: the generalized eigenvalues (alpha, beta), the complex Schur form (A, B), and optionally left and/or right Schur vectors (VSL and VSR).

(If only the generalized eigenvalues are needed, use the driver CGEGV instead.)

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

The (generalized) Schur form of a pair of matrices is the result of multiplying both matrices on the left by one unitary matrix and both on the right by another unitary matrix, these two unitary matrices being chosen so as to bring the pair of matrices into upper triangular form with the diagonal elements of B being non-negative real numbers (this is also called complex Schur form.)

The left and right Schur vectors are the columns of VSL and VSR, respectively, where VSL and VSR are the unitary matrices which reduce A and B to Schur form:

Schur form of (A,B) = ((VSL)**H A (VSR), (VSL)**H B (VSR))

ARGUMENTS

JOBVSL (input)
= 'N': do not compute the left Schur vectors;
= 'V': compute the left Schur vectors.
JOBVSR (input)
= 'N': do not compute the right Schur vectors;
= 'V': compute the right Schur vectors.
N (input) The order of the matrices A, B, VSL, and VSR. N
>= 0.

A (input/output)
 On entry, the first of the pair of matrices whose generalized eigenvalues and (optionally) Schur vectors are to be computed. On exit, the generalized Schur form of A.

LDA (input)
 The leading dimension of A. $LDA \geq \max(1,N)$.

B (input/output)
 On entry, the second of the pair of matrices whose generalized eigenvalues and (optionally) Schur vectors are to be computed. On exit, the generalized Schur form of B.

LDB (input)
 The leading dimension of B. $LDB \geq \max(1,N)$.

ALPHA (output)
 On exit, $ALPHA(j)/BETA(j)$, $j=1,\dots,N$, will be the generalized eigenvalues. $ALPHA(j)$, $j=1,\dots,N$ and $BETA(j)$, $j=1,\dots,N$ are the diagonals of the complex Schur form (A,B) output by CGEGS. The $BETA(j)$ will be non-negative real.

Note: the quotients $ALPHA(j)/BETA(j)$ may easily over- or underflow, and $BETA(j)$ may even be zero. Thus, the user should avoid naively computing the ratio $alpha/beta$. However, $ALPHA$ will be always less than and usually comparable with $norm(A)$ in magnitude, and $BETA$ always less than and usually comparable with $norm(B)$.

BETA (output)
 See the description of ALPHA.

VSL (input)
 If $JOBVSL = 'V'$, VSL will contain the left Schur vectors. (See "Purpose", above.) Not referenced if $JOBVSL = 'N'$.

LDVSL (input)
 The leading dimension of the matrix VSL. $LDVSL \geq 1$, and if $JOBVSL = 'V'$, $LDVSL \geq N$.

VSR (input)
 If $JOBVSR = 'V'$, VSR will contain the right Schur vectors. (See "Purpose", above.) Not referenced if $JOBVSR = 'N'$.

LDVSR (input)
 The leading dimension of the matrix VSR. $LDVSR \geq 1$, and if $JOBVSR = 'V'$, $LDVSR \geq N$.

WORK (workspace)
 On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

LDWORK (input)
 The dimension of the array WORK. $LDWORK \geq \max(1,2*N)$. For good performance, LDWORK must generally be larger. To compute the optimal value of LDWORK, call ILAENV to get blocksizes (for CGEQR, CUNMQR, and CUNGQR.) Then compute: NB as

the MAX of the blocksizes for CGEQRF, CUNMQR, and CUNGQR; the optimal LDWORK is $N*(NB+1)$.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
dimension(3*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
=1,...,N: The QZ iteration failed. (A,B) are not in Schur form, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,...,N. > N: errors that usually indicate LAPACK problems:
=N+1: error return from CGGBAL
=N+2: error return from CGEQRF
=N+3: error return from CUNMQR
=N+4: error return from CUNGQR
=N+5: error return from CGGHRD
=N+6: error return from CHGEQZ (other than failed iteration) =N+7: error return from CGGBAK (computing VSL)
=N+8: error return from CGGBAK (computing VSR)
=N+9: error return from CLASCL (various places)

              complex *beta, complex *vl, long ldvl, complex
              *vr, long ldvr, long *info);
```

PURPOSE

cgegv routine is deprecated and has been replaced by routine CGGEV.

CGEGV computes for a pair of N-by-N complex nonsymmetric matrices A and B, the generalized eigenvalues (alpha, beta), and optionally, the left and/or right generalized eigenvectors (VL and VR).

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio $\alpha/\beta = w$, such that $A - wB$ is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for $\beta=0$, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

A right generalized eigenvector corresponding to a generalized eigenvalue w for a pair of matrices (A,B) is a vector r such that $(A - w B) r = 0$. A left generalized eigenvector is a vector l such that $l^*H * (A - w B) = 0$, where l^*H is the conjugate-transpose of l.

Note: this routine performs "full balancing" on A and B. See "Further Details", below.

ARGUMENTS

JOBVL (input)
= 'N': do not compute the left generalized eigenvectors;
= 'V': compute the left generalized eigenvectors.

JOBVR (input)
= 'N': do not compute the right generalized eigenvectors;
= 'V': compute the right generalized eigenvectors.

N (input) The order of the matrices A, B, VL, and VR. $N \geq 0$.

A (input/output)
On entry, the first of the pair of matrices whose

generalized eigenvalues and (optionally) generalized eigenvectors are to be computed. On exit, the contents will have been destroyed. (For a description of the contents of A on exit, see "Further Details", below.)

LDA (input)

The leading dimension of A. $LDA \geq \max(1, N)$.

B (input/output)

On entry, the second of the pair of matrices whose generalized eigenvalues and (optionally) generalized eigenvectors are to be computed. On exit, the contents will have been destroyed. (For a description of the contents of B on exit, see "Further Details", below.)

LDB (input)

The leading dimension of B. $LDB \geq \max(1, N)$.

ALPHA (output)

On exit, $ALPHA(j)/VL(j)$, $j=1, \dots, N$, will be the generalized eigenvalues.

Note: the quotients $ALPHA(j)/VL(j)$ may easily overflow or underflow, and $VL(j)$ may even be zero. Thus, the user should avoid naively computing the ratio $alpha/beta$. However, ALPHA will be always less than and usually comparable with $norm(A)$ in magnitude, and VL always less than and usually comparable with $norm(B)$.

VL (output)

If $JOBVL = 'V'$, the left generalized eigenvectors. (See "Purpose", above.) Each eigenvector will be scaled so the largest component will have $abs(\text{real part}) + abs(\text{imag. part}) = 1$, *except* that for eigenvalues with $alpha=beta=0$, a zero vector will be returned as the corresponding eigenvector. Not referenced if $JOBVL = 'N'$.

BETA (output)

If $JOBVL = 'V'$, the left generalized eigenvectors. (See "Purpose", above.) Each eigenvector will be scaled so the largest component will have $abs(\text{real part}) + abs(\text{imag. part}) = 1$, *except* that for eigenvalues with $alpha=beta=0$, a zero vector will be returned as the corresponding eigenvector. Not referenced if $JOBVL = 'N'$.

LDVL (input)

The leading dimension of the matrix VL. $LDVL \geq 1$, and if $JOBVL = 'V'$, $LDVL \geq N$.

VR (output)

If $JOBVR = 'V'$, the right generalized eigenvectors. (See "Purpose", above.) Each eigenvector will be scaled so the largest component will have $abs(\text{real part}) + abs(\text{imag. part}) = 1$, *except* that for eigenvalues with $alpha=beta=0$, a zero vector will be returned as the corresponding eigenvector. Not referenced if $JOBVR = 'N'$.

LDVR (input)

The leading dimension of the matrix VR. $LDVR \geq 1$,

and if JOBVR = 'V', LDVR >= N.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK >= max(1,2*N). For good performance, LDWORK must generally be larger. To compute the optimal value of LDWORK, call ILAENV to get blocksizes (for CGEQRF, CUNMQR, and CUNGQR.) Then compute: NB as the MAX of the blocksizes for CGEQRF, CUNMQR, and CUNGQR; The optimal LDWORK is MAX(2*N, N*(NB+1)).

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)

dimension(8*N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
=1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHA(j) and VL(j) should be correct for j=INFO+1,...,N. > N: errors that usually indicate LAPACK problems:
=N+1: error return from CGGBAL
=N+2: error return from CGEQRF
=N+3: error return from CUNMQR
=N+4: error return from CUNGQR
=N+5: error return from CGGHRD
=N+6: error return from CHGEQZ (other than failed iteration) =N+7: error return from CTGEVC
=N+8: error return from CGGBAK (computing VL)
=N+9: error return from CGGBAK (computing VR)
=N+10: error return from CLASCL (various calls)

FURTHER DETAILS

Balancing

This driver calls CGGBAL to both permute and scale rows and columns of A and B. The permutations PL and PR are chosen so that PL*A*PR and PL*B*PR will be upper triangular except for the diagonal blocks A(i:j,i:j) and B(i:j,i:j), with i and j as close together as possible. The diagonal scaling matrices DL and DR are chosen so that the pair DL*PL*A*PR*DR, DL*PL*B*PR*DR have elements close to one (except for the elements that start out zero.)

After the eigenvalues and eigenvectors of the balanced matrices have been computed, CGGBAK transforms the eigenvectors back to what they would have been (in perfect arithmetic) if they had not been balanced.

Contents of A and B on Exit

If any eigenvectors are computed (either JOBVL='V' or JOBVR='V' or both), then on exit the arrays A and B will contain the complex Schur form[*] of the "balanced" versions of A and B. If no eigenvectors are computed, then only the diagonal blocks will be correct.

[*] In other words, upper triangular form.

[INFO])
```

```
COMPLEX, DIMENSION(:) :: TAU, WORKIN  
COMPLEX, DIMENSION(:,:) :: A  
INTEGER(8) :: N, ILO, IHI, LDA, LWORKIN, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgehrd(int n, int ilo, int ihi, complex *a, int lda,  
complex *tau, int *info);
```

```
void cgehrd_64(long n, long ilo, long ihi, complex *a, long  
lda, complex *tau, long *info);
```

PURPOSE

cgehrd reduces a complex general matrix A to upper Hessenberg form H by a unitary similarity transformation: $Q' * A * Q = H$.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

ILO (input)

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to CGEBAL; otherwise they should be set to 1 and N respectively. See Further Details.

IHI (input)

See the description of ILO.

A (input/output)

On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details). Elements 1:ILO-1 and IHI:N-1 of TAU are set to zero.

WORKIN (workspace)

On exit, if INFO = 0, WORKIN(1) returns the optimal LWORKIN.

LWORKIN (input)

The length of the array WORKIN. $LWORKIN \geq \max(1, N)$. For optimum performance $LWORKIN \geq N * NB$, where NB is the optimal blocksize.

If $LWORKIN = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORKIN array, returns this value as the first entry of the WORKIN array, and no error message related to LWORKIN is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of $(ihi-ilo)$ elementary reflectors

$$Q = H(ilo) H(ilo+1) \dots H(ihi-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a complex scalar, and v is a complex vector with $v(1:i) = 0$, $v(i+1) = 1$ and $v(ihi+1:n) = 0$; $v(i+2:ihi)$ is stored on exit in $A(i+2:ihi,i)$, and τ in $TAU(i)$.

The contents of A are illustrated by the following example, with $n = 7$, $ilo = 2$ and $ihi = 6$:

on entry,

on exit,

$\begin{pmatrix} a & a & a & a & a & a & a \\ a & & & & & & \\ h & a & & & & & \\ h & h & h & & & & \\ h & h & h & h & & & \\ v3 & h & h & h & h & & \\ v2 & v3 & v4 & h & h & h & \\ a & & & & & & \end{pmatrix}$	$\begin{pmatrix} a & a & h & h & h & h \\ & a & h & h & h & \\ & & h & h & h & \\ & & & v2 & h & \\ & & & & v2 & \\ & & a & a & a & a & a \\ & & & & a & a & a & a \\ & & & & & a & & \\ & & & & & & a & \\ & & & & & & & a \end{pmatrix}$
--	--

where a denotes an element of the original matrix A , h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(i)$.

```

```
COMPLEX A(LDA,*), TAU(*), WORK(*)  
INTEGER*8 M, N, LDA, LDWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE GELQF([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
COMPLEX, DIMENSION(:) :: TAU, WORK  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER :: M, N, LDA, LDWORK, INFO
```

```
SUBROUTINE GELQF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
COMPLEX, DIMENSION(:) :: TAU, WORK  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, LDA, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgelqf(int m, int n, complex *a, int lda, complex *tau,  
           int *info);
```

```
void cgelqf_64(long m, long n, complex *a, long lda, complex  
              *tau, long *info);
```

PURPOSE

cgelqf computes an LQ factorization of a complex M-by-N matrix A: $A = L * Q$.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the m-by-min(m,n) lower trapezoidal matrix L (L is lower triangular if $m \leq n$); the elements above the diagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. $LDWORK \geq \max(1, M)$. For optimum performance $LDWORK \geq M * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)', \text{ where } k = \min(m, n).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a complex scalar, and v is a complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $\text{conjg}(v(i+1:n))$ is stored on exit in $A(i, i+1:n)$, and τ in $TAU(i)$.

COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:, :) :: A, B  
INTEGER :: M, N, NRHS, LDA, LDB, LDWORK, INFO
```

```
SUBROUTINE GELS_64([TRANSA], [M], [N], [NRHS], A, [LDA], B, [LDB],  
[WORK], LDWORK, [INFO])
```

```
CHARACTER(LEN=1) :: TRANSA  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:, :) :: A, B  
INTEGER(8) :: M, N, NRHS, LDA, LDB, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgels (char, int, int, int, complex*, int, complex*,  
int, int*);
```

```
void cgels_64 (char, long, long, long, complex*, long, complex*, long, long*);
```

PURPOSE

cgels solves overdetermined or underdetermined complex linear systems involving an M-by-N matrix A, or its conjugate-transpose, using a QR or LQ factorization of A. It is assumed that A has full rank.

The following options are provided:

1. If TRANS = 'N' and $m \geq n$: find the least squares solution of an overdetermined system, i.e., solve the least squares problem

$$\text{minimize } \| B - A * X \|^2.$$

2. If TRANS = 'N' and $m < n$: find the minimum norm solution of an underdetermined system $A * X = B$.

3. If TRANS = 'C' and $m \geq n$: find the minimum norm solution of an undetermined system $A^{*H} * X = B$.

4. If TRANS = 'C' and $m < n$: find the least squares solution of an overdetermined system, i.e., solve the least squares problem

$$\text{minimize } \| B - A^{*H} * X \|^2.$$

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

ARGUMENTS

TRANSA (input)

= 'N': the linear system involves A;
= 'C': the linear system involves A^{*H} .

TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS ≥ 0 .

A (input/output)

On entry, the M-by-N matrix A. if $M \geq N$, A is overwritten by details of its QR factorization as returned by CGEQRF; if $M < N$, A is overwritten by details of its LQ factorization as returned by CGELQF.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input/output)

On entry, the matrix B of right hand side vectors, stored columnwise; B is M-by-NRHS if TRANSA = 'N', or N-by-NRHS if TRANSA = 'C'. On exit, B is overwritten by the solution vectors, stored columnwise: if TRANSA = 'N' and $m \geq n$, rows 1 to n of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements N+1 to M in that column; if TRANSA = 'N' and $m < n$, rows 1 to N of B contain the minimum norm solution vectors; if TRANSA = 'C' and $m \geq n$, rows 1 to M of B contain the minimum norm solution vectors; if TRANSA = 'C' and $m < n$, rows 1 to M of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements M+1 to N in that column.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, M, N)$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (output)

The dimension of the array WORK. $LDWORK \geq \max(1, MN + \max(MN, NRHS))$. For optimal performance, $LDWORK \geq \max(1, MN + \max(MN, NRHS) * NB)$. where $MN = \min(M, N)$ and NB is the optimum block size.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

```
REAL :: RCOND
REAL, DIMENSION(:) :: S, RWORK
```

C INTERFACE

```
#include <sunperf.h>
void cgelsd(int m, int n, int nrhs, complex *a, int lda,
            complex *b, int ldb, float *s, float rcond, int
            *rank, int *info);

void cgelsd_64(long m, long n, long nrhs, complex *a, long
              lda, complex *b, long ldb, float *s, float rcond,
              long *rank, long *info);
```

PURPOSE

cgelsd computes the minimum-norm solution to a real linear least squares problem:

$$\text{minimize } 2\text{-norm}(|b - A*x|)$$

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The problem is solved in three steps:

- (1) Reduce the coefficient matrix A to bidiagonal form with Householder transformations, reducing the original problem into a "bidiagonal least squares problem" (BLS)
- (2) Solve the BLS using a divide and conquer approach.
- (3) Apply back all the Householder transformations to solve the original least squares problem.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input/output)

On entry, the M-by-N matrix A. On exit, A has been destroyed.

LDA (input)
 The leading dimension of the array A. LDA \geq max(1,M).

B (input/output)
 On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If $m \geq n$ and RANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements n+1:m in that column.

LDB (input)
 The leading dimension of the array B. LDB \geq max(1,M,N).

S (output)
 The singular values of A in decreasing order. The condition number of A in the 2-norm = $S(1)/S(\min(m,n))$.

RCOND (input)
 RCOND is used to determine the effective rank of A. Singular values $S(i) \leq RCOND*S(1)$ are treated as zero. If RCOND < 0, machine precision is used instead.

RANK (output)
 The effective rank of A, i.e., the number of singular values which are greater than RCOND*S(1).

WORK (workspace)
 On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
 The dimension of the array WORK. LWORK \geq 1. The exact minimum amount of workspace needed depends on M, N and NRHS. If $M \geq N$, LWORK $\geq 2*N + N*NRHS$. If $M < N$, LWORK $\geq 2*M + M*NRHS$. For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
 If $M \geq N$, LRWORK $\geq 8*N + 2*N*SMLSIZ + 8*N*NLVL + N*NRHS$. If $M < N$, LRWORK $\geq 8*M + 2*M*SMLSIZ + 8*M*NLVL + M*NRHS$. SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25), and NLVL = INT(LOG_2(MIN(M,N)/(SMLSIZ+1))) + 1

IWORK (workspace)
 LIWORK $\geq 3 * \text{MINMN} * \text{NLVL} + 11 * \text{MINMN}$, where MINMN = MIN(M,N).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: the algorithm for computing the SVD failed to converge; if INFO = i, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

```

PURPOSE

cgelss computes the minimum norm solution to a complex linear least squares problem:

Minimize $\|b - A*x\|_2$.

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output)
On entry, the M-by-N matrix A. On exit, the first $\min(m,n)$ rows of A are overwritten with its right singular vectors, stored rowwise.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1,M)$.

B (input/output)
On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If $m \geq n$ and $IRANK = n$, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements $n+1:m$ in that column.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1,M,N)$.

SING (output)
The singular values of A in decreasing order. The condition number of A in the 2-norm =

SING(1)/SING(min(m,n)).

RCOND (input)

RCOND is used to determine the effective rank of A. Singular values SING(i) \leq RCOND*SING(1) are treated as zero. If RCOND < 0 , machine precision is used instead.

IRANK (output)

The effective rank of A, i.e., the number of singular values which are greater than RCOND*SING(1).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK ≥ 1 , and also: LDWORK $\geq 2*\min(M,N) + \max(M,N,NRHS)$ For good performance, LDWORK should generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)

dimension(5*min(M,N))

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: the algorithm for computing the SVD failed to converge; if INFO = i, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

              rcond, long *irank, long *info);
```

PURPOSE

cgelsx routine is deprecated and has been replaced by routine CGELSY.

CGELSX computes the minimum-norm solution to a complex linear least squares problem:

minimize $\|A * X - B\|$
using a complete orthogonal factorization of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The routine first computes a QR factorization with column pivoting:

$$A * P = Q * \begin{bmatrix} R11 & R12 \\ 0 & R22 \end{bmatrix}$$

with R11 defined as the largest leading submatrix whose estimated condition number is less than 1/RCOND. The order of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihilated by unitary transformations from the right, arriving at the complete orthogonal factorization:

$$A * P = Q * \begin{bmatrix} T11 & 0 \\ 0 & 0 \end{bmatrix} * Z$$

The minimum-norm solution is then

$$X = P * Z' \begin{bmatrix} \text{inv}(T11) * Q1' * B \\ 0 \end{bmatrix}$$

where Q1 consists of the first RANK columns of Q.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of matrices B and X. $NRHS \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, A has been overwritten by details of its complete orthogonal factorization.

LDA (input)
The leading dimension of the array A. LDA \geq max(1,M).

B (input/output)
On entry, the M-by-NRHS right hand side matrix B.
On exit, the N-by-NRHS solution matrix X. If $m \geq n$ and IRANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements N+1:M in that column.

LDB (input)
The leading dimension of the array B. LDB \geq max(1,M,N).

JPIVOT (input/output)
On entry, if JPIVOT(i) \neq 0, the i-th column of A is an initial column, otherwise it is a free column. Before the QR factorization of A, all initial columns are permuted to the leading positions; only the remaining free columns are moved as a result of column pivoting during the factorization. On exit, if JPIVOT(i) = k, then the i-th column of A*P was the k-th column of A.

RCOND (input)
RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number $< 1/\text{RCOND}$.

IRANK (output)
The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

WORK (workspace)
(min(M,N) + max(N, 2*min(M,N)+NRHS)),

WORK2 (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```
#include <sunperf.h>
void cgelsy(int m, int n, int nrhs, complex *a, int lda,
            complex *b, int ldb, int *jpvt, float rcond, int
            *rank, int *info);

void cgelsy_64(long m, long n, long nrhs, complex *a, long
               lda, complex *b, long ldb, long *jpvt, float
               rcond, long *rank, long *info);
```

PURPOSE

cgelsy computes the minimum-norm solution to a complex linear least squares problem:

$$\text{minimize } || A * X - B ||$$

using a complete orthogonal factorization of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The routine first computes a QR factorization with column pivoting:

$$A * P = Q * \begin{bmatrix} R11 & R12 \\ 0 & R22 \end{bmatrix}$$

with R11 defined as the largest leading submatrix whose estimated condition number is less than 1/RCOND. The order of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihilated by unitary transformations from the right, arriving at the complete orthogonal factorization:

$$A * P = Q * \begin{bmatrix} T11 & 0 \\ 0 & 0 \end{bmatrix} * Z$$

The minimum-norm solution is then

$$X = P * Z' \begin{bmatrix} \text{inv}(T11) * Q1' * B \\ 0 \end{bmatrix}$$

where Q1 consists of the first RANK columns of Q.

This routine is basically identical to the original xGELSX except three differences:

- o The permutation of matrix B (the right hand side) is faster and more simple.
- o The call to the subroutine xGEQPF has been substituted by the call to the subroutine xGEQ3. This subroutine is a Blas-3 version of the QR factorization with column pivoting.
- o Matrix B (the right hand side) is updated with Blas-3.

ARGUMENTS

- M (input) The number of rows of the matrix A. $M \geq 0$.
- N (input) The number of columns of the matrix A. $N \geq 0$.
- NRHS (input)
The number of right hand sides, i.e., the number of columns of matrices B and X. $NRHS \geq 0$.
- A (input/output)
On entry, the M-by-N matrix A. On exit, A has been overwritten by details of its complete orthogonal factorization.
- LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, M)$.
- B (input/output)
On entry, the M-by-NRHS right hand side matrix B. On exit, the N-by-NRHS solution matrix X.
- LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, M, N)$.
- JPVT (input/output)
On entry, if $JPVT(i) \neq 0$, the i-th column of A is permuted to the front of AP, otherwise column i is a free column. On exit, if $JPVT(i) = k$, then the i-th column of A^*P was the k-th column of A.
- RCOND (input)
RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number $< 1/RCOND$.
- RANK (output)
The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.
- WORK (workspace)
On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.
- LWORK (input)
The dimension of the array WORK. The unblocked strategy requires that: $LWORK \geq MN + \max(2*MN, N+1, MN+NRHS)$ where $MN = \min(M, N)$. The block algorithm requires that: $LWORK \geq MN + \max(2*MN, NB*(N+1), MN+MN*NB, MN+NB*NRHS)$ where NB is an upper bound on the blocksize returned by ILAENV for the routines CGEQP3, CTZRZF, CTZRQF, CUNMQR, and CUNMRZ.
- If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message

related to LWORK is issued by XERBLA.

RWORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgemm(char transa, char transb, int m, int n, int k,
  complex *alpha, complex *a, int lda, complex *b,
```

```

        int ldb, complex *beta, complex *c, int ldc);

void cgemm_64(char transa, char transb, long m, long n, long
k, complex *alpha, complex *a, long lda, complex
*b, long ldb, complex *beta, complex *c, long
ldc);

```

PURPOSE

cgemm performs one of the matrix-matrix operations

$$C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C$$

where $\text{op}(X)$ is one of

$\text{op}(X) = X$ or $\text{op}(X) = X'$ or $\text{op}(X) = \text{conjg}(X')$, α and β are scalars, and A , B and C are matrices, with $\text{op}(A)$ an m by k matrix, $\text{op}(B)$ a k by n matrix and C an m by n matrix.

ARGUMENTS

TRANSA (input)

On entry, TRANSA specifies the form of $\text{op}(A)$ to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n', $\text{op}(A) = A$.

TRANSA = 'T' or 't', $\text{op}(A) = A'$.

TRANSA = 'C' or 'c', $\text{op}(A) = \text{conjg}(A')$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

TRANSB (input)

On entry, TRANSB specifies the form of $\text{op}(B)$ to be used in the matrix multiplication as follows:

TRANSB = 'N' or 'n', $\text{op}(B) = B$.

TRANSB = 'T' or 't', $\text{op}(B) = B'$.

TRANSB = 'C' or 'c', $\text{op}(B) = \text{conjg}(B')$.

Unchanged on exit.

TRANSB is defaulted to 'N' for F95 INTERFACE.

M (input)

On entry, M specifies the number of rows of the matrix $\text{op}(A)$ and of the matrix C . $M \geq 0$. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix $\text{op}(B)$ and the number of columns of the matrix C . $N \geq 0$. Unchanged on exit.

K (input)
On entry, K specifies the number of columns of the matrix $op(A)$ and the number of rows of the matrix $op(B)$. $K \geq 0$. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
COMPLEX array of DIMENSION (LDA, ka), where ka is K when TRANSA = 'N' or 'n', and is M otherwise. Before entry with TRANSA = 'N' or 'n', the leading M by K part of the array A must contain the matrix A, otherwise the leading K by M part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then $LDA \geq \max(1, M)$, otherwise $LDA \geq \max(1, K)$. Unchanged on exit.

B (input)
COMPLEX array of DIMENSION (LDB, kb), where kb is n when TRANSB = 'N' or 'n', and is k otherwise. Before entry with TRANSB = 'N' or 'n', the leading k by n part of the array B must contain the matrix B, otherwise the leading n by k part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)
On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSB = 'N' or 'n' then $LDB \geq \max(1, k)$, otherwise $LDB \geq \max(1, n)$. Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

C (input/output)
COMPLEX array of DIMENSION (LDC, n). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n matrix ($\alpha * op(A) * op(B) + \beta * C$).

LDC (input)
On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. $LDC \geq \max(1, m)$. Unchanged on exit.

CHARACTER(LEN=1) :: TRANSA  
COMPLEX :: ALPHA, BETA  
COMPLEX, DIMENSION(:) :: X, Y  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, LDA, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```

void cgemv(char transa, int m, int n, complex *alpha, complex
 *a, int lda, complex *x, int incx, complex
 *beta, complex *y, int incy);
void cgemv_64(char transa, long m, long n, complex *alpha,
 complex *a, long lda, complex *x, long incx, complex
 *beta, complex *y, long incy);

```

PURPOSE

cgemv performs one of the matrix-vector operations $y := \alpha A x + \beta y$, or $y := \alpha A^T x + \beta y$, or $y := \alpha \text{conjg}(A) x + \beta y$ where α and β are scalars, x and y are vectors and A is an m by n matrix.

ARGUMENTS

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $y := \alpha A x + \beta y$.

TRANSA = 'T' or 't' $y := \alpha A^T x + \beta y$.

TRANSA = 'C' or 'c' $y := \alpha \text{conjg}(A) x + \beta y$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input)

On entry, M specifies the number of rows of the matrix A. $M \geq 0$. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix A. $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

A (input)

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, m)$. Unchanged on exit.

X (input)

$(1 + (n - 1) \cdot \text{abs}(\text{INCX}))$ when TRANSA = 'N' or 'n' and at least $(1 + (m - 1) \cdot \text{abs}(\text{INCX}))$ otherwise. Before entry, the incremented array X must contain the vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)

($1 + (m - 1) * \text{abs}(\text{ INCY })$) when TRANSA = 'N' or 'n' and at least ($1 + (n - 1) * \text{abs}(\text{ INCY })$) otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

cgeqlf - compute a QL factorization of a complex M-by-N matrix A

SYNOPSIS

```
SUBROUTINE CGEQLF(M, N, A, LDA, TAU, WORK, LDWORK, INFO)
```

```
COMPLEX A(LDA,*), TAU(*), WORK(*)  
INTEGER M, N, LDA, LDWORK, INFO
```

```
SUBROUTINE CGEQLF_64(M, N, A, LDA, TAU, WORK, LDWORK, INFO)
```

```
COMPLEX A(LDA,*), TAU(*), WORK(*)  
INTEGER*8 M, N, LDA, LDWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE GEQLF([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
COMPLEX, DIMENSION(:) :: TAU, WORK  
COMPLEX, DIMENSION(:,:) :: A  
INTEGER :: M, N, LDA, LDWORK, INFO
```

```
SUBROUTINE GEQLF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
COMPLEX, DIMENSION(:) :: TAU, WORK  
COMPLEX, DIMENSION(:,:) :: A  
INTEGER(8) :: M, N, LDA, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgeqlf(int m, int n, complex *a, int lda, complex *tau,  
           int *info);
```

```
void cgeqlf_64(long m, long n, complex *a, long lda, complex  
              *tau, long *info);
```

PURPOSE

cgeqlf computes a QL factorization of a complex M-by-N matrix A: $A = Q * L$.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, if $m \geq n$, the lower triangle of the subarray A(m-n+1:m,1:n) contains the N-by-N lower triangular matrix L; if $m \leq n$, the elements on and below the (n-m)-th superdiagonal contain the M-by-N lower trapezoidal matrix L; the remaining elements, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)

On exit, if $INFO = 0$, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. $LDWORK \geq \max(1, N)$. For optimum performance $LDWORK \geq N * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$Q = H(k) \dots H(2) H(1)$, where $k = \min(m, n)$.
Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a complex scalar, and v is a complex vector

with $v(m-k+i+1:m) = 0$ and $v(m-k+i) = 1$; $v(1:m-k+i-1)$ is stored on exit in $A(1:m-k+i-1, n-k+i)$, and tau in $TAU(i)$.

NAME

cgeqp3 - compute a QR factorization with column pivoting of a matrix A

SYNOPSIS

```
SUBROUTINE CGEQP3(M, N, A, LDA, JPVT, TAU, WORK, LWORK, RWORK, INFO)
```

```
COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER M, N, LDA, LWORK, INFO
INTEGER JPVT(*)
REAL RWORK(*)
```

```
SUBROUTINE CGEQP3_64(M, N, A, LDA, JPVT, TAU, WORK, LWORK, RWORK,
INFO)
```

```
COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 M, N, LDA, LWORK, INFO
INTEGER*8 JPVT(*)
REAL RWORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEQP3([M], [N], A, [LDA], JPVT, TAU, [WORK], [LWORK],
[RWORK], [INFO])
```

```
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: M, N, LDA, LWORK, INFO
INTEGER, DIMENSION(:) :: JPVT
REAL, DIMENSION(:) :: RWORK
```

```
SUBROUTINE GEQP3_64([M], [N], A, [LDA], JPVT, TAU, [WORK], [LWORK],
[RWORK], [INFO])
```

```
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: M, N, LDA, LWORK, INFO
INTEGER(8), DIMENSION(:) :: JPVT
REAL, DIMENSION(:) :: RWORK
```

C INTERFACE

```
#include <sunperf.h>
```

```

void cgeqp3(int m, int n, complex *a, int lda, int *jpvt,
            complex *tau, int *info);

void cgeqp3_64(long m, long n, complex *a, long lda, long
               *jpvt, complex *tau, long *info);

```

PURPOSE

cgeqp3 computes a QR factorization with column pivoting of a matrix A: $A^*P = Q^*R$ using Level 3 BLAS.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the $\min(M,N)$ -by-N upper trapezoidal matrix R; the elements below the diagonal, together with the array TAU, represent the unitary matrix Q as a product of $\min(M,N)$ elementary reflectors.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,M)$.

JPVT (input/output)

On entry, if $JPVT(J) \neq 0$, the J-th column of A is permuted to the front of A^*P (a leading column); if $JPVT(J)=0$, the J-th column of A is a free column. On exit, if $JPVT(J)=K$, then the J-th column of A^*P was the K-th column of A.

TAU (output)

The scalar factors of the elementary reflectors.

WORK (workspace)

On exit, if $INFO=0$, $WORK(1)$ returns the optimal $LWORK$.

LWORK (input)

The dimension of the array WORK. $LWORK \geq N+1$. For optimal performance $LWORK \geq (N+1)*NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to $LWORK$ is issued by XERBLA.

RWORK (workspace)

dimension($2*N$)

INFO (output)

= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(k), \text{ where } k = \min(m,n).$$

Each H(i) has the form

$$H(i) = I - \tau * v * v'$$

where tau is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(i+1:m,i)$, and tau in $TAU(i)$.

INTEGER(8), DIMENSION(:) :: JPIVOT
REAL, DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```

void cgeqpf(int m, int n, complex *a, int lda, int *jpivot,
            complex *tau, int *info);

void cgeqpf_64(long m, long n, complex *a, long lda, long
               *jpivot, complex *tau, long *info);

```

PURPOSE

cgeqpf routine is deprecated and has been replaced by routine CGEQP3.

CGEQPF computes a QR factorization with column pivoting of a complex M-by-N matrix A: $A^*P = Q^*R$.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$

A (input/output)
 On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the $\min(M,N)$ -by-N upper triangular matrix R; the elements below the diagonal, together with the array TAU, represent the unitary matrix Q as a product of $\min(m,n)$ elementary reflectors.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1,M)$.

JPIVOT (input/output)
 On entry, if $JPIVOT(i) \neq 0$, the i-th column of A is permuted to the front of A^*P (a leading column); if $JPIVOT(i) = 0$, the i-th column of A is a free column. On exit, if $JPIVOT(i) = k$, then the i-th column of A^*P was the k-th column of A.

TAU (output)
 The scalar factors of the elementary reflectors.

WORK (workspace)
 dimension(N)

WORK2 (workspace)
 dimension($2*N$)

INFO (output)
 = 0: successful exit
 < 0: if $INFO = -i$, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(n)$$

Each $H(i)$ has the form

$$H = I - \tau * v * v'$$

where τ is a complex scalar, and v is a complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(i+1:m,i)$.

The matrix P is represented in `jpvt` as follows: If

$$\text{jpvt}(j) = i$$

then the j th column of P is the i th canonical unit vector.

COMPLEX, DIMENSION(:, :) :: A  
INTEGER :: M, N, LDA, LDWORK, INFO
```

```
SUBROUTINE GEQRF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
COMPLEX, DIMENSION(:) :: TAU, WORK  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, LDA, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgeqrf(int m, int n, complex *a, int lda, complex *tau,  
           int *info);
```

```
void cgeqrf_64(long m, long n, complex *a, long lda, complex  
              *tau, long *info);
```

PURPOSE

cgeqrf computes a QR factorization of a complex M-by-N matrix A: $A = Q * R$.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M,N)-by-N upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array TAU, represent the unitary matrix Q as a product of min(m,n) elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,M)$.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. $LDWORK \geq \max(1,N)$. For optimum performance $LDWORK \geq N * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(k), \text{ where } k = \min(m,n).$$

Each H(i) has the form

$$H(i) = I - \tau * v * v'$$

where tau is a complex scalar, and v is a complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(i+1:m,i)$, and tau in TAU(i).

NAME

cgerc - perform the rank 1 operation $A := \alpha x \text{conjg}(y') + A$

SYNOPSIS

```
SUBROUTINE CGERC(M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
```

```
COMPLEX ALPHA  
COMPLEX X(*), Y(*), A(LDA,*)  
INTEGER M, N, INCX, INCY, LDA
```

```
SUBROUTINE CGERC_64(M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
```

```
COMPLEX ALPHA  
COMPLEX X(*), Y(*), A(LDA,*)  
INTEGER*8 M, N, INCX, INCY, LDA
```

F95 INTERFACE

```
SUBROUTINE GERC([M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
```

```
COMPLEX :: ALPHA  
COMPLEX, DIMENSION(:) :: X, Y  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER :: M, N, INCX, INCY, LDA
```

```
SUBROUTINE GERC_64([M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
```

```
COMPLEX :: ALPHA  
COMPLEX, DIMENSION(:) :: X, Y  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, INCX, INCY, LDA
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgerc(int m, int n, complex *alpha, complex *x, int  
          incx, complex *y, int incy, complex *a, int lda);
```

```
void cgerc_64(long m, long n, complex *alpha, complex *x,  
             long incx, complex *y, long incy, complex *a, long  
             lda);
```

PURPOSE

cgerc performs the rank 1 operation $A := \alpha * x * \text{conjg}(y')$ + A where alpha is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

ARGUMENTS

M (input)

On entry, M specifies the number of rows of the matrix A. $M \geq 0$. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix A. $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)

$(1 + (m - 1) * \text{abs}(INCX))$. Before entry, the incremented array X must contain the m element vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input)

$(1 + (n - 1) * \text{abs}(INCY))$. Before entry, the incremented array Y must contain the n element vector y. Unchanged on exit.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

A (input/output)

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, m)$. Unchanged on exit.

C INTERFACE

```
#include <sunperf.h>
void cgerfs(char transa, int n, int nrhs, complex *a, int
    lda, complex *af, int ldaf, int *ipivot, complex
    *b, int ldb, complex *x, int ldx, float *ferr,
    float *berr, int *info);

void cgerfs_64(char transa, long n, long nrhs, complex *a,
    long lda, complex *af, long ldaf, long *ipivot,
    complex *b, long ldb, complex *x, long ldx, float
    *ferr, float *berr, long *info);
```

PURPOSE

cgerfs improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

ARGUMENTS

TRANSA (input)
Specifies the form of the system of equations:
= 'N': $A * X = B$ (No transpose)
= 'T': $A^{**T} * X = B$ (Transpose)
= 'C': $A^{**H} * X = B$ (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The original N-by-N matrix A.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, N)$.

AF (input)
The factors L and U from the factorization $A = P * L * U$ as computed by CGETRF.

LDAF (input)
The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

IPIVOT (input)
The pivot indices from CGETRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, N)$.

X (input/output)

On entry, the solution matrix X, as computed by CGETRS. On exit, the improved solution matrix X.

LDX (input)

The leading dimension of the array X. LDX \geq max(1,N).

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

dimension(2*N)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

```

```
COMPLEX, DIMENSION(:) :: TAU, WORK  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER :: M, N, LDA, LDWORK, INFO
```

```
SUBROUTINE GERQF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
COMPLEX, DIMENSION(:) :: TAU, WORK  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, LDA, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgerqf(int m, int n, complex *a, int lda, complex *tau,  
           int *info);
```

```
void cgerqf_64(long m, long n, complex *a, long lda, complex  
              *tau, long *info);
```

PURPOSE

cgerqf computes an RQ factorization of a complex M-by-N matrix A: $A = R * Q$.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, if $m \leq n$, the upper triangle of the subarray A(1:m,n-m+1:n) contains the M-by-M upper triangular matrix R; if $m > n$, the elements on and above the (m-n)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAU, represent the unitary matrix Q as a product of $\min(m,n)$ elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,M)$.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. $LDWORK \geq \max(1,M)$. For optimum performance $LDWORK \geq M * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$Q = H(1)' H(2)' \dots H(k)'$, where $k = \min(m,n)$.
Each H(i) has the form

$$H(i) = I - \tau * v * v'$$

where tau is a complex scalar, and v is a complex vector

with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $\text{conjg}(v(1:n-k+i-1))$
is stored on exit in $A(m-k+i, 1:n-k+i-1)$, and tau in $\text{TAU}(i)$.

COMPLEX :: ALPHA  
COMPLEX, DIMENSION(:) :: X, Y  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, INCX, INCY, LDA
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgeru(int m, int n, complex *alpha, complex *x, int  
          incx, complex *y, int incy, complex *a, int lda);
```

```
void cgeru_64(long m, long n, complex *alpha, complex *x,  
             long incx, complex *y, long incy, complex *a, long  
             lda);
```

PURPOSE

cgeru performs the rank 1 operation $A := \alpha * x * y' + A$ where alpha is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

ARGUMENTS

- M (input)
On entry, M specifies the number of rows of the matrix A. $M \geq 0$. Unchanged on exit.
- N (input)
On entry, N specifies the number of columns of the matrix A. $N \geq 0$. Unchanged on exit.
- ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
- X (input)
($1 + (m - 1) * \text{abs}(\text{INCX})$). Before entry, the incremented array X must contain the m element vector x. Unchanged on exit.
- INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.
- Y (input)
($1 + (n - 1) * \text{abs}(\text{INCY})$). Before entry, the incremented array Y must contain the n element vector y. Unchanged on exit.
- INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.
- A (input/output)
Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.
- LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, m)$. Unchanged on exit.

               lda, float *s, complex *u, long ldu, complex *vt,
               long ldvt, long *info);
```

PURPOSE

cgesdd computes the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors, by using divide-and-conquer method. The SVD is written

$$= U * SIGMA * conjugate-transpose(V)$$

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M unitary matrix, and V is an N-by-N unitary matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns $VT = V^{*H}$, not V.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)

Specifies options for computing all or part of the matrix U:

= 'A': all M columns of U and all N rows of V^{*H} are returned in the arrays U and VT; = 'S': the first min(M,N) columns of U and the first min(M,N) rows of V^{*H} are returned in the arrays U and VT; = 'O': If $M \geq N$, the first N columns of U are overwritten on the array A and all rows of V^{*H} are returned in the array VT; otherwise, all columns of U are returned in the array U and the first M rows of V^{*H} are overwritten in the array VT; = 'N': no columns of U or rows of V^{*H} are computed.

M (input) The number of rows of the input matrix A. $M \geq 0$.

N (input) The number of columns of the input matrix A. $N \geq 0$.

A (input/output)
On entry, the M-by-N matrix A. On exit, if JOBZ = 'O', A is overwritten with the first N columns of U (the left singular vectors, stored columnwise) if $M \geq N$; A is overwritten with the first M rows of V^*H (the right singular vectors, stored rowwise) otherwise. If JOBZ .ne. 'O', the contents of A are destroyed.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, M)$.

S (output)
The singular values of A, sorted so that $S(i) \geq S(i+1)$.

U (output)
 $UCOL = M$ if JOBZ = 'A' or JOBZ = 'O' and $M < N$;
 $UCOL = \min(M, N)$ if JOBZ = 'S'. If JOBZ = 'A' or JOBZ = 'O' and $M < N$, U contains the M-by-M unitary matrix U; if JOBZ = 'S', U contains the first $\min(M, N)$ columns of U (the left singular vectors, stored columnwise); if JOBZ = 'O' and $M \geq N$, or JOBZ = 'N', U is not referenced.

LDU (input)
The leading dimension of the array U. $LDU \geq 1$;
if JOBZ = 'S' or 'A' or JOBZ = 'O' and $M < N$, $LDU \geq M$.

VT (output)
If JOBZ = 'A' or JOBZ = 'O' and $M \geq N$, VT contains the N-by-N unitary matrix V^*H ; if JOBZ = 'S', VT contains the first $\min(M, N)$ rows of V^*H (the right singular vectors, stored rowwise); if JOBZ = 'O' and $M < N$, or JOBZ = 'N', VT is not referenced.

LDVT (input)
The leading dimension of the array VT. $LDVT \geq 1$;
if JOBZ = 'A' or JOBZ = 'O' and $M \geq N$, $LDVT \geq N$;
if JOBZ = 'S', $LDVT \geq \min(M, N)$.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. $LWORK \geq 1$.
if JOBZ = 'N', $LWORK \geq 2 \cdot \min(M, N) + \max(M, N)$.
if JOBZ = 'O', $LWORK \geq 2 \cdot \min(M, N) \cdot \min(M, N) + 2 \cdot \min(M, N) + \max(M, N)$.
if JOBZ = 'S' or 'A', $LWORK \geq \min(M, N) \cdot \min(M, N) + 2 \cdot \min(M, N) + \max(M, N)$.
For good performance, LWORK should generally be larger. If $LWORK < 0$ but other input arguments are legal, WORK(1) returns optimal LWORK.

RWORK (workspace)
If JOBZ = 'N', LRWORK $\geq 7 \cdot \min(M, N)$. Otherwise,

$LWORK \geq 5 \cdot \min(M,N) \cdot \min(M,N) + 5 \cdot \min(M,N)$

IWORK (workspace)
dimension(8*MIN(M,N))

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: The updating process of SBDSDC did not converge.

```

```
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER :: N, NRHS, LDA, LDB, INFO
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE GESV_64([N], [NRHS], A, [LDA], IPIVOT, B, [LDB], [INFO])
```

```
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgsv(int n, int nrhs, complex *a, int lda, int
         *ipivot, complex *b, int ldb, int *info);
```

```
void cgsv_64(long n, long nrhs, complex *a, long lda, long
            *ipivot, complex *b, long ldb, long *info);
```

PURPOSE

cgsv computes the solution to a complex system of linear equations

$A * X = B$, where A is an N -by- N matrix and X and B are N -by- $NRHS$ matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as

$$A = P * L * U,$$

where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

N (input) The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

$NRHS$ (input)
The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input/output)
On entry, the N -by- N coefficient matrix A . On exit, the factors L and U from the factorization $A = P*L*U$; the unit diagonal elements of L are not stored.

LDA (input)
The leading dimension of the array A . $LDA \geq \max(1,N)$.

$IPIVOT$ (output)
The pivot indices that define the permutation matrix P ; row i of the matrix was interchanged with row $IPIVOT(i)$.

B (input/output)
On entry, the N -by- $NRHS$ matrix of right hand side matrix B . On exit, if $INFO = 0$, the N -by- $NRHS$ solution matrix X .

LDB (input)
The leading dimension of the array B . $LDB \geq \max(1,N)$.

$INFO$ (output)
= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value
> 0: if $INFO = i$, $U(i,i)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.

               plex *a, long lda, float *sing, complex *u, long
               ldu, complex *vt, long ldvt, long *info);

```

PURPOSE

cgesvd computes the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors. The SVD is written

$$= U * \text{SIGMA} * \text{conjugate-transpose}(V)$$

where SIGMA is an M-by-N matrix which is zero except for its $\min(m,n)$ diagonal elements, U is an M-by-M unitary matrix, and V is an N-by-N unitary matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first $\min(m,n)$ columns of U and V are the left and right singular vectors of A.

Note that the routine returns V^{*H} , not V.

ARGUMENTS

JOBU (input)

Specifies options for computing all or part of the matrix U:

- = 'A': all M columns of U are returned in array U;
- = 'S': the first $\min(m,n)$ columns of U (the left singular vectors) are returned in the array U;
- = 'O': the first $\min(m,n)$ columns of U (the left singular vectors) are overwritten on the array A;
- = 'N': no columns of U (no left singular vectors) are computed.

JOBVT (input)

Specifies options for computing all or part of the matrix V^{*H} :

- = 'A': all N rows of V^{*H} are returned in the array VT;
- = 'S': the first $\min(m,n)$ rows of V^{*H} (the right singular vectors) are returned in the array VT;
- = 'O': the first $\min(m,n)$ rows of V^{*H} (the right singular vectors) are overwritten on the array A;
- = 'N': no rows of V^{*H} (no right singular vectors) are computed.

JOBVT and JOBVT cannot both be 'O'.

M (input) The number of rows of the input matrix A. $M \geq 0$.

N (input) The number of columns of the input matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, if JOBVT = 'O', A is overwritten with the first $\min(m,n)$

columns of U (the left singular vectors, stored columnwise); if JOBVT = 'O', A is overwritten with the first min(m,n) rows of V**H (the right singular vectors, stored rowwise); if JOBU .ne. 'O' and JOBVT .ne. 'O', the contents of A are destroyed.

LDA (input)

The leading dimension of the array A. LDA \geq max(1,M).

SING (output)

The singular values of A, sorted so that SING(i) \geq SING(i+1).

U (input) (LDU,M) if JOBU = 'A' or (LDU,min(M,N)) if JOBU = 'S'. If JOBU = 'A', U contains the M-by-M unitary matrix U; if JOBU = 'S', U contains the first min(m,n) columns of U (the left singular vectors, stored columnwise); if JOBU = 'N' or 'O', U is not referenced.

LDU (input)

The leading dimension of the array U. LDU \geq 1; if JOBU = 'S' or 'A', LDU \geq M.

VT (input)

If JOBVT = 'A', VT contains the N-by-N unitary matrix V**H; if JOBVT = 'S', VT contains the first min(m,n) rows of V**H (the right singular vectors, stored rowwise); if JOBVT = 'N' or 'O', VT is not referenced.

LDVT (input)

The leading dimension of the array VT. LDVT \geq 1; if JOBVT = 'A', LDVT \geq N; if JOBVT = 'S', LDVT \geq min(M,N).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK \geq 1. LDWORK \geq 2*MIN(M,N)+MAX(M,N) For good performance, LDWORK should generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)

DIMENSION(5*MIN(M,N)). On exit, if INFO $>$ 0, WORK2(1:MIN(M,N)-1) contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in SING (not necessarily sorted). B satisfies $A = U * B * VT$, so it has the same singular values as A, and singular vectors related by U and VT.

INFO (output)

= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

> 0: if CBDSQR did not converge, INFO specifies how many superdiagonals of an intermediate bidiagonal form B did not converge to zero. See the description of WORK2 above for details.

```

C INTERFACE

```
#include <sunperf.h>
```

```

void cgesvx(char fact, char transa, int n, int nrhs, complex
    *a, int lda, complex *af, int ldaf, int *ipivot,
    char equed, float *rowsc, float *colsc, complex
    *b, int ldb, complex *x, int ldx, float *rcond,
    float *ferr, float *berr, int *info);

```

```

void cgesvx_64(char fact, char transa, long n, long nrhs,
    complex *a, long lda, complex *af, long ldaf, long
    *ipivot, char equed, float *rowsc, float *colsc,
    complex *b, long ldb, complex *x, long ldx, float
    *rcond, float *ferr, float *berr, long *info);

```

PURPOSE

cgesvx uses the LU factorization to compute the solution to a complex system of linear equations

$A * X = B$, where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to equilibrate the system:

```

TRANS = 'N': diag(R)*A*diag(C)      *inv(diag(C))*X =
diag(R)*B
TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X =
diag(C)*B
TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X =
diag(C)*B

```

Whether or not the system will be equilibrated depends on the

scaling of the matrix A, but if equilibration is used, A is

overwritten by $\text{diag}(R)*A*\text{diag}(C)$ and B by $\text{diag}(R)*B$ (if TRANS='N')

or $\text{diag}(C)*B$ (if TRANS = 'T' or 'C').

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the

matrix A (after equilibration if FACT = 'E') as

$$A = P * L * U,$$

where P is a permutation matrix, L is a unit lower triangular

matrix, and U is upper triangular.

3. If some $U(i,i)=0$, so that U is exactly singular, then the

routine
returns with INFO = i. Otherwise, the factored form of A
is used
to estimate the condition number of the matrix A. If the
reciprocal of the condition number is less than machine
precision,
INFO = N+1 is returned as a warning, but the routine
still goes on
to solve for X and compute error bounds as described
below.

4. The system of equations is solved for X using the fac-
tored form
of A.

5. Iterative refinement is applied to improve the computed
solution
matrix and calculate error bounds and backward error
estimates
for it.

6. If equilibration was used, the matrix X is premultiplied
by
diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or
'C') so
that it solves the original system before equilibration.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of the
matrix A is supplied on entry, and if not, whether
the matrix A should be equilibrated before it is
factored. = 'F': On entry, AF and IPIVOT contain
the factored form of A. If EQUED is not 'N', the
matrix A has been equilibrated with scaling fac-
tors given by ROWSC and COLSC. A, AF, and IPIVOT
are not modified. = 'N': The matrix A will be
copied to AF and factored.
= 'E': The matrix A will be equilibrated if
necessary, then copied to AF and factored.

TRANS (input)

Specifies the form of the system of equations:
= 'N': $A * X = B$ (No transpose)
= 'T': $A^{**T} * X = B$ (Transpose)
= 'COLSC': $A^{**H} * X = B$ (Conjugate transpose)

TRANS is defaulted to 'N' for F95 INTERFACE.

N (input) The number of linear equations, i.e., the order of
the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number
of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output)

On entry, the N-by-N matrix A. If FACT = 'F' and
EQUED is not 'N', then A must have been equili-
brated by the scaling factors in ROWSC and/or
COLSC. A is not modified if FACT = 'F' or 'N', or

if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows:
EQUED = 'ROWSC': A := diag(ROWSC) * A
EQUED = 'COLSC': A := A * diag(COLSC)
EQUED = 'B': A := diag(ROWSC) * A * diag(COLSC).

LDA (input)

The leading dimension of the array A. LDA >= max(1,N).

AF (input/output)

If FACT = 'F', then AF is an input argument and on entry contains the factors L and U from the factorization $A = P*L*U$ as computed by CGETRF. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization $A = P*L*U$ of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization $A = P*L*U$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)

The leading dimension of the array AF. LDAF >= max(1,N).

IPIVOT (input or output)

If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the factorization $A = P*L*U$ as computed by CGETRF; row i of the matrix was interchanged with row IPIVOT(i).

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = P*L*U$ of the original matrix A.

If FACT = 'E', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = P*L*U$ of the equilibrated matrix A.

EQUED (input)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'ROWSC': Row equilibration, i.e., A has been premultiplied by diag(ROWSC).
= 'COLSC': Column equilibration, i.e., A has been postmultiplied by diag(COLSC).
= 'B': Both row and column equilibration, i.e., A has been replaced by $\text{diag}(\text{ROWSC}) * A * \text{diag}(\text{COLSC})$. EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

ROWSC (input/output)

The row scale factors for A. If EQUED = 'ROWSC' or 'B', A is multiplied on the left by diag(ROWSC); if EQUED = 'N' or 'COLSC', ROWSC is not accessed. ROWSC is an input argument if FACT

= 'F'; otherwise, ROWSC is an output argument. If FACT = 'F' and EQUED = 'ROWSC' or 'B', each element of ROWSC must be positive.

COLSC (input/output)

The column scale factors for A. If EQUED = 'COLSC' or 'B', A is multiplied on the right by diag(COLSC); if EQUED = 'N' or 'ROWSC', COLSC is not accessed. COLSC is an input argument if FACT = 'F'; otherwise, COLSC is an output argument. If FACT = 'F' and EQUED = 'COLSC' or 'B', each element of COLSC must be positive.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANSA = 'N' and EQUED = 'ROWSC' or 'B', B is overwritten by diag(ROWSC)*B; if TRANSA = 'T' or 'COLSC' and EQUED = 'COLSC' or 'B', B is overwritten by diag(COLSC)*B.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,N).

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(COLSC))*X if TRANSA = 'N' and EQUED = 'COLSC' or 'B', or inv(diag(ROWSC))*X if TRANSA = 'T' or 'COLSC' and EQUED = 'ROWSC' or 'B'.

LDX (input)

The leading dimension of the array X. LDX \geq max(1,N).

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO $>$ 0.

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

dimension(2*N)

WORK2 (workspace)

dimension(2*N) On exit, WORK2(1) contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$. The "max absolute element" norm is used. If WORK2(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with $0 < \text{INFO} \leq N$, then WORK2(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

```

```
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, LDA, INFO  
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgetf2(int m, int n, complex *a, int lda, int *ipiv,  
           int *info);
```

```
void cgetf2_64(long m, long n, complex *a, long lda, long  
              *ipiv, long *info);
```

PURPOSE

cgetf2 computes an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges.

The factorization has the form

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$).

This is the right-looking Level 2 BLAS version of the algorithm.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the m by n matrix to be factored. On exit, the factors L and U from the factorization $A = P*L*U$; the unit diagonal elements of L are not stored.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

IPIV (output)

The pivot indices; for $1 \leq i \leq \min(M, N)$, row i of the matrix was interchanged with row IPIV(i).

INFO (output)

= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

           int *info);
```

```
void cgetrf_64(long m, long n, complex *a, long lda, long  
              *ipivot, long *info);
```

PURPOSE

cgetrf computes an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges.

The factorization has the form

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$).

This is the right-looking Level 3 BLAS version of the algorithm.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix to be factored. On exit, the factors L and U from the factorization $A = P*L*U$; the unit diagonal elements of L are not stored.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,M)$.

IPIVOT (output)

The pivot indices; for $1 \leq i \leq \min(M,N)$, row i of the matrix was interchanged with row IPIVOT(i).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NAME

cgetri - compute the inverse of a matrix using the LU factorization computed by CGETRF

SYNOPSIS

```
SUBROUTINE CGETRI(N, A, LDA, IPIVOT, WORK, LDWORK, INFO)
```

```
COMPLEX A(LDA,*), WORK(*)
INTEGER N, LDA, LDWORK, INFO
INTEGER IPIVOT(*)
```

```
SUBROUTINE CGETRI_64(N, A, LDA, IPIVOT, WORK, LDWORK, INFO)
```

```
COMPLEX A(LDA,*), WORK(*)
INTEGER*8 N, LDA, LDWORK, INFO
INTEGER*8 IPIVOT(*)
```

F95 INTERFACE

```
SUBROUTINE GETRI([N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])
```

```
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:,:) :: A
INTEGER :: N, LDA, LDWORK, INFO
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE GETRI_64([N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])
```

```
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, LDWORK, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgetri(int n, complex *a, int lda, int *ipivot, int
           *info);
```

```
void cgetri_64(long n, complex *a, long lda, long *ipivot,
              long *info);
```

PURPOSE

cgetri computes the inverse of a matrix using the LU factorization computed by CGETRF.

This method inverts U and then computes $\text{inv}(A)$ by solving the system $\text{inv}(A)*L = \text{inv}(U)$ for $\text{inv}(A)$.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
On entry, the factors L and U from the factorization $A = P*L*U$ as computed by CGETRF. On exit, if $\text{INFO} = 0$, the inverse of the original matrix A.

LDA (input)
The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

IPIVOT (input)
The pivot indices from CGETRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

WORK (workspace)
On exit, if $\text{INFO} = 0$, then $\text{WORK}(1)$ returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. $\text{LDWORK} \geq \max(1, N)$. For optimal performance $\text{LDWORK} \geq N*NB$, where NB is the optimal blocksize returned by ILAENV.

If $\text{LDWORK} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if $\text{INFO} = -i$, the i-th argument had an illegal value
> 0: if $\text{INFO} = i$, $U(i, i)$ is exactly zero; the matrix is singular and its inverse could not be computed.

              *info);
```

PURPOSE

cgetrs solves a system of linear equations

$A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$ with a general N -by- N matrix A using the LU factorization computed by CGETRF.

ARGUMENTS

TRANSA (input)

Specifies the form of the system of equations:

= 'N': $A * X = B$ (No transpose)

= 'T': $A^{**T} * X = B$ (Transpose)

= 'C': $A^{**H} * X = B$ (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input) The factors L and U from the factorization $A = P * L * U$ as computed by CGETRF.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (input)

The pivot indices from CGETRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

B (input/output)

On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

INFO (output)

= 0: successful exit

< 0: if $INFO = -i$, the i -th argument had an illegal value

```

```
CHARACTER(LEN=1) :: JOB, SIDE
COMPLEX, DIMENSION(:, :) :: V
INTEGER(8) :: N, ILO, IHI, M, LDV, INFO
REAL, DIMENSION(:) :: LSCALE, RSCALE
```

C INTERFACE

```
#include <sunperf.h>

void cggbak(char job, char side, int n, int ilo, int ihi,
            float *lscale, float *rscale, int m, complex *v,
            int ldv, int *info);
void cggbak_64(char job, char side, long n, long ilo, long
               ihi, float *lscale, float *rscale, long m, complex
               *v, long ldv, long *info);
```

PURPOSE

cggbak forms the right or left eigenvectors of a complex generalized eigenvalue problem $A*x = \lambda*B*x$, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by CGGBAL.

ARGUMENTS

JOB (input)
 Specifies the type of backward transformation required:
 = 'N': do nothing, return immediately;
 = 'P': do backward transformation for permutation only;
 = 'S': do backward transformation for scaling only;
 = 'B': do backward transformations for both permutation and scaling. JOB must be the same as the argument JOB supplied to CGGBAL.

SIDE (input)
 = 'R': V contains right eigenvectors;
 = 'L': V contains left eigenvectors.

N (input) The number of rows of the matrix V. $N \geq 0$.

ILO (input)
 The integers ILO and IHI determined by CGGBAL. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

IHI (input)
 The integers ILO and IHI determined by CGGBAL. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

LSCALE (input)
 Details of the permutations and/or scaling factors applied to the left side of A and B, as returned by CGGBAL.

RSCALE (input)
 Details of the permutations and/or scaling factors applied to the right side of A and B, as returned by CGGBAL.

M (input) The number of columns of the matrix V. $M \geq 0$.

V (input/output)
 On entry, the matrix of right or left eigenvectors to be transformed, as returned by CTGEVC. On

exit, V is overwritten by the transformed eigenvectors.

LDV (input)

The leading dimension of the matrix V. LDV \geq max(1,N).

INFO (output)

= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value.

#include <sunperf.h>
```

```
void cggbal(char job, int n, complex *a, int lda, complex
```

```

        *b, int ldb, int *ilo, int *ihi, float *lscale,
        float *rscale, int *info);

void cggbal_64(char job, long n, complex *a, long lda, com-
plex *b, long ldb, long *ilo, long *ihi, float
*lscale, float *rscale, long *info);

```

PURPOSE

cggbal balances a pair of general complex matrices (A,B). This involves, first, permuting A and B by similarity transformations to isolate eigenvalues in the first 1 to ILO-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem $A*x = \lambda*B*x$.

ARGUMENTS

JOB (input)

Specifies the operations to be performed on A and B:
 = 'N': none: simply set ILO = 1, IHI = N, LSCALE(I) = 1.0 and RSCALE(I) = 1.0 for i=1,...,N;
 = 'P': permute only;
 = 'S': scale only;
 = 'B': both permute and scale.

N (input) The order of the matrices A and B. N >= 0.

A (input/output)

On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced.

LDA (input)

The leading dimension of the array A. LDA >= max(1,N).

B (input) On entry, the input matrix B. On exit, B is overwritten by the balanced matrix. If JOB = 'N', B is not referenced.

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

ILO (output)

ILO and IHI are set to integers such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i = IHI+1, \dots, N$. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

IHI (output)

ILO and IHI are set to integers such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j =$

1,...,ILO-1 or $i = IHI+1, \dots, N$.

LSCALE (input)

Details of the permutations and scaling factors applied to the left side of A and B. If $P(j)$ is the index of the row interchanged with row j , and $D(j)$ is the scaling factor applied to row j , then $LSCALE(j) = P(j)$ for $J = 1, \dots, ILO-1 = D(j)$ for $J = ILO, \dots, IHI = P(j)$ for $J = IHI+1, \dots, N$. The order in which the interchanges are made is N to $IHI+1$, then 1 to $ILO-1$.

RSCALE (input)

Details of the permutations and scaling factors applied to the right side of A and B. If $P(j)$ is the index of the column interchanged with column j , and $D(j)$ is the scaling factor applied to column j , then $RSCALE(j) = P(j)$ for $J = 1, \dots, ILO-1 = D(j)$ for $J = ILO, \dots, IHI = P(j)$ for $J = IHI+1, \dots, N$. The order in which the interchanges are made is N to $IHI+1$, then 1 to $ILO-1$.

WORK (workspace)

dimension(6*N)

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value.

FURTHER DETAILS

See R.C. WARD, Balancing the generalized eigenvalue problem, SIAM J. Sci. Stat. Comp. 2 (1981), 141-152.

  *a,  long lda,  complex *b,  long ldb,  long *sdim,
  complex *alpha,  complex *beta,  complex *vsl,  long
  ldvsl,  complex *vsr,  long ldvsr,  long *info);

```

PURPOSE

cggas computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized complex Schur form (S, T), and optionally left and/or right Schur vectors (VSL and VSR). This gives the generalized Schur factorization

$$(A,B) = ((VSL)*S*(VSR)**H, (VSL)*T*(VSR)**H)$$

where (VSR)**H is the conjugate-transpose of VSR.

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper triangular matrix S and the upper triangular matrix T. The leading columns of VSL and VSR then form an unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver CGGEV instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

A pair of matrices (S,T) is in generalized complex Schur form if S and T are upper triangular and, in addition, the diagonal elements of T are non-negative real numbers.

ARGUMENTS

JOBVSL (input)
= 'N': do not compute the left Schur vectors;
= 'V': compute the left Schur vectors.

JOBVSR (input)
= 'N': do not compute the right Schur vectors;
= 'V': compute the right Schur vectors.

SORT (input)
Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered;
= 'S': Eigenvalues are ordered (see SELCTG).

SELCTG (input)
SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue ALPHA(j)/BETA(j) is selected if SELCTG(ALPHA(j),BETA(j)) is true.

Note that a selected complex eigenvalue may no longer satisfy SELCTG(ALPHA(j),BETA(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+2 (See INFO below).

N (input) The order of the matrices A, B, VSL, and VSR. N >= 0.

A (input/output)
On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA (input)
The leading dimension of A. LDA >= max(1,N).

B (input/output)
On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB (input)
The leading dimension of B. LDB >= max(1,N).

SDIM (output)
If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELCTG is true.

ALPHA (output)
On exit, ALPHA(j)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHA(j), j=1,...,N and BETA(j), j=1,...,N are the diagonals of the complex Schur form (A,B) output by CGGES. The BETA(j) will be non-negative real.

Note: the quotients ALPHA(j)/BETA(j) may easily overflow or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the

ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

BETA (output)

See description of ALPHA.

VSL (input)

If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL (input)

The leading dimension of the matrix VSL. LDVSL \geq 1, and if JOBVSL = 'V', LDVSL \geq N.

VSR (input)

If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR (input)

The leading dimension of the matrix VSR. LDVSR \geq 1, and if JOBVSR = 'V', LDVSR \geq N.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK \geq max(1,2*N). For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

dimension(8*N)

BWORK (workspace)

dimension(N) Not referenced if SORT = 'N'.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
=1,...,N: The QZ iteration failed. (A,B) are not in Schur form, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in CHGEQZ
=N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy SELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in CTGSEN.

```

PURPOSE

cggesx computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the complex Schur form (S,T), and, optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization $A,B) = (VSL) S (VSR)**H$, $(VSL) T (VSR)**H$)

where $(VSR)**H$ is the conjugate-transpose of VSR.

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper triangular matrix S and the upper triangular matrix T; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues (RCONDV). The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio $\alpha/\beta = w$, such that $A - w*B$ is singular. It is usually represented as the pair

(alpha,beta), as there is a reasonable interpretation for beta=0 or for both being zero.

A pair of matrices (S,T) is in generalized complex Schur form if T is upper triangular with non-negative diagonal and S is upper triangular.

ARGUMENTS

JOBVSL (input)

= 'N': do not compute the left Schur vectors;
= 'V': compute the left Schur vectors.

JOBVSR (input)

= 'N': do not compute the right Schur vectors;
= 'V': compute the right Schur vectors.

SORT (input)

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered;
= 'S': Eigenvalues are ordered (see SELCTG).

SELCTG (input)

SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. Note that a selected complex eigenvalue may no longer satisfy SELCTG(ALPHA(j),BETA(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+3 see INFO below).

SENSE (input)

Determines which reciprocal condition numbers are computed. = 'N' : None are computed;
= 'E' : Computed for average of selected eigenvalues only;
= 'V' : Computed for selected deflating subspaces only;
= 'B' : Computed for both. If SENSE = 'E', 'V', or 'B', SORT must equal 'S'.

N (input) The order of the matrices A, B, VSL, and VSR. N >= 0.

A (input/output)

On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA (input)

The leading dimension of A. LDA >= max(1,N).

B (input/output)

On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB (input)

The leading dimension of B. $LDB \geq \max(1,N)$.

SDIM (output)

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELECTG is true.

ALPHA (output)

On exit, ALPHA(j)/BETA(j), $j=1,\dots,N$, will be the generalized eigenvalues. ALPHA(j) and BETA(j), $j=1,\dots,N$ are the diagonals of the complex Schur form (S,T). BETA(j) will be non-negative real.

Note: the quotients ALPHA(j)/BETA(j) may easily overflow or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

BETA (output)

See description of ALPHA.

VSL (input)

If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL (input)

The leading dimension of the matrix VSL. LDVSL ≥ 1 , and if JOBVSL = 'V', LDVSL $\geq N$.

VSR (input)

If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR (input)

The leading dimension of the matrix VSR. LDVSR ≥ 1 , and if JOBVSR = 'V', LDVSR $\geq N$.

RCONDE (output)

If SENSE = 'E' or 'B', RCONDE(1) and RCONDE(2) contain the reciprocal condition numbers for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

RCONDV (output)

If SENSE = 'V' or 'B', RCONDV(1) and RCONDV(2) contain the reciprocal condition number for the selected deflating subspaces. Not referenced if SENSE = 'N' or 'E'.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK $\geq 2*N$. If SENSE = 'E', 'V', or 'B', LWORK $\geq \max(2*N, 2*SDIM*(N-SDIM))$.

RWORK (workspace)

dimension(8*N) Real workspace.

IWORK (workspace/output)

Not referenced if SENSE = 'N'. On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of the array WORK. LIWORK \geq N+2.

BWORK (workspace)

dimension(N) Not referenced if SORT = 'N'.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value.

= 1,...,N: The QZ iteration failed. (A,B) are not in Schur form, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in CHGEQZ

=N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy SELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in CTGSEN.

#include <sunperf.h>
void cggev(char jobvl, char jobvr, int n, complex *a, int
           lda, complex *b, int ldb, complex *alpha, complex
           *beta, complex *vl, int ldvl, complex *vr, int
           ldvr, int *info);

void cggev_64(char jobvl, char jobvr, long n, complex *a,
              long lda, complex *b, long ldb, complex *alpha,
              complex *beta, complex *vl, long ldvl, complex
              *vr, long ldvr, long *info);
```

PURPOSE

cggev computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar λ or a ratio $\alpha/\beta = \lambda$, such that $A - \lambda B$ is singular. It is usually represented as the pair (α, β), as there is a reasonable interpretation for $\beta=0$, and even for both being zero.

The right generalized eigenvector $v(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A,B) satisfies

$$A * v(j) = \lambda(j) * B * v(j).$$

The left generalized eigenvector $u(j)$ corresponding to the generalized eigenvalues $\lambda(j)$ of (A,B) satisfies

$$u(j)**H * A = \lambda(j) * u(j)**H * B$$

where $u(j)**H$ is the conjugate-transpose of $u(j)$.

ARGUMENTS

JOBVL (input)

= 'N': do not compute the left generalized eigenvectors;
= 'V': compute the left generalized eigenvectors.

JOBVR (input)

= 'N': do not compute the right generalized eigenvectors;
= 'V': compute the right generalized eigenvectors.

N (input) The order of the matrices A, B, VL, and VR. $N \geq 0$.

A (input/output)

On entry, the matrix A in the pair (A,B). On exit, A has been overwritten.

LDA (input)

The leading dimension of A. $LDA \geq \max(1, N)$.

B (input/output)

On entry, the matrix B in the pair (A,B). On

exit, B has been overwritten.

LDB (input)

The leading dimension of B. $LDB \geq \max(1, N)$.

ALPHA (output)

On exit, $ALPHA(j)/BETA(j)$, $j=1, \dots, N$, will be the generalized eigenvalues.

Note: the quotients $ALPHA(j)/BETA(j)$ may easily overflow or underflow, and $BETA(j)$ may even be zero. Thus, the user should avoid naively computing the ratio $alpha/beta$. However, $ALPHA$ will be always less than and usually comparable with $norm(A)$ in magnitude, and $BETA$ always less than and usually comparable with $norm(B)$.

BETA (output)

See description of ALPHA.

VL (input)

If $JOBVL = 'V'$, the left generalized eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have $abs(\text{real part}) + abs(\text{imag. part}) = 1$. Not referenced if $JOBVL = 'N'$.

LDVL (input)

The leading dimension of the matrix VL. $LDVL \geq 1$, and if $JOBVL = 'V'$, $LDVL \geq N$.

VR (input)

If $JOBVR = 'V'$, the right generalized eigenvectors $v(j)$ are stored one after another in the columns of VR, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have $abs(\text{real part}) + abs(\text{imag. part}) = 1$. Not referenced if $JOBVR = 'N'$.

LDVR (input)

The leading dimension of the matrix VR. $LDVR \geq 1$, and if $JOBVR = 'V'$, $LDVR \geq N$.

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. $LWORK \geq \max(1, 2*N)$. For good performance, LWORK must generally be larger.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

dimension($8*N$)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value.
=1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,...,N. >
N: =N+1: other than QZ iteration failed in SHGEQZ,
=N+2: error return from STGEVC.

```

PURPOSE

cggev computes for a pair of N-by-N complex nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally, it also computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, LSCALE, RSCALE, ABNRM, and BBNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right eigenvector v(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

$$A * v(j) = lambda(j) * B * v(j) .$$

The left eigenvector u(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

$$u(j)**H * A = lambda(j) * u(j)**H * B .$$

where u(j)**H is the conjugate-transpose of u(j).

ARGUMENTS

BALANC (input)

Specifies the balance option to be performed:
= 'N': do not diagonally scale or permute;
= 'P': permute only;
= 'S': scale only;
= 'B': both permute and scale. Computed reciprocal condition numbers will be for the matrices after permuting and/or balancing. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL (input)

= 'N': do not compute the left generalized eigenvectors;
= 'V': compute the left generalized eigenvectors.

JOBVR (input)

= 'N': do not compute the right generalized eigenvectors;
= 'V': compute the right generalized eigenvectors.

SENSE (input)

Determines which reciprocal condition numbers are computed. = 'N': none are computed;
= 'E': computed for eigenvalues only;
= 'V': computed for eigenvectors only;
= 'B': computed for eigenvalues and eigenvectors.

N (input) The order of the matrices A, B, VL, and VR. $N \geq 0$.

A (input/output)

On entry, the matrix A in the pair (A,B). On exit, A has been overwritten. If JOBVL='V' or JOBVR='V' or both, then A contains the first part of the complex Schur form of the "balanced" versions of the input A and B.

LDA (input)

The leading dimension of A. $LDA \geq \max(1,N)$.

B (input/output)

On entry, the matrix B in the pair (A,B). On exit, B has been overwritten. If JOBVL='V' or JOBVR='V' or both, then B contains the second part of the complex Schur form of the "balanced" versions of the input A and B.

LDB (input)

The leading dimension of B. $LDB \geq \max(1,N)$.

ALPHA (output)

On exit, $ALPHA(j)/BETA(j)$, $j=1,\dots,N$, will be the generalized eigenvalues.

Note: the quotient $ALPHA(j)/BETA(j)$ may easily overflow or underflow, and $BETA(j)$ may even be zero. Thus, the user should avoid naively computing the ratio $ALPHA/BETA$. However, $ALPHA$ will be always less than and usually comparable with $norm(A)$ in

magnitude, and BETA always less than and usually comparable with norm(B).

BETA (output)

See description of ALPHA.

VL (output)

If JOBVL = 'V', the left generalized eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$. Not referenced if JOBVL = 'N'.

LDVL (input)

The leading dimension of the matrix VL. LDVL ≥ 1 , and if JOBVL = 'V', LDVL $\geq N$.

VR (input)

If JOBVR = 'V', the right generalized eigenvectors $v(j)$ are stored one after another in the columns of VR, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$. Not referenced if JOBVR = 'N'.

LDVR (input)

The leading dimension of the matrix VR. LDVR ≥ 1 , and if JOBVR = 'V', LDVR $\geq N$.

ILO (output)

ILO is an integer value such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1, \dots, \text{ILO}-1$ or $i = \text{IHI}+1, \dots, N$. If BALANC = 'N' or 'S', ILO = 1 and IHI = N.

IHI (output)

IHI is an integer value such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1, \dots, \text{ILO}-1$ or $i = \text{IHI}+1, \dots, N$. If BALANC = 'N' or 'S', ILO = 1 and IHI = N.

LSCALE (output)

Details of the permutations and scaling factors applied to the left side of A and B. If PL(j) is the index of the row interchanged with row j, and DL(j) is the scaling factor applied to row j, then LSCALE(j) = PL(j) for $j = 1, \dots, \text{ILO}-1$ = DL(j) for $j = \text{ILO}, \dots, \text{IHI}$ = PL(j) for $j = \text{IHI}+1, \dots, N$. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

RSCALE (output)

Details of the permutations and scaling factors applied to the right side of A and B. If PR(j) is the index of the column interchanged with column j, and DR(j) is the scaling factor applied to column j, then RSCALE(j) = PR(j) for $j = 1, \dots, \text{ILO}-1$ = DR(j) for $j = \text{ILO}, \dots, \text{IHI}$ = PR(j) for $j = \text{IHI}+1, \dots, N$. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

ABNRM (output)

The one-norm of the balanced matrix A.

BBNRM (output)

The one-norm of the balanced matrix B.

RCONDE (output)

If SENSE = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. If SENSE = 'V', RCONDE is not referenced.

RCONDV (output)

If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. If the eigenvalues cannot be reordered to compute RCONDV(j), RCONDV(j) is set to 0; this can only occur when the true value would be very small anyway. If SENSE = 'E', RCONDV is not referenced. Not referenced if JOB = 'E'.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK \geq max(1,2*N). If SENSE = 'N' or 'E', LWORK \geq 2*N. If SENSE = 'V' or 'B', LWORK \geq 2*N*N+2*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

dimension(6*N) Real workspace.

IWORK (workspace)

dimension(N+2) If SENSE = 'E', IWORK is not referenced.

BWORK (workspace)

dimension(N) If SENSE = 'N', BWORK is not referenced.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,...,N.
> N: =N+1: other than QZ iteration failed in CHGEQZ.
=N+2: error return from CTGEVC.

FURTHER DETAILS

Balancing a matrix pair (A,B) includes, first, permuting rows and columns to isolate eigenvalues, second, applying diagonal similarity transformation to the rows and columns to make the rows and columns as close in norm as possible. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal

scaling will. For further explanation of balancing, see section 4.11.1.2 of LAPACK Users' Guide.

An approximate error bound on the chordal distance between the i -th computed generalized eigenvalue w and the corresponding exact eigenvalue λ is

$$\text{hord}(w, \lambda) \leq \text{EPS} * \text{norm}(\text{ABNRM}, \text{BBNRM}) / \text{RCONDE}(I)$$

An approximate error bound for the angle between the i -th computed eigenvector $\text{VL}(i)$ or $\text{VR}(i)$ is given by

$$\text{PS} * \text{norm}(\text{ABNRM}, \text{BBNRM}) / \text{DIF}(i).$$

For further explanation of the reciprocal condition numbers RCONDE and RCONDV , see section 4.11 of LAPACK User's Guide.

```

```
void cgggglm_64(long n, long m, long p, complex *a, long lda,
  complex *b, long ldb, complex *d, complex *x, com-
  plex *y, long *info);
```

PURPOSE

cgglm solves a general Gauss-Markov linear model (GLM) problem:

$$\underset{x}{\text{minimize}} \quad || y ||_2 \quad \text{subject to} \quad d = A*x + B*y$$

where A is an N-by-M matrix, B is an N-by-P matrix, and d is a given N-vector. It is assumed that $M \leq N \leq M+P$, and

$$\text{rank}(A) = M \quad \text{and} \quad \text{rank}(A \ B) = N.$$

Under these assumptions, the constrained equation is always consistent, and there is a unique solution x and a minimal 2-norm solution y, which is obtained using a generalized QR factorization of A and B.

In particular, if matrix B is square nonsingular, then the problem GLM is equivalent to the following weighted linear least squares problem

$$\underset{x}{\text{minimize}} \quad || \text{inv}(B)*(d-A*x) ||_2$$

where inv(B) denotes the inverse of B.

ARGUMENTS

N (input) The number of rows of the matrices A and B. $N \geq 0$.

M (input) The number of columns of the matrix A. $0 \leq M \leq N$.

P (input) The number of columns of the matrix B. $P \geq N-M$.

A (input/output)
On entry, the N-by-M matrix A. On exit, A is destroyed.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1,N)$.

B (input/output)
On entry, the N-by-P matrix B. On exit, B is destroyed.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1,N)$.

D (input/output)
On entry, D is the left hand side of the GLM equation. On exit, D is destroyed.

X (output)
On exit, X and Y are the solutions of the GLM problem.

Y (output)

On exit, X and Y are the solutions of the GLM problem.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK \geq $\max(1, N+M+P)$. For optimum performance, LDWORK $\geq M + \min(N, P) + \max(N, P) * NB$, where NB is an upper bound for the optimal blocksizes for CGEQRF, CGERQF, CUNMQR and CUNMRQ.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value.

```

```
void cgghrd_64(char compq, char compz, long n, long ilo,
              long ihi, complex *a, long lda, complex *b, long
              ldb, complex *q, long ldq, complex *z, long ldz,
              long *info);
```

PURPOSE

cgghrd reduces a pair of complex matrices (A,B) to generalized upper Hessenberg form using unitary transformations, where A is a general matrix and B is upper triangular: $Q' * A * Z = H$ and $Q' * B * Z = T$, where H is upper Hessenberg, T is upper triangular, and Q and Z are unitary, and ' ' means conjugate transpose.

The unitary matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q1 and Z1, so that

$$1 * A * Z1' = (Q1*Q) * H * (Z1*Z)'$$

ARGUMENTS

COMPQ (input)

= 'N': do not compute Q;
 = 'I': Q is initialized to the unit matrix, and the unitary matrix Q is returned; = 'V': Q must contain a unitary matrix Q1 on entry, and the product Q1*Q is returned.

COMPZ (input)

= 'N': do not compute Q;
 = 'I': Q is initialized to the unit matrix, and the unitary matrix Q is returned; = 'V': Q must contain a unitary matrix Q1 on entry, and the product Q1*Q is returned.

N (input) The order of the matrices A and B. $N \geq 0$.

ILO (input)

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to CGGBAL; otherwise they should be set to 1 and N respectively. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; ILO=1 and IHI=0, if $N=0$.

IHI (input)

See description of ILO.

A (input/output)

On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the rest is set to zero.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,N)$.

B (input/output)
On entry, the N-by-N upper triangular matrix B.
On exit, the upper triangular matrix $T = Q' B Z$.
The elements below the diagonal are set to zero.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, N)$.

Q (input/output)
If COMPQ='N': Q is not referenced.
If COMPQ='I': on entry, Q need not be set, and on exit it contains the unitary matrix Q, where Q' is the product of the Givens transformations which are applied to A and B on the left. If COMPQ='V': on entry, Q must contain a unitary matrix Q1, and on exit this is overwritten by $Q1*Q$.

LDQ (input)
The leading dimension of the array Q. $LDQ \geq N$ if COMPQ='V' or 'I'; $LDQ \geq 1$ otherwise.

Z (input/output)
If COMPZ='N': Z is not referenced.
If COMPZ='I': on entry, Z need not be set, and on exit it contains the unitary matrix Z, which is the product of the Givens transformations which are applied to A and B on the right. If COMPZ='V': on entry, Z must contain a unitary matrix Z1, and on exit this is overwritten by $Z1*Z$.

LDZ (input)
The leading dimension of the array Z. $LDZ \geq N$ if COMPZ='V' or 'I'; $LDZ \geq 1$ otherwise.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

This routine reduces A to Hessenberg and B to triangular form by an unblocked reduction, as described in Matrix Computations, by Golub and van Loan (Johns Hopkins Press).

cgglse - solve the linear equality-constrained least squares (LSE) problem

SYNOPSIS

```
SUBROUTINE CGGLSE(M, N, P, A, LDA, B, LDB, C, D, X, WORK, LDWORK,
  INFO)
```

```
COMPLEX A(LDA,*), B(LDB,*), C(*), D(*), X(*), WORK(*)
INTEGER M, N, P, LDA, LDB, LDWORK, INFO
```

```
SUBROUTINE CGGLSE_64(M, N, P, A, LDA, B, LDB, C, D, X, WORK, LDWORK,
  INFO)
```

```
COMPLEX A(LDA,*), B(LDB,*), C(*), D(*), X(*), WORK(*)
INTEGER*8 M, N, P, LDA, LDB, LDWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE GGLSE([M], [N], [P], A, [LDA], B, [LDB], C, D, X, [WORK],
  [LDWORK], [INFO])
```

```
COMPLEX, DIMENSION(:) :: C, D, X, WORK
COMPLEX, DIMENSION(:,:) :: A, B
INTEGER :: M, N, P, LDA, LDB, LDWORK, INFO
```

```
SUBROUTINE GGLSE_64([M], [N], [P], A, [LDA], B, [LDB], C, D, X, [WORK],
  [LDWORK], [INFO])
```

```
COMPLEX, DIMENSION(:) :: C, D, X, WORK
COMPLEX, DIMENSION(:,:) :: A, B
INTEGER(8) :: M, N, P, LDA, LDB, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgglse(int m, int n, int p, complex *a, int lda, com-
  plex *b, int ldb, complex *c, complex *d, complex
  *x, int *info);
```

```
void cgglse_64(long m, long n, long p, complex *a, long lda,
  complex *b, long ldb, complex *c, complex *d, com-
  plex *x, long *info);
```

PURPOSE

cgglse solves the linear equality-constrained least squares (LSE) problem:

$$\text{minimize } \| c - A*x \|_2 \quad \text{subject to } B*x = d$$

where A is an M-by-N matrix, B is a P-by-N matrix, c is a given M-vector, and d is a given P-vector. It is assumed that

P <= N <= M+P, and

$$\text{rank}(B) = P \text{ and } \text{rank} \begin{pmatrix} A \\ B \end{pmatrix} = N.$$

These conditions ensure that the LSE problem has a unique solution, which is obtained using a GRQ factorization of the matrices B and A.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrices A and B. N >= 0.

P (input) The number of rows of the matrix B. 0 <= P <= N <= M+P.

A (input/output)
On entry, the M-by-N matrix A. On exit, A is destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the P-by-N matrix B. On exit, B is destroyed.

LDB (input)
The leading dimension of the array B. LDB >= max(1,P).

C (input/output)
On entry, C contains the right hand side vector for the least squares part of the LSE problem. On exit, the residual sum of squares for the solution is given by the sum of squares of elements N-P+1 to M of vector C.

D (input/output)
On entry, D contains the right hand side vector for the constrained equation. On exit, D is destroyed.

X (output)
On exit, X is the solution of the LSE problem.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK \geq max(1,M+N+P). For optimum performance LDWORK \geq P+min(M,N)+max(M,N)*NB, where NB is an upper bound for the optimal blocksizes for CGEQRF, CGERQF, CUNMQR and CUNMRQ.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

COMPLEX, DIMENSION(:, :) :: A, B
INTEGER(8) :: N, M, P, LDA, LDB, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cggqrf(int n, int m, int p, complex *a, int lda, complex *tau,
           complex *b, int ldb, complex *taub, int *info);
```

```
void cggqrf_64(long n, long m, long p, complex *a, long lda, complex *tau,
              complex *b, long ldb, complex
```

B (input/output)

On entry, the N-by-P matrix B. On exit, if $N \leq P$, the upper triangle of the subarray B(1:N,P-N+1:P) contains the N-by-N upper triangular matrix T; if $N > P$, the elements on and above the (N-P)-th subdiagonal contain the N-by-P upper trapezoidal matrix T; the remaining elements, with the array TAUB, represent the unitary matrix Z as a product of elementary reflectors (see Further Details).

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

TAUB (output)

The scalar factors of the elementary reflectors which represent the unitary matrix Z (see Further Details).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. $LWORK \geq \max(1,N,M,P)$. For optimum performance $LWORK \geq \max(N,M,P) * \max(NB1,NB2,NB3)$, where NB1 is the optimal blocksize for the QR factorization of an N-by-M matrix, NB2 is the optimal blocksize for the RQ factorization of an N-by-P matrix, and NB3 is the optimal blocksize for a call of CUNMQR.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(k), \text{ where } k = \min(n,m).$$

Each H(i) has the form

$$H(i) = I - \tau \cdot v \cdot v'$$

where τ is a complex scalar, and v is a complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:n)$ is stored on exit in A(i+1:n,i), and τ in TAUA(i).

To form Q explicitly, use LAPACK subroutine CUNGQR.

To use Q to update another matrix, use LAPACK subroutine CUNMQR.

The matrix Z is represented as a product of elementary

reflectors

$Z = H(1) H(2) \dots H(k)$, where $k = \min(n,p)$.

Each $H(i)$ has the form

$$H(i) = I - \text{taub} * v * v'$$

where taub is a complex scalar, and v is a complex vector with $v(p-k+i+1:p) = 0$ and $v(p-k+i) = 1$; $v(1:p-k+i-1)$ is stored on exit in $B(n-k+i,1:p-k+i-1)$, and taub in $\text{TAUB}(i)$. To form Z explicitly, use LAPACK subroutine CUNGRQ. To use Z to update another matrix, use LAPACK subroutine CUNMRQ.

[WORK], [LWORK], [INFO])
```

```
COMPLEX, DIMENSION(:) :: TAU, TAUB, WORK
COMPLEX, DIMENSION(:, :) :: A, B
INTEGER(8) :: M, P, N, LDA, LDB, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cggrqf(int m, int p, int n, complex *a, int lda, complex *tau,
complex *b, int ldb, complex *taub, int *info);
```

```
void cggrqf_64(long m, long p, long n, complex *a, long lda, complex *tau,
complex *b, long ldb, complex
```

*taub, long *info);

PURPOSE

cggrqf computes a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B:

$$A = R*Q, \quad B = Z*T*Q,$$

where Q is an N-by-N unitary matrix, Z is a P-by-P unitary matrix, and R and T assume one of the forms:

$$\text{if } M \leq N, \quad R = \begin{pmatrix} 0 & R12 \\ & M \end{pmatrix} M, \quad \text{or if } M > N, \quad R = \begin{pmatrix} R11 \\ & (R21) \\ & & N \\ & & & N \end{pmatrix} M-N,$$

where R12 or R21 is upper triangular, and

$$\text{if } P \geq N, \quad T = \begin{pmatrix} T11 \\ & N \end{pmatrix} N, \quad \text{or if } P < N, \quad T = \begin{pmatrix} T11 & T12 \\ & P & N-P \\ & & N \end{pmatrix} P,$$

where T11 is upper triangular.

In particular, if B is square and nonsingular, the GRQ factorization of A and B implicitly gives the RQ factorization of $A \cdot \text{inv}(B)$:

$$A \cdot \text{inv}(B) = (R \cdot \text{inv}(T)) \cdot Z'$$

where $\text{inv}(B)$ denotes the inverse of the matrix B, and Z' denotes the conjugate transpose of the matrix Z.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

P (input) The number of rows of the matrix B. $P \geq 0$.

N (input) The number of columns of the matrices A and B. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, if $M \leq N$, the upper triangle of the subarray $A(1:M, N-M+1:N)$ contains the M-by-M upper triangular matrix R; if $M > N$, the elements on and above the (M-N)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAU A, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

TAUA (output)

The scalar factors of the elementary reflectors which represent the unitary matrix Q (see Further

Details).

B (input/output)

On entry, the P-by-N matrix B. On exit, the elements on and above the diagonal of the array contain the min(P,N)-by-N upper trapezoidal matrix T (T is upper triangular if P >= N); the elements below the diagonal, with the array TAUB, represent the unitary matrix Z as a product of elementary reflectors (see Further Details).

LDB (input)

The leading dimension of the array B. LDB >= max(1,P).

TAUB (output)

The scalar factors of the elementary reflectors which represent the unitary matrix Z (see Further Details).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK >= max(1,N,M,P). For optimum performance LWORK >= max(N,M,P)*max(NB1,NB2,NB3), where NB1 is the optimal blocksize for the RQ factorization of an M-by-N matrix, NB2 is the optimal blocksize for the QR factorization of a P-by-N matrix, and NB3 is the optimal blocksize for a call of CUNMRQ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO=-i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(k), \text{ where } k = \min(m,n).$$

Each H(i) has the form

$$H(i) = I - \text{taua} * v * v'$$

where taua is a complex scalar, and v is a complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ is stored on exit in $A(m-k+i,1:n-k+i-1)$, and taua in TAUA(i).

To form Q explicitly, use LAPACK subroutine CUNGRQ.

To use Q to update another matrix, use LAPACK subroutine CUNMRQ.

The matrix Z is represented as a product of elementary reflectors

$Z = H(1) H(2) \dots H(k)$, where $k = \min(p,n)$.

Each $H(i)$ has the form

$$H(i) = I - \text{taub} * v * v'$$

where taub is a complex scalar, and v is a complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:p)$ is stored on exit in $B(i+1:p,i)$, and taub in $\text{TAUB}(i)$.

To form Z explicitly, use LAPACK subroutine CUNGQR.

To use Z to update another matrix, use LAPACK subroutine CUNMQR.

```

PURPOSE

cggsvd computes the generalized singular value decomposition (GSVD) of an M-by-N complex matrix A and P-by-N complex matrix B:

$$U^* A Q = D_1 \begin{pmatrix} 0 & R \end{pmatrix}, \quad V^* B Q = D_2 \begin{pmatrix} 0 & R \end{pmatrix}$$

where U, V and Q are unitary matrices, and Z' means the conjugate transpose of Z. Let K+L = the effective numerical rank of the matrix (A', B')', then R is a (K+L)-by-(K+L) non-singular upper triangular matrix, D1 and D2 are M-by-(K+L) and P-by-(K+L) "diagonal" matrices and of the following structures, respectively:

If M-K-L >= 0,

$$D_1 = \begin{matrix} & & & K & L \\ & & & K & (I & 0) \\ & & & L & (0 & C) \\ & & M-K-L & (0 & 0) \end{matrix}$$

$$D_2 = \begin{matrix} & & & K & L \\ & & & L & (0 & S) \\ & & P-L & (0 & 0) \end{matrix}$$

$$\begin{pmatrix} 0 & R \end{pmatrix} = \begin{matrix} & & & N-K-L & K & L \\ & & & K & (0 & R_{11} & R_{12}) \\ & & & L & (0 & 0 & R_{22}) \end{matrix}$$

where

$$\begin{aligned}
C &= \text{diag}(\text{ALPHA}(K+1), \dots, \text{ALPHA}(K+L)), \\
S &= \text{diag}(\text{BETA}(K+1), \dots, \text{BETA}(K+L)), \\
C^{**2} + S^{**2} &= I.
\end{aligned}$$

R is stored in A(1:K+L, N-K-L+1:N) on exit.
If M-K-L < 0,

$$D_1 = \begin{matrix} & & & K & M-K & K+L-M \\ & & & K & (I & 0 & 0) \\ & & M-K & (0 & C & 0) \end{matrix}$$

$$D2 = \begin{matrix} & & K & M-K & K+L-M \\ M-K & (& 0 & S & 0 &) \\ K+L-M & (& 0 & 0 & I &) \\ P-L & (& 0 & 0 & 0 &) \end{matrix}$$

$$(\ 0 \ R \) = \begin{matrix} & & N-K-L & K & M-K & K+L-M \\ & K & (& 0 & R11 & R12 & R13 &) \\ & M-K & (& 0 & 0 & R22 & R23 &) \\ & K+L-M & (& 0 & 0 & 0 & R33 &) \end{matrix}$$

where

$$C = \text{diag}(\text{ALPHA}(K+1), \dots, \text{ALPHA}(M)),$$

$$S = \text{diag}(\text{BETA}(K+1), \dots, \text{BETA}(M)),$$

$$C^{**2} + S^{**2} = I.$$

(R11 R12 R13) is stored in A(1:M, N-K-L+1:N), and R33 is stored

$$(\ 0 \ R22 \ R23 \)$$

in B(M-K+1:L, N+M-K-L+1:N) on exit.

The routine computes C, S, R, and optionally the unitary transformation matrices U, V and Q.

In particular, if B is an N-by-N nonsingular matrix, then the GSVD of A and B implicitly gives the SVD of A*inv(B):

$$A * \text{inv}(B) = U * (D1 * \text{inv}(D2)) * V'$$

If (A', B')' has orthonormal columns, then the GSVD of A and B is also equal to the CS decomposition of A and B. Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem:

$$A' * A \ x = \text{lambda} * B' * B \ x.$$

In some literature, the GSVD of A and B is presented in the form

$$U' * A * X = (\ 0 \ D1 \), \quad V' * B * X = (\ 0 \ D2 \)$$

where U and V are orthogonal and X is nonsingular, and D1 and D2 are ``diagonal''. The former GSVD form can be converted to the latter form by taking the nonsingular matrix X as

$$X = Q * \begin{pmatrix} I & 0 \\ 0 & \text{inv}(R) \end{pmatrix}$$

ARGUMENTS

JOBU (input)
 = 'U': Unitary matrix U is computed;
 = 'N': U is not computed.

JOBV (input)
 = 'V': Unitary matrix V is computed;
 = 'N': V is not computed.

JOBQ (input)
 = 'Q': Unitary matrix Q is computed;
 = 'N': Q is not computed.

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrices A and B. N >= 0.

P (input) The number of rows of the matrix B. $P \geq 0$.

K (output)
On exit, K and L specify the dimension of the sub-blocks described in Purpose. $K + L =$ effective numerical rank of (A',B')'.

L (output)
On exit, K and L specify the dimension of the sub-blocks described in Purpose. $K + L =$ effective numerical rank of (A',B')'.

A (input/output)
On entry, the M-by-N matrix A. On exit, A contains the triangular matrix R, or part of R. See Purpose for details.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input/output)
On entry, the P-by-N matrix B. On exit, B contains part of the triangular matrix R if $M - K - L < 0$. See Purpose for details.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, P)$.

ALPHA (output)
On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; $ALPHA(1:K) = 1$, $ALPHA(1:K) = 1$, $BETA(1:K) = 0$, and if $M - K - L \geq 0$, $ALPHA(K+1:K+L) = C$, $BETA(K+1:K+L) = S$, or if $M - K - L < 0$, $ALPHA(K+1:M) = C$, $ALPHA(M+1:K+L) = 0$, $BETA(K+1:M) = S$, $BETA(M+1:K+L) = 1$ and $ALPHA(K+L+1:N) = 0$, $BETA(K+L+1:N) = 0$.

BETA (output)
See description of ALPHA.

U (output)
If $JOB_U = 'U'$, U contains the M-by-M unitary matrix U. If $JOB_U = 'N'$, U is not referenced.

LDU (input)
The leading dimension of the array U. $LDU \geq \max(1, M)$ if $JOB_U = 'U'$; $LDU \geq 1$ otherwise.

V (output)
If $JOB_V = 'V'$, V contains the P-by-P unitary matrix V. If $JOB_V = 'N'$, V is not referenced.

LDV (input)
The leading dimension of the array V. $LDV \geq \max(1, P)$ if $JOB_V = 'V'$; $LDV \geq 1$ otherwise.

Q (output)
If $JOB_Q = 'Q'$, Q contains the N-by-N unitary matrix Q. If $JOB_Q = 'N'$, Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ \geq
 $\max(1, N)$ if JOBQ = 'Q'; LDQ ≥ 1 otherwise.

WORK (workspace)
dimension($\max(3*N, M, P) + N$)

WORK2 (workspace)
dimension($2*N$)

IWORK3 (output)
dimension(N) On exit, IWORK3 stores the sorting
information. More precisely, the following loop
will sort ALPHA for $I = K+1, \min(M, K+L)$ swap
ALPHA(I) and ALPHA(IWORK3(I)) endfor such that
ALPHA(1) \geq ALPHA(2) $\geq \dots \geq$ ALPHA(N).

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an ille-
gal value.
> 0: if INFO = 1, the Jacobi-type procedure
failed to converge. For further details, see sub-
routine CTGSJA.

  p, long n, complex *a, long lda, complex *b, long
  ldb, float tola, float tolb, long *k, long *l,
  complex *u, long ldu, complex *v, long ldv, com-
  plex *q, long ldq, long *info);

```

PURPOSE

cggsvp computes unitary matrices U, V and Q such that

$$\begin{array}{ccc}
 & L & (\begin{array}{ccc} 0 & 0 & A23 \end{array}) \\
 M-K-L & (\begin{array}{ccc} 0 & 0 & 0 \end{array}) \\
 & & \\
 & & \begin{array}{ccc} N-K-L & K & L \\ K & (\begin{array}{ccc} 0 & A12 & A13 \end{array}) & \text{if } M-K-L < 0; \\
 M-K & (\begin{array}{ccc} 0 & 0 & A23 \end{array})
 \end{array}$$

$$V' * B * Q = \begin{array}{ccc} & N-K-L & K & L \\ L & (\begin{array}{ccc} 0 & 0 & B13 \end{array}) \\ P-L & (\begin{array}{ccc} 0 & 0 & 0 \end{array})
 \end{array}$$

where the K-by-K matrix A12 and L-by-L matrix B13 are non-singular upper triangular; A23 is L-by-L upper triangular if M-K-L >= 0, otherwise A23 is (M-K)-by-L upper trapezoidal. K+L = the effective numerical rank of the (M+P)-by-N matrix (A',B)'. Z' denotes the conjugate transpose of Z.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see subroutine CGGSVD.

ARGUMENTS

JOBV (input)
 = 'U': Unitary matrix U is computed;
 = 'N': U is not computed.

JOBV (input)
 = 'V': Unitary matrix V is computed;
 = 'N': V is not computed.

JOBQ (input)
 = 'Q': Unitary matrix Q is computed;
 = 'N': Q is not computed.

M (input) The number of rows of the matrix A. $M \geq 0$.

P (input) The number of rows of the matrix B. $P \geq 0$.

N (input) The number of columns of the matrices A and B. $N \geq 0$.

A (input/output)
 On entry, the M-by-N matrix A. On exit, A contains the triangular (or trapezoidal) matrix described in the Purpose section.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input/output)
 On entry, the P-by-N matrix B. On exit, B contains the triangular matrix described in the Purpose section.

LDB (input)
 The leading dimension of the array B. $LDB \geq \max(1, P)$.

TOLA (input)
 TOLA and TOLB are the thresholds to determine the effective numerical rank of matrix B and a sub-block of A. Generally, they are set to $TOLA = \max(M, N) * \text{norm}(A) * \text{MACHEPS}$, $TOLB = \max(P, N) * \text{norm}(B) * \text{MACHEPS}$. The size of TOLA and TOLB may affect the size of backward errors of the decomposition.

TOLB (input)
 See description of TOLA.

K (output)
 On exit, K and L specify the dimension of the sub-blocks described in Purpose section. $K + L =$ effective numerical rank of (A', B') .

L (output)
 See the description of K.

U (input) If JOBU = 'U', U contains the unitary matrix U. If JOBU = 'N', U is not referenced.

LDU (input)
 The leading dimension of the array U. $LDU \geq \max(1, M)$ if JOBU = 'U'; $LDU \geq 1$ otherwise.

V (input) If JOBV = 'V', V contains the unitary matrix V. If JOBV = 'N', V is not referenced.

LDV (input)
 The leading dimension of the array V. $LDV \geq \max(1, P)$ if JOBV = 'V'; $LDV \geq 1$ otherwise.

Q (input) If JOBQ = 'Q', Q contains the unitary matrix Q.

If JOBQ = 'N', Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ \geq
max(1,N) if JOBQ = 'Q'; LDQ \geq 1 otherwise.

IWORK (workspace)
dimension(N)

RWORK (workspace)
dimension(2*N)

TAU (workspace)
dimension(N)

WORK (workspace)
dimension(MAX(3*N,M,P))

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The subroutine uses LAPACK subroutine CGEQPF for the QR factorization with column pivoting to detect the effective numerical rank of the a matrix. It may be replaced by a better rank determination strategy.

- [PURPOSE](#)
- [PARAMETERS](#)

NAME

cgssco - General sparse solver condition number estimate.

SYNOPSIS

```
SUBROUTINE CGSSCO ( COND, HANDLE, IER )  
  
INTEGER          IER  
REAL             COND  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

CGSSCO - Condition number estimate.

PARAMETERS

COND - REAL
On exit, an estimate of the condition number of the factored matrix. Must be called after the numerical factorization subroutine, *CGSSFA()*.

HANDLE(150) - DOUBLE PRECISION array
On entry, *HANDLE(*)* is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine.
Modified on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-700 : Invalid calling sequence - need to call *CGSSFA* first.
-710 : Condition number estimate not available (not implemented for this *HANDLE*'s matrix type).

Contents

NAME

cgssda - Deallocate working storage for the general sparse solver.

SYNOPSIS

```
SUBROUTINE CGSSDA ( HANDLE, IER )  
  
INTEGER          IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

CGSSDA - Deallocate dynamically allocated working storage.

PARAMETERS

HANDLE(150) - DOUBLE PRECISION array
On entry, *HANDLE*(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine.
Modified on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

none

- [PARAMETERS](#)

NAME

cgssfa - General sparse solver numeric factorization.

SYNOPSIS

```
SUBROUTINE CGSSFA ( NEQNS, COLSTR, ROWIND, VALUES, HANDLE, IER )  
  
INTEGER          NEQNS, COLSTR(*), ROWIND(*), IER  
COMPLEX          VALUES(*)  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

CGSSFA - Numeric factorization of a sparse matrix.

PARAMETERS

NEQNS - INTEGER
On entry, **NEQNS** specifies the number of equations in coefficient matrix. Unchanged on exit.

COLSTR(*) - INTEGER array
On entry, **COLSTR(*)** is an array of size (NEQNS+1), containing the pointers of the matrix structure. Unchanged on exit.

ROWIND(*) - INTEGER array
On entry, **ROWIND(*)** is an array of size COLSTR(NEQNS+1)-1, containing the indices of the matrix structure. Unchanged on exit.

VALUES(*) - COMPLEX array
On entry, **VALUES(*)** is an array of size COLSTR(NEQNS+1)-1, containing the numeric values of the sparse matrix to be factored. Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array
On entry, **HANDLE(*)** is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on

exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- 300 : Invalid calling sequence - need to call CGSSOR first.
- 301 : Failure to dynamically allocate memory.
- 666 : Internal error.

NAME

cgssfs - General sparse solver one call interface.

SYNOPSIS

```
SUBROUTINE CGSSFS ( MTXTYP, PIVOT , NEQNS, COLSTR, ROWIND,
                   VALUES, NRHS , RHS , LDRHS , ORDMTHD,
                   OUTUNT, MSGLVL, HANDLE, IER )
```

```
CHARACTER*2      MTXTYP
CHARACTER*1      PIVOT
INTEGER          NEQNS, COLSTR(*), ROWIND(*), NRHS, LDRHS,
                OUTUNT, MSGLVL, IER
CHARACTER*3      ORDMTHD
COMPLEX          VALUES(*), RHS(*)
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

CGSSFS - General sparse solver one call interface.

PARAMETERS

MTXTYP - CHARACTER*2
On entry, MTXTYP specifies the coefficient matrix type. Specifically, the valid options are:

- 'sp' or 'SP' - symmetric structure, Hermitian positive definite values
- 'ss' or 'SS' - symmetric structure, symmetric values
- 'su' or 'SU' - symmetric structure, unsymmetric values
- 'uu' or 'UU' - unsymmetric structure, unsymmetric values

Unchanged on exit.

PIVOT - CHARACTER*1
On entry, pivot specifies whether or not pivoting is used in the course of the numeric factorization. The valid options are:

- 'n' or 'N' - no pivoting is used (Pivoting is not supported for this release).

Unchanged on exit.

NEQNS - INTEGER

On entry, `NEQNS` specifies the number of equations in the coefficient matrix. `NEQNS` must be at least one. Unchanged on exit.

`COLSTR(*)` - INTEGER array

On entry, `COLSTR(*)` is an array of size $(NEQNS+1)$, containing the pointers of the matrix structure. Unchanged on exit.

`ROWIND(*)` - INTEGER array

On entry, `ROWIND(*)` is an array of size $COLSTR(NEQNS+1)-1$, containing the indices of the matrix structure. Unchanged on exit.

`VALUES(*)` - COMPLEX array

On entry, `VALUES(*)` is an array of size $COLSTR(NEQNS+1)-1$, containing the non-zero numeric values of the sparse matrix to be factored. Unchanged on exit.

`NRHS` - INTEGER

On entry, `NRHS` specifies the number of right hand sides to solve for. Unchanged on exit.

`RHS(*)` - COMPLEX array

On entry, `RHS(LDRHS, NRHS)` contains the `NRHS` right hand sides. On exit, it contains the solutions.

`LDRHS` - INTEGER

On entry, `LDRHS` specifies the leading dimension of the `RHS` array. Unchanged on exit.

`ORDMTHD` - CHARACTER*3

On entry, `ORDMTHD` specifies the fill-reducing ordering to be used by the sparse solver. Specifically, the valid options are:

- 'nat' or 'NAT' - natural ordering (no ordering)
- 'mmd' or 'MMD' - multiple minimum degree
- 'gnd' or 'GND' - general nested dissection
- 'uso' or 'USO' - user specified ordering (see `CGSSUO`)

Unchanged on exit.

`OUTUNT` - INTEGER

Output unit. Unchanged on exit.

`MSGLVL` - INTEGER

Message level.

- 0 - no output from solver.
- (No messages supported for this release.)

Unchanged on exit.

`HANDLE(150)` - DOUBLE PRECISION array

On entry, `HANDLE(*)` is an array of containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

`IER` - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-101 : Failure to dynamically allocate memory.
-102 : Invalid matrix type.
-103 : Invalid pivot option.
-104 : Number of nonzeros is less than NEQNS.
-105 : NEQNS < 1
-201 : Failure to dynamically allocate memory.
-301 : Failure to dynamically allocate memory.
-401 : Failure to dynamically allocate memory.
-402 : NRHS < 1
-403 : NEQNS > LDRHS
-666 : Internal error.

Contents

- [NAME](#)
- [SYNOPSIS](#)
- [PURPOSE](#)
- [PARAMETERS](#)

NAME

cgssin - Initialize the general sparse solver.

SYNOPSIS

```
SUBROUTINE CGSSIN ( MTXTYP, PIVOT, NEQNS, COLSTR, ROWIND, OUTUNT,  
                  MSGLVL, HANDLE, IER )
```

```
CHARACTER*2      MTXTYP  
CHARACTER*1      PIVOT  
INTEGER          NEQNS, COLSTR(*), ROWIND(*), OUTUNT, MSGLVL, IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

CGSSIN - Initialize the sparse solver and input the matrix structure.

PARAMETERS

MTXTYP - CHARACTER*2
On entry, MTXTYP specifies the coefficient matrix type. Specifically, the valid options are:

- 'sp' or 'SP' - symmetric structure, Hermitian positive definite values
- 'ss' or 'SS' - symmetric structure, symmetric values
- 'su' or 'SU' - symmetric structure, unsymmetric values
- 'uu' or 'UU' - unsymmetric structure, unsymmetric values

Unchanged on exit.

PIVOT - CHARACTER*1
On entry, PIVOT specifies whether or not pivoting is used in the course of the numeric factorization. The valid options are:

- 'n' or 'N' - no pivoting is used
(Pivoting is not supported for this release).

Unchanged on exit.

NEQNS - INTEGER
On entry, NEQNS specifies the number of equations in the coefficient matrix. NEQNS must be at least one. Unchanged on exit.

COLSTR(*) - INTEGER array
On entry, *COLSTR*(*) is an array of size (NEQNS+1),
containing the pointers of the matrix structure.
Unchanged on exit.

ROWIND(*) - INTEGER array
On entry, *ROWIND*(*) is an array of size
COLSTR(NEQNS+1)-1, containing the indices of the
matrix structure. Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array
On entry, *HANDLE*(*) is an array containing
information needed by the solver, and must be passed
unchanged to each sparse solver subroutine.
Modified on exit.

OUTUNT - INTEGER
Output unit. Unchanged on exit.

MSGLVL - INTEGER
Message level.

0 - no output from solver.
(No messages supported for this release.)

Unchanged on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on
exit. If error encountered, it is set to a non-zero
integer. Error numbers set by this subroutine:

-101 : Failure to dynamically allocate memory.
-102 : Invalid matrix type.
-103 : Invalid pivot option.
-104 : Number of nonzeros less than NEQNS.
-105 : NEQNS < 1

cgssor - General sparse solver ordering and symbolic factorization.

SYNOPSIS

```
SUBROUTINE CGSSOR ( ORDMTHD, HANDLE, IER )
```

```
CHARACTER*3      ORDMTHD
INTEGER          IER
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

CGSSOR - Orders and symbolically factors a sparse matrix.

PARAMETERS

ORDMTHD - CHARACTER*3
On entry, ORDMTHD specifies the fill-reducing ordering to be used by the sparse solver. Specifically, the valid options are:

- 'nat' or 'NAT' - natural ordering (no ordering)
- 'mmd' or 'MMD' - multiple minimum degree
- 'gnd' or 'GND' - general nested dissection
- 'uso' or 'USO' - user specified ordering (see CGSSUO)

Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array
On entry, HANDLE(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- 200 : Invalid calling sequence - need to call CGSSIN first.
- 201 : Failure to dynamically allocate memory.
- 666 : Internal error.

cgssps - Print general sparse solver statics.

SYNOPSIS

```
SUBROUTINE CGSSPS ( HANDLE, IER )  
  
INTEGER          IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

CGSSPS - Print solver statistics.

PARAMETERS

HANDLE(150) - DOUBLE PRECISION array
On entry, *HANDLE*(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- 800 : Invalid calling sequence - need to call CGSSSL first.
- 899 : Printed solver statistics not supported this release.

cgssrp - Return permutation used by the general sparse solver.

SYNOPSIS

```
SUBROUTINE CGSSRP ( PERM, HANDLE, IER )
```

```
INTEGER          PERM(*), IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

CGSSRP - Returns the permutation used by the solver for the fill-reducing ordering.

PARAMETERS

PERM(NEQNS) - INTEGER array

Undefined on entry. PERM(NEQNS) is the permutation array used by the sparse solver for the fill-reducing ordering. Modified on exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, HANDLE(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-600 : Invalid calling sequence - need to call CGSSOR first.

Contents

- [NAME](#)

NAME

cgsssl - Solve routine for the general sparse solver.

SYNOPSIS

```
SUBROUTINE CGSSSL ( NRHS, RHS, LDRHS, HANDLE, IER )  
  
INTEGER          NRHS, LDRHS, IER  
COMPLEX          RHS(LDRHS,NRHS)  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

CGSSSL - Triangular solve of a factored sparse matrix.

PARAMETERS

NRHS - INTEGER
On entry, NRHS specifies the number of right hand sides to solve for. Unchanged on exit.

RHS(LDRHS,*) - COMPLEX array
On entry, RHS(LDRHS,NRHS) contains the NRHS right hand sides. On exit, it contains the solutions.

LDRHS - INTEGER
On entry, LDRHS specifies the leading dimension of the RHS array. Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array
On entry, HANDLE(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- 400 : Invalid calling sequence - need to call CGSSFA first.
- 401 : Failure to dynamically allocate memory.
- 402 : NRHS < 1
- 403 : NEQNS > LDRHS

NAME

cgssuo - User supplied permutation for ordering used in the general sparse solver.

SYNOPSIS

```
SUBROUTINE CGSSUO ( PERM, HANDLE, IER )
```

```
INTEGER          PERM(*), IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

CGSSUO - User supplied permutation for ordering. Must be called after **CGSSIN()** (sparse solver initialization) and before **CGSSOR()** (sparse solver ordering).

PARAMETERS

PERM(NEQNS) - INTEGER array
On entry, PERM(NEQNS) is a permutation array supplied by the user for the fill-reducing ordering. Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array
On entry, HANDLE(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-500 : Invalid calling sequence - need to call CGSSIN first.

            anorm, float *rcond, int *info);

void cgtcon_64(char norm, long n, complex *low, complex
              *diag, complex *up1, complex *up2, long *ipivot,
              float anorm, float *rcond, long *info);
```

PURPOSE

cgtcon estimates the reciprocal of the condition number of a complex tridiagonal matrix A using the LU factorization as computed by CGTTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

NORM (input)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I': Infinity-norm.

N (input) The order of the matrix A. $N \geq 0$.

LOW (input)

The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by CGTTRF.

DIAG (input)

The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UP1 (input)

The (n-1) elements of the first superdiagonal of U.

UP2 (input)

The (n-2) elements of the second superdiagonal of U.

IPIVOT (input)

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

ANORM (input)

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND (output)

The reciprocal of the condition number of the

matrix A, computed as $RCOND = 1/(ANORM * AINVNM)$,
where AINVNM is an estimate of the 1-norm of
inv(A) computed in this routine.

WORK (workspace)
dimension(2*N)

NAME

cgthr - Gathers specified elements from y into x.

SYNOPSIS

```
SUBROUTINE CGTHR(NZ, Y, X, INDX)

COMPLEX Y(*), X(*)
INTEGER NZ
INTEGER INDX(*)

SUBROUTINE CGTHR_64(NZ, Y, X, INDX)

COMPLEX Y(*), X(*)
INTEGER*8 NZ
INTEGER*8 INDX(*)

F95 INTERFACE
SUBROUTINE GTHR([NZ], Y, X, INDX)

COMPLEX, DIMENSION(:) :: Y, X
INTEGER :: NZ
INTEGER, DIMENSION(:) :: INDX

SUBROUTINE GTHR_64([NZ], Y, X, INDX)

COMPLEX, DIMENSION(:) :: Y, X
INTEGER(8) :: NZ
INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

CGTHR - Gathers the specified elements from a vector y in full storage form into a vector x in compressed form. Only the elements of y whose indices are listed in indx are referenced.

```
do i = 1, n
  x(i) = y(indx(i))
enddo
```

ARGUMENTS

NZ (input) - INTEGER

Number of elements in the compressed form.
Unchanged on exit.

Y (input)

Vector in full storage form. Unchanged on exit.

X (output)

Vector in compressed form. Contains elements of y
whose indices are listed in indx on exit.

INDX (input) - INTEGER

Vector containing the indices of the compressed
form. It is assumed that the elements in INDX are
distinct and greater than zero. Unchanged on exit.

COMPLEX, DIMENSION(:) :: Y, X
INTEGER(8) :: NZ
INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

CGTHRZ - Gathers the specified elements from a vector y in full storage form into a vector x in compressed form. The gathered elements of y are set to zero. Only the elements of y whose indices are listed in indx are referenced.

```
do i = 1, n
  x(i) = y(indx(i))
  y(indx(i)) = 0
enddo
```

ARGUMENTS

NZ (input) - INTEGER

Number of elements in the compressed form.
Unchanged on exit.

Y (input/output)

Vector in full storage form. Gathered elements are
set to zero.

X (output)

Vector in compressed form. Contains elements of y
whose indices are listed in indx on exit.

INDX (input) - INTEGER

Vector containing the indices of the compressed
form. It is assumed that the elements in INDX are
distinct and greater than zero. Unchanged on exit.

ldx, float *ferr, float *berr, long *info);
```

PURPOSE

cgtrfs improves the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

TRANSA (input)

Specifies the form of the system of equations:

= 'N': $A * X = B$ (No transpose)

= 'T': $A^{**T} * X = B$ (Transpose)

= 'C': $A^{**H} * X = B$ (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

LOW (input)

The (n-1) subdiagonal elements of A.

DIAG (input)

The diagonal elements of A.

UP (input)

The (n-1) superdiagonal elements of A.

LOWF (input)

The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by CGTTRF.

DIAGF (input)
The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UPF1 (input)
The (n-1) elements of the first superdiagonal of U.

UPF2 (input)
The (n-2) elements of the second superdiagonal of U.

IPIVOT (input)
The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, N)$.

X (input/output)
On entry, the solution matrix X, as computed by CGTTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. $LDX \geq \max(1, N)$.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

          complex *up, complex *b, int ldb, int *info);
```

```
void cgtsv_64(long n, long nrhs, complex *low, complex  
             *diag, complex *up, complex *b, long ldb, long  
             *info);
```

PURPOSE

cgtsv solves the equation

where A is an N-by-N tridiagonal matrix, by Gaussian elimination with partial pivoting.

Note that the equation $A^*X = B$ may be solved by interchanging the order of the arguments DU and DL.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

LOW (input/output)
On entry, LOW must contain the (n-1) subdiagonal elements of A. On exit, LOW is overwritten by the (n-2) elements of the second superdiagonal of the upper triangular matrix U from the LU factorization of A, in LOW(1), ..., LOW(n-2).

DIAG (input/output)
On entry, DIAG must contain the diagonal elements of A. On exit, DIAG is overwritten by the n diagonal elements of U.

UP (input/output)
On entry, UP must contain the (n-1) superdiagonal elements of A. On exit, UP is overwritten by the (n-1) elements of the first superdiagonal of U.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1,N)$.

INFO (output)
= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value
> 0: if $INFO = i$, $U(i,i)$ is exactly zero, and the solution has not been computed. The factorization has not been completed unless $i = N$.

```

PURPOSE

cgtsvx uses the LU factorization to compute the solution to a complex system of linear equations $A * X = B$, $A^{*T} * X = B$, or $A^{*H} * X = B$, where A is a tridiagonal matrix of order N and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the LU decomposition is used to factor the matrix A as $A = L * U$, where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.
2. If some $U(i,i)=0$, so that U is exactly singular, then the routine returns with $INFO = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $INFO = N+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form of A.
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of A has been supplied on entry. = 'F': LOWF, DIAGF, UPF1, UPF2, and IPIVOT contain the factored form of A; LOW, DIAG, UP, LOWF, DIAGF, UPF1, UPF2 and IPIVOT will not be modified. = 'N': The matrix will be copied to LOWF, DIAGF, and UPF1 and factored.

TRANSA (input)

Specifies the form of the system of equations:
 = 'N': $A * X = B$ (No transpose)
 = 'T': $A^{**T} * X = B$ (Transpose)
 = 'C': $A^{**H} * X = B$ (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

LOW (input)

The (n-1) subdiagonal elements of A.

DIAG (input)

The n diagonal elements of A.

UP (input)

The (n-1) superdiagonal elements of A.

LOWF (input/output)

If FACT = 'F', then LOWF is an input argument and on entry contains the (n-1) multipliers that define the matrix L from the LU factorization of A as computed by CGTTRF.

If FACT = 'N', then LOWF is an output argument and on exit contains the (n-1) multipliers that define the matrix L from the LU factorization of A.

DIAGF (input/output)

If FACT = 'F', then DIAGF is an input argument and on entry contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

If FACT = 'N', then DIAGF is an output argument

and on exit contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UPF1 (input/output)

If FACT = 'F', then UPF1 is an input argument and on entry contains the (n-1) elements of the first superdiagonal of U.

If FACT = 'N', then UPF1 is an output argument and on exit contains the (n-1) elements of the first superdiagonal of U.

UPF2 (input/output)

If FACT = 'F', then UPF2 is an input argument and on entry contains the (n-2) elements of the second superdiagonal of U.

If FACT = 'N', then UPF2 is an output argument and on exit contains the (n-2) elements of the second superdiagonal of U.

IPIVOT (input/output)

If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the LU factorization of A as computed by CGTTRF.

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the LU factorization of A; row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,N).

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)

The leading dimension of the array X. LDX \geq max(1,N).

RCOND (output)

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO $>$ 0.

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as

reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

dimension($2*N$)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if INFO = $-i$, the i -th argument had an illegal value

> 0: if INFO = i , and i is

$\leq N$: $U(i,i)$ is exactly zero. The factorization has not been completed unless $i = N$, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = $N+1$: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

            *up1, complex *up2, int *ipivot, int *info);
```

```
void cgtrfs_64(long n, complex *low, complex *diag, complex
               *up1, complex *up2, long *ipivot, long *info);
```

PURPOSE

cgtrrf computes an LU factorization of a complex tridiagonal matrix A using elimination with partial pivoting and row interchanges.

The factorization has the form

$$A = L * U$$

where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.

ARGUMENTS

N (input) The order of the matrix A.

LOW (input/output)

On entry, LOW must contain the (n-1) sub-diagonal elements of A.

On exit, LOW is overwritten by the (n-1) multipliers that define the matrix L from the LU factorization of A.

DIAG (input/output)

On entry, DIAG must contain the diagonal elements of A.

On exit, DIAG is overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UP1 (input/output)

On entry, UP1 must contain the (n-1) super-diagonal elements of A.

On exit, UP1 is overwritten by the (n-1) elements of the first super-diagonal of U.

UP2 (output)

On exit, UP2 is overwritten by the (n-2) elements of the second super-diagonal of U.

IPIVOT (output)

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

INFO (output)

= 0: successful exit

< 0: if INFO = -k, the k-th argument had an illegal value

> 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

```

```

void cgttrs(char transa, int n, int nrhs, complex *low, complex
 *diag, complex *upl, complex *up2, int
 *ipivot, complex *b, int ldb, int *info);
void cgttrs_64(char transa, long n, long nrhs, complex *low,
 complex *diag, complex *upl, complex *up2, long
 *ipivot, complex *b, long ldb, long *info);

```

PURPOSE

cgttrs solves one of the systems of equations
 $A * X = B$, $A^{*T} * X = B$, or $A^{*H} * X = B$, with a tri-
diagonal matrix A using the LU factorization computed by
CGTTRF.

ARGUMENTS

TRANSA (input)
Specifies the form of the system of equations. =
'N': $A * X = B$ (No transpose)
= 'T': $A^{*T} * X = B$ (Transpose)
= 'C': $A^{*H} * X = B$ (Conjugate transpose)
TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A.

NRHS (input)
The number of right hand sides, i.e., the number
of columns of the matrix B. NRHS >= 0.

LOW (input)
The (n-1) multipliers that define the matrix L
from the LU factorization of A.

DIAG (input)
The n diagonal elements of the upper triangular
matrix U from the LU factorization of A.

UP1 (input)
The (n-1) elements of the first super-diagonal of
U.

UP2 (input)
The (n-2) elements of the second super-diagonal of
U.

IPIVOT (input)
The pivot indices; for $1 \leq i \leq n$, row i of the
matrix was interchanged with row IPIVOT(i).
IPIVOT(i) will always be either i or i+1;
IPIVOT(i) = i indicates a row interchange was not
required.

B (input/output)
On entry, the matrix of right hand side vectors B.
On exit, B is overwritten by the solution vectors
X.

LDB (input)
The leading dimension of the array B. LDB >=

max(1,N).

INFO (output)

= 0: successful exit

< 0: if INFO = -k, the k-th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>
```

```

void chbev(char jobz, char uplo, int n, int ndiag, complex
          *a, int lda, float *w, complex *z, int ldz, int
          *info);
void chbev_64(char jobz, char uplo, long n, long ndiag, com-
             plex *a, long lda, float *w, complex *z, long ldz,
             long *info);

```

PURPOSE

chbev computes all the eigenvalues and, optionally, eigen-
vectors of a complex Hermitian band matrix A.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

NDIAG (input)
 The number of superdiagonals of the matrix A if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. $NDIAG \geq 0$.

A (input/output)
 On entry, the upper or lower triangle of the Her-
 mitian band matrix A, stored in the first NDIAG+1
 rows of the array. The j-th column of A is stored
 in the j-th column of the array A as follows: if
 UPLO = 'U', $A(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-$
 $kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = A(i, j)$
 for $j \leq i \leq \min(n, j+kd)$.

On exit, A is overwritten by values generated dur-
 ing the reduction to tridiagonal form. If UPLO =
 'U', the first superdiagonal and the diagonal of
 the tridiagonal matrix T are returned in rows
 NDIAG and NDIAG+1 of A, and if UPLO = 'L', the
 diagonal and first subdiagonal of T are returned
 in the first two rows of A.

LDA (input)
 The leading dimension of the array A. $LDA \geq$
 $NDIAG + 1$.

W (output)
 If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the
 orthonormal eigenvectors of the matrix A, with the
 i-th column of Z holding the eigenvector associ-
 ated with W(i). If JOBZ = 'N', then Z is not
 referenced.

LDZ (input)
 The leading dimension of the array Z. $LDZ \geq 1$,

and if JOBZ = 'V', LDZ \geq max(1,N).

WORK (workspace)
dimension(N)

WORK2 (workspace)
dimension(max(1,3*N-2))

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

```

C INTERFACE

```
#include <sunperf.h>
void chbevd(char jobz, char uplo, int n, int kd, complex
            *ab, int ldab, float *w, complex *z, int ldz, int
            *info);

void chbevd_64(char jobz, char uplo, long n, long kd, com-
               plex *ab, long ldab, float *w, complex *z, long
               ldz, long *info);
```

PURPOSE

chbevd computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)

= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

AB (input/output)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB (input)

The leading dimension of the array AB. $LDAB \geq KD$

+ 1.

W (output)

If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ \geq 1, and if JOBZ = 'V', LDZ \geq max(1,N).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If $N \leq 1$, LWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LWORK must be at least N. If JOBZ = 'V' and $N > 1$, LWORK must be at least $2*N**2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK (input)

The dimension of array RWORK. If $N \leq 1$, LRWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LRWORK must be at least N. If JOBZ = 'V' and $N > 1$, LRWORK must be at least $1 + 5*N + 2*N**2$.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of array IWORK. If JOBZ = 'N' or $N \leq 1$, LIWORK must be at least 1. If JOBZ = 'V' and $N > 1$, LIWORK must be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an ille-

gal value.
> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

              ldz, long *ifail, long *info);

```

PURPOSE

chbevz computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
 = 'A': all eigenvalues will be found;
 = 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

NDIAG (input)
 The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. NDIAG >= 0.

A (input/output)
 On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if

UPLO = 'U', $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

On exit, A is overwritten by values generated during the reduction to tridiagonal form.

LDA (input)

The leading dimension of the array A. LDA \geq NDIAG + 1.

Q (output)

If JOBZ = 'V', the N-by-N unitary matrix used in the reduction to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

LDQ (input)

The leading dimension of the array Q. If JOBZ = 'V', then LDQ \geq max(1,N).

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; IL = 1 and IU = 0 if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; IL = 1 and IU = 0 if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

ABTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

$$ABTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2 * SLAMCH('S')$, not zero. If this routine returns with INFO > 0, indicating that some eigenvectors did not converge, try setting ABTOL to $2 * SLAMCH('S')$.

See "Computing Small Singular Values of Bidiagonal

Matrices with Guaranteed High Relative Accuracy,"
by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)

The total number of eigenvalues found. $0 \leq$
NFOUND \leq N. If RANGE = 'A', NFOUND = N, and if
RANGE = 'I', NFOUND = IU-IL+1.

W (output)

The first NFOUND elements contain the selected
eigenvalues in ascending order.

Z (input)

If JOBZ = 'V', then if INFO = 0, the first NFOUND
columns of Z contain the orthonormal eigenvectors
of the matrix A corresponding to the selected
eigenvalues, with the i-th column of Z holding the
eigenvector associated with W(i). If an eigenvec-
tor fails to converge, then that column of Z con-
tains the latest approximation to the eigenvector,
and the index of the eigenvector is returned in
IFAIL. If JOBZ = 'N', then Z is not referenced.
Note: the user must ensure that at least
 $\max(1, \text{NFOUND})$ columns are supplied in the array Z;
if RANGE = 'V', the exact value of NFOUND is not
known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. LDZ \geq 1,
and if JOBZ = 'V', LDZ \geq $\max(1, N)$.

WORK (workspace)

dimension(N)

WORK2 (workspace)

dimension(7*N)

IWORK3 (workspace)

dimension(5*N)

IFAIL (output)

If JOBZ = 'V', then if INFO = 0, the first NFOUND
elements of IFAIL are zero. If INFO > 0, then
IFAIL contains the indices of the eigenvectors
that failed to converge. If JOBZ = 'N', then
IFAIL is not referenced.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-
gal value
> 0: if INFO = i, then i eigenvectors failed to
converge. Their indices are stored in array
IFAIL.

void chbgst_64(char vect, char uplo, long n, long ka, long
               kb, complex *ab, long ldab, complex *bb, long
               ldbb, complex *x, long ldx, long *info);

```

PURPOSE

chbgst reduces a complex Hermitian-definite banded generalized eigenproblem $A*x = \lambda*B*x$ to standard form $C*y = \lambda*y$, such that C has the same bandwidth as A.

B must have been previously factorized as $S**H*S$ by CPBSTF, using a split Cholesky factorization. A is overwritten by $C = X**H*A*X$, where $X = S**(-1)*Q$ and Q is a unitary matrix chosen to preserve the bandwidth of A.

ARGUMENTS

VECT (input)
 = 'N': do not form the transformation matrix X;
 = 'V': form X.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrices A and B. $N \geq 0$.

KA (input)
 The number of superdiagonals of the matrix A if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. $KA \geq 0$.

KB (input)
 The number of superdiagonals of the matrix B if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. $KA \geq KB \geq 0$.

AB (input/output)
 On entry, the upper or lower triangle of the Her-
 mitian band matrix A, stored in the first ka+1
 rows of the array. The j-th column of A is stored
 in the j-th column of the array AB as follows: if
 UPLO = 'U', $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-$
 $ka) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$
 for $j \leq i \leq \min(n,j+ka)$.
 On exit, the transformed matrix $X**H*A*X$, stored
 in the same format as A.

LDAB (input)
 The leading dimension of the array AB. $LDAB \geq$
 $KA+1$.

BB (input)
 The banded factor S from the split Cholesky fac-
 torization of B, as returned by CPBSTF, stored in
 the first kb+1 rows of the array.

LDBB (input)
The leading dimension of the array BB. LDBB \geq KB+1.

X (output)
If VECT = 'V', the n-by-n matrix X. If VECT = 'N', the array X is not referenced.

LDX (input)
The leading dimension of the array X. LDX \geq max(1,N) if VECT = 'V'; LDX \geq 1 otherwise.

WORK (workspace)
dimension(N)

RWORK (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

```

PURPOSE

chbgv computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A*x=(\lambda)*B*x$. Here A and B are assumed to be Hermitian and banded, and B is also positive definite.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangles of A and B are stored;
 = 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

KA (input)
 The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KA \geq 0$.

KB (input)
 The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KB \geq 0$.

AB (input/output)
 On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first $ka+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+ka)$.
 On exit, the contents of AB are destroyed.

LDAB (input)
 The leading dimension of the array AB. $LDAB \geq ka+1$.

BB (input/output)
 On entry, the upper or lower triangle of the Hermitian band matrix B, stored in the first $kb+1$ rows of the array. The j -th column of B is stored in the j -th column of the array BB as follows: if UPLO = 'U', $BB(kb+1+i-j,j) = B(i,j)$ for $\max(1,j-kb) \leq i \leq j$; if UPLO = 'L', $BB(1+i-j,j) = B(i,j)$ for $j \leq i \leq \min(n,j+kb)$.

On exit, the factor S from the split Cholesky factorization $B = S^*H^*S$, as returned by CPBSTF.

LDBB (input)

The leading dimension of the array BB. LDBB \geq KB+1.

W (output)

If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so that $Z^*H^*B^*Z = I$. If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ \geq 1, and if JOBZ = 'V', LDZ \geq N.

WORK (workspace)

dimension(N)

RWORK (workspace)

dimension(3*N)

INFO (output)

               ldbb, float *w, complex *z, long ldz, long *info);
```

PURPOSE

chbgvd computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A*x=(\lambda)*B*x$. Here A and B are assumed to be Hermitian and banded, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
= 'U': Upper triangles of A and B are stored;
= 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

KA (input)
The number of superdiagonals of the matrix A if
UPLO = 'U', or the number of subdiagonals if UPLO
= 'L'. $KA \geq 0$.

KB (input)
The number of superdiagonals of the matrix B if
UPLO = 'U', or the number of subdiagonals if UPLO
= 'L'. $KB \geq 0$.

AB (input/output)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+ka)$.

On exit, the contents of AB are destroyed.

LDAB (input)

The leading dimension of the array AB. LDAB \geq KA+1.

BB (input/output)

On entry, the upper or lower triangle of the Hermitian band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', $BB(kb+1+i-j,j) = B(i,j)$ for $\max(1,j-kb) \leq i \leq j$; if UPLO = 'L', $BB(1+i-j,j) = B(i,j)$ for $j \leq i \leq \min(n,j+kb)$.

On exit, the factor S from the split Cholesky factorization $B = S^*H^*S$, as returned by CPBSTF.

LDBB (input)

The leading dimension of the array BB. LDBB \geq KB+1.

W (output)

If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so that $Z^*H^*B^*Z = I$. If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ \geq 1, and if JOBZ = 'V', LDZ \geq N.

WORK (workspace)

On exit, if INFO=0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If $N \leq 1$, LWORK \geq 1. If JOBZ = 'N' and $N > 1$, LWORK \geq N. If JOBZ = 'V' and $N > 1$, LWORK $\geq 2*N^2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

On exit, if INFO=0, RWORK(1) returns the optimal LRWORK.

LRWORK (input)

The dimension of array RWORK. If $N \leq 1$, LRWORK \geq 1. If JOBZ = 'N' and $N > 1$, LRWORK \geq

N. If JOBZ = 'V' and $N > 1$, LRWORK $\geq 1 + 5*N + 2*N**2$.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO=0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of array IWORK. If JOBZ = 'N' or $N \leq 1$, LIWORK ≥ 1 . If JOBZ = 'V' and $N > 1$, LIWORK $\geq 3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is:
<= N: the algorithm failed to converge: i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for $1 \leq i \leq N$, then CPBSTF returned INFO = i: B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

```

PURPOSE

chbgvx computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A*x=(\lambda)B*x$. Here A and B are assumed to be Hermitian and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)

= 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)

= 'A': all eigenvalues will be found;
 = 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)

= 'U': Upper triangles of A and B are stored;
 = 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B . $N \geq 0$.

KA (input)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KA \geq 0$.

KB (input)
 The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KB >= 0.

AB (input/output)
 On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).
 On exit, the contents of AB are destroyed.

LDAB (input)
 The leading dimension of the array AB. LDAB >= KA+1.

BB (input/output)
 On entry, the upper or lower triangle of the Hermitian band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', BB(kb+1+i-j,j) = B(i,j) for max(1,j-kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j) for j<=i<=min(n,j+kb).
 On exit, the factor S from the split Cholesky factorization $B = S^*H^*S$, as returned by CPBSTF.

LDBB (input)
 The leading dimension of the array BB. LDBB >= KB+1.

Q (output)
 If JOBZ = 'V', the n-by-n matrix used in the reduction of $A*x = (\lambda)*B*x$ to standard form, i.e. $C*x = (\lambda)*x$, and consequently C to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

LDQ (input)
 The leading dimension of the array Q. If JOBZ = 'N', LDQ >= 1. If JOBZ = 'V', LDQ >= max(1,N).

VL (input)
 If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)
 If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL (input)
 If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

ABSTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing AP to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2 * SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABSTOL to $2 * SLAMCH('S')$.

M (output)

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

W (output)

If $INFO = 0$, the eigenvalues in ascending order.

Z (input)

If $JOBZ = 'V'$, then if $INFO = 0$, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized so that $Z^H * B * Z = I$. If $JOBZ = 'N'$, then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq N$.

WORK (workspace)

dimension(N)

RWORK (workspace)

dimension(7*N)

IWORK (workspace)

dimension(5*N)

IFAIL (output)

If $JOBZ = 'V'$, then if $INFO = 0$, the first M elements of IFAIL are zero. If $INFO > 0$, then IFAIL contains the indices of the eigenvectors that failed to converge. If $JOBZ = 'N'$, then IFAIL is not referenced.

INFO (output)

= 0: successful exit

< 0: if $INFO = -i$, the i-th argument had an ille-

gal value
> 0: if INFO = i, and i is:
<= N: then i eigenvectors failed to converge.
Their indices are stored in array IFAIL. > N:
if INFO = N + i, for 1 <= i <= N, then CPBSTF
returned INFO = i: B is not positive definite.
The factorization of B could not be completed and
no eigenvalues or eigenvectors were computed.

NAME

chbmw - perform the matrix-vector operation $y := \alpha A x + \beta y$

SYNOPSIS

```
SUBROUTINE CHBMV(UPLO, N, NDIAG, ALPHA, A, LDA, X, INCX, BETA, Y,
                INCY)
```

```
CHARACTER * 1 UPLO
COMPLEX ALPHA, BETA
COMPLEX A(LDA,*), X(*), Y(*)
INTEGER N, NDIAG, LDA, INCX, INCY
```

```
SUBROUTINE CHBMV_64(UPLO, N, NDIAG, ALPHA, A, LDA, X, INCX, BETA, Y,
                  INCY)
```

```
CHARACTER * 1 UPLO
COMPLEX ALPHA, BETA
COMPLEX A(LDA,*), X(*), Y(*)
INTEGER*8 N, NDIAG, LDA, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE HBMV(UPLO, [N], NDIAG, ALPHA, A, [LDA], X, [INCX], BETA,
               Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:) :: X, Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: N, NDIAG, LDA, INCX, INCY
```

```
SUBROUTINE HBMV_64(UPLO, [N], NDIAG, ALPHA, A, [LDA], X, [INCX],
                  BETA, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:) :: X, Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: N, NDIAG, LDA, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```

void chbmvc(char uplo, int n, int ndiag, complex *alpha, complex
            *a, int lda, complex *x, int incx, complex
            *beta, complex *y, int incy);
void chbmvc_64(char uplo, long n, long ndiag, complex *alpha,
               complex *a, long lda, complex *x, long incx, complex
               *beta, complex *y, long incy);

```

PURPOSE

chbmvc performs the matrix-vector operation $y := \alpha A x + \beta y$ where α and β are scalars, x and y are n element vectors and A is an n by n hermitian band matrix, with $ndiag$ super-diagonals.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the band matrix A is being supplied as follows:

UPLO = 'U' or 'u' The upper triangular part of A is being supplied.

UPLO = 'L' or 'l' The lower triangular part of A is being supplied.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

NDIAG (input)

On entry, NDIAG specifies the number of super-diagonals of the matrix A . NDIAG must satisfy $0 \leq \text{NDIAG}$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading $(ndiag + 1)$ by n part of the array A must contain the upper triangular band part of the hermitian matrix, supplied column by column, with the leading diagonal of the matrix in row $(ndiag + 1)$ of the array, the first super-diagonal starting at position 2 in row $ndiag$, and so on. The top left $ndiag$ by $ndiag$ triangle of the array A is not referenced. The following program segment will transfer the upper triangular part of a hermitian band matrix from conventional full matrix storage to band storage:

```

DO 20, J = 1, N
  M = NDIAG + 1 - J
  DO 10, I = MAX( 1, J - NDIAG ), J
    A( M + I, J ) = matrix( I, J )

```

```
10 CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (ndiag + 1) by n part of the array A must contain the lower triangular band part of the hermitian matrix, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right ndiag by ndiag triangle of the array A is not referenced. The following program segment will transfer the lower triangular part of a hermitian band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
         M = 1 - J
         DO 10, I = J, MIN( N, J + NDIAG )
            A( M + I, J ) = matrix( I, J )
10      CONTINUE
20      CONTINUE
```

Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= (ndiag + 1). Unchanged on exit.

X (input)

(1 + (n - 1) * abs(INCX)). Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. Unchanged on exit.

Y (input/output)

(1 + (n - 1) * abs(INCY)). Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

[WORK], [INFO])
```

```
CHARACTER(LEN=1) :: VECT, UPLO  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:, :) :: AB, Q  
INTEGER(8) :: N, KD, LDAB, LDQ, INFO  
REAL, DIMENSION(:) :: D, E
```

C INTERFACE

```
#include <sunperf.h>

void chbtrd(char vect, char uplo, int n, int kd, complex
            *ab, int ldab, float *d, float *e, complex *q, int
            ldq, int *info);
void chbtrd_64(char vect, char uplo, long n, long kd, com-
               plex *ab, long ldab, float *d, float *e, complex
               *q, long ldq, long *info);
```

PURPOSE

chbtrd reduces a complex Hermitian band matrix A to real symmetric tridiagonal form T by a unitary similarity transformation: $Q^*H * A * Q = T$.

ARGUMENTS

VECT (input)

= 'N': do not form Q;
= 'V': form Q;
= 'U': update a matrix X, by forming $X*Q$.

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

AB (input/output)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first $KD+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$. On exit, the diagonal elements of AB are overwritten by the diagonal elements of the tridiagonal matrix T; if $KD > 0$, the elements on the first superdiagonal (if UPLO = 'U') or the first subdiagonal (if UPLO = 'L') are overwritten by the off-diagonal elements of T; the rest of AB is overwritten by values generated during the reduction.

LDAB (input)

The leading dimension of the array AB. $LDAB \geq KD+1$.

D (output)

The diagonal elements of the tridiagonal matrix T.

E (output)

The off-diagonal elements of the tridiagonal matrix T: $E(i) = T(i, i+1)$ if UPLO = 'U'; $E(i) =$

T(i+1,i) if UPLO = 'L'.

Q (input/output)

On entry, if VECT = 'U', then Q must contain an N-by-N matrix X; if VECT = 'N' or 'V', then Q need not be set.

On exit: if VECT = 'V', Q contains the N-by-N unitary matrix Q; if VECT = 'U', Q contains the product X*Q; if VECT = 'N', the array Q is not referenced.

LDQ (input)

The leading dimension of the array Q. LDQ >= 1, and LDQ >= N if VECT = 'V' or 'U'.

WORK (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>
void checon(char uplo, int n, complex *a, int lda, int
            *ipivot, float anorm, float *rcond, int *info);

void checon_64(char uplo, long n, complex *a, long lda, long
              *ipivot, float anorm, float *rcond, long *info);
```

PURPOSE

checon estimates the reciprocal of the condition number of a complex Hermitian matrix A using the factorization $A = U*D*U**H$ or $A = L*D*L**H$ computed by CHETRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is $A = U*D*U**H$;
= 'L': Lower triangular, form is $A = L*D*L**H$.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by CHETRF.

ANORM (input)

The 1-norm of the original matrix A.

RCOND (output)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

WORK (workspace)

dimension(2*N)

SUBROUTINE HEEV(JOBZ, UPLO, [N], A, [LDA], W, [WORK], [LDWORK],  
[WORK2], [INFO])
```

```
CHARACTER(LEN=1) :: JOBZ, UPLO  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER :: N, LDA, LDWORK, INFO  
REAL, DIMENSION(:) :: W, WORK2
```

```
SUBROUTINE HEEV_64(JOBZ, UPLO, [N], A, [LDA], W, [WORK], [LDWORK],  
[WORK2], [INFO])
```

```
CHARACTER(LEN=1) :: JOBZ, UPLO  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: N, LDA, LDWORK, INFO  
REAL, DIMENSION(:) :: W, WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cheev(char jobz, char uplo, int n, complex *a, int lda,
```

```
float *w, int *info);

void cheev_64(char jobz, char uplo, long n, complex *a, long
             lda, float *w, long *info);
```

PURPOSE

cheev computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, N)$.

W (output)
If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of the array WORK. $LDWORK \geq \max(1, 2*N-1)$. For optimal efficiency, $LDWORK \geq (NB+1)*N$, where NB is the blocksize for CHETRD returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
dimension($\max(1, 3*N-2)$)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

  [RWORK], [LRWORK], [IWORK], [LIWORK], [INFO])
```

```
CHARACTER(LEN=1) :: JOBZ, UPLO  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:,:) :: A  
INTEGER(8) :: N, LDA, LWORK, LRWORK, LIWORK, INFO
```

```
INTEGER(8), DIMENSION(:) :: IWORK
REAL, DIMENSION(:) :: W, RWORK
```

C INTERFACE

```
#include <sunperf.h>
void cheevd(char jobz, char uplo, int n, complex *a, int
            lda, float *w, int *info);

void cheevd_64(char jobz, char uplo, long n, complex *a,
              long lda, float *w, long *info);
```

PURPOSE

cheevd computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, N)$.

W (output)
If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The length of the array WORK. If $N \leq 1$, LWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LWORK must be at least $N + 1$. If JOBZ = 'V' and $N > 1$, LWORK must be at least $2*N + N**2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK (input)

The dimension of the array RWORK. If $N \leq 1$, LRWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LRWORK must be at least N . If JOBZ = 'V' and $N > 1$, LRWORK must be at least $1 + 5*N + 2*N**2$.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of the array IWORK. If $N \leq 1$, LIWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LIWORK must be at least 1. If JOBZ = 'V' and $N > 1$, LIWORK must be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

  ldz, int *isuppz, int *info);

```

```

void cheevr_64(char jobz, char range, char uplo, long n,
  complex *a, long lda, float vl, float vu, long il,
  long iu, float abstol, long *m, float *w, complex
  *z, long ldz, long *isuppz, long *info);

```

PURPOSE

cheevr computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian tridiagonal matrix T. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, CHEEVR calls CSTEGR to compute the eigenspectrum using Relatively Robust Representations. CSTEGR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" L D L^T representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i-th unreduced block of T,

- (a) Compute $T - \sigma_i = L_i D_i L_i^T$, such that $L_i D_i L_i^T$ is a relatively robust representation,
- (b) Compute the eigenvalues, λ_j , of $L_i D_i L_i^T$ to high relative accuracy by the dqds algorithm,
- (c) If there is a cluster of close eigenvalues, "choose" σ_i close to the cluster, and go to step (a),
- (d) Given the approximate eigenvalue λ_j of $L_i D_i L_i^T$, compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new $O(n^2)$ algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by

Inderjit Dhillon, Computer Science Division Technical Report
No. UCB//CSD-97-971, UC Berkeley, May 1997.

Note 1 : CHEEVR calls CSTEGR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. CHEEVR calls SSTEGBZ and CSTEIN on non-ieee machines and when partial spectrum requests are made.

Normal execution of CSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

ARGUMENTS

JOBZ (input)

= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)

= 'A': all eigenvalues will be found.
= 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,N)$.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

VU (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

ABSTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to SLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but future releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

M (output)

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

W (output)

The first M elements contain the selected eigenvalues in ascending order.

Z (output)

If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

ISUPPZ (output)

The support of the eigenvectors in Z, i.e., the

indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The length of the array WORK. LWORK \geq max(1,2*N). For optimal efficiency, LWORK \geq (NB+1)*N, where NB is the max of the blocksize for CHETRD and for CUNMTR as returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

On exit, if INFO = 0, RWORK(1) returns the optimal (and minimal) LRWORK.

LRWORK (input)

The length of the array RWORK. LRWORK \geq max(1,24*N).

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO = 0, IWORK(1) returns the optimal (and minimal) LIWORK.

LIWORK (input)

The dimension of the array IWORK. LIWORK \geq max(1,10*N).

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: Internal error

               plex *z, long ldz, long *ifail, long *info);

```

PURPOSE

cheevx computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)

```

= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

```

RANGE (input)

```

= 'A': all eigenvalues will be found.
= 'V': all eigenvalues in the half-open interval
(VL,VU] will be found. = 'I': the IL-th through
IU-th eigenvalues will be found.

```

UPLO (input)

```

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

```

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

ABTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

$$ABTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2 * SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABTOL to $2 * SLAMCH('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)

The total number of eigenvalues found. $0 \leq NFOUND \leq N$. If RANGE = 'A', $NFOUND = N$, and if RANGE = 'I', $NFOUND = IU - IL + 1$.

W (output)

On normal exit, the first NFOUND elements contain the selected eigenvalues in ascending order.

Z (input)

If $JOBZ = 'V'$, then if $INFO = 0$, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If an eigenvector fails to converge, then that column of Z con-

tains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, \text{NFOUND})$ columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. LDZ \geq 1, and if JOBZ = 'V', LDZ \geq $\max(1, N)$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The length of the array WORK. LDWORK \geq $\max(1, 2*N)$. For optimal efficiency, LDWORK \geq $(\text{NB}+1)*N$, where NB is the max of the blocksize for CHETRD and for CUNMTR as returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)

dimension(7*N)

IWORK3 (workspace)

dimension(5*N)

IFAIL (output)

If JOBZ = 'V', then if INFO = 0, the first NFOUND elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

           lda, complex *b, int ldb, int *info);
```

```
void chegs2_64(long itype, char uplo, long n, complex *a,  
              long lda, complex *b, long ldb, long *info);
```

PURPOSE

chegs2 reduces a complex Hermitian-definite generalized eigenproblem to standard form.

If ITYPE = 1, the problem is $A*x = \lambda*B*x$, and A is overwritten by $\text{inv}(U')*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L')$.
If ITYPE = 2 or 3, the problem is $A*B*x = \lambda*x$ or $B*A*x = \lambda*x$, and A is overwritten by $U*A*U'$ or $L'*A*L$.

B must have been previously factorized as $U'*U$ or $L*L'$ by CPOTRF.

ARGUMENTS

ITYPE (input)

= 1: compute $\text{inv}(U')*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L')$;
= 2 or 3: compute $U*A*U'$ or $L'*A*L$.

UPLO (input)

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored, and how B has been factorized. = 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

B (input) The triangular factor from the Cholesky factorization of B, as returned by CPOTRF.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

INFO (output)

= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

void chegst(int itype, char uplo, int n, complex *a, int  
           lda, complex *b, int ldb, int *info);
```

```
void chegst_64(long itype, char uplo, long n, complex *a,  
              long lda, complex *b, long ldb, long *info);
```

PURPOSE

chegst reduces a complex Hermitian-definite generalized eigenproblem to standard form.

If ITYPE = 1, the problem is $A*x = \lambda*B*x$, and A is overwritten by $\text{inv}(U^{**H})*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^{**H})$

If ITYPE = 2 or 3, the problem is $A*B*x = \lambda*x$ or $B*A*x = \lambda*x$, and A is overwritten by $U*A*U^{**H}$ or $L^{**H}*A*L$.

B must have been previously factorized as $U^{**H}*U$ or $L*L^{**H}$ by CPOTRF.

ARGUMENTS

ITYPE (input)
= 1: compute $\text{inv}(U^{**H})*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^{**H})$;
= 2 or 3: compute $U*A*U^{**H}$ or $L^{**H}*A*L$.

UPLO (input)
= 'U': Upper triangle of A is stored and B is factored as $U^{**H}*U$; = 'L': Lower triangle of A is stored and B is factored as $L*L^{**H}$.

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)
On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1,N)$.

B (input) The triangular factor from the Cholesky factorization of B, as returned by CPOTRF.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1,N)$.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>

void chegv(int itype, char jobz, char uplo, int n, complex
           *a, int lda, complex *b, int ldb, float *w, int
           *info);

void chegv_64(long itype, char jobz, char uplo, long n, com-
              plex *a, long lda, complex *b, long ldb, float *w,
              long *info);
```

PURPOSE

chegv computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be Hermitian and B is also positive definite.

ARGUMENTS

ITYPE (input)
 Specifies the problem type to be solved:
 = 1: $A*x = (\lambda)*B*x$
 = 2: $A*B*x = (\lambda)*x$
 = 3: $B*A*x = (\lambda)*x$

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangles of A and B are stored;
 = 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)
 On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.
 On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z**H*B*Z = I$; if ITYPE = 3, $Z**H*inv(B)*Z = I$. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1,N)$.

B (input/output)
 On entry, the Hermitian positive definite matrix B. If UPLO = 'U', the leading N-by-N upper tri-

angular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO \leq N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^*H^*U$ or $B = L^*L^*H$.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,N).

W (output)

If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The length of the array WORK. LDWORK \geq max(1,2*N-1). For optimal efficiency, LDWORK \geq (NB+1)*N, where NB is the blocksize for CHETRD returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)

dimension(max(1,3*N-2))

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: CPOTRF or CHEEV returned an error code:
<= N: if INFO = i, CHEEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 \leq i \leq N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

C INTERFACE

```

#include <sunperf.h>

void chegvd(int itype, char jobz, char uplo, int n, complex
*a, int lda, complex *b, int ldb, float *w, int
*info);

void chegvd_64(long itype, char jobz, char uplo, long n,
complex *a, long lda, complex *b, long ldb, float
*w, long *info);

```

PURPOSE

chegvd computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be Hermitian and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

ITYPE (input)

Specifies the problem type to be solved:
= 1: $A*x = (\lambda)*B*x$
= 2: $A*B*x = (\lambda)*x$
= 3: $B*A*x = (\lambda)*x$

JOBZ (input)

= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)

= 'U': Upper triangles of A and B are stored;
= 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A con-

tains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z^{*H}B*Z = I$; if ITYPE = 3, $Z^{*H}inv(B)*Z = I$. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

LDA (input)

The leading dimension of the array A. LDA \geq max(1,N).

B (input/output)

On entry, the Hermitian matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO \leq N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^{*H}U$ or $B = L*L^{*H}$.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,N).

W (output)

If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The length of the array WORK. If $N \leq 1$, LWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LWORK $\geq N + 1$. If JOBZ = 'V' and $N > 1$, LWORK $\geq 2*N + N^{*2}$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK (input)

The dimension of the array RWORK. If $N \leq 1$, LRWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LRWORK $\geq N$. If JOBZ = 'V' and $N > 1$, LRWORK $\geq 1 + 5*N + 2*N^{*2}$.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of the array IWORK. If $N \leq 1$, LIWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LIWORK ≥ 1 . If JOBZ = 'V' and $N > 1$, LIWORK $\geq 3 + 5*N$.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: CPOTRF or CHEEVD returned an error code:
<= N: if INFO = i, CHEEVD failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for $1 \leq i \leq N$, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

```

PURPOSE

chegvx computes selected eigenvalues, and optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*B*x=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be Hermitian and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

ITYPE (input)

Specifies the problem type to be solved:

= 1: $A*x = (\lambda)*B*x$

= 2: $A*B*x = (\lambda)*x$

= 3: $B*A*x = (\lambda)*x$

JOBZ (input)

= 'N': Compute eigenvalues only;

= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)

= 'A': all eigenvalues will be found.

= 'V': all eigenvalues in the half-open interval

(VL,VU] will be found. = 'I': the IL-th through

IU-th eigenvalues will be found.

UPLO (input)

= 'U': Upper triangles of A and B are stored;

= 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)
 On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.
 On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1, N)$.

B (input/output)
 On entry, the Hermitian matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.
 On exit, if $INFO \leq N$, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^*H*U$ or $B = L*L^*H$.

LDB (input)
 The leading dimension of the array B. $LDB \geq \max(1, N)$.

VL (input)
 If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

VU (input)
 If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

IL (input)
 If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)
 If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

ABSTOL (input)
 The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

$ABSTOL + EPS * \max(|a|, |b|)$,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS*|T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2*SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABSTOL to $2*SLAMCH('S')$.

M (output)

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

W (output)

The first M elements contain the selected eigenvalues in ascending order.

Z (output)

If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if $INFO = 0$, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized as follows: if $ITYPE = 1$ or 2 , $Z^T B Z = I$; if $ITYPE = 3$, $Z^T \text{inv}(B) Z = I$.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

WORK (workspace/output)

On exit, if $INFO = 0$, WORK(1) returns the optimal LWORK.

LWORK (input)

The length of the array WORK. $LWORK \geq \max(1, 2*N - 1)$. For optimal efficiency, $LWORK \geq (NB + 1)*N$, where NB is the blocksize for CHETRD returned by ILAENV.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

dimension(7*N)

IWORK (workspace)
dimension(5*N)

IFAIL (output)
If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: CPOTRF or CHEEVX returned an error code:
<= N: if INFO = i, CHEEVX failed to converge; i eigenvectors failed to converge. Their indices are stored in array IFAIL. > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

```

```
void chemm(char side, char uplo, int m, int n, complex
           *alpha, complex *a, int lda, complex *b, int ldb,
```

```

        complex *beta, complex *c, int ldc);

void chemm_64(char side, char uplo, long m, long n, complex
             *alpha, complex *a, long lda, complex *b, long
             ldb, complex *beta, complex *c, long ldc);

```

PURPOSE

chemm performs one of the matrix-matrix operations $C := \alpha A^*B + \beta C$ or $C := \alpha B^*A + \beta C$ where α and β are scalars, A is an hermitian matrix and B and C are m by n matrices.

ARGUMENTS

SIDE (input)

On entry, SIDE specifies whether the hermitian matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l' $C := \alpha A^*B + \beta C$,

SIDE = 'R' or 'r' $C := \alpha B^*A + \beta C$,

Unchanged on exit.

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the hermitian matrix A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of the hermitian matrix is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of the hermitian matrix is to be referenced.

Unchanged on exit.

M (input)

On entry, M specifies the number of rows of the matrix C . $M \geq 0$. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix C . $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

A (input)

COMPLEX array of DIMENSION (LDA, ka), where ka is m when SIDE = 'L' or 'l' and is n otherwise.

Before entry with SIDE = 'L' or 'l', the m by m part of the array A must contain the hermitian matrix, such that when UPLO = 'U' or 'u', the leading m by m upper triangular part of the array A must contain the upper triangular part

of the hermitian matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading m by m lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced.

Before entry with SIDE = 'R' or 'r', the n by n part of the array A must contain the hermitian matrix, such that when UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced.

Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then $LDA \geq \max(1, m)$, otherwise $LDA \geq \max(1, n)$. Unchanged on exit.

B (input)

COMPLEX array of DIMENSION (LDB, n). Before entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least $\max(1, m)$. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

C (input/output)

COMPLEX array of DIMENSION (LDC, n).

Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry.

On exit, the array C is overwritten by the m by n updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, m)$. Unchanged on exit.

```

```
void chemv(char uplo, int n, complex *alpha, complex *a, int  
lda, complex *x, int incx, complex *beta, complex  
*y, int incy);
```

```
void chemv_64(char uplo, long n, complex *alpha, complex *a,
              long lda, complex *x, long incx, complex *beta,
              complex *y, long incy);
```

PURPOSE

chemv performs the matrix-vector operation $y := \alpha A x + \beta y$ where α and β are scalars, x and y are n element vectors and A is an n by n hermitian matrix.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, n)$. Unchanged on exit.

X (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. $\text{INCX} \neq 0$. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)

($1 + (n - 1) * \text{abs}(\text{INCY})$). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

REAL :: ALPHA
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cher(char uplo, int n, float alpha, complex *x, int  
         incx, complex *a, int lda);
```

```
void cher_64(char uplo, long n, float alpha, complex *x,
```

```
long incx, complex *a, long lda);
```

PURPOSE

cher performs the hermitian rank 1 operation $A := \alpha x \text{conjg}(x') + A$ where α is a real scalar, x is an n element vector and A is an n by n hermitian matrix.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

X (input)

$(1 + (n - 1) \cdot \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X . $\text{INCX} \neq 0$. Unchanged on exit.

A (input/output)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA \geq max(1, n). Unchanged on exit.

C INTERFACE

```
#include <sunperf.h>
```

```
void cher2(char uplo, int n, complex *alpha, complex *x, int  
          incx, complex *y, int incy, complex *a, int lda);
```

```
void cher2_64(char uplo, long n, complex *alpha, complex *x,
```

```
long incx, complex *y, long incy, complex *a, long
lda);
```

PURPOSE

cher2 performs the hermitian rank 2 operation $A := \alpha x \text{conjg}(y) + \text{conjg}(\alpha) y \text{conjg}(x) + A$ where α is a scalar, x and y are n element vectors and A is an n by n hermitian matrix.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

X (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. $\text{INCX} \neq 0$. Unchanged on exit.

Y (input)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector y . Unchanged on exit.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

A (input/output)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n

lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA \geq max(1, n). Unchanged on exit.

SUBROUTINE HER2K_64(UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], B,
                   [LDB], BETA, C, [LDC])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA
COMPLEX :: ALPHA
COMPLEX, DIMENSION(:, :) :: A, B, C
INTEGER(8) :: N, K, LDA, LDB, LDC
REAL :: BETA
```

C INTERFACE

```
#include <sunperf.h>
void cher2k(char uplo, char transa, int n, int k, complex*
    alpha, complex *a, int lda, complex *b, int ldb,
    float beta, complex *c, int ldc);

void cher2k_64(char uplo, char transa, long n, long k, com-
    plex *alpha, complex *a, long lda, complex *b,
    long ldb, float beta, complex *c, long ldc);
```

PURPOSE

cher2k performs one of the Hermitian rank 2k operations $C := \alpha A \text{conjg}(B') + \text{conjg}(\alpha) B \text{conjg}(A') + \beta C$ or $C := \alpha \text{conjg}(A') B + \text{conjg}(\alpha) \text{conjg}(B') A + \beta C$ where α and β are scalars with β real, C is an n by n Hermitian matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $C := \alpha A \text{conjg}(B') + \text{conjg}(\alpha) B \text{conjg}(A') + \beta C$.

TRANSA = 'C' or 'c' $C := \alpha \text{conjg}(A') B + \text{conjg}(\alpha) \text{conjg}(B') A + \beta C$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)

On entry, N specifies the order of the matrix C . N must be at least zero. Unchanged on exit.

K (input)

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrices A and B , and on entry with TRANSA = 'C' or 'c', K specifies the number of rows of the matrices A and B . K must be at least zero. Unchanged on

exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

COMPLEX array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least $\max(1, n)$, otherwise LDA must be at least $\max(1, k)$. Unchanged on exit.

B (input)

COMPLEX array of DIMENSION (LDB, kb), where kb is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array B must contain the matrix B, otherwise the leading k by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDB must be at least $\max(1, n)$, otherwise LDB must be at least $\max(1, k)$. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. Unchanged on exit.

C (input/output)

COMPLEX array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be

zero, and on exit they are set to zero.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, n)$. Unchanged on exit.

```

PURPOSE

cherfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1, N)$.

AF (input)
 The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^*H$ or $A = L*D*L^*H$ as computed by CHETRF.

LDAF (input)
 The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

IPIVOT (input)
 Details of the interchanges and the block struc-

ture of D as determined by CHETRF.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB \geq
max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by
CHETRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX \geq
max(1,N).

FERR (output)
The estimated forward error bound for each solu-
tion vector X(j) (the j-th column of the solution
matrix X). If XTRUE is the true solution
corresponding to X(j), FERR(j) is an estimated
upper bound for the magnitude of the largest ele-
ment in (X(j) - XTRUE) divided by the magnitude of
the largest element in X(j). The estimate is as
reliable as the estimate for RCOND, and is almost
always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each
solution vector X(j) (i.e., the smallest relative
change in any element of A or B that makes X(j) an
exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-
gal value

```

```
CHARACTER(LEN=1) :: UPLO, TRANSA  
COMPLEX, DIMENSION(:, :) :: A, C  
INTEGER(8) :: N, K, LDA, LDC  
REAL :: ALPHA, BETA
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cherk(char uplo, char transa, int n, int k, float  
alpha, complex *a, int lda, float beta, complex  
*c, int ldc);
```

```
void cherk_64(char uplo, char transa, long n, long k, float
alpha, complex *a, long lda, float beta, complex
*c, long ldc);
```

PURPOSE

cherk performs one of the Hermitian rank k operations $C := \alpha A \text{conjg}(A') + \beta C$ or $C := \alpha \text{conjg}(A') A + \beta C$ where α and β are real scalars, C is an n by n Hermitian matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $C := \alpha A \text{conjg}(A') + \beta C$.

TRANSA = 'C' or 'c' $C := \alpha \text{conjg}(A') A + \beta C$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)

On entry, N specifies the order of the matrix C . N must be at least zero. Unchanged on exit.

K (input)

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrix A , and on entry with TRANSA = 'C' or 'c', K specifies the number of rows of the matrix A . K must be at least zero. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

A (input)

COMPLEX array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or

'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least $\max(1, n)$, otherwise LDA must be at least $\max(1, k)$. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. Unchanged on exit.

C (input/output)

COMPLEX array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, n)$. Unchanged on exit.

```

```

void chesv(char uplo, int n, int nrhs, complex *a, int lda,
           int *ipivot, complex *b, int ldb, int *info);
void chesv_64(char uplo, long n, long nrhs, complex *a, long
              lda, long *ipivot, complex *b, long ldb, long
              *info);

```

PURPOSE

chesv computes the solution to a complex system of linear equations

$A * X = B$, where A is an N-by-N Hermitian matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$A = U * D * U^{*H}$, if UPLO = 'U', or

$A = L * D * L^{*H}$, if UPLO = 'L',

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input/output)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U * D * U^{*H}$ or $A = L * D * L^{*H}$ as computed by CHETRF.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (output)

Details of the interchanges and the block structure of D, as determined by CHETRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were

interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If $UPL0 = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns $k+1$ and $-IPIVOT(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B.
On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

LDWORK (input)

The length of WORK. $LDWORK \geq 1$, and for best performance $LDWORK \geq N \cdot NB$, where NB is the optimal blocksize for CHETRF.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value
> 0: if $INFO = i$, $D(i, i)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

```

PURPOSE

chesvx uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N Hermitian matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the diagonal pivoting method is used to factor A .

The form of the factorization is

$A = U * D * U^{*H}$, if $UPLO = 'U'$, or

$A = L * D * L^{*H}$, if $UPLO = 'L'$,

where U (or L) is a product of permutation and unit upper (lower)

triangular matrices, and D is Hermitian and block diagonal with

1-by-1 and 2-by-2 diagonal blocks.

2. If some $D(i,i)=0$, so that D is exactly singular, then the routine

returns with $INFO = i$. Otherwise, the factored form of A is used

to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision,

$INFO = N+1$ is returned as a warning, but the routine still goes on

to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form

of A .

4. Iterative refinement is applied to improve the computed solution

matrix and calculate error bounds and backward error estimates for it.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AF and IPIVOT contain the factored form of A. A, AF and IPIVOT will not be modified. = 'N': The matrix A will be copied to AF and factored.

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

AF (input/output)

If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^*H$ or $A = L*D*L^*H$ as computed by CHETRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^*H$ or $A = L*D*L^*H$.

LDAF (input)

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

IPIVOT (input or output)

If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CHETRF. If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged and $D(k, k)$ is a 1-by-1 diagonal block. If UPLO = 'U' and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns

$k-1$ and $-IPIVOT(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns $k+1$ and $-IPIVOT(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

If $FACT = 'N'$, then $IPIVOT$ is an output argument and on exit contains details of the interchanges and the block structure of D , as determined by $CHETRF$.

B (input) The N -by- $NRHS$ right hand side matrix B .

LDB (input)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

X (output)

If $INFO = 0$ or $INFO = N+1$, the N -by- $NRHS$ solution matrix X .

LDX (input)

The leading dimension of the array X . $LDX \geq \max(1, N)$.

RCOND (output)

The estimate of the reciprocal condition number of the matrix A . If $RCOND$ is less than the machine precision (in particular, if $RCOND = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $INFO > 0$.

FERR (output)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If $XTRUE$ is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$.

LDWORK (input)

The length of $WORK$. $LDWORK \geq 2*N$, and for best performance $LDWORK \geq N*NB$, where NB is the optimal blocksize for $CHETRF$.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LDWORK$ is issued by $XERBLA$.

WORK2 (workspace)
dimension(N)
INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

```

```
void chetf2(char uplo, int n, complex *a, int lda, int  
          *ipiv, int *info);
```

```
void chetf2_64(char uplo, long n, complex *a, long lda, long
```

```
*ipiv, long *info);
```

PURPOSE

chetf2 computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method:

$A = U^*D^*U'$ or $A = L^*D^*L'$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U' is the conjugate transpose of U, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored:

= 'U': Upper triangular

= 'L': Lower triangular

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIV (output)

Details of the interchanges and the block structure of D. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k, k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1, k:k+1) is a 2-by-2 diagonal block.

INFO (output)

= 0: successful exit

< 0: if INFO = -k, the k-th argument had an illegal value

> 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

1-96 - Based on modifications by

J. Lewis, Boeing Computer Services Company

A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

If UPLO = 'U', then $A = U^*D^*U$, where

$$U = P(n)^*U(n)^* \dots *P(k)^*U(k)^* \dots,$$

i.e., U is a product of terms $P(k)^*U(k)$, where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIV(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

$$U(k) = \begin{pmatrix} I & v & 0 &) & k-s \\ 0 & I & 0 &) & s \\ 0 & 0 & I &) & n-k \\ k-s & s & n-k & & \end{pmatrix}$$

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k). If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then $A = L^*D^*L$, where

$$L = P(1)^*L(1)^* \dots *P(k)^*L(k)^* \dots,$$

i.e., L is a product of terms $P(k)^*L(k)$, where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIV(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

$$L(k) = \begin{pmatrix} I & 0 & 0 &) & k-1 \\ 0 & I & 0 &) & s \\ 0 & v & I &) & n-k-s+1 \\ k-1 & s & n-k-s+1 & & \end{pmatrix}$$

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

```

C INTERFACE

```
#include <sunperf.h>
```

```

void chetrd(char uplo, int n, complex *a, int lda, float *d,
            float *e, complex *tau, int *info);

void chetrd_64(char uplo, long n, complex *a, long lda,
               float *d, float *e, complex *tau, long *info);

```

PURPOSE

chetrd reduces a complex Hermitian matrix A to real symmetric tridiagonal form T by a unitary similarity transformation: $Q^*H * A * Q = T$.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input) On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1,N)$.

D (output)
 The diagonal elements of the tridiagonal matrix T:
 $D(i) = A(i,i)$.

E (output)
 The off-diagonal elements of the tridiagonal matrix T: $E(i) = A(i,i+1)$ if UPLO = 'U', $E(i) = A(i+1,i)$ if UPLO = 'L'.

TAU (output)
 The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)
 On exit, if INFO = 0, WORK(1) returns the optimal

LWORK.

LWORK (input)

The dimension of the array WORK. LWORK ≥ 1 . For optimum performance LWORK $\geq N \cdot NB$, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

If UPLO = 'U', the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) \dots H(2) H(1).$$

Each H(i) has the form

$$H(i) = I - \tau * v * v'$$

where tau is a complex scalar, and v is a complex vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(1:i-1, i+1)$, and tau in TAU(i).

If UPLO = 'L', the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(n-1).$$

Each H(i) has the form

$$H(i) = I - \tau * v * v'$$

where tau is a complex scalar, and v is a complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(i+2:n, i)$, and tau in TAU(i).

The contents of A on exit are illustrated by the following examples with $n = 5$:

if UPLO = 'U':

```
(  d   e   v2  v3  v4  )
)
(      d   e   v3  v4  )
)
(          d   e   v4  )
)
(              d   e   )
)
(                  d   )
)
```

if UPLO = 'L':

```
(  d
)
( e  d
)
( v1 e  d
)
( v1 v2 e  d
)
( v1 v2 v3 e  d
)
```

where d and e denote diagonal and off-diagonal elements of T , and v_i denotes an element of the vector defining $H(i)$.

INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chetrf(char uplo, int n, complex *a, int lda, int
```

```

        *ipivot, int *info);

void chetrf_64(char uplo, long n, complex *a, long lda, long
        *ipivot, long *info);

```

PURPOSE

chetrf computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

$$A = U*D*U^*H \quad \text{or} \quad A = L*D*L^*H$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (output)

Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k, k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1, k:k+1) is a 2-by-2 diagonal block.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The length of WORK. LDWORK ≥ 1 . For best performance LDWORK $\geq N \cdot NB$, where NB is the block size returned by ILAENV.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

If UPLO = 'U', then $A = U \cdot D \cdot U'$, where

$U = P(n) \cdot U(n) \cdot \dots \cdot P(k) \cdot U(k) \cdot \dots$,
i.e., U is a product of terms $P(k) \cdot U(k)$, where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

$$U(k) = \begin{pmatrix} I & v & 0 &) & k-s \\ 0 & I & 0 &) & s \\ 0 & 0 & I &) & n-k \\ k-s & s & n-k & & \end{pmatrix}$$

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k). If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then $A = L \cdot D \cdot L'$, where

$L = P(1) \cdot L(1) \cdot \dots \cdot P(k) \cdot L(k) \cdot \dots$,
i.e., L is a product of terms $P(k) \cdot L(k)$, where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

$$L(k) = \begin{pmatrix} I & 0 & 0 &) & k-1 \\ 0 & I & 0 &) & s \\ 0 & v & I &) & n-k-s+1 \\ k-1 & s & n-k-s+1 & & \end{pmatrix}$$

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

```

C INTERFACE

```
#include <sunperf.h>
```

```
void chetri(char uplo, int n, complex *a, int lda, int  
            *ipivot, int *info);
```

```
void chetri_64(char uplo, long n, complex *a, long lda, long
               *ipivot, long *info);
```

PURPOSE

chetri computes the inverse of a complex Hermitian indefinite matrix A using the factorization $A = U*D*U^{*H}$ or $A = L*D*L^{*H}$ computed by CHETRF.

ARGUMENTS

UPLO (input)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is $A = U*D*U^{*H}$;
= 'L': Lower triangular, form is $A = L*D*L^{*H}$.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF.

On exit, if INFO = 0, the (Hermitian) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by CHETRF.

WORK (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, $D(i,i) = 0$; the matrix is singular and its inverse could not be computed.

PURPOSE

chetrs solves a system of linear equations $A \cdot X = B$ with a complex Hermitian matrix A using the factorization $A = U \cdot D \cdot U^* \cdot H$ or $A = L \cdot D \cdot L^* \cdot H$ computed by CHETRF.

ARGUMENTS

UPLO (input)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is $A = U \cdot D \cdot U^* \cdot H$;
= 'L': Lower triangular, form is $A = L \cdot D \cdot L^* \cdot H$.

N (input) The order of the matrix A . $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF.

LDA (input)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by CHETRF.

B (input/output)

On entry, the right hand side matrix B . On exit, the solution matrix X .

LDB (input)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value

              *info);

```

PURPOSE

chgeqz implements a single-shift version of the QZ method for finding the generalized eigenvalues $w(i)=\text{ALPHA}(i)/\text{BETA}(i)$ of the equation A are then $\text{ALPHA}(1), \dots, \text{ALPHA}(N)$, and of B are $\text{BETA}(1), \dots, \text{BETA}(N)$.

If $\text{JOB}='S'$ and COMPQ and COMPZ are 'V' or 'I', then the unitary transformations used to reduce (A,B) are accumulated into the arrays Q and Z s.t.:

(in) $A(\text{in}) Z(\text{in})^* = Q(\text{out}) A(\text{out}) Z(\text{out})^*$

Ref: C.B. Moler & G.W. Stewart, "An Algorithm for Generalized Matrix Eigenvalue Problems", SIAM J. Numer. Anal., 10(1973), p. 241--256.

ARGUMENTS

JOB (input)
 = 'E': compute only ALPHA and BETA. A and B will not necessarily be put into generalized Schur form. = 'S': put A and B into generalized Schur form, as well as computing ALPHA and BETA.

COMPQ (input)
 = 'N': do not modify Q .
 = 'V': multiply the array Q on the right by the conjugate transpose of the unitary transformation that is applied to the left side of A and B to reduce them to Schur form. = 'I': like $\text{COMPQ}='V'$, except that Q will be initialized to the identity first.

COMPZ (input)
 = 'N': do not modify Z .
 = 'V': multiply the array Z on the right by the unitary transformation that is applied to the right side of A and B to reduce them to Schur form. = 'I': like $\text{COMPZ}='V'$, except that Z will be initialized to the identity first.

N (input) The order of the matrices A, B, Q, and Z. $N \geq 0$.

ILO (input)

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; ILO=1 and IHI=0, if $N=0$.

IHI (input)

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; ILO=1 and IHI=0, if $N=0$.

A (input) On entry, the N-by-N upper Hessenberg matrix A. Elements below the subdiagonal must be zero. If JOB='S', then on exit A and B will have been simultaneously reduced to upper triangular form. If JOB='E', then on exit A will have been destroyed.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

B (input) On entry, the N-by-N upper triangular matrix B. Elements below the diagonal must be zero. If JOB='S', then on exit A and B will have been simultaneously reduced to upper triangular form. If JOB='E', then on exit B will have been destroyed.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

ALPHA (output)

The diagonal elements of A when the pair (A,B) has been reduced to Schur form. ALPHA(i)/BETA(i) $i=1, \dots, N$ are the generalized eigenvalues.

BETA (output)

The diagonal elements of B when the pair (A,B) has been reduced to Schur form. ALPHA(i)/BETA(i) $i=1, \dots, N$ are the generalized eigenvalues. A and B are normalized so that BETA(1), ..., BETA(N) are non-negative real numbers.

Q (input/output)

If COMPQ='N', then Q will not be referenced. If COMPQ='V' or 'I', then the conjugate transpose of the unitary transformations which are applied to A and B on the left will be applied to the array Q on the right.

LDQ (input)

The leading dimension of the array Q. $LDQ \geq 1$. If COMPQ='V' or 'I', then $LDQ \geq N$.

Z (input/output)

If COMPZ='N', then Z will not be referenced. If COMPZ='V' or 'I', then the unitary transformations which are applied to A and B on the right will be applied to the array Z on the right.

LDZ (input)

The leading dimension of the array Z. LDZ >= 1.
If COMPZ='V' or 'I', then LDZ >= N.

WORK (workspace)

On exit, if INFO >= 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK >= max(1,N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

= 1,...,N: the QZ iteration did not converge. (A,B) is not in Schur form, but ALPHA(i) and BETA(i), i=INFO+1,...,N should be correct.

= N+1,...,2*N: the shift calculation failed. (A,B) is not in Schur form, but ALPHA(i) and BETA(i), i=INFO-N+1,...,N should be correct. > 2*N: various "impossible" errors.

FURTHER DETAILS

We assume that complex ABS works as long as its value is less than overflow.

```

PURPOSE

chpcon estimates the reciprocal of the condition number of a complex Hermitian packed matrix A using the factorization $A = U^*D^*U^{**H}$ or $A = L^*D^*L^{**H}$ computed by CHPTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is $A = U^*D^*U^{**H}$;
= 'L': Lower triangular, form is $A = L^*D^*L^{**H}$.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHPTRF, stored as a packed triangular matrix.

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by CHPTRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

WORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if $\text{INFO} = -i$, the i-th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>
```

```
void chpev(char jobz, char uplo, int n, complex *a, float  
*w, complex *z, int ldz, int *info);
```

```
void chpev_64(char jobz, char uplo, long n, complex *a,
              float *w, complex *z, long ldz, long *info);
```

PURPOSE

chpev computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix in packed storage.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

W (output)
If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

WORK (workspace)
dimension(MAX(1,2*N-1))

WORK2 (workspace)
dimension(max(1,3*N-2))

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the algorithm failed to con-

verge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

```

C INTERFACE

```
#include <sunperf.h>
void chpevd(char jobz, char uplo, int n, complex *ap, float
            *w, complex *z, int ldz, int *info);

void chpevd_64(char jobz, char uplo, long n, complex *ap,
              float *w, complex *z, long ldz, long *info);
```

PURPOSE

chpevd computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)

= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

AP (input/output)

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

W (output)

If INFO = 0, the eigenvalues in ascending order.

Z (input)

If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with $W(i)$. If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ \geq 1, and if JOBZ = 'V', LDZ \geq max(1,N).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of array WORK. If N \leq 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be at least N. If JOBZ = 'V' and N > 1, LWORK must be at least 2*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK (input)

The dimension of array RWORK. If N \leq 1, LRWORK must be at least 1. If JOBZ = 'N' and N > 1, LRWORK must be at least N. If JOBZ = 'V' and N > 1, LRWORK must be at least $1 + 5*N + 2*N**2$.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of array IWORK. If JOBZ = 'N' or N \leq 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value.

> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

              long ldz, long *ifail, long *info);

```

PURPOSE

chpevx computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage. Eigenvalues/vectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
 = 'A': all eigenvalues will be found;
 = 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
 On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.
 On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

ABTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

$$ABTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2 * SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABTOL to $2 * SLAMCH('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)

The total number of eigenvalues found. $0 \leq NFOUND \leq N$. If RANGE = 'A', $NFOUND = N$, and if RANGE = 'I', $NFOUND = IU - IL + 1$.

W (output)

If $INFO = 0$, the selected eigenvalues in ascending order.

Z (input)

If $JOBZ = 'V'$, then if $INFO = 0$, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in

IFAIL. If JOBZ = 'N', then Z is not referenced.
Note: the user must ensure that at least
max(1,NFOUND) columns are supplied in the array Z;
if RANGE = 'V', the exact value of NFOUND is not
known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. LDZ \geq 1,
and if JOBZ = 'V', LDZ \geq max(1,N).

WORK (workspace)

dimension(2*N)

WORK2 (workspace)

dimension(7*N)

IWORK3 (workspace)

dimension(5*N)

IFAIL (output)

If JOBZ = 'V', then if INFO = 0, the first NFOUND
elements of IFAIL are zero. If INFO > 0, then
IFAIL contains the indices of the eigenvectors
that failed to converge. If JOBZ = 'N', then
IFAIL is not referenced.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an ille-
gal value

> 0: if INFO = i, then i eigenvectors failed to
converge. Their indices are stored in array
IFAIL.

```

F95 INTERFACE

```
SUBROUTINE HPGST(ITYPE, UPLO, N, AP, BP, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:) :: AP, BP  
INTEGER :: ITYPE, N, INFO
```

```
SUBROUTINE HPGST_64(ITYPE, UPLO, N, AP, BP, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:) :: AP, BP  
INTEGER(8) :: ITYPE, N, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chpgst(int itype, char uplo, int n, complex *ap, complex *bp, int *info);
```

```
void chpgst_64(long itype, char uplo, long n, complex *ap, complex *bp, long *info);
```

PURPOSE

chpgst reduces a complex Hermitian-definite generalized eigenproblem to standard form, using packed storage.

If ITYPE = 1, the problem is $A*x = \lambda*B*x$, and A is overwritten by $\text{inv}(U^{*H})*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^{*H})$

If ITYPE = 2 or 3, the problem is $A*B*x = \lambda*x$ or $B*A*x = \lambda*x$, and A is overwritten by $U*A*U^{*H}$ or $L^{*H}*A*L$.

B must have been previously factorized as $U^{*H}*U$ or $L*L^{*H}$ by CPPTRF.

ARGUMENTS

ITYPE (input)
= 1: compute $\text{inv}(U^{*H})*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^{*H})$;
= 2 or 3: compute $U*A*U^{*H}$ or $L^{*H}*A*L$.

UPLO (input)
= 'U': Upper triangle of A is stored and B is factored as $U^{*H}*U$; = 'L': Lower triangle of A is stored and B is factored as $L*L^{*H}$.

N (input) The order of the matrices A and B. $N \geq 0$.

AP (input/output)
On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

BP (input)
The triangular factor from the Cholesky factorization of B, stored in the same format as A, as returned by CPPTRF.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

                  [WORK2], [INFO])
```

```
CHARACTER(LEN=1) :: JOBZ, UPLO
COMPLEX, DIMENSION(:) :: A, B, WORK
COMPLEX, DIMENSION(:, :) :: Z
INTEGER(8) :: ITYPE, N, LDZ, INFO
REAL, DIMENSION(:) :: W, WORK2
```

C INTERFACE

```
#include <sunperf.h>

void chpgv(int itype, char jobz, char uplo, int n, complex
          *a, complex *b, float *w, complex *z, int ldz, int
          *info);

void chpgv_64(long itype, char jobz, char uplo, long n, com-
             plex *a, complex *b, float *w, complex *z, long
             ldz, long *info);
```

PURPOSE

chpgv computes all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite.

ARGUMENTS

ITYPE (input)

Specifies the problem type to be solved:
 = 1: $A*x = (\lambda)*B*x$
 = 2: $A*B*x = (\lambda)*x$
 = 3: $B*A*x = (\lambda)*x$

JOBZ (input)

= 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)

= 'U': Upper triangles of A and B are stored;
 = 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the contents of A are destroyed.

B (input/output)

On entry, the upper or lower triangle of the Hermitian matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array B as follows: if UPLO = 'U', $B(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $B(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U**H*U$ or $B = L*L**H$, in the same storage format as B.

W (output)

If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z^*H*B*Z = I$; if ITYPE = 3, $Z^*H*inv(B)*Z = I$. If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
dimension(MAX(1,2*N-1))

WORK2 (workspace)
dimension(MAX(1,3*N-2))

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: CPPTRF or CHPEV returned an error code:
<= N: if INFO = i, CHPEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not convergeto zero; > N: if INFO = N + i, for 1 <= i <= n, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

C INTERFACE

```

#include <sunperf.h>

void chpgvd(int itype, char jobz, char uplo, int n, complex
            *ap, complex *bp, float *w, complex *z, int ldz,
            int *info);

void chpgvd_64(long itype, char jobz, char uplo, long n,
               complex *ap, complex *bp, float *w, complex *z,
               long ldz, long *info);

```

PURPOSE

chpgvd computes all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*B*x=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

ITYPE (input)

Specifies the problem type to be solved:
 = 1: $A*x = (\lambda)*B*x$
 = 2: $A*B*x = (\lambda)*x$
 = 3: $B*A*x = (\lambda)*x$

JOBZ (input)

= 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)

= 'U': Upper triangles of A and B are stored;
 = 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

AP (input/output)

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the contents of AP are destroyed.

BP (input/output)

On entry, the upper or lower triangle of the Hermitian matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', $BP(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $BP(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U**H*U$ or $B = L*L**H$, in the same storage format as B.

W (output)

If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z**H*B*Z = I$; if ITYPE = 3, $Z**H*inv(B)*Z = I$. If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ ≥ 1 , and if JOBZ = 'V', LDZ $\geq \max(1,N)$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of array WORK. If $N \leq 1$, LWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LWORK $\geq N$. If JOBZ = 'V' and $N > 1$, LWORK $\geq 2*N$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK (input)

The dimension of array RWORK. If $N \leq 1$, LRWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LRWORK $\geq N$. If JOBZ = 'V' and $N > 1$, LRWORK $\geq 1 + 5*N + 2*N**2$.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of array IWORK. If JOBZ = 'N' or $N \leq 1$, LIWORK ≥ 1 . If JOBZ = 'V' and $N > 1$,

LIWORK $\geq 3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: CPPTRF or CHPEVD returned an error code:
<= N: if INFO = i, CHPEVD failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not convergeto zero; > N: if INFO = N + i, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

```

PURPOSE

chpgvx computes selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*B*x=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

ITYPE (input)

Specifies the problem type to be solved:

= 1: $A*x = (\lambda)*B*x$

= 2: $A*B*x = (\lambda)*x$

= 3: $B*A*x = (\lambda)*x$

JOBZ (input)

= 'N': Compute eigenvalues only;

= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)

= 'A': all eigenvalues will be found;

= 'V': all eigenvalues in the half-open interval
(VL,VU] will be found; = 'I': the IL-th through
IU-th eigenvalues will be found.

UPLO (input)

= 'U': Upper triangles of A and B are stored;

= 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

AP (input/output)

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the contents of AP are destroyed.

BP (input/output)

On entry, the upper or lower triangle of the Hermitian matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', $BP(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $BP(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U**H*U$ or $B = L*L**H$, in the same storage format as B.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

VU (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

ABSTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

$$ABSTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS*|T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing AP to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2*SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABSTOL to $2*SLAMCH('S')$.

M (output)
 The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

W (output)
 On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z^*H*B*Z = I$; if ITYPE = 3, $Z^*H*inv(B)*Z = I$.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)
 The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

WORK (workspace)
 dimension(2*N)

RWORK (workspace)
 dimension(7*N)

IWORK (workspace)
 dimension(5*N)

IFAIL (output)
 If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: CPPTRF or CHPEVX returned an error code:
 <= N: if INFO = i, CHPEVX failed to converge; i eigenvectors failed to converge. Their indices are stored in array IFAIL. > N: if INFO = N + i, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

SUBROUTINE HPMV_64(UPLO, [N], ALPHA, A, X, [INCX], BETA, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX :: ALPHA, BETA  
COMPLEX, DIMENSION(:) :: A, X, Y  
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chpmv(char uplo, int n, complex *alpha, complex *a,  
           complex *x, int incx, complex *beta, complex *y,  
           int incy);
```

```
void chpmv_64(char uplo, long n, complex *alpha, complex *a,  
              complex *x, long incx, complex *beta, complex *y,
```

long incy);

PURPOSE

chpmv performs the matrix-vector operation $y := \alpha A x + \beta y$ where α and β are scalars, x and y are n element vectors and A is an n by n hermitian matrix, supplied in packed form.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in A .

UPLO = 'L' or 'l' The lower triangular part of A is supplied in A .

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

A (input)

$((n*(n+1))/2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the hermitian matrix packed sequentially, column by column, so that $A(1)$ contains $a(1,1)$, $A(2)$ and $A(3)$ contain $a(1,2)$ and $a(2,2)$ respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the hermitian matrix packed sequentially, column by column, so that $A(1)$ contains $a(1,1)$, $A(2)$ and $A(3)$ contain $a(2,1)$ and $a(3,1)$ respectively, and so on. Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero. Unchanged on exit.

X (input)

$(1 + (n-1)*\text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X . $\text{INCX} \neq 0$. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar β . When BETA is supplied as zero then Y need not be set on

input. Unchanged on exit.

Y (input/output)

(1 + (n - 1) * abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

```

```
void chpr(char uplo, int n, float alpha, complex *x, int  
incx, complex *a);
```

```
void chpr_64(char uplo, long n, float alpha, complex *x,  
long incx, complex *a);
```

PURPOSE

chpr performs the hermitian rank 1 operation $A := \alpha x \text{conjg}(x) + A$ where α is a real scalar, x is an n element vector and A is an n by n hermitian matrix, supplied in packed form.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in A .

UPLO = 'L' or 'l' The lower triangular part of A is supplied in A .

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

X (input)

$(1 + (n - 1) \cdot \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X . $\text{INCX} \neq 0$. Unchanged on exit.

A (input/output)

$((n * (n + 1)) / 2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the hermitian matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(1, 2)$ and $a(2, 2)$ respectively, and so on. On exit, the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the hermitian matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(2, 1)$ and $a(3, 1)$ respectively, and so on. On exit, the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

```

PURPOSE

chpr2 performs the Hermitian rank 2 operation $A := \alpha x \text{conjg}(y') + \text{conjg}(\alpha) y \text{conjg}(x') + A$ where α is a scalar, x and y are n element vectors and A is an n by n hermitian matrix, supplied in packed form.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in A .

UPLO = 'L' or 'l' The lower triangular part of A is supplied in A .

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

X (input)

$(1 + (n - 1) \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X . $\text{INCX} \neq 0$. Unchanged on exit.

Y (input)

$(1 + (n - 1) \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector y . Unchanged on exit.

INCY (input)

On entry, INCY specifies the increment for the elements of Y . $\text{INCY} \neq 0$. Unchanged on exit.

A (input/output)

$((n * (n + 1)) / 2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the hermitian matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(1, 2)$ and $a(2, 2)$ respectively, and so on. On exit, the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the hermitian matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain

a(2, 1) and a(3, 1) respectively, and so on. On exit, the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

        long *info);

```

PURPOSE

chprfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

AF (input)
 The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{*H}$ or $A = L*D*L^{*H}$ as computed by CHPTRF, stored as a packed triangular matrix.

IPIVOT (input)
 Details of the interchanges and the block structure of D as determined by CHPTRF.

B (input) The right hand side matrix B.

LDB (input)
 The leading dimension of the array B. $LDB \geq \max(1,N)$.

X (input/output)
 On entry, the solution matrix X, as computed by CHPTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX \geq max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>
```

```
void chpsv(char uplo, int n, int nrhs, complex *a, int  
          *ipivot, complex *b, int ldb, int *info);
```

```
void chpsv_64(char uplo, long n, long nrhs, complex *a, long
             *ipivot, complex *b, long ldb, long *info);
```

PURPOSE

chpsv computes the solution to a complex system of linear equations

$A * X = B$, where A is an N-by-N Hermitian matrix stored in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$A = U * D * U^{*H}$, if UPLO = 'U', or

$A = L * D * L^{*H}$, if UPLO = 'L',

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input/output)

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U * D * U^{*H}$ or $A = L * D * L^{*H}$ as computed by CHPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIVOT (output)

Details of the interchanges and the block structure of D, as determined by CHPTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B (input/output)
 On entry, the N-by-NRHS right hand side matrix B.
 On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
 The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when N = 4, UPLO = 'U':

Two-dimensional storage of the Hermitian matrix A:

```

a11 a12 a13 a14
  a22 a23 a24
    a33 a34      (aij = conjg(aji))
      a44

```

Packed storage of the upper triangle of A:

A = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]

```
#include <sunperf.h>
```

```
void chpsvx(char fact, char uplo, int n, int nrhs, complex  
*a, complex *af, int *ipivot, complex *b, int ldb,  
complex *x, int ldx, float *rcond, float *ferr,  
float *berr, int *info);
```

```
void chpsvx_64(char fact, char uplo, long n, long nrhs, com-  
plex *a, complex *af, long *ipivot, complex *b,  
long ldb, complex *x, long ldx, float *rcond,  
float *ferr, float *berr, long *info);
```

PURPOSE

chpsvx uses the diagonal pivoting factorization $A = U^*D^*U^{**H}$ or $A = L^*D^*L^{**H}$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N Hermitian matrix stored in packed format and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the diagonal pivoting method is used to factor A as

$A = U * D * U^{**H}$, if $UPLO = 'U'$, or

$A = L * D * L^{**H}$, if $UPLO = 'L'$,

where U (or L) is a product of permutation and unit upper (lower)

triangular matrices and D is Hermitian and block diagonal with

1-by-1 and 2-by-2 diagonal blocks.

2. If some $D(i,i)=0$, so that D is exactly singular, then the routine

returns with $INFO = i$. Otherwise, the factored form of A is used

to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision,

$INFO = N+1$ is returned as a warning, but the routine still goes on

to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form of A .

4. Iterative refinement is applied to improve the computed

solution
matrix and calculate error bounds and backward error
estimates
for it.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AF and IPIVOT contain the factored form of A. AF and IPIVOT will not be modified. = 'N': The matrix A will be copied to AF and factored.

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

AF (input/output)

If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{*H}$ or $A = L*D*L^{*H}$ as computed by CHPTRF, stored as a packed triangular matrix in the same storage format as A.

If FACT = 'N', then AF is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{*H}$ or $A = L*D*L^{*H}$ as computed by CHPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIVOT (input or output)

If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CHPTRF. If $IPIVOT(k) > 0$, then rows and columns k and IPIVOT(k) were interchanged and $D(k,k)$ is a 1-by-1 diagonal block. If UPLO = 'U' and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and -IPIVOT(k) were interchanged and $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. If UPLO = 'L' and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and -IPIVOT(k) were interchanged and $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument

and on exit contains details of the interchanges and the block structure of D, as determined by CHPTRF.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,N).

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)

The leading dimension of the array X. LDX \geq max(1,N).

RCOND (output)

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO $>$ 0.

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

dimension(2*N)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
 \leq N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would

suggest.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when $N = 4$, $UPLO = 'U'$:

Two-dimensional storage of the Hermitian matrix A:

```
a11 a12 a13 a14
    a22 a23 a24
        a33 a34      (aij = conjg(aji))
            a44
```

Packed storage of the upper triangle of A:

```
A = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]
```

```

```
void chptrd(char uplo, int n, complex *ap, float *d, float  
*e, complex *tau, int *info);
```

```
void chptrd_64(char uplo, long n, complex *ap, float *d,  
float *e, complex *tau, long *info);
```

PURPOSE

chptrd reduces a complex Hermitian matrix A stored in packed form to real symmetric tridiagonal form T by a unitary similarity transformation: $Q^*H * A * Q = T$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

AP (input)

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

D (output)

The diagonal elements of the tridiagonal matrix T:
 $D(i) = A(i,i)$.

E (output)

The off-diagonal elements of the tridiagonal matrix T: $E(i) = A(i,i+1)$ if UPLO = 'U', $E(i) = A(i+1,i)$ if UPLO = 'L'.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

If UPLO = 'U', the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) \dots H(2) H(1).$$

Each H(i) has the form

$$H(i) = I - \tau * v * v'$$

where tau is a complex scalar, and v is a complex vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in AP, overwriting $A(1:i-1,i+1)$, and tau is stored in TAU(i).

If UPLO = 'L', the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(n-1).$$

Each H(i) has the form

$$H(i) = I - \tau * v * v'$$

where tau is a complex scalar, and v is a complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in AP, overwriting $A(i+2:n,i)$, and tau is stored in TAU(i).

CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:) :: A  
INTEGER :: N, INFO  
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE HPTRF_64(UPLO, [N], A, IPIVOT, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:) :: A  
INTEGER(8) :: N, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chptrf(char uplo, int n, complex *a, int *ipivot, int *info);
```

```
void chptrf_64(char uplo, long n, complex *a, long *ipivot,
              long *info);
```

PURPOSE

chptrf computes the factorization of a complex Hermitian packed matrix A using the Bunch-Kaufman diagonal pivoting method:

$$A = U^*D^*U^{**H} \quad \text{or} \quad A = L^*D^*L^{**H}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L, stored as a packed triangular matrix overwriting A (see below for further details).

IPIVOT (output)

Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

5-96 - Based on modifications by J. Lewis, Boeing Computer Services Company

If UPLO = 'U', then $A = U*D*U'$, where

$U = P(n)*U(n)* \dots *P(k)U(k)* \dots$,
i.e., U is a product of terms $P(k)*U(k)$, where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

$$U(k) = \begin{pmatrix} I & v & 0 &) & k-s \\ 0 & I & 0 &) & s \\ 0 & 0 & I &) & n-k \\ k-s & s & n-k & & \end{pmatrix}$$

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k). If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then $A = L*D*L'$, where

$L = P(1)*L(1)* \dots *P(k)*L(k)* \dots$,
i.e., L is a product of terms $P(k)*L(k)$, where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

$$L(k) = \begin{pmatrix} I & 0 & 0 &) & k-1 \\ 0 & I & 0 &) & s \\ 0 & v & I &) & n-k-s+1 \\ k-1 & s & n-k-s+1 & & \end{pmatrix}$$

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

C INTERFACE

```
#include <sunperf.h>
```

```
void chptri(char uplo, int n, complex *a, int *ipivot, int *info);
```

```
void chptri_64(char uplo, long n, complex *a, long *ipivot, long *info);
```

PURPOSE

chptri computes the inverse of a complex Hermitian indefinite matrix A in packed storage using the factorization $A = U*D*U**H$ or $A = L*D*L**H$ computed by CHPTRF.

ARGUMENTS

UPLO (input)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is $A = U*D*U**H$;
= 'L': Lower triangular, form is $A = L*D*L**H$.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHPTRF, stored as a packed triangular matrix.

On exit, if INFO = 0, the (Hermitian) inverse of the original matrix, stored as a packed triangular matrix. The j-th column of $\text{inv}(A)$ is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = \text{inv}(A)(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = \text{inv}(A)(i,j)$ for $j \leq i \leq n$.

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by CHPTRF.

WORK (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, $D(i,i) = 0$; the matrix is singular and its inverse could not be computed.

```
void chptrs_64(char uplo, long n, long nrhs, complex *a,  
              long *ipivot, complex *b, long ldb, long *info);
```

PURPOSE

chptrs solves a system of linear equations $A \cdot X = B$ with a complex Hermitian matrix A stored in packed format using the factorization $A = U \cdot D \cdot U^* \cdot H$ or $A = L \cdot D \cdot L^* \cdot H$ computed by CHPTRF.

ARGUMENTS

UPLO (input)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is $A = U \cdot D \cdot U^* \cdot H$;
= 'L': Lower triangular, form is $A = L \cdot D \cdot L^* \cdot H$.

N (input) The order of the matrix A . $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHPTRF, stored as a packed triangular matrix.

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by CHPTRF.

B (input/output)

On entry, the right hand side matrix B . On exit, the solution matrix X .

LDB (input)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value

#include <sunperf.h>

void chsein(char side, char eigsrc, char initv, int *select,
            int n, complex *h, int ldh, complex *w, complex
            *vl, int ldvl, complex *vr, int ldvr, int mm, int
            *m, int *ifailL, int *ifailR, int *info);

void chsein_64(char side, char eigsrc, char initv, long
               *select, long n, complex *h, long ldh, complex *w,
               complex *vl, long ldvl, complex *vr, long ldvr,
               long mm, long *m, long *ifailL, long *ifailR, long
               *info);

```

PURPOSE

chsein uses inverse iteration to find specified right and/or left eigenvectors of a complex upper Hessenberg matrix H.

The right eigenvector x and the left eigenvector y of the matrix H corresponding to an eigenvalue w are defined by:

$$H * x = w * x, \quad y^{*h} * H = w * y^{*h}$$

where y^{*h} denotes the conjugate transpose of the vector y .

ARGUMENTS

SIDE (input)

= 'R': compute right eigenvectors only;
 = 'L': compute left eigenvectors only;
 = 'B': compute both right and left eigenvectors.

EIGSRC (input)

Specifies the source of eigenvalues supplied in W:
 = 'Q': the eigenvalues were found using CHSEQR; thus, if H has zero subdiagonal elements, and so is block-triangular, then the j -th eigenvalue can be assumed to be an eigenvalue of the block containing the j -th row/column. This property allows CHSEIN to perform inverse iteration on just one diagonal block. = 'N': no assumptions are made on the correspondence between eigenvalues and diagonal blocks. In this case, CHSEIN must always perform inverse iteration using the whole matrix H.

INITV (input)

= 'N': no initial vectors are supplied;
 = 'U': user-supplied initial vectors are stored in the arrays VL and/or VR.

SELECT (input)

Specifies the eigenvectors to be computed. To select the eigenvector corresponding to the eigenvalue $W(j)$, $SELECT(j)$ must be set to `.TRUE.`.

N (input) The order of the matrix H . $N \geq 0$.

H (input) The upper Hessenberg matrix H .

LDH (input)
The leading dimension of the array H . $LDH \geq \max(1, N)$.

W (input/output)
On entry, the eigenvalues of H . On exit, the real parts of W may have been altered since close eigenvalues are perturbed slightly in searching for independent eigenvectors.

VL (input/output)
On entry, if $INITV = 'U'$ and $SIDE = 'L'$ or $'B'$, VL must contain starting vectors for the inverse iteration for the left eigenvectors; the starting vector for each eigenvector must be in the same column in which the eigenvector will be stored. On exit, if $SIDE = 'L'$ or $'B'$, the left eigenvectors specified by $SELECT$ will be stored consecutively in the columns of VL , in the same order as their eigenvalues. If $SIDE = 'R'$, VL is not referenced.

LDVL (input)
The leading dimension of the array VL . $LDVL \geq \max(1, N)$ if $SIDE = 'L'$ or $'B'$; $LDVL \geq 1$ otherwise.

VR (input/output)
On entry, if $INITV = 'U'$ and $SIDE = 'R'$ or $'B'$, VR must contain starting vectors for the inverse iteration for the right eigenvectors; the starting vector for each eigenvector must be in the same column in which the eigenvector will be stored. On exit, if $SIDE = 'R'$ or $'B'$, the right eigenvectors specified by $SELECT$ will be stored consecutively in the columns of VR , in the same order as their eigenvalues. If $SIDE = 'L'$, VR is not referenced.

LDVR (input)
The leading dimension of the array VR . $LDVR \geq \max(1, N)$ if $SIDE = 'R'$ or $'B'$; $LDVR \geq 1$ otherwise.

MM (input)
The number of columns in the arrays VL and/or VR . $MM \geq M$.

M (output)
The number of columns in the arrays VL and/or VR required to store the eigenvectors (= the number of `.TRUE.` elements in $SELECT$).

WORK (workspace)
dimension($N*N$)

RWORK (workspace)
dimension(N)

IFAILL (output)
If SIDE = 'L' or 'B', IFAILL(i) = j > 0 if the left eigenvector in the i-th column of VL (corresponding to the eigenvalue w(j)) failed to converge; IFAILL(i) = 0 if the eigenvector converged satisfactorily. If SIDE = 'R', IFAILL is not referenced.

IFAILR (output)
If SIDE = 'R' or 'B', IFAILR(i) = j > 0 if the right eigenvector in the i-th column of VR (corresponding to the eigenvalue w(j)) failed to converge; IFAILR(i) = 0 if the eigenvector converged satisfactorily. If SIDE = 'L', IFAILR is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, i is the number of eigenvectors which failed to converge; see IFAILL and IFAILR for further details.

FURTHER DETAILS

Each eigenvector is normalized so that the element of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be $|x|+|y|$.

#include <sunperf.h>
```

```
void chseqr (char, char, int, int, int, complex*, int, com-
```

```

plex*, complex*, int, int*);

void chseqr_64 (char, char, long, long, long, complex*,
long, complex*, complex*, long, long*);

```

PURPOSE

chseqr computes the eigenvalues of a complex upper Hessenberg matrix H, and, optionally, the matrices T and Z from the Schur decomposition $H = Z T Z^* H$, where T is an upper triangular matrix (the Schur form), and Z is the unitary matrix of Schur vectors.

Optionally Z may be postmultiplied into an input unitary matrix Q, so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the unitary matrix Q: $A = Q^* H Q^* H = (QZ)^* T (QZ)^* H$.

ARGUMENTS

JOB (input)
= 'E': compute eigenvalues only;
= 'S': compute eigenvalues and the Schur form T.

COMPZ (input)
= 'N': no Schur vectors are computed;
= 'I': Z is initialized to the unit matrix and the matrix Z of Schur vectors of H is returned; = 'V': Z must contain an unitary matrix Q on entry, and the product Q*Z is returned.

N (input) The order of the matrix H. $N \geq 0$.

ILO (input)
It is assumed that H is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to CGEBAL, and then passed to CGEHRD when the matrix output by CGEBAL is reduced to Hessenberg form. Otherwise ILO and IHI should be set to 1 and N respectively. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; ILO=1 and IHI=0, if $N=0$.

IHI (input)
See the description of ILO.

H (input/output)
On entry, the upper Hessenberg matrix H. On exit, if JOB = 'S', H contains the upper triangular matrix T from the Schur decomposition (the Schur form). If JOB = 'E', the contents of H are unspecified on exit.

LDH (input)
The leading dimension of the array H. $LDH \geq \max(1, N)$.

W (output)
The computed eigenvalues. If JOB = 'S', the eigen-

values are stored in the same order as on the diagonal of the Schur form returned in H, with $W(i) = H(i,i)$.

Z (input) If COMPZ = 'N': Z is not referenced.
If COMPZ = 'I': on entry, Z need not be set, and on exit, Z contains the unitary matrix Z of the Schur vectors of H. If COMPZ = 'V': on entry Z must contain an N-by-N matrix Q, which is assumed to be equal to the unit matrix except for the submatrix Z(ILO:IHI,ILO:IHI); on exit Z contains Q*Z. Normally Q is the unitary matrix generated by CUNGHR after the call to CGEHRD which formed the Hessenberg matrix H.

LDZ (input)
The leading dimension of the array Z. LDZ \geq max(1,N) if COMPZ = 'I' or 'V'; LDZ \geq 1 otherwise.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (output)
The dimension of the array WORK. LWORK \geq max(1,N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, CHSEQR failed to compute all the eigenvalues in a total of 30*(IHI-ILO+1) iterations; elements 1:i-1 and i+1:n of W contain those eigenvalues which have been successfully computed.

INTEGER*8 TRANSA, M, K, MAXNZ  
INTEGER*8, DIMENSION(:) :: DESCRA, INDX, PNTR, IPERM  
COMPLEX ALPHA, BETA  
COMPLEX, DIMENSION(:) :: VAL  
COMPLEX, DIMENSION(:, :) :: B, C
```

DESCRIPTION

```
C <- alpha op(A) B + beta C
```

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in jagged-diagonal format and
op(A) is one of
op(A) = A or op(A) = A' or op(A) = conjg(A').
(' indicates matrix transpose)

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real.
M	Number of rows in matrix A
N	Number of columns in matrix C
K	Number of columns in matrix A
ALPHA	Scalar parameter
DESCRA()	Descriptor argument. Five element integer array DESCRA(1) matrix structure 0 : general 1 : symmetric (A=A') 2 : Hermitian (A= CONJG(A')) 3 : Triangular 4 : Skew(Anti)-Symmetric (A=-A') 5 : Diagonal 6 : Skew-Hermitian (A= -CONJG(A')) DESCRA(2) upper/lower triangular indicator 1 : lower 2 : upper DESCRA(3) main diagonal type 0 : non-unit 1 : unit DESCRA(4) Array base (NOT IMPLEMENTED) 0 : C/C++ compatible 1 : Fortran compatible DESCRA(5) repeated indices? (NOT IMPLEMENTED) 0 : unknown 1 : no repeated indices
VAL()	array of length NNZ consisting of entries of A. VAL can be viewed as a column major ordering of a row permutation of the Ellpack representation of A, where the Ellpack representation is permuted so that the rows are non-increasing in the number of nonzero entries. Values added for padding in Ellpack are not included in the Jagged-Diagonal format.
INDX()	array of length NNZ consisting of the column indices of the corresponding entries in VAL.
PNTR()	array of length MAXNZ+1, where PNTR(I)-PNTR(1)+1 points to the location in VAL of the first element in the row-permuted Ellpack representation of A.

MAXNZ max number of nonzeros elements per row.

IPERM() integer array of length M such that $I = \text{IPERM}(I')$, where row I in the original Ellpack representation corresponds to row I' in the permuted representation. If $\text{IPERM}(1) = 0$, it is assumed by convention that $\text{IPERM}(I) = I$. IPERM is used to determine the order in which rows of C are updated.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK. WORK is not referenced in the current version.

LWORK length of WORK array. LWORK is not referenced in the current version.

NAME

cjadrp - right permutation of a jagged diagonal matrix

SYNOPSIS

```
SUBROUTINE CJADRP( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,  
*                IPERM, WORK, LWORK )  
INTEGER          TRANSP, M, K, MAXNZ, LWORK  
INTEGER          INDX(*), PNTR(MAXNZ+1), IPERM(K), WORK(LWORK)  
COMPLEX          VAL(*)
```

```
SUBROUTINE CJADRP_64( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,  
*                   IPERM, WORK, LWORK )  
INTEGER*8        TRANSP, M, K, MAXNZ, LWORK  
INTEGER*8        INDX(*), PNTR(MAXNZ+1), IPERM(K), WORK(LWORK)  
COMPLEX          VAL(*)
```

F95 INTERFACE

```
SUBROUTINE JADRP( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,  
*               IPERM, [WORK], [LWORK] )  
INTEGER TRANSP, M, K, MAXNZ  
INTEGER, DIMENSION(:) :: INDX, PNTR, IPERM  
COMPLEX, DIMENSION(:) :: VAL
```

```
SUBROUTINE JADRP_64( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,  
*                  IPERM, [WORK], [LWORK] )  
INTEGER*8 TRANSP, M, K, MAXNZ  
INTEGER*8, DIMENSION(:) :: INDX, PNTR, IPERM  
COMPLEX, DIMENSION(:) :: VAL
```

DESCRIPTION

```
A <- A P  
A <- A P'
```

(' indicates matrix transpose)

where permutation P is represented by an integer vector IPERM, such that IPERM(I) is equal to the position of the only nonzero element in row I of permutation matrix P.

NOTE: In order to get a symmetrically permuted jagged diagonal matrix $P A P'$, one can explicitly permute the columns $P A$ by

calling

```
SJADRP(0, M, M, VAL, INDX, PNTR, MAXNZ, IPERM, WORK, LWORK)
```

where parameters VAL, INDX, PNTR, MAXNZ, IPERM are the representation of A in the jagged diagonal format. The operation makes sense if the original matrix A is square.

ARGUMENTS

TRANSP	Indicates how to operate with the permutation matrix 0 : operate with matrix 1 : operate with transpose matrix
M	Number of rows in matrix A
K	Number of columns in matrix A
VAL()	array of length PNTR(MAXNZ+1)-PNTR(1) consisting of entries of A. VAL can be viewed as a column major ordering of a row permutation of the Ellpack representation of A, where the Ellpack representation is permuted so that the rows are non-increasing in the number of nonzero entries. Values added for padding in Ellpack are not included in the Jagged-Diagonal format.
INDX()	array of length PNTR(MAXNZ+1)-PNTR(1) consisting of the column indices of the corresponding entries in VAL.
PNTR()	array of length MAXNZ+1, where PNTR(I)-PNTR(1)+1 points to the location in VAL of the first element in the row-permuted Ellpack representation of A.
MAXNZ	max number of nonzeros elements per row.
IPERM()	integer array of length K such that $I = \text{IPERM}(I')$. Array IPERM represents a permutation P, such that IPERM(I) is equal to the position of the only nonzero element in row I of permutation matrix P. For example, if $P = \begin{vmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{vmatrix}$ then IPERM = (3, 1, 2).
WORK()	scratch array of length LWORK. LWORK should be at least K.
LWORK	length of WORK array If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

COMPLEX          DV(M), VAL(NNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
```

where $NNZ=PNTR(MAXNZ+1)-PNTR(1)+1$ is the number of non-zero elements

F95 INTERFACE

```
SUBROUTINE JADSM(TRANSA, M, [N], UNITD, DV, ALPHA, DESCRA, VAL, INDX,
* PNTR, MAXNZ, IPERM, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
INTEGER          TRANSA, M, MAXNZ
INTEGER, DIMENSION(:) :: DESCRA, INDX, PNTR, IPERM
COMPLEX          ALPHA, BETA
COMPLEX, DIMENSION(:) :: VAL, DV
COMPLEX, DIMENSION(:, :) :: B, C
```

```
SUBROUTINE JADSM_64(TRANSA, M, [N], UNITD, DV, ALPHA, DESCRA, VAL, INDX,
* PNTR, MAXNZ, IPERM, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
INTEGER*8        TRANSA, M, MAXNZ
INTEGER*8, DIMENSION(:) :: DESCRA, INDX, PNTR, IPERM
COMPLEX          ALPHA, BETA
COMPLEX, DIMENSION(:) :: VAL, DV
COMPLEX, DIMENSION(:, :) :: B, C
```

DESCRIPTION

```
C <- ALPHA op(A) B + BETA C      C <- ALPHA D op(A) B + BETA C
C <- ALPHA op(A) D B + BETA C
```

where ALPHA and BETA are scalar, C and B are m by n dense matrices, D is a diagonal scaling matrix, A is a unit, or non-unit, upper or lower triangular matrix represented in jagged-diagonal format and op(A) is one of
op(A) = inv(A) or op(A) = inv(A') or op(A) =inv(conjg(A'))
(inv denotes matrix inverse, ' indicates matrix transpose)

ARGUMENTS

TRANSA Indicates how to operate with the sparse matrix
 0 : operate with matrix
 1 : operate with transpose matrix
 2 : operate with the conjugate transpose of matrix.
 2 is equivalent to 1 if matrix is real.

M Number of rows in matrix A

N Number of columns in matrix C

UNITD Type of scaling:
 1 : Identity matrix (argument DV[] is ignored)
 2 : Scale on left (row scaling)
 3 : Scale on right (column scaling)
 4 : Automatic row scaling (see section NOTES for
 further details)

DV() Array of length M containing the diagonal entries of the
 scaling diagonal matrix D.

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array
DESCRA(1) matrix structure
 0 : general
 1 : symmetric (A=A')
 2 : Hermitian (A= CONJG(A'))
 3 : Triangular
 4 : Skew(Anti)-Symmetric (A=-A')
 5 : Diagonal
 6 : Skew-Hermitian (A= -CONJG(A'))
Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper

DESCRA(3) main diagonal type
 0 : non-unit
 1 : unit

DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL() array of length NNZ consisting of entries of A.
VAL can be viewed as a column major ordering of a

row permutation of the Ellpack representation of A, where the Ellpack representation is permuted so that the rows are non-increasing in the number of nonzero entries. Values added for padding in Ellpack are not included in the Jagged-Diagonal format.

INDX() array of length NNZ consisting of the column indices of the corresponding entries in VAL.

PNTR() array of length MAXNZ+1, where PNTR(I)-PNTR(1)+1 points to the location in VAL of the first element in the row-permuted Ellpack representation of A.

MAXNZ max number of nonzeros elements per row.

IPERM() integer array of length M such that $I = \text{IPERM}(I')$, where row I in the original Ellpack representation corresponds to row I' in the permuted representation. If IPERM(1)=0, it's assumed by convention that IPERM(I)=I. IPERM is used to determine the order in which rows of C are updated.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK.
On exit, if LWORK = -1, WORK(1) returns the optimum LWORK.

LWORK length of WORK array. LWORK should be at least 2*M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK $>= 2 * M * N_CPUS$ where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If `UNITD =4`, the routine scales the rows of `A` such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of `VAL` are changed only in the particular case. On return `DV` matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. `UNITD=2` should be used for the next calls to the routine with overwritten `VAL` and `DV`.

`WORK(1)=0` on return if the scaling has been completed successfully, otherwise `WORK(1) = -i` where `i` is the row number which 2-norm is exactly zero.

3. If `DESCRA(3)=1` and `UNITD < 4`, the unit diagonal elements might or might not be referenced in the JAD representation of a sparse matrix. They are not used anyway in these cases. But if `UNITD=4`, the unit diagonal elements MUST be referenced in the JAD representation.

4. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix `A` is used. However `DESCRA(1)` must be equal to 3 in this case.

```

C INTERFACE

```
#include <sunperf.h>
```

```
void clarz(char side, int m, int n, int l, complex *v, int  
          incv, complex *tau, complex *c, int ldc);
```

```
void clarz_64(char side, long m, long n, long l, complex *v,  
             long incv, complex *tau, complex *c, long ldc);
```

PURPOSE

clarz applies a complex elementary reflector H to a complex M-by-N matrix C, from either the left or the right. H is represented in the form

$$H = I - \tau * v * v'$$

where tau is a complex scalar and v is a complex vector.

If tau = 0, then H is taken to be the unit matrix.

To apply H' (the conjugate transpose of H), supply conjg(tau) instead tau.

H is a product of k elementary reflectors as returned by CTZRZF.

ARGUMENTS

SIDE (input)

= 'L': form $H * C$
= 'R': form $C * H$

M (input) The number of rows of the matrix C.

N (input) The number of columns of the matrix C.

L (input) The number of entries of the vector V containing the meaningful part of the Householder vectors. If SIDE = 'L', $M \geq L \geq 0$, if SIDE = 'R', $N \geq L \geq 0$.

V (input) The vector v in the representation of H as returned by CTZRZF. V is not used if TAU = 0.

INCV (input)

The increment between elements of v. INCV $\neq 0$.

TAU (input)

The value tau in the representation of H.

C (input/output)

On entry, the M-by-N matrix C. On exit, C is overwritten by the matrix $H * C$ if SIDE = 'L', or $C * H$ if SIDE = 'R'.

LDC (input)

The leading dimension of the array C. LDC $\geq \max(1, M)$.

WORK (workspace)

(N) if SIDE = 'L' or (M) if SIDE = 'R'

```
#include <sunperf.h>
```

```
void clarzb(char side, char trans, char direct, char storev,
            int m, int n, int k, int l, complex *v, int ldv,
            complex *t, int ldt, complex *c, int ldc, int
```

```

        ldwork);

void clarzb_64(char side, char trans, char direct, char
storev, long m, long n, long k, long l, complex
*v, long ldv, complex *t, long ldt, complex *c,
long ldc, long ldwork);

```

PURPOSE

clarzb applies a complex block reflector H or its transpose H^*H to a complex distributed M-by-N C from the left or the right.

Currently, only STOREV = 'R' and DIRECT = 'B' are supported.

ARGUMENTS

SIDE (input)
= 'L': apply H or H' from the Left
= 'R': apply H or H' from the Right

TRANS (input)
= 'N': apply H (No transpose)
= 'C': apply H' (Conjugate transpose)

DIRECT (input)
Indicates how H is formed from a product of elementary reflectors = 'F': $H = H(1) H(2) \dots H(k)$ (Forward, not supported yet)
= 'B': $H = H(k) \dots H(2) H(1)$ (Backward)

STOREV (input)
Indicates how the vectors which define the elementary reflectors are stored:
= 'C': Columnwise (not supported yet)
= 'R': Rowwise

M (input) The number of rows of the matrix C.

N (input) The number of columns of the matrix C.

K (input) The order of the matrix T (= the number of elementary reflectors whose product defines the block reflector).

L (input) The number of columns of the matrix V containing the meaningful part of the Householder reflectors. If SIDE = 'L', $M \geq L \geq 0$, if SIDE = 'R', $N \geq L \geq 0$.

V (input) If STOREV = 'C', NV = K; if STOREV = 'R', NV = L.

LDV (input)
The leading dimension of the array V. If STOREV = 'C', $LDV \geq L$; if STOREV = 'R', $LDV \geq K$.

T (input) The triangular K-by-K matrix T in the representation of the block reflector.

LDT (input)

The leading dimension of the array T. $LDT \geq K$.

C (input/output)

On entry, the M-by-N matrix C. On exit, C is overwritten by $H*C$ or $H'*C$ or $C*H$ or $C*H'$.

LDC (input)

The leading dimension of the array C. $LDC \geq \max(1,M)$.

WORK (workspace)

dimension($\max(M,N),K$)

LDWORK (input)

The leading dimension of the array WORK. If SIDE = 'L', $LDWORK \geq \max(1,N)$; if SIDE = 'R', $LDWORK \geq \max(1,M)$.

NAME

clarzt - form the triangular factor T of a complex block reflector H of order > n, which is defined as a product of k elementary reflectors

SYNOPSIS

```
SUBROUTINE CLARZT(DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)
```

```
CHARACTER * 1 DIRECT, STOREV  
COMPLEX V(LDV,*), TAU(*), T(LDT,*)  
INTEGER N, K, LDV, LDT
```

```
SUBROUTINE CLARZT_64(DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)
```

```
CHARACTER * 1 DIRECT, STOREV  
COMPLEX V(LDV,*), TAU(*), T(LDT,*)  
INTEGER*8 N, K, LDV, LDT
```

F95 INTERFACE

```
SUBROUTINE LARZT(DIRECT, STOREV, N, K, V, [LDV], TAU, T, [LDT])
```

```
CHARACTER(LEN=1) :: DIRECT, STOREV  
COMPLEX, DIMENSION(:) :: TAU  
COMPLEX, DIMENSION(:, :) :: V, T  
INTEGER :: N, K, LDV, LDT
```

```
SUBROUTINE LARZT_64(DIRECT, STOREV, N, K, V, [LDV], TAU, T, [LDT])
```

```
CHARACTER(LEN=1) :: DIRECT, STOREV  
COMPLEX, DIMENSION(:) :: TAU  
COMPLEX, DIMENSION(:, :) :: V, T  
INTEGER(8) :: N, K, LDV, LDT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void clarzt(char direct, char storev, int n, int k, complex  
            *v, int ldv, complex *tau, complex *t, int ldt);
```

```
void clarzt_64(char direct, char storev, long n, long k,  
               complex *v, long ldv, complex *tau, complex *t,
```

long ldt);

PURPOSE

clarzt forms the triangular factor T of a complex block reflector H of order $> n$, which is defined as a product of k elementary reflectors.

If `DIRECT = 'F'`, $H = H(1) H(2) \dots H(k)$ and T is upper triangular;

If `DIRECT = 'B'`, $H = H(k) \dots H(2) H(1)$ and T is lower triangular.

If `STOREV = 'C'`, the vector which defines the elementary reflector $H(i)$ is stored in the i -th column of the array V , and

$$H = I - V * T * V'$$

If `STOREV = 'R'`, the vector which defines the elementary reflector $H(i)$ is stored in the i -th row of the array V , and

$$H = I - V' * T * V$$

Currently, only `STOREV = 'R'` and `DIRECT = 'B'` are supported.

ARGUMENTS

`DIRECT` (input)

Specifies the order in which the elementary reflectors are multiplied to form the block reflector:

= 'F': $H = H(1) H(2) \dots H(k)$ (Forward, not supported yet)

= 'B': $H = H(k) \dots H(2) H(1)$ (Backward)

`STOREV` (input)

Specifies how the vectors which define the elementary reflectors are stored (see also Further Details):

= 'R': rowwise

`N` (input) The order of the block reflector H . $N \geq 0$.

`K` (input) The order of the triangular factor T (= the number of elementary reflectors). $K \geq 1$.

`V` (input) (`LDV,K`) if `STOREV = 'C'` (`LDV,N`) if `STOREV = 'R'`
The matrix V . See further details.

`LDV` (input)

The leading dimension of the array V . If `STOREV = 'C'`, $LDV \geq \max(1,N)$; if `STOREV = 'R'`, $LDV \geq K$.

`TAU` (input)

$TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$.

`T` (input) The k by k triangular factor T of the block

reflector. If DIRECT = 'F', T is upper triangular; if DIRECT = 'B', T is lower triangular. The rest of the array is not used.

LDT (input)

The leading dimension of the array T. LDT >= K.

FURTHER DETAILS

Based on contributions by

A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

The shape of the matrix V and the storage of the vectors which define the H(i) is best illustrated by the following example with n = 5 and k = 3. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

DIRECT = 'F' and STOREV = 'C': DIRECT = 'F' and STOREV = 'R':

<pre> (v1 v2 v3) (v1 v2 v3)) V = (v1 v2 v3) . . 1) (v1 v2 v3) . 1) (v1 v2 v3) . . . 1 . . . 1 . . . 1 </pre>	$\frac{\text{V}}{\text{V}}$ <pre> / (v1 v1 v1 v1 v1 . . . 1) (v2 v2 v2 v2 v2 .) (v3 v3 v3 v3 v3 .) </pre>
---	---

DIRECT = 'B' and STOREV = 'C': DIRECT = 'B' and STOREV = 'R':

<pre> 1 . 1 . . 1 v2 v2 v2) . . . v3 v3 v3) . . . (v1 v2 v3) V = (v1 v2 v3) (v1 v2 v3) </pre>	$\frac{\text{V}}{\text{V}}$ <pre> / (1 v1 v1 v1 v1 v1) (. 1 v2 v2) (. . 1 . . . v3 v3) </pre>
---	---

C INTERFACE

```
#include <sunperf.h>
```

```
void clatzm(char side, int m, int n, complex *v, int incv,  
            complex *tau, complex *c1, complex *c2, int ldc);
```

```
void clatzm_64(char side, long m, long n, complex *v, long
    incv, complex *tau, complex *c1, complex *c2, long
    ldc);
```

PURPOSE

clatzm routine is deprecated and has been replaced by routine CUNMRZ.

CLATZM applies a Householder matrix generated by CTZRQF to a matrix.

Let $P = I - \tau \cdot u \cdot u'$, $u = \begin{pmatrix} 1 \\ v \end{pmatrix}$,

where v is an $(m-1)$ vector if $SIDE = 'L'$, or a $(n-1)$ vector if $SIDE = 'R'$.

If $SIDE$ equals $'L'$, let

$$C = \begin{bmatrix} C1 & 1 \\ C2 & m-1 \\ & n \end{bmatrix}$$

Then C is overwritten by $P \cdot C$.

If $SIDE$ equals $'R'$, let

$$C = \begin{bmatrix} C1 & C2 \\ 1 & n-1 \end{bmatrix} \begin{matrix} m \\ m \end{matrix}$$

Then C is overwritten by $C \cdot P$.

ARGUMENTS

$SIDE$ (input)

= $'L'$: form $P \cdot C$
 = $'R'$: form $C \cdot P$

M (input) The number of rows of the matrix C .

N (input) The number of columns of the matrix C .

V (input) $(1 + (M-1) \cdot \text{abs}(\text{INCV}))$ if $SIDE = 'L'$ $(1 + (N-1) \cdot \text{abs}(\text{INCV}))$ if $SIDE = 'R'$ The vector v in the representation of P . V is not used if $\text{TAU} = 0$.

INCV (input)

The increment between elements of v . $\text{INCV} \neq 0$

TAU (input)

The value τ in the representation of P .

$C1$ (input/output)

(LDC, N) if $SIDE = 'L'$ $(M, 1)$ if $SIDE = 'R'$ On entry, the n -vector $C1$ if $SIDE = 'L'$, or the m -vector $C1$ if $SIDE = 'R'$.

On exit, the first row of $P \cdot C$ if $SIDE = 'L'$, or the first column of $C \cdot P$ if $SIDE = 'R'$.

$C2$ (input/output)

(LDC, N) if $SIDE = 'L'$ $(LDC, N-1)$ if $SIDE = 'R'$
 On entry, the $(m-1) \times n$ matrix $C2$ if $SIDE = 'L'$, or the $m \times (n-1)$ matrix $C2$ if $SIDE = 'R'$.

On exit, rows 2:m of P*C if SIDE = 'L', or columns
2:m of C*P if SIDE = 'R'.

LDC (input)

The leading dimension of the arrays C1 and C2.
LDC \geq max(1,M).

WORK (workspace)

(N) if SIDE = 'L' (M) if SIDE = 'R'

NAME

cosqb - synthesize a Fourier sequence from its representation in terms of a cosine series with odd wave numbers. The COSQ operations are unnormalized inverses of themselves, so a call to COSQF followed by a call to COSQB will multiply the input sequence by $4 * N$.

SYNOPSIS

```
SUBROUTINE COSQB(N, X, WSAVE)
```

```
INTEGER N  
REAL X(*), WSAVE(*)
```

```
SUBROUTINE COSQB_64(N, X, WSAVE)
```

```
INTEGER*8 N  
REAL X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQB(N, X, WSAVE)
```

```
INTEGER :: N  
REAL, DIMENSION(:) :: X, WSAVE
```

```
SUBROUTINE COSQB_64(N, X, WSAVE)
```

```
INTEGER(8) :: N  
REAL, DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cosqb(int n, float *x, float *wsave);
```

```
void cosqb_64(long n, float *x, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

X (input/output)

On entry, an array of length N containing the sequence to be transformed. On exit, the quarter-wave cosine synthesis of the input.

WSAVE (input)

On entry, an array with dimension of at least $(3 * N + 15)$ that has been initialized by COSQI.

```

```
INTEGER :: N  
REAL, DIMENSION(:) :: X, WSAVE
```

```
SUBROUTINE COSQF_64(N, X, WSAVE)
```

```
INTEGER(8) :: N  
REAL, DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cosqf(int n, float *x, float *wsave);
```

```
void cosqf_64(long n, float *x, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

X (input/output)

On entry, an array of length N containing the sequence to be transformed. On exit, the quarter-wave cosine transform of the input.

WSAVE (input)

On entry, an array with dimension of at least (3 * N + 15) that has been initialized by COSQI.

Contents

- [ARGUMENTS](#)

NAME

cosqi - initialize the array WSAVE, which is used in both COSQF and COSQB.

SYNOPSIS

```
SUBROUTINE COSQI(N, WSAVE)

INTEGER N
REAL WSAVE(*)

SUBROUTINE COSQI_64(N, WSAVE)

INTEGER*8 N
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQI(N, WSAVE)

INTEGER :: N
REAL, DIMENSION(:) :: WSAVE

SUBROUTINE COSQI_64(N, WSAVE)

INTEGER(8) :: N
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void cosqi(int n, float *wsave);

void cosqi_64(long n, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. The method is most efficient when N is a product of small primes.

WSAVE (input)
On entry, an array of dimension (3 * N + 15) or greater. COSQI needs to be called only once to

initialize WSAVE before calling COSQF and/or COSQB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

#include <sunperf.h>

void cpbcon(char uplo, int n, int ndiag, complex *a, int
            lda, float anorm, float *rcond, int *info);

void cpbcon_64(char uplo, long n, long ndiag, complex *a,
              long lda, float anorm, float *rcond, long *info);

```

PURPOSE

cpbcon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite band matrix using the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ computed by CPBTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangular factor stored in A;
 = 'L': Lower triangular factor stored in A.

N (input) The order of the matrix A. $N \geq 0$.

NDIAG (input)
 The number of superdiagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. $\text{NDIAG} \geq 0$.

A (input) The triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ of the band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of U or L is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j, j) = U(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = L(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

LDA (input)
 The leading dimension of the array A. $\text{LDA} \geq \text{NDIAG}+1$.

ANORM (input)
 The 1-norm (or infinity-norm) of the Hermitian band matrix A.

RCOND (output)
 The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

WORK (workspace)
 dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

SUBROUTINE CPBEQU_64(UPLO, N, NDIAG, A, LDA, SCALE, SCOND, AMAX,  
INFO)
```

```
CHARACTER * 1 UPLO  
COMPLEX A(LDA,*)  
INTEGER*8 N, NDIAG, LDA, INFO  
REAL SCOND, AMAX  
REAL SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE PBEQU(UPLO, [N], NDIAG, A, [LDA], SCALE, SCOND, AMAX,  
[INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER :: N, NDIAG, LDA, INFO  
REAL :: SCOND, AMAX  
REAL, DIMENSION(:) :: SCALE
```

```
SUBROUTINE PBEQU_64(UPLO, [N], NDIAG, A, [LDA], SCALE, SCOND, AMAX,  
[INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: N, NDIAG, LDA, INFO  
REAL :: SCOND, AMAX  
REAL, DIMENSION(:) :: SCALE
```

C INTERFACE

```

#include <sunperf.h>

void cpbequ(char uplo, int n, int ndiag, complex *a, int
            lda, float *scale, float *scond, float *amax, int
            *info);

void cpbequ_64(char uplo, long n, long ndiag, complex *a,
              long lda, float *scale, float *scond, float *amax,
              long *info);

```

PURPOSE

cpbequ computes row and column scalings intended to equilibrate a Hermitian positive definite band matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i) = 1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j) = S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangular of A is stored;
 = 'L': Lower triangular of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

NDIAG (input)
 The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $NDIAG \geq 0$.

A (input) The upper or lower triangle of the Hermitian band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

LDA (input)
 The leading dimension of the array A. $LDA \geq NDIAG+1$.

SCALE (output)
 If INFO = 0, SCALE contains the scale factors for A.

SCOND (output)
 If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND ≥ 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

AMAX (output)
 Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value.

> 0: if INFO = i, the i-th diagonal element is nonpositive.

```

PURPOSE

cpbrfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

NDIAG (input)
 The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $NDIAG \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The upper or lower triangle of the Hermitian band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

LDA (input)
 The leading dimension of the array A. $LDA \geq NDIAG+1$.

AF (input)
 The triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ of the band matrix A as computed by CPBTRF, in the same storage format as A (see A).

LDAF (input)
 The leading dimension of the array AF. $LDAF \geq NDIAG+1$.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB \geq
max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by
CPBTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX \geq
max(1,N).

FERR (output)
The estimated forward error bound for each solu-
tion vector X(j) (the j-th column of the solution
matrix X). If XTRUE is the true solution
corresponding to X(j), FERR(j) is an estimated
upper bound for the magnitude of the largest ele-
ment in (X(j) - XTRUE) divided by the magnitude of
the largest element in X(j). The estimate is as
reliable as the estimate for RCOND, and is almost
always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each
solution vector X(j) (i.e., the smallest relative
change in any element of A or B that makes X(j) an
exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-
gal value

```

```
SUBROUTINE PBSTF_64(UPLO, [N], KD, AB, [LDAB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:, :) :: AB  
INTEGER(8) :: N, KD, LDAB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpbstf(char uplo, int n, int kd, complex *ab, int ldab,  
            int *info);
```

```
void cpbstf_64(char uplo, long n, long kd, complex *ab, long  
               ldab, long *info);
```

PURPOSE

cpbstf computes a split Cholesky factorization of a complex Hermitian positive definite band matrix A.

This routine is designed to be used in conjunction with CHBGST.

The factorization has the form $A = S^*H^*S$ where S is a band matrix of the same bandwidth as A and the following structure:

$$S = \begin{pmatrix} U & \\ & (M \ L) \end{pmatrix}$$

where U is upper triangular of order $m = (n+kd)/2$, and L is lower triangular of order $n-m$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

AB (input/output)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

On exit, if INFO = 0, the factor S from the split Cholesky factorization $A = S^*H^*S$. See Further Details.

LDAB (input)

The leading dimension of the array AB. $LDAB \geq kd+1$.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the factorization could not be completed, because the updated element $a(i, i)$ was negative; the matrix A is not positive definite.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when $N = 7$, $KD = 2$:

```
S = ( s11  s12  s13           )
     (      s22  s23  s24     )
     (          s33  s34     )
     (              s44     )
     (          s53  s54  s55  )
     (              s64  s65  s66  )
     (                  s75  s76  s77  )
```

If $UPLO = 'U'$, the array AB holds:

```
on entry:                                on exit:

*      *  a13  a24  a35  a46  a57  *      *  s13  s24  s53'
s64' s75'
*      a12  a23  a34  a45  a56  a67  *  s12  s23  s34  s54'
s65' s76' a11  a22  a33  a44  a55  a66  a77  s11  s22  s33
s44  s55  s66  s77
```

If $UPLO = 'L'$, the array AB holds:

```
on entry:                                on exit:

a11  a22  a33  a44  a55  a66  a77  s11  s22  s33  s44  s55
s66  s77  a21  a32  a43  a54  a65  a76  *  s12' s23' s34'
s54  s65  s76  * a31  a42  a53  a64  a64  *      *  s13'
s24' s53  s64  s75  *      *
```

Array elements marked * are not used by the routine; s12' denotes $\text{conjg}(s12)$; the diagonal elements of S are real.

INTEGER :: N, NDIAG, NRHS, LDA, LDB, INFO
```

```
SUBROUTINE PBSV_64(UPLO, [N], NDIAG, [NRHS], A, [LDA], B, [LDB],  
[INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:,:) :: A, B  
INTEGER(8) :: N, NDIAG, NRHS, LDA, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpbsv(char uplo, int n, int ndiag, int nrhs, complex  
*a, int lda, complex *b, int ldb, int *info);
```

```
void cpbsv_64(char uplo, long n, long ndiag, long nrhs, com-  
plex *a, long lda, complex *b, long ldb, long  
*info);
```

PURPOSE

cpbsv computes the solution to a complex system of linear equations

$A * X = B$, where A is an N-by-N Hermitian positive definite band matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

$A = U^{*H} * U$, if UPLO = 'U', or

$A = L * L^{*H}$, if UPLO = 'L',

where U is an upper triangular band matrix, and L is a lower triangular band matrix, with the same number of superdiagonals or subdiagonals as A. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NDIAG (input)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $NDIAG \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input/output)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(NDIAG+1+i-j, j) = A(i, j)$ for $\max(1, j-NDIAG) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(N, j+NDIAG)$. See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization $A = U^{*H} * U$ or $A = L * L^{*H}$ of the band matrix A, in the same storage format as A.

LDA (input)

The leading dimension of the array A. $LDA \geq NDIAG+1$.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 6, NDIAG = 2, and UPLO = 'U':

On entry:	On exit:
<pre> * * a13 a24 a35 a46 u46 * * a12 a23 a34 a45 a56 u56 a11 a22 a33 a44 a55 a66 u66 </pre>	<pre> * * u13 u24 u35 * u12 u23 u34 u45 u11 u22 u33 u44 u55 u66 </pre>

Similarly, if UPLO = 'L' the format of A is as follows:

On entry:	On exit:
<pre> a11 a22 a33 a44 a55 a66 l66 a21 a32 a43 a54 a65 * * a31 a42 a53 a64 * * * </pre>	<pre> l11 l22 l33 l44 l55 l21 l32 l43 l54 l65 l31 l42 l53 l64 * * </pre>

Array elements marked * are not used by the routine.

```

PURPOSE

cpbsvx uses the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ to compute the solution to a complex system of linear equations

$A * X = B$, where A is an N -by- N Hermitian positive definite band matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'E'$, real scaling factors are computed to equilibrate

the system:

$$\text{diag}(S) * A * \text{diag}(S) * \text{inv}(\text{diag}(S)) * X = \text{diag}(S) * B$$

Whether or not the system will be equilibrated depends on the

scaling of the matrix A , but if equilibration is used, A

is

overwritten by $\text{diag}(S)*A*\text{diag}(S)$ and B by $\text{diag}(S)*B$.

2. If $FACT = 'N'$ or $'E'$, the Cholesky decomposition is used to

factor the matrix A (after equilibration if $FACT = 'E'$)

as

$$A = U^*H * U, \text{ if } UPLO = 'U', \text{ or}$$

$$A = L * L^*H, \text{ if } UPLO = 'L',$$

where U is an upper triangular band matrix, and L is a lower

triangular band matrix.

3. If the leading i -by- i principal minor is not positive definite,

then the routine returns with $INFO = i$. Otherwise, the factored

form of A is used to estimate the condition number of the matrix

A . If the reciprocal of the condition number is less

than machine

precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(S)$ so that it solves the original system before equilibration.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by SCALE. A and AF will not be modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NDIAG (input)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $NDIAG \geq 0$.

NRHS (input)

The number of right-hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first NDIAG+1 rows of the array, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(\text{NDIAG}+1+i-j, j) = A(i, j)$ for $\max(1, j-\text{NDIAG}) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(N, j+\text{NDIAG})$. See below for further details.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$.

LDA (input)

The leading dimension of the array A. LDA \geq NDIAG+1.

AF (input/output)

If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U * H * U$ or $A = L * L * H$ of the band matrix A, in the same storage format as A (see A). If EQUED = 'Y', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U * H * U$ or $A = L * L * H$.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U * H * U$ or $A = L * L * H$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)

The leading dimension of the array AF. LDAF \geq NDIAG+1.

EQUED (input)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'Y': Equilibration was done, i.e., A has been replaced by $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$. EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

SCALE (input/output)

The scale factors for A; not accessed if EQUED = 'N'. SCALE is an input argument if FACT = 'F'; otherwise, SCALE is an output argument. If FACT = 'F' and EQUED = 'Y', each element of SCALE must be positive.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by $\text{diag}(\text{SCALE}) * B$.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,N).

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(\text{SCALE})) * X$.

LDX (input)
 The leading dimension of the array X. LDX \geq max(1,N).

RCOND (output)
 The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO $>$ 0.

FERR (output)
 The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
 The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
 dimension(2*N)

WORK2 (workspace)
 dimension(N)

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, and i is
 <= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 6, NDIAG = 2, and UPLO = 'U':

Two-dimensional storage of the Hermitian matrix A:

```

a11  a12  a13
     a22  a23  a24
           a33  a34  a35
                   a44  a45  a46
                           a55  a56

```

(aij=conjg(aji)) a66

Band storage of the upper triangle of A:

```
  *      *   a13  a24  a35  a46
  *   a12  a23  a34  a45  a56
a11  a22  a33  a44  a55  a66
```

Similarly, if UPLO = 'L' the format of A is as follows:

```
a11  a22  a33  a44  a55  a66
a21  a32  a43  a54  a65   *
a31  a42  a53  a64   *   *
```

Array elements marked * are not used by the routine.

               ldab, long *info);
```

PURPOSE

cpbtf2 computes the Cholesky factorization of a complex Hermitian positive definite band matrix A.

The factorization has the form

$$A = U' * U, \text{ if UPLO} = 'U', \text{ or}$$

$$A = L * L', \text{ if UPLO} = 'L',$$

where U is an upper triangular matrix, U' is the conjugate transpose of U, and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored:

= 'U': Upper triangular

= 'L': Lower triangular

N (input) The order of the matrix A. $N \geq 0$.

KD (input)

The number of super-diagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. $KD \geq 0$.

AB (input/output)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization $A = U' * U$ or $A = L * L'$ of the band matrix A, in the same storage format as A.

LDAB (input)

The leading dimension of the array AB. $LDAB \geq KD+1$.

INFO (output)

= 0: successful exit

< 0: if INFO = -k, the k-th argument had an illegal value

> 0: if INFO = k, the leading minor of order k is not positive definite, and the factorization could not be completed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when $N = 6$, $KD = 2$, and $UPLO = 'U'$:

On entry:						On exit:							
	*	*	a13	a24	a35	a46	*	*	u13	u24	u35		
u46		*	a12	a23	a34	a45	a56	*	u12	u23	u34	u45	
u56			a11	a22	a33	a44	a55	a66	u11	u22	u33	u44	u55
u66													

Similarly, if $UPLO = 'L'$ the format of A is as follows:

On entry:						On exit:							
	a11	a22	a33	a44	a55	a66	l11	l22	l33	l44	l55		
l66		a21	a32	a43	a54	a65	*	l21	l32	l43	l54	l65	
*			a31	a42	a53	a64	*	*	l31	l42	l53	l64	*
*													

Array elements marked * are not used by the routine.

[INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:,:) :: A, B  
INTEGER(8) :: N, NDIAG, NRHS, LDA, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpbtrs(char uplo, int n, int ndiag, int nrhs, complex  
*a, int lda, complex *b, int ldb, int *info);
```

```
void cpbtrs_64(char uplo, long n, long ndiag, long nrhs,  
complex *a, long lda, complex *b, long ldb, long  
*info);
```

PURPOSE

cpbtrs solves a system of linear equations $A \cdot X = B$ with a Hermitian positive definite band matrix A using the Cholesky factorization $A = U \cdot U^H$ or $A = L \cdot L^H$ computed by CPBTRF.

ARGUMENTS

UPLO (input)
= 'U': Upper triangular factor stored in A;
= 'L': Lower triangular factor stored in A.

N (input) The order of the matrix A. $N \geq 0$.

NDIAG (input)
The number of superdiagonals of the matrix A if
UPLO = 'U', or the number of subdiagonals if UPLO
= 'L'. $NDIAG \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number
of columns of the matrix B. $NRHS \geq 0$.

A (input) The triangular factor U or L from the Cholesky
factorization $A = U \cdot U^H$ or $A = L \cdot L^H$ of the band
matrix A, stored in the first NDIAG+1 rows of the
array. The j-th column of U or L is stored in the
j-th column of the array A as follows: if UPLO
= 'U', $A(kd+1+i-j, j) = U(i, j)$ for $\max(1, j-
kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = L(i, j)$
for $j \leq i \leq \min(n, j+kd)$.

LDA (input)
The leading dimension of the array A. $LDA \geq$
 $NDIAG+1$.

B (input/output)
On entry, the right hand side matrix B. On exit,
the solution matrix X.

LDB (input)
The leading dimension of the array B. $LDB \geq$
 $\max(1, N)$.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-
gal value

void cpocon_64(char uplo, long n, complex *a, long lda,
              float anorm, float *rcond, long *info);
```

PURPOSE

cpocon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite matrix using the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ computed by CPOTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$, as computed by CPOTRF.

LDA (input)
The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

ANORM (input)
The 1-norm (or infinity-norm) of the Hermitian matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

NAME

cpoequ - compute row and column scalings intended to equilibrate a Hermitian positive definite matrix A and reduce its condition number (with respect to the two-norm)

SYNOPSIS

```
SUBROUTINE CPOEQU(N, A, LDA, SCALE, SCOND, AMAX, INFO)
```

```
COMPLEX A(LDA,*)  
INTEGER N, LDA, INFO  
REAL SCOND, AMAX  
REAL SCALE(*)
```

```
SUBROUTINE CPOEQU_64(N, A, LDA, SCALE, SCOND, AMAX, INFO)
```

```
COMPLEX A(LDA,*)  
INTEGER*8 N, LDA, INFO  
REAL SCOND, AMAX  
REAL SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE POEQU([N], A, [LDA], SCALE, SCOND, AMAX, [INFO])
```

```
COMPLEX, DIMENSION(:, :) :: A  
INTEGER :: N, LDA, INFO  
REAL :: SCOND, AMAX  
REAL, DIMENSION(:) :: SCALE
```

```
SUBROUTINE POEQU_64([N], A, [LDA], SCALE, SCOND, AMAX, [INFO])
```

```
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: N, LDA, INFO  
REAL :: SCOND, AMAX  
REAL, DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpoequ(int n, complex *a, int lda, float *scale, float  
           *scond, float *amax, int *info);
```

```
void cpoequ_64(long n, complex *a, long lda, float *scale,  
              float *scond, float *amax, long *info);
```

PURPOSE

cpoequ computes row and column scalings intended to equilibrate a Hermitian positive definite matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i) = 1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j) = S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

A (input) The N-by-N Hermitian positive definite matrix whose scaling factors are to be computed. Only the diagonal elements of A are referenced.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1,N)$.

SCALE (output)
If INFO = 0, SCALE contains the scale factors for A.

SCOND (output)
If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND ≥ 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

AMAX (output)
Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element is nonpositive.

               ldb, complex *x, long ldx, float *ferr, float
               *berr, long *info);
```

PURPOSE

cporfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, N)$.

AF (input)
The triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$, as computed by CPOTRF.

LDAF (input)
The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, N)$.

X (input/output)
On entry, the solution matrix X, as computed by

CPOTRS. On exit, the improved solution matrix X.

LDX (input)

The leading dimension of the array X. LDX \geq max(1,N).

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

dimension(2*N)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>
```

```
void cposv(char uplo, int n, int nrhs, complex *a, int lda,  
          complex *b, int ldb, int *info);
```

```
void cposv_64(char uplo, long n, long nrhs, complex *a, long  
            lda, complex *b, long ldb, long *info);
```

PURPOSE

cposv computes the solution to a complex system of linear equations

$A * X = B$, where A is an N-by-N Hermitian positive definite matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

$A = U^{*}H*U$, if UPLO = 'U', or

$A = L * L^{*}H$, if UPLO = 'L',

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input/output)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization $A = U^{*}H*U$ or $A = L^{*}L^{*}H$.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,N)$.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

REAL, DIMENSION(:) :: SCALE, FERR, BERR, WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cposvx(char fact, char uplo, int n, int nrhs, complex
    *a, int lda, complex *af, int ldaf, char equed,
    float *scale, complex *b, int ldb, complex *x, int
    ldx, float *rcond, float *ferr, float *berr, int
    *info);
```

```
void cposvx_64(char fact, char uplo, long n, long nrhs, com-
    plex *a, long lda, complex *af, long ldaf, char
    equed, float *scale, complex *b, long ldb, complex
    *x, long ldx, float *rcond, float *ferr, float
    *berr, long *info);
```

PURPOSE

cposvx uses the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ to compute the solution to a complex system of linear equations

$A * X = B$, where A is an N -by- N Hermitian positive definite matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'E'$, real scaling factors are computed to equilibrate

the system:

$$\text{diag}(S) * A * \text{diag}(S) * \text{inv}(\text{diag}(S)) * X = \text{diag}(S) * B$$

Whether or not the system will be equilibrated depends on the

scaling of the matrix A , but if equilibration is used, A

is

overwritten by $\text{diag}(S)*A*\text{diag}(S)$ and B by $\text{diag}(S)*B$.

2. If $FACT = 'N'$ or $'E'$, the Cholesky decomposition is used to

factor the matrix A (after equilibration if $FACT = 'E'$)

as

$$A = U^*H^* U, \text{ if } UPLO = 'U', \text{ or}$$

$$A = L * L^*H, \text{ if } UPLO = 'L',$$

where U is an upper triangular matrix and L is a lower triangular matrix.

3. If the leading i -by- i principal minor is not positive definite,

then the routine returns with $INFO = i$. Otherwise, the factored

form of A is used to estimate the condition number of the matrix

A . If the reciprocal of the condition number is less than machine

precision, $INFO = N+1$ is returned as a warning, but the routine

still goes on to solve for X and compute error bounds as

described below.

4. The system of equations is solved for X using the factored form of A.
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(S)$ so that it solves the original system before equilibration.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by SCALE. A and AF will not be modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $\text{NRHS} \geq 0$.

A (input/output)

On entry, the Hermitian matrix A, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$.

LDA (input)

The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

AF (input/output)

If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$, in the same storage format as A. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix $\text{diag}(\text{SCALE})^*A^*\text{diag}(\text{SCALE})$.

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)

The leading dimension of the array AF. LDAF \geq max(1,N).

EQUED (input)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'Y': Equilibration was done, i.e., A has been replaced by $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$. EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

SCALE (input/output)

The scale factors for A; not accessed if EQUED = 'N'. SCALE is an input argument if FACT = 'F'; otherwise, SCALE is an output argument. If FACT = 'F' and EQUED = 'Y', each element of SCALE must be positive.

B (input/output)

On entry, the N-by-NRHS righthand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by $\text{diag}(\text{SCALE}) * B$.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,N).

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(\text{SCALE}))^*X$.

LDX (input)

The leading dimension of the array X. LDX \geq max(1,N).

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in par-

ticular, if $RCOND = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $INFO > 0$.

FERR (output)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If $XTRUE$ is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

dimension($2*N$)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value
> 0: if $INFO = i$, and i is
<= N : the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. $RCOND = 0$ is returned. = $N+1$: U is nonsingular, but $RCOND$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $RCOND$ would suggest.

```
SUBROUTINE POTF2_64(UPLO, [N], A, [LDA], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:,:) :: A  
INTEGER(8) :: N, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpotf2(char uplo, int n, complex *a, int lda, int  
           *info);
```

```
void cpotf2_64(char uplo, long n, complex *a, long lda, long  
              *info);
```

PURPOSE

cpotf2 computes the Cholesky factorization of a complex Hermitian positive definite matrix A.

The factorization has the form

$A = U' * U$, if UPLO = 'U', or

$A = L * L'$, if UPLO = 'L',

where U is an upper triangular matrix and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored. = 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization $A = U' * U$ or $A = L * L'$.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

INFO (output)

= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, the leading minor of order k is not positive definite, and the factorization could not be completed.

            *info);
```

```
void cpotrf_64(char uplo, long n, complex *a, long lda, long  
              *info);
```

PURPOSE

cpotrf computes the Cholesky factorization of a complex Hermitian positive definite matrix A.

The factorization has the form

$A = U^{*H} * U$, if UPLO = 'U', or

$A = L * L^{*H}$, if UPLO = 'L',

where U is an upper triangular matrix and L is lower triangular.

This is the block version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization $A = U^{*H}U$ or $A = L^{*H}L$.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

REAL, DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```

void cppcon(char uplo, int n, complex *a, float anorm, float
            *rcond, int *info);
void cppcon_64(char uplo, long n, complex *a, float anorm,
               float *rcond, long *info);

```

PURPOSE

cppcon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite packed matrix using the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ computed by CPPTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$, packed columnwise in a linear array. The j-th column of U or L is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = U(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = L(i,j)$ for $j \leq i \leq n$.

ANORM (input)

The 1-norm (or infinity-norm) of the Hermitian matrix A.

RCOND (output)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

WORK (workspace)

dimension(2*N)

WORK2 (workspace)

dimension(N)

INFO (output)

```

```
SUBROUTINE PPEQU_64(UPLO, [N], A, SCALE, SCOND, AMAX, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:) :: A  
INTEGER(8) :: N, INFO  
REAL :: SCOND, AMAX  
REAL, DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>
```

```

void cppequ(char uplo, int n, complex *a, float *scale,
            float *scond, float *amax, int *info);
void cppequ_64(char uplo, long n, complex *a, float *scale,
              float *scond, float *amax, long *info);

```

PURPOSE

cppequ computes row and column scalings intended to equilibrate a Hermitian positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i)=1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j)=S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

SCALE (output)

If INFO = 0, SCALE contains the scale factors for A.

SCOND (output)

If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND ≥ 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

AMAX (output)

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, the i-th diagonal element is nonpositive.

C INTERFACE

```
#include <sunperf.h>

void cprfs(char uplo, int n, int nrhs, complex *a, complex
           *af, complex *b, int ldb, complex *x, int ldx,
           float *ferr, float *berr, int *info);

void cprfs_64(char uplo, long n, long nrhs, complex *a,
              complex *af, complex *b, long ldb, complex *x,
              long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

cprfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i, j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i, j)$ for $j \leq i \leq n$.

AF (input)
 The triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$, as computed by SPTRF/CPTRF, packed columnwise in a linear array in the same format as A (see A).

B (input) The right hand side matrix B.

LDB (input)
 The leading dimension of the array B. $LDB \geq \max(1, N)$.

X (input/output)
 On entry, the solution matrix X, as computed by CPTRF. On exit, the improved solution matrix X.

LDX (input)
 The leading dimension of the array X. $LDX \geq \max(1, N)$.

FERR (output)
 The estimated forward error bound for each solution vector $X(j)$ (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated

upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

dimension($2*N$)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if $INFO = -i$, the i -th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>
```

```
void cppsv(char uplo, int n, int nrhs, complex *a, complex  
*b, int ldb, int *info);
```

```
void cppsv_64(char uplo, long n, long nrhs, complex *a, com-  
plex *b, long ldb, long *info);
```

PURPOSE

cppsv computes the solution to a complex system of linear equations

$A * X = B$, where A is an N-by-N Hermitian positive definite matrix stored in packed format and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

$A = U^{**H} * U$, if UPLO = 'U', or

$A = L * L^{**H}$, if UPLO = 'L',

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input/output)

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization $A = U^{**H} * U$ or $A = L * L^{**H}$, in the same storage format as A.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when $N = 4$, $UPLO = 'U'$:

Two-dimensional storage of the Hermitian matrix A:

```
a11 a12 a13 a14
    a22 a23 a24
        a33 a34   (aij = conjg(aji))
            a44
```

Packed storage of the upper triangle of A:

```
A = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]
```

                plex *a, complex *af, char equed, float *scale,
                complex *b, long ldb, complex *x, long ldx, float
                *rcond, float *ferr, float *berr, long *info);
```

PURPOSE

cppsvx uses the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ to compute the solution to a complex system of linear equations

$A * X = B$, where A is an N -by- N Hermitian positive definite matrix stored in packed format and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'E'$, real scaling factors are computed to equilibrate

the system:

$$\text{diag}(S) * A * \text{diag}(S) * \text{inv}(\text{diag}(S)) * X = \text{diag}(S) * B$$

Whether or not the system will be equilibrated depends on the

scaling of the matrix A , but if equilibration is used, A is

overwritten by $\text{diag}(S)*A*\text{diag}(S)$ and B by $\text{diag}(S)*B$.

2. If $FACT = 'N'$ or $'E'$, the Cholesky decomposition is used to

factor the matrix A (after equilibration if $FACT = 'E'$)

as

$$A = U^* * U, \quad \text{if } UPLO = 'U', \text{ or}$$

$$A = L * L', \quad \text{if } UPLO = 'L',$$

where U is an upper triangular matrix, L is a lower triangular

matrix, and $'$ indicates conjugate transpose.

3. If the leading i -by- i principal minor is not positive definite,

then the routine returns with $INFO = i$. Otherwise, the factored

form of A is used to estimate the condition number of the matrix

A . If the reciprocal of the condition number is less than machine

precision, $INFO = N+1$ is returned as a warning, but the routine

still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(S)$ so that it solves the original system before equilibration.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by SCALE. A and AF will not be modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO (input)

= 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $\text{NRHS} \geq 0$.

A (input/output)

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$.

AF (input/output)

If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U * H * U$ or $A = L * L * H$, in the same storage format as A. If EQUED

.ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

EQUED (input)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'Y': Equilibration was done, i.e., A has been replaced by $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$. EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

SCALE (input/output)

The scale factors for A; not accessed if EQUED = 'N'. SCALE is an input argument if FACT = 'F'; otherwise, SCALE is an output argument. If FACT = 'F' and EQUED = 'Y', each element of SCALE must be positive.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by $\text{diag}(\text{SCALE}) * B$.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(\text{SCALE})) * X$.

LDX (input)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest ele-

ment in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

dimension($2*N$)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value
> 0: if $INFO = i$, and i is
 $\leq N$: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. $RCOND = 0$ is returned. $= N+1$: U is non-singular, but $RCOND$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $RCOND$ would suggest.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when $N = 4$, $UPLO = 'U'$:

Two-dimensional storage of the Hermitian matrix A :

```
a11 a12 a13 a14
    a22 a23 a24
        a33 a34   (aij = conjg(aji))
            a44
```

Packed storage of the upper triangle of A :

$A = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]$

```

PURPOSE

cpptrf computes the Cholesky factorization of a complex Hermitian positive definite matrix A stored in packed format.

The factorization has the form

$A = U^{*H} * U$, if UPLO = 'U', or

$A = L * L^{*H}$, if UPLO = 'L',

where U is an upper triangular matrix and L is lower triangular.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization $A = U^{*H} * U$ or $A = L * L^{*H}$, in the same storage format as A.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when $N = 4$, UPLO = 'U':

Two-dimensional storage of the Hermitian matrix A:

```
a11 a12 a13 a14
  a22 a23 a24
    a33 a34      (aij = conjg(aji))
      a44
```

```

```
void cpptri_64(char uplo, long n, complex *a, long *info);
```

PURPOSE

cpptri computes the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ computed by CPPTRF.

ARGUMENTS

UPLO (input)

= 'U': Upper triangular factor is stored in A;
= 'L': Lower triangular factor is stored in A.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$, packed columnwise as a linear array. The j-th column of U or L is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = U(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = L(i,j)$ for $j \leq i \leq n$.

On exit, the upper or lower triangle of the (Hermitian) inverse of A, overwriting the input factor U or L.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the (i,i) element of the factor U or L is zero, and the inverse could not be computed.

```

PURPOSE

cpptrs solves a system of linear equations $A \cdot X = B$ with a Hermitian positive definite matrix A in packed storage using the Cholesky factorization $A = U \cdot U^H$ or $A = L \cdot L^H$ computed by CPPTRF.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A . $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input) The triangular factor U or L from the Cholesky factorization $A = U \cdot U^H$ or $A = L \cdot L^H$, packed columnwise in a linear array. The j -th column of U or L is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1) \cdot j / 2) = U(i, j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1) \cdot (2n-j) / 2) = L(i, j)$ for $j \leq i \leq n$.

B (input/output)

On entry, the right hand side matrix B . On exit, the solution matrix X .

LDB (input)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

INFO (output)

= 0: successful exit
< 0: if INFO = $-i$, the i -th argument had an illegal value

NAME

cptcon - compute the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite tridiagonal matrix using the factorization $A = L*D*L^*H$ or $A = U^*H*D*U$ computed by CPTTRF

SYNOPSIS

```
SUBROUTINE CPTCON(N, DIAG, OFFD, ANORM, RCOND, WORK, INFO)
```

```
COMPLEX OFFD(*)
INTEGER N, INFO
REAL ANORM, RCOND
REAL DIAG(*), WORK(*)
```

```
SUBROUTINE CPTCON_64(N, DIAG, OFFD, ANORM, RCOND, WORK, INFO)
```

```
COMPLEX OFFD(*)
INTEGER*8 N, INFO
REAL ANORM, RCOND
REAL DIAG(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE PTCON([N], DIAG, OFFD, ANORM, RCOND, [WORK], [INFO])
```

```
COMPLEX, DIMENSION(:) :: OFFD
INTEGER :: N, INFO
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: DIAG, WORK
```

```
SUBROUTINE PTCON_64([N], DIAG, OFFD, ANORM, RCOND, [WORK], [INFO])
```

```
COMPLEX, DIMENSION(:) :: OFFD
INTEGER(8) :: N, INFO
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: DIAG, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cptcon(int n, float *diag, complex *offd, float anorm,
            float *rcond, int *info);
```

```
void cptcon_64(long n, float *diag, complex *offd, float
              anorm, float *rcond, long *info);
```

PURPOSE

cptcon computes the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite tridiagonal matrix using the factorization $A = L^*D*L^{**H}$ or $A = U^{**H}*D*U$ computed by CPTTRF.

Norm(inv(A)) is computed by a direct method, and the reciprocal of the condition number is computed as
 $RCOND = 1 / (ANORM * norm(inv(A)))$.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

DIAG (input)
The n diagonal elements of the diagonal matrix DIAG from the factorization of A, as computed by CPTTRF.

OFFD (input)
The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization of A, as computed by CPTTRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(ANORM * AINVNM)$, where AINVNM is the 1-norm of inv(A) computed in this routine.

WORK (workspace)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The method used is described in Nicholas J. Higham, "Efficient Algorithms for Computing the Condition Number of a Tridiagonal Matrix", SIAM J. Sci. Stat. Comput., Vol. 7, No. 1, January 1986.

```

```
CHARACTER(LEN=1) :: COMPZ  
COMPLEX, DIMENSION(:,*) :: Z  
INTEGER :: N, LDZ, INFO  
REAL, DIMENSION(:) :: D, E, WORK
```

```
SUBROUTINE PTEQR_64(COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: COMPZ  
COMPLEX, DIMENSION(:,*) :: Z  
INTEGER(8) :: N, LDZ, INFO  
REAL, DIMENSION(:) :: D, E, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpteqr(char compz, int n, float *d, float *e, complex  
            *z, int ldz, int *info);
```

```
void cpteqr_64(char compz, long n, float *d, float *e, complex *z, long ldz, long *info);
```

PURPOSE

cpteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF and then calling CBDSQR to compute the singular values of the bidiagonal factor.

This routine computes the eigenvalues of the positive definite tridiagonal matrix to high relative accuracy. This means that if the eigenvalues range over many orders of magnitude in size, then the small eigenvalues and corresponding eigenvectors will be computed more accurately than, for example, with the standard QR method.

The eigenvectors of a full or band positive definite Hermitian matrix can also be found if CHETRD, CHPTRD, or CHBTRD has been used to reduce this matrix to tridiagonal form. (The reduction to tridiagonal form, however, may preclude the possibility of obtaining high relative accuracy in the small eigenvalues of the original matrix, if these eigenvalues range over many orders of magnitude.)

ARGUMENTS

COMPZ (input)

= 'N': Compute eigenvalues only.
= 'V': Compute eigenvectors of original Hermitian matrix also. Array Z contains the unitary matrix used to reduce the original matrix to tridiagonal form.
= 'I': Compute eigenvectors of tridiagonal matrix also.

N (input) The order of the matrix. $N \geq 0$.

D (input/output)

On entry, the n diagonal elements of the tridiagonal matrix. On normal exit, D contains the eigenvalues, in descending order.

E (input/output)

On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z (input) On entry, if COMPZ = 'V', the unitary matrix used in the reduction to tridiagonal form. On exit, if COMPZ = 'V', the orthonormal eigenvectors of the original Hermitian matrix; if COMPZ = 'I', the orthonormal eigenvectors of the tridiagonal matrix. If INFO > 0 on exit, Z contains the eigenvectors associated with only the stored eigenvalues. If COMPZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. $LDZ \geq 1$,

and if COMPZ = 'V' or 'I', LDZ \geq max(1,N).

WORK (workspace)
dimension(4*N)

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, and i is: $\leq N$ the Cholesky factorization of the matrix could not be performed because the i-th principal minor was not positive definite. $> N$ the SVD algorithm failed to converge; if INFO = N+i, i off-diagonal elements of the bidiagonal factor did not converge to zero.

              *ferr, float *berr, long *info);

```

PURPOSE

cptrfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix A is stored and the form of the factorization:
 = 'U': OFFD is the superdiagonal of A, and $A = U^*H*DIAG*U$;
 = 'L': OFFD is the subdiagonal of A, and $A = L*DIAG*L^*H$. (The two forms are equivalent if A is real.)

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

DIAG (input)
 The n real diagonal elements of the tridiagonal matrix A.

OFFD (input)
 The (n-1) off-diagonal elements of the tridiagonal matrix A (see UPLO).

DIAGF (input)
 The n diagonal elements of the diagonal matrix DIAG from the factorization computed by CPTTRF.

OFFDF (input)
 The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization computed by CPTTRF (see UPLO).

B (input) The right hand side matrix B.

LDB (input)
 The leading dimension of the array B. $LDB \geq \max(1,N)$.

X (input/output)

On entry, the solution matrix X, as computed by CPTTRS. On exit, the improved solution matrix X.

LDX (input)

The leading dimension of the array X. LDX \geq max(1,N).

FERR (output)

The forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j).

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

dimension(N)

WORK2 (workspace)

dimension(N)

COMPLEX, DIMENSION(:, :) :: B  
INTEGER(8) :: N, NRHS, LDB, INFO  
REAL, DIMENSION(:) :: DIAG
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cptsv(int n, int nrhs, float *diag, complex *sub, complex *b, int ldb, int *info);
```

```
void cptsv_64(long n, long nrhs, float *diag, complex *sub, complex *b, long ldb, long *info);
```

PURPOSE

cptsv computes the solution to a complex system of linear equations $A \cdot X = B$, where A is an N -by- N Hermitian positive definite tridiagonal matrix, and X and B are N -by- $NRHS$ matrices.

A is factored as $A = L \cdot D \cdot L^* \cdot H$, and the factored form of A is then used to solve the system of equations.

ARGUMENTS

N (input) The order of the matrix A . $N \geq 0$.

$NRHS$ (input)
The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

$DIAG$ (input/output)
On entry, the n diagonal elements of the tridiagonal matrix A . On exit, the n diagonal elements of the diagonal matrix $DIAG$ from the factorization $A = L \cdot DIAG \cdot L^* \cdot H$.

SUB (input/output)
On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix A . On exit, the $(n-1)$ subdiagonal elements of the unit bidiagonal factor L from the $L \cdot DIAG \cdot L^* \cdot H$ factorization of A . SUB can also be regarded as the superdiagonal of the unit bidiagonal factor U from the $U^* \cdot H \cdot DIAG \cdot U$ factorization of A .

B (input/output)
On entry, the N -by- $NRHS$ right hand side matrix B .
On exit, if $INFO = 0$, the N -by- $NRHS$ solution matrix X .

LDB (input)
The leading dimension of the array B . $LDB \geq \max(1, N)$.

$INFO$ (output)
= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value
> 0: if $INFO = i$, the leading minor of order i is not positive definite, and the solution has not been computed. The factorization has not been completed unless $i = N$.

               float *ferr, float *berr, long *info);

```

PURPOSE

cptsvx uses the factorization $A = L^*D^*L^{**}H$ to compute the solution to a complex system of linear equations $A^*X = B$, where A is an N -by- N Hermitian positive definite tridiagonal matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If `FACT = 'N'`, the matrix A is factored as $A = L^*D^*L^{**}H$, where L is a unit lower bidiagonal matrix and D is diagonal. The factorization can also be regarded as having the form $A = U^{**}H^*D^*U$.
2. If the leading i -by- i principal minor is not positive definite, then the routine returns with `INFO = i`. Otherwise, the factored form of A is used to estimate the condition number of the matrix.
 - A. If the reciprocal of the condition number is less than machine precision, `INFO = N+1` is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
3. The system of equations is solved for X using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of the matrix A is supplied on entry. = 'F': On entry, DIAGF and SUBF contain the factored form of A. DIAG, SUB, DIAGF, and SUBF will not be modified. = 'N': The matrix A will be copied to DIAGF and SUBF and factored.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

DIAG (input)

The n diagonal elements of the tridiagonal matrix A.

SUB (input)

The (n-1) subdiagonal elements of the tridiagonal matrix A.

DIAGF (input/output)

If FACT = 'F', then DIAGF is an input argument and on entry contains the n diagonal elements of the diagonal matrix DIAG from the $L*DIAG*L**H$ factorization of A. If FACT = 'N', then DIAGF is an output argument and on exit contains the n diagonal elements of the diagonal matrix DIAG from the $L*DIAG*L**H$ factorization of A.

SUBF (input/output)

If FACT = 'F', then SUBF is an input argument and on entry contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the $L*DIAG*L**H$ factorization of A. If FACT = 'N', then SUBF is an output argument and on exit contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the $L*DIAG*L**H$ factorization of A.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)

The leading dimension of the array X. $LDX \geq \max(1,N)$.

RCOND (output)

The reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)

The forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If $XTRUE$ is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

dimension(N)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = $-i$, the i -th argument had an illegal value
> 0: if INFO = i , and i is
 $\leq N$: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned.
 $= N+1$: U is non-singular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

C INTERFACE

```
#include <sunperf.h>
```

```
void cpttrf(int n, float *diag, complex *offd, int *info);
```

```
void cpttrf_64(long n, float *diag, complex *offd, long
               *info);
```

PURPOSE

cpttrf computes the L^*D^*L' factorization of a complex Hermitian positive definite tridiagonal matrix A. The factorization may also be regarded as having the form $A = U^*D^*U$.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

DIAG (input/output)

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix DIAG from the L^*DIAG^*L' factorization of A.

OFFD (input/output)

On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L^*DIAG^*L' factorization of A. OFFD can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U^*DIAG^*U factorization of A.

INFO (output)

= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, the leading minor of order k is not positive definite; if $k < N$, the factorization could not be completed, while if $k = N$, the factorization was completed, but $DIAG(N) = 0$.

NAME

cpttrs - solve a tridiagonal system of the form $A * X = B$ using the factorization $A = U * D * U$ or $A = L * D * L'$ computed by CPTTRF

SYNOPSIS

```
SUBROUTINE CPTTRS(UPLO, N, NRHS, DIAG, OFFD, B, LDB, INFO)
```

```
CHARACTER * 1 UPLO  
COMPLEX OFFD(*), B(LDB,*)  
INTEGER N, NRHS, LDB, INFO  
REAL DIAG(*)
```

```
SUBROUTINE CPTTRS_64(UPLO, N, NRHS, DIAG, OFFD, B, LDB, INFO)
```

```
CHARACTER * 1 UPLO  
COMPLEX OFFD(*), B(LDB,*)  
INTEGER*8 N, NRHS, LDB, INFO  
REAL DIAG(*)
```

F95 INTERFACE

```
SUBROUTINE PTTRS(UPLO, [N], [NRHS], DIAG, OFFD, B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:) :: OFFD  
COMPLEX, DIMENSION(:, :) :: B  
INTEGER :: N, NRHS, LDB, INFO  
REAL, DIMENSION(:) :: DIAG
```

```
SUBROUTINE PTTRS_64(UPLO, [N], [NRHS], DIAG, OFFD, B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:) :: OFFD  
COMPLEX, DIMENSION(:, :) :: B  
INTEGER(8) :: N, NRHS, LDB, INFO  
REAL, DIMENSION(:) :: DIAG
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpttrs(char uplo, int n, int nrhs, float *diag, complex  
            *offd, complex *b, int ldb, int *info);
```

```
void cpttrs_64(char uplo, long n, long nrhs, float *diag,
               complex *offd, complex *b, long ldb, long *info);
```

PURPOSE

cpttrs solves a tridiagonal system of the form $A * X = B$ using the factorization $A = U'D*U$ or $A = L*D*L'$ computed by CPTTRF. D is a diagonal matrix specified in the vector D, U (or L) is a unit bidiagonal matrix whose superdiagonal (subdiagonal) is specified in the vector E, and X and B are N by NRHS matrices.

ARGUMENTS

UPLO (input)

Specifies the form of the factorization and whether the vector OFFD is the superdiagonal of the upper bidiagonal factor U or the subdiagonal of the lower bidiagonal factor L. = 'U': $A = U'DIAG*U$, OFFD is the superdiagonal of U
= 'L': $A = L'DIAG*L'$, OFFD is the subdiagonal of L

N (input) The order of the tridiagonal matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

DIAG (input)

The n diagonal elements of the diagonal matrix DIAG from the factorization $A = U'DIAG*U$ or $A = L'DIAG*L'$.

OFFD (input/output)

If UPLO = 'U', the (n-1) superdiagonal elements of the unit bidiagonal factor U from the factorization $A = U'DIAG*U$. If UPLO = 'L', the (n-1) subdiagonal elements of the unit bidiagonal factor L from the factorization $A = L'DIAG*L'$.

B (input/output)

On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

INFO (output)

= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value

NAME

cptts2 - solve a tridiagonal system of the form $A * X = B$ using the factorization $A = U' * D * U$ or $A = L * D * L'$ computed by CPTTRF

SYNOPSIS

```
SUBROUTINE CPTTS2(IUPLO, N, NRHS, D, E, B, LDB)
```

```
COMPLEX E(*), B(LDB,*)  
INTEGER IUPLO, N, NRHS, LDB  
REAL D(*)
```

```
SUBROUTINE CPTTS2_64(IUPLO, N, NRHS, D, E, B, LDB)
```

```
COMPLEX E(*), B(LDB,*)  
INTEGER*8 IUPLO, N, NRHS, LDB  
REAL D(*)
```

F95 INTERFACE

```
SUBROUTINE CPTTS2(IUPLO, N, NRHS, D, E, B, LDB)
```

```
COMPLEX, DIMENSION(:) :: E  
COMPLEX, DIMENSION(:, :) :: B  
INTEGER :: IUPLO, N, NRHS, LDB  
REAL, DIMENSION(:) :: D
```

```
SUBROUTINE CPTTS2_64(IUPLO, N, NRHS, D, E, B, LDB)
```

```
COMPLEX, DIMENSION(:) :: E  
COMPLEX, DIMENSION(:, :) :: B  
INTEGER(8) :: IUPLO, N, NRHS, LDB  
REAL, DIMENSION(:) :: D
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cptts2(int iuplo, int n, int nrhs, float *d, complex  
           *e, complex *b, int ldb);
```

```
void cptts2_64(long iuplo, long n, long nrhs, float *d, com-  
              plex *e, complex *b, long ldb);
```

PURPOSE

cptts2 solves a tridiagonal system of the form
 $A * X = B$ using the factorization $A = U'D*U$ or $A = L*D*L'$ computed by CPTTRF. D is a diagonal matrix specified in the vector D, U (or L) is a unit bidiagonal matrix whose superdiagonal (subdiagonal) is specified in the vector E, and X and B are N by NRHS matrices.

ARGUMENTS

IUPLO (input)

Specifies the form of the factorization and whether the vector E is the superdiagonal of the upper bidiagonal factor U or the subdiagonal of the lower bidiagonal factor L. = 1: $A = U'D*U$, E is the superdiagonal of U
= 0: $A = L*D*L'$, E is the subdiagonal of L

N (input) The order of the tridiagonal matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

D (input) The n diagonal elements of the diagonal matrix D from the factorization $A = U'D*U$ or $A = L*D*L'$.

E (input) If IUPLO = 1, the (n-1) superdiagonal elements of the unit bidiagonal factor U from the factorization $A = U'D*U$. If IUPLO = 0, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the factorization $A = L*D*L'$.

B (input/output)

On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

NAME

crot - apply a plane rotation, where the cos (C) is real and the sin (S) is complex, and the vectors X and Y are complex

SYNOPSIS

```
SUBROUTINE CROT(N, X, INCX, Y, INCY, C, S)
```

```
COMPLEX S  
COMPLEX X(*), Y(*)  
INTEGER N, INCX, INCY  
REAL C
```

```
SUBROUTINE CROT_64(N, X, INCX, Y, INCY, C, S)
```

```
COMPLEX S  
COMPLEX X(*), Y(*)  
INTEGER*8 N, INCX, INCY  
REAL C
```

F95 INTERFACE

```
SUBROUTINE ROT([N], X, [INCX], Y, [INCY], C, S)
```

```
COMPLEX :: S  
COMPLEX, DIMENSION(:) :: X, Y  
INTEGER :: N, INCX, INCY  
REAL :: C
```

```
SUBROUTINE ROT_64([N], X, [INCX], Y, [INCY], C, S)
```

```
COMPLEX :: S  
COMPLEX, DIMENSION(:) :: X, Y  
INTEGER(8) :: N, INCX, INCY  
REAL :: C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void crot(int n, complex *x, int incx, complex *y, int incy,  
         float c, complex *s);
```

```
void crot_64(long n, complex *x, long incx, complex *y, long  
            incy, float c, complex *s);
```

PURPOSE

crot applies a plane rotation, where the cos (C) is real and the sin (S) is complex, and the vectors X and Y are complex.

ARGUMENTS

N (input)
The number of elements in the vectors X and Y.

X (input/output)
On input, the vector X. On output, X is overwritten with $C*X + S*Y$.

INCX (input)
The increment between successive values of Y.
INCX \neq 0.

Y (input/output)
On input, the vector Y. On output, Y is overwritten with $-CONJG(S)*X + C*Y$.

INCY (input)
The increment between successive values of Y.
INCY \neq 0.

C (input)

S (input)
C and S define a rotation
$$\begin{bmatrix} C & S \\ -conjg(S) & C \end{bmatrix}$$

where $C*C + S*CONJG(S) = 1.0$.

NAME

crotg - Construct a Given's plane rotation

SYNOPSIS

```
SUBROUTINE CROTG(A, B, C, S)
```

```
COMPLEX A, B, S  
REAL C
```

```
SUBROUTINE CROTG_64(A, B, C, S)
```

```
COMPLEX A, B, S  
REAL C
```

F95 INTERFACE

```
SUBROUTINE ROTG(A, B, C, S)
```

```
COMPLEX :: A, B, S  
REAL :: C
```

```
SUBROUTINE ROTG_64(A, B, C, S)
```

```
COMPLEX :: A, B, S  
REAL :: C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void crotg(complex *a, complex *b, float *c, complex *s);
```

```
void crotg_64(complex *a, complex *b, float *c, complex *s);
```

PURPOSE

crotg Construct a Given's plane rotation that will annihilate an element of a vector.

ARGUMENTS

A (input/output)

On entry, A contains the entry in the first vector that corresponds to the element to be annihilated in the second vector. On exit, contains the nonzero element of the rotated vector.

B (input)

On entry, B contains the entry to be annihilated in the second vector. Unchanged on exit.

C (output)

On exit, C and S are the elements of the rotation matrix that will be applied to annihilate B.

S (output)

On exit, C and S are the elements of the rotation matrix that will be applied to annihilate B.

NAME

cscal - Compute $y := \alpha * y$

SYNOPSIS

```
SUBROUTINE CSCAL(N, ALPHA, Y, INCY)
```

```
COMPLEX ALPHA  
COMPLEX Y(*)  
INTEGER N, INCY
```

```
SUBROUTINE CSCAL_64(N, ALPHA, Y, INCY)
```

```
COMPLEX ALPHA  
COMPLEX Y(*)  
INTEGER*8 N, INCY
```

F95 INTERFACE

```
SUBROUTINE SCAL([N], ALPHA, Y, [INCY])
```

```
COMPLEX :: ALPHA  
COMPLEX, DIMENSION(:) :: Y  
INTEGER :: N, INCY
```

```
SUBROUTINE SCAL_64([N], ALPHA, Y, [INCY])
```

```
COMPLEX :: ALPHA  
COMPLEX, DIMENSION(:) :: Y  
INTEGER(8) :: N, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cscal(int n, complex *alpha, complex *y, int incy);
```

```
void cscal_64(long n, complex *alpha, complex *y, long  
incy);
```

PURPOSE

cscal Compute $y := \text{alpha} * y$ where alpha is a scalar and y is an n-vector.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

Y (input/output)

($1 + (n - 1) * \text{abs}(\text{INCY})$). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

csctr - Scatters elements from x into y.

SYNOPSIS

```
SUBROUTINE CSCTR(NZ, X, INDX, Y)

COMPLEX X(*), Y(*)
INTEGER NZ
INTEGER INDX(*)

SUBROUTINE CSCTR_64(NZ, X, INDX, Y)

COMPLEX X(*), Y(*)
INTEGER*8 NZ
INTEGER*8 INDX(*)

F95 INTERFACE
SUBROUTINE SCTR([NZ], X, INDX, Y)

COMPLEX, DIMENSION(:) :: X, Y
INTEGER :: NZ
INTEGER, DIMENSION(:) :: INDX

SUBROUTINE SCTR_64([NZ], X, INDX, Y)

COMPLEX, DIMENSION(:) :: X, Y
INTEGER(8) :: NZ
INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

CSCTR - Scatters the components of a sparse vector x stored in compressed form into specified components of a vector y in full storage form.

```
do i = 1, n
  y(indx(i)) = x(i)
enddo
```

ARGUMENTS

NZ (input) - INTEGER

Number of elements in the compressed form.
Unchanged on exit.

X (input)

Vector containing the values to be scattered from
compressed form into full storage form. Unchanged
on exit.

INDX (input) - INTEGER

Vector containing the indices of the compressed
form. It is assumed that the elements in INDX are
distinct and greater than zero. Unchanged on exit.

Y (output)

Vector whose elements specified by indx have been
set to the corresponding entries of x. Only the
elements corresponding to the indices in indx have
been modified.

COMPLEX ALPHA, BETA  
COMPLEX VAL(NNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
```

```
SUBROUTINE CSKYMM_64( TRANSA, M, N, K, ALPHA, DESCRA,  
* VAL, PNTR, B, LDB, BETA, C, LDC, WORK, LWORK )  
INTEGER*8 TRANSA, M, N, K, DESCRA(5),  
* LDB, LDC, LWORK  
INTEGER*8 PNTR(*),  
COMPLEX ALPHA, BETA  
COMPLEX VAL(NNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
```

where NNZ = PNTR(K+1)-PNTR(1) (upper triangular)
NNZ = PNTR(M+1)-PNTR(1) (lower triangular)
PNTR() size = (K+1) (upper triangular)
PNTR() size = (M+1) (lower triangular)

F95 INTERFACE

```
SUBROUTINE SKYMM( TRANSA, M, [N], K, ALPHA, DESCRA, VAL,  
* PNTR, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])  
INTEGER TRANSA, M, K  
INTEGER, DIMENSION(:) :: DESCRA, PNTR  
COMPLEX ALPHA, BETA  
COMPLEX, DIMENSION(:) :: VAL  
COMPLEX, DIMENSION(:, :) :: B, C
```

```
SUBROUTINE SKYMM_64( TRANSA, M, [N], K, ALPHA, DESCRA, VAL,  
* PNTR, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])  
INTEGER*8 TRANSA, M, K  
INTEGER*8, DIMENSION(:) :: DESCRA, PNTR  
COMPLEX ALPHA, BETA  
COMPLEX, DIMENSION(:) :: VAL  
COMPLEX, DIMENSION(:, :) :: B, C
```

DESCRIPTION

```
C <- alpha op(A) B + beta C
```

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in skyline format and
op(A) is one of
op(A) = A or op(A) = A' or op(A) = conjg(A').
(' indicates matrix transpose)

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real.
M	Number of rows in matrix A
N	Number of columns in matrix C
K	Number of columns in matrix A
ALPHA	Scalar parameter
DESCRA()	Descriptor argument. Five element integer array DESCRA(1) matrix structure 0 : general (NOT SUPPORTED) 1 : symmetric (A=A') 2 : Hermitian (A= CONJG(A')) 3 : Triangular 4 : Skew(Anti)-Symmetric (A=-A') 5 : Diagonal 6 : Skew-Hermitian (A= -CONJG(A')) DESCRA(2) upper/lower triangular indicator 1 : lower 2 : upper DESCRA(3) main diagonal type 0 : non-unit 1 : unit DESCRA(4) Array base (NOT IMPLEMENTED) 0 : C/C++ compatible 1 : Fortran compatible DESCRA(5) repeated indices? (NOT IMPLEMENTED) 0 : unknown 1 : no repeated indices
VAL()	array contain the nonzeros of A in skyline profile form. Row-oriented if DESCRA(2) = 1 (lower triangular), column oriented if DESCRA(2) = 2 (upper triangular).
PNTR()	integer array of length M+1 (lower triangular) or K+1 (upper triangular) such that PNTR(I)-PNTR(1)+1 points to the location in VAL of the first element of the skyline profile in row (column) I.
B() LDB	rectangular array with first dimension LDB. leading dimension of B
BETA	Scalar parameter

C()	rectangular array with first dimension LDC.
LDC	leading dimension of C
WORK()	scratch array of length LWORK. WORK is not referenced in the current version.
LWORK	length of WORK array. LWORK is not referenced in the current version.

NOTES/BUGS

The SKY data structure is not supported for a general matrix structure (*DESCRA*(1)=0).

Also not supported:

1. lower triangular matrix A of size m by n where $m > n$
2. upper triangular matrix A of size m by n where $m < n$

INTEGER*8 TRANSA, M, UNITD  
INTEGER*8, DIMENSION(:) :: DESCRA, PNTR  
COMPLEX ALPHA, BETA  
COMPLEX, DIMENSION(:) :: VAL, DV  
COMPLEX, DIMENSION(:, :) :: B, C
```

DESCRIPTION

```
C <- ALPHA op(A) B + BETA C      C <- ALPHA D op(A) B + BETA C
C <- ALPHA op(A) D B + BETA C
```

where ALPHA and BETA are scalar, C and B are m by n dense matrices, D is a diagonal scaling matrix, A is a unit, or non-unit, upper or lower triangular matrix represented in skyline format and op(A) is one of

op(A) = inv(A) or op(A) = inv(A') or op(A) =inv(conjg(A')).
(inv denotes matrix inverse, ' indicates matrix transpose)

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real.
M	Number of rows in matrix A
N	Number of columns in matrix C
UNITD	Type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) 4 : Automatic row or column scaling (see section NOTES for further details)
DV()	Array of length M containing the diagonal entries of the scaling diagonal matrix D.
ALPHA	Scalar parameter
DESCRA()	Descriptor argument. Five element integer array DESCRA(1) matrix structure 0 : general 1 : symmetric (A=A') 2 : Hermitian (A= CONJG(A')) 3 : Triangular 4 : Skew(Anti)-Symmetric (A=-A') 5 : Diagonal 6 : Skew-Hermitian (A= -CONJG(A')) Note: For the routine, DESCRA(1)=3 is only supported. DESCRA(2) upper/lower triangular indicator 1 : lower 2 : upper DESCRA(3) main diagonal type 0 : non-unit 1 : unit DESCRA(4) Array base (NOT IMPLEMENTED) 0 : C/C++ compatible 1 : Fortran compatible DESCRA(5) repeated indices? (NOT IMPLEMENTED) 0 : unknown 1 : no repeated indices

VAL() array contain the nonzeros of A in skyline profile form.
Row-oriented if DESCRA(2) = 1 (lower triangular),
column oriented if DESCRA(2) = 2 (upper triangular).

PNTR() integer array of length M+1 (lower triangular) or
K+1 (upper triangular) such that PNTR(I)-PNTR(1)+1
points to the location in VAL of the first element of
the skyline profile in row (column) I.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK.
On exit, if LWORK = -1, WORK(1) returns the optimum LWORK.

LWORK length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger.
For optimum performance on multiple processors, LWORK
>=M*N_CPUS where N_CPUS is the maximum number of
processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the
routine only calculates the optimum size of the WORK
array, returns this value as the first entry of the WORK
array, and no error message related to LWORK is issued
by XERBLA.

SEE ALSO

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

"Document for the Basic Linear Algebra Subprograms (BLAS)
Standard", University of Tennessee, Knoxville, Tennessee,
1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. Also not supported:
 - a. lower triangular matrix A of size m by n where m > n
 - b. upper triangular matrix A of size m by n where m < n
2. No test for singularity or near-singularity is included
in this routine. Such tests must be performed before calling
this routine.
3. If UNITD =4, the routine scales the rows of A if
DESCRA(2)=1 and the columns of A if DESCRA(2)=2 such that
their 2-norms are one. The scaling may improve the accuracy

of the computed solution. Corresponding entries of VAL are changed only in this particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows (columns) have been scaled. UNITD=2 if DESCRA(2)=1 and UNITD=3 if DESCRA(2)=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise WORK(1) = -i where i is the row (column) number which 2-norm is exactly zero.

4. If DESCRA(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the SKY representation of a sparse matrix. They are not used anyway in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the SKY representation.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However DESCRA(1) must be equal to 3 in this case.

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:) :: A, WORK  
INTEGER(8) :: N, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT  
REAL :: ANORM, RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cspcon(char uplo, int n, complex *a, int *ipivot, float
            anorm, float *rcond, int *info);
void cspcon_64(char uplo, long n, complex *a, long *ipivot,
               float anorm, float *rcond, long *info);
```

PURPOSE

cspcon estimates the reciprocal of the condition number (in the 1-norm) of a complex symmetric packed matrix A using the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ computed by CSPTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is $A = U*D*U^{**T}$;
= 'L': Lower triangular, form is $A = L*D*L^{**T}$.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSPTRF, stored as a packed triangular matrix.

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by CSPTRF.

ANORM (input)

The 1-norm of the original matrix A.

RCOND (output)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

```

PURPOSE

csprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i, j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i, j)$ for $j \leq i \leq n$.

AF (input)
 The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by CSPTRF, stored as a packed triangular matrix.

IPIVOT (input)
 Details of the interchanges and the block structure of D as determined by CSPTRF.

B (input) The right hand side matrix B.

LDB (input)
 The leading dimension of the array B. $LDB \geq \max(1, N)$.

X (input/output)
 On entry, the solution matrix X, as computed by CSPTRS. On exit, the improved solution matrix X.

LDX (input)

The leading dimension of the array X. LDX \geq max(1,N).

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

dimension(2*N)

WORK2 (workspace)

dimension(N)

```

C INTERFACE

```
#include <sunperf.h>
```

```
void cspsv(char uplo, int n, int nrhs, complex *a, int  
          *ipivot, complex *b, int ldb, int *info);
```

```
void cspsv_64(char uplo, long n, long nrhs, complex *a, long
             *ipivot, complex *b, long ldb, long *info);
```

PURPOSE

cspsv computes the solution to a complex system of linear equations

$A * X = B$, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$A = U * D * U^{**T}$, if UPLO = 'U', or

$A = L * D * L^{**T}$, if UPLO = 'L',

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input/output)

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by CSPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIVOT (output)

Details of the interchanges and the block structure of D, as determined by CSPTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B (input/output)
 On entry, the N-by-NRHS right hand side matrix B.
 On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
 The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when N = 4, UPLO = 'U':

Two-dimensional storage of the symmetric matrix A:

```

a11 a12 a13 a14
  a22 a23 a24
    a33 a34      (aij = aji)
      a44

```

Packed storage of the upper triangle of A:

A = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]

float *ferr, float *berr, long *info);
```

PURPOSE

cspsvx uses the diagonal pivoting factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N symmetric matrix stored in packed format and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the diagonal pivoting method is used to factor A as

$A = U * D * U^{**T}$, if $UPLO = 'U'$, or

$A = L * D * L^{**T}$, if $UPLO = 'L'$,

where U (or L) is a product of permutation and unit upper (lower)

triangular matrices and D is symmetric and block diagonal with

1-by-1 and 2-by-2 diagonal blocks.

2. If some $D(i,i)=0$, so that D is exactly singular, then the routine

returns with $INFO = i$. Otherwise, the factored form of A is used

to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision,

$INFO = N+1$ is returned as a warning, but the routine still goes on

to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form

of A .

4. Iterative refinement is applied to improve the computed

solution
matrix and calculate error bounds and backward error
estimates
for it.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AF and IPIVOT contain the factored form of A. A, AF and IPIVOT will not be modified. = 'N': The matrix A will be copied to AF and factored.

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

AF (input/output)

If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by CSPTRF, stored as a packed triangular matrix in the same storage format as A.

If FACT = 'N', then AF is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by CSPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIVOT (input or output)

If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CSPTRF. If $IPIVOT(k) > 0$, then rows and columns k and IPIVOT(k) were interchanged and $D(k,k)$ is a 1-by-1 diagonal block. If UPLO = 'U' and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and -IPIVOT(k) were interchanged and $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. If UPLO = 'L' and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and -IPIVOT(k) were interchanged and $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument

and on exit contains details of the interchanges and the block structure of D, as determined by CSPTRF.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,N).

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)

The leading dimension of the array X. LDX \geq max(1,N).

RCOND (output)

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO $>$ 0.

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

dimension(2*N)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
 \leq N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would

suggest.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when $N = 4$, $UPLO = 'U'$:

Two-dimensional storage of the symmetric matrix A:

```
a11 a12 a13 a14
    a22 a23 a24
        a33 a34      (aij = aji)
            a44
```

Packed storage of the upper triangle of A:

```
A = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]
```

```

```
void csptf_64(char uplo, long n, complex *a, long *ipivot,
              long *info);
```

PURPOSE

csptf computes the factorization of a complex symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method:

$$A = U^*D^*U^{**T} \quad \text{or} \quad A = L^*D^*L^{**T}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L, stored as a packed triangular matrix overwriting A (see below for further details).

IPIVOT (output)

Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

5-96 - Based on modifications by J. Lewis, Boeing Computer Services Company

If UPLO = 'U', then $A = U^*D^*U'$, where

$U = P(n)*U(n)* \dots *P(k)U(k)* \dots$,
i.e., U is a product of terms $P(k)*U(k)$, where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

$$U(k) = \begin{pmatrix} I & v & 0 &) & k-s \\ 0 & I & 0 &) & s \\ 0 & 0 & I &) & n-k \\ k-s & s & n-k & & \end{pmatrix}$$

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k). If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then $A = L^*D^*L'$, where

$L = P(1)*L(1)* \dots *P(k)*L(k)* \dots$,
i.e., L is a product of terms $P(k)*L(k)$, where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

$$L(k) = \begin{pmatrix} I & 0 & 0 &) & k-1 \\ 0 & I & 0 &) & s \\ 0 & v & I &) & n-k-s+1 \\ k-1 & s & n-k-s+1 & & \end{pmatrix}$$

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

NAME

csptri - compute the inverse of a complex symmetric indefinite matrix A in packed storage using the factorization $A = U^*D^*U^*T$ or $A = L^*D^*L^*T$ computed by CSPTRF

SYNOPSIS

```
SUBROUTINE CSPTRI(UPLO, N, A, IPIVOT, WORK, INFO)
```

```
CHARACTER * 1 UPLO  
COMPLEX A(*), WORK(*)  
INTEGER N, INFO  
INTEGER IPIVOT(*)
```

```
SUBROUTINE CSPTRI_64(UPLO, N, A, IPIVOT, WORK, INFO)
```

```
CHARACTER * 1 UPLO  
COMPLEX A(*), WORK(*)  
INTEGER*8 N, INFO  
INTEGER*8 IPIVOT(*)
```

F95 INTERFACE

```
SUBROUTINE SPTRI(UPLO, [N], A, IPIVOT, [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:) :: A, WORK  
INTEGER :: N, INFO  
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE SPTRI_64(UPLO, [N], A, IPIVOT, [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:) :: A, WORK  
INTEGER(8) :: N, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csptri(char uplo, int n, complex *a, int *ipivot, int  
           *info);
```

```
void csptri_64(char uplo, long n, complex *a, long *ipivot,  
              long *info);
```

PURPOSE

csptri computes the inverse of a complex symmetric indefinite matrix A in packed storage using the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ computed by CSPTRF.

ARGUMENTS

UPLO (input)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is $A = U*D*U^{**T}$;
= 'L': Lower triangular, form is $A = L*D*L^{**T}$.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSPTRF, stored as a packed triangular matrix.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix, stored as a packed triangular matrix. The j-th column of $\text{inv}(A)$ is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = \text{inv}(A)(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = \text{inv}(A)(i,j)$ for $j \leq i \leq n$.

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by CSPTRF.

WORK (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, $D(i,i) = 0$; the matrix is singular and its inverse could not be computed.

```

F95 INTERFACE

```
SUBROUTINE SPTRS(UPLO, [N], [NRHS], A, IPIVOT, B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:) :: A  
COMPLEX, DIMENSION(:, :) :: B  
INTEGER :: N, NRHS, LDB, INFO  
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE SPTRS_64(UPLO, [N], [NRHS], A, IPIVOT, B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:) :: A  
COMPLEX, DIMENSION(:, :) :: B  
INTEGER(8) :: N, NRHS, LDB, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csptrs(char uplo, int n, int nrhs, complex *a, int  
            *ipivot, complex *b, int ldb, int *info);
```

```
void cspttrs_64(char uplo, long n, long nrhs, complex *a,
               long *ipivot, complex *b, long ldb, long *info);
```

PURPOSE

cspttrs solves a system of linear equations $A \cdot X = B$ with a complex symmetric matrix A stored in packed format using the factorization $A = U \cdot D \cdot U^{**T}$ or $A = L \cdot D \cdot L^{**T}$ computed by CSPTRF.

ARGUMENTS

UPLO (input)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is $A = U \cdot D \cdot U^{**T}$;
= 'L': Lower triangular, form is $A = L \cdot D \cdot L^{**T}$.

N (input) The order of the matrix A . $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSPTRF, stored as a packed triangular matrix.

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by CSPTRF.

B (input/output)

On entry, the right hand side matrix B . On exit, the solution matrix X .

LDB (input)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value

NAME

csrot - Apply a plane rotation.

SYNOPSIS

```
SUBROUTINE CSROT(N, X, INCX, Y, INCY, C, S)
```

```
REAL C, S  
COMPLEX X(*), Y(*)  
INTEGER N, INCX, INCY
```

```
SUBROUTINE CSROT_64(N, X, INCX, Y, INCY, C, S)
```

```
REAL C, S  
COMPLEX X(*), Y(*)  
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE ROT([N], X, [INCX], Y, [INCY], C, S)
```

```
REAL :: C, S  
COMPLEX, DIMENSION(:) :: X, Y  
INTEGER :: N, INCX, INCY
```

```
SUBROUTINE ROT_64([N], X, [INCX], Y, [INCY], C, S)
```

```
REAL :: C, S  
COMPLEX, DIMENSION(:) :: X, Y  
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csrot(int n, complex *x, int incx, complex *y, int  
          incy, float c, float s);
```

```
void csrot_64(long n, complex *x, long incx, complex *y,  
             long incy, float c, float s);
```

PURPOSE

csrot Apply a plane rotation, where the cos and sin (c and s) are real and the vectors x and y are complex.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input/output)

Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input/output)

On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

C (input)

On entry, the cosine. Unchanged on exit.

S (input)

On entry, the sin. Unchanged on exit.

SUBROUTINE SCAL([N], ALPHA, Y, [INCY])
```

```
COMPLEX, DIMENSION(:) :: Y
INTEGER :: N, INCY
REAL :: ALPHA
```

```
SUBROUTINE SCAL_64([N], ALPHA, Y, [INCY])
```

```
COMPLEX, DIMENSION(:) :: Y
INTEGER(8) :: N, INCY
REAL :: ALPHA
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csscal(int n, float alpha, complex *y, int incy);
```

```
void csscal_64(long n, float alpha, complex *y, long incy);
```

PURPOSE

csscal Compute $y := \alpha * y$ where α is a scalar and y is an n -vector.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

Y (input/output)

($1 + (n - 1) * \text{abs}(\text{INCY})$). On entry, the incremented array Y must contain the vector y . On exit, Y is overwritten by the updated vector y .

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

REAL, DIMENSION(:) :: D, E, RWORK
```

```
SUBROUTINE STEDC_64(COMPZ, [N], D, E, Z, [LDZ], [WORK], [LWORK],  
                   [RWORK], [LRWORK], [IWORK], [LIWORK], [INFO])
```

```
CHARACTER(LEN=1) :: COMPZ  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:,) :: Z
```

```
INTEGER(8) :: N, LDZ, LWORK, LRWORK, LIWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL, DIMENSION(:) :: D, E, RWORK
```

C INTERFACE

```
#include <sunperf.h>
void cstedc(char compz, int n, float *d, float *e, complex
            *z, int ldz, int *info);

void cstedc_64(char compz, long n, float *d, float *e, complex
              *z, long ldz, long *info);
```

PURPOSE

cstedc computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method. The eigenvectors of a full or band complex Hermitian matrix can also be found if CHETRD or CHPTRD or CHBTRD has been used to reduce this matrix to tridiagonal form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See SLAED3 for details.

ARGUMENTS

COMPZ (input)

= 'N': Compute eigenvalues only.
= 'I': Compute eigenvectors of tridiagonal matrix also.
= 'V': Compute eigenvectors of original Hermitian matrix also. On entry, Z contains the unitary matrix used to reduce the original matrix to tridiagonal form.

N (input) The dimension of the symmetric tridiagonal matrix.
N >= 0.

D (input/output)

On entry, the diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E (input/output)

On entry, the subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z (input) On entry, if COMPZ = 'V', then Z contains the unitary matrix used in the reduction to tridiagonal form. On exit, if INFO = 0, then if COMPZ = 'V', Z contains the orthonormal eigenvectors of the original Hermitian matrix, and if COMPZ = 'I', Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If COMPZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ \geq 1.
If eigenvectors are desired, then LDZ \geq max(1,N).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal
LWORK.

LWORK (input)

The dimension of the array WORK. If COMPZ = 'N'
or 'I', or $N \leq 1$, LWORK must be at least 1. If
COMPZ = 'V' and $N > 1$, LWORK must be at least $N*N$.

If LWORK = -1, then a workspace query is assumed;
the routine only calculates the optimal size of
the WORK array, returns this value as the first
entry of the WORK array, and no error message
related to LWORK is issued by XERBLA.

RWORK (workspace)

dimension (LRWORK) On exit, if INFO = 0, RWORK(1)
returns the optimal LRWORK.

LRWORK (input)

The dimension of the array RWORK. If COMPZ = 'N'
or $N \leq 1$, LRWORK must be at least 1. If COMPZ =
'V' and $N > 1$, LRWORK must be at least $1 + 3*N +$
 $2*N*\lg N + 3*N**2$, where $\lg(N)$ = smallest
integer k such that $2**k \geq N$. If COMPZ = 'I' and
 $N > 1$, LRWORK must be at least $1 + 4*N + 2*N**2$.

If LRWORK = -1, then a workspace query is assumed;
the routine only calculates the optimal size of
the RWORK array, returns this value as the first
entry of the RWORK array, and no error message
related to LRWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO = 0, IWORK(1) returns the optimal
LIWORK.

LIWORK (input)

The dimension of the array IWORK. If COMPZ = 'N'
or $N \leq 1$, LIWORK must be at least 1. If COMPZ =
'V' or $N > 1$, LIWORK must be at least $6 + 6*N +$
 $5*N*\lg N$. If COMPZ = 'I' or $N > 1$, LIWORK must
be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed;
the routine only calculates the optimal size of
the IWORK array, returns this value as the first
entry of the IWORK array, and no error message
related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: The algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

              ldz, long *isuppz, long *info);
```

PURPOSE

cstegr b) Compute the eigenvalues, λ_j , of $L_i D_i L_i^T$ to high relative accuracy by the dqds algorithm,
(c) If there is a cluster of close eigenvalues, "choose" σ_i close to the cluster, and go to step (a),
(d) Given the approximate eigenvalue λ_j of $L_i D_i L_i^T$, compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new $O(n^2)$ algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB/CSD-97-971, UC Berkeley, May 1997.

Note 1 : Currently CSTEGR is only set up to find ALL the n eigenvalues and eigenvectors of T in $O(n^2)$ time

Note 2 : Currently the routine CSTEIN is called when an appropriate σ_i cannot be chosen in step (c) above. CSTEIN invokes modified Gram-Schmidt when eigenvalues are close.

Note 3 : CSTEGR works only on machines which follow ieee-754 floating-point standard in their handling of infinities and NaNs. Normal execution of CSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not conform to the ieee standard.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
= 'A': all eigenvalues will be found.
= 'V': all eigenvalues in the half-open interval $(VL, VU]$ will be found. = 'I': the IL -th through IU -th eigenvalues will be found.

N (input) The order of the matrix. $N \geq 0$.

D (input/output)
On entry, the n diagonal elements of the tridiagonal matrix T . On exit, D is overwritten.

E (input/output)
On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix T in elements 1 to $N-1$ of E ; $E(N)$ need not be set. On exit, E is overwritten.

VL (input)
If $RANGE='V'$, the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if $RANGE = 'A'$ or $'I'$.

VU (input)
If $RANGE='V'$, the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if $RANGE = 'A'$ or $'I'$.

IL (input)
If $RANGE='I'$, the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if $RANGE = 'A'$ or $'V'$.

IU (input)
If $RANGE='I'$, the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if $RANGE = 'A'$ or $'V'$.

ABSTOL (input)
The absolute error tolerance for the eigenvalues/eigenvectors. If $JOBZ = 'V'$, the eigenvalues and eigenvectors output have residual norms bounded by $ABSTOL$, and the dot products between different eigenvectors are bounded by $ABSTOL$. If $ABSTOL$ is less than $N*EPS*|T|$, then $N*EPS*|T|$ will be used in its place, where EPS is the machine precision and $|T|$ is the 1-norm of the tridiagonal matrix. The eigenvalues are computed to an accuracy of $EPS*|T|$ irrespective of $ABSTOL$. If high relative accuracy is important, set $ABSTOL$ to $DLAMCH('Safe minimum')$. See Barlow and Demmel "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7 for a discussion of which matrices define their eigenvalues to high relative accuracy.

M (output)
The total number of eigenvalues found. $0 \leq M \leq N$. If $RANGE = 'A'$, $M = N$, and if $RANGE = 'I'$, $M = IU-IL+1$.

W (output)
The first M elements contain the selected eigenvalues in ascending order.

Z (input/output)
If $JOBZ = 'V'$, then if $INFO = 0$, the first M

columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1,M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

ISUPPZ (output)

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

LWORK (input)

The dimension of the array WORK. LWORK >= max(1,18*N)

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of the array IWORK. LIWORK >= max(1,10*N)

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = 1, internal error in SLARRE, if INFO = 2, internal error in CLARRV.

INTEGER(8) :: N, M, LDZ, INFO
INTEGER(8), DIMENSION(:) :: IBLOCK, ISPLIT, IWORK, IFAIL
REAL, DIMENSION(:) :: D, E, W, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cstein(int n, float *d, float *e, int m, float *w, int
```

```

        *iblock, int *isplit, complex *z, int ldz, int
        *ifail, int *info);
void cstein_64(long n, float *d, float *e, long m, float *w,
long *iblock, long *isplit, complex *z, long ldz,
long *ifail, long *info);

```

PURPOSE

cstein computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter MAXITS (currently set to 5).

Although the eigenvectors are real, they are stored in a complex array, which may be passed to CUNMTR or CUPMTR for back transformation to the eigenvectors of a complex Hermitian matrix which was reduced to tridiagonal form.

ARGUMENTS

- N (input) The order of the matrix. $N \geq 0$.
- D (input) The n diagonal elements of the tridiagonal matrix T.
- E (input) The (n-1) subdiagonal elements of the tridiagonal matrix T, stored in elements 1 to N-1; E(N) need not be set.
- M (input) The number of eigenvectors to be found. $0 \leq M \leq N$.
- W (input) The first M elements of W contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array W from SSTEBSZ with ORDER = 'B' is expected here.)
- IBLOCK (input)
The submatrix indices associated with the corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue W(i) belongs to the first submatrix from the top, =2 if W(i) belongs to the second submatrix, etc. (The output array IBLOCK from SSTEBSZ is expected here.)
- ISPLIT (input)
The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc. (The output array ISPLIT from SSTEBSZ is expected here.)
- Z (output)

The computed eigenvectors. The eigenvector associated with the eigenvalue $W(i)$ is stored in the i -th column of Z . Any vector which fails to converge is set to its current iterate after MAXITS iterations. The imaginary parts of the eigenvectors are set to zero.

LDZ (input)

The leading dimension of the array Z . LDZ \geq max(1,N).

WORK (workspace)

dimension(5*N)

IWORK (workspace)

dimension(N)

IFAIL (output)

On normal exit, all elements of IFAIL are zero. If one or more eigenvectors fail to converge after MAXITS iterations, then their indices are stored in array IFAIL.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i -th argument had an illegal value
> 0: if INFO = i, then i eigenvectors failed to converge in MAXITS iterations. Their indices are stored in array IFAIL.

NAME

csteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method

SYNOPSIS

```
SUBROUTINE CSTEQR(COMPZ, N, D, E, Z, LDZ, WORK, INFO)
```

```
CHARACTER * 1 COMPZ  
COMPLEX Z(LDZ,*)  
INTEGER N, LDZ, INFO  
REAL D(*), E(*), WORK(*)
```

```
SUBROUTINE CSTEQR_64(COMPZ, N, D, E, Z, LDZ, WORK, INFO)
```

```
CHARACTER * 1 COMPZ  
COMPLEX Z(LDZ,*)  
INTEGER*8 N, LDZ, INFO  
REAL D(*), E(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE STEQR(COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: COMPZ  
COMPLEX, DIMENSION(:,) :: Z  
INTEGER :: N, LDZ, INFO  
REAL, DIMENSION(:) :: D, E, WORK
```

```
SUBROUTINE STEQR_64(COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: COMPZ  
COMPLEX, DIMENSION(:,) :: Z  
INTEGER(8) :: N, LDZ, INFO  
REAL, DIMENSION(:) :: D, E, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csteqr(char compz, int n, float *d, float *e, complex  
           *z, int ldz, int *info);
```

```
void csteqr_64(char compz, long n, float *d, float *e, com-  
              plex *z, long ldz, long *info);
```

PURPOSE

csteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. The eigenvectors of a full or band complex Hermitian matrix can also be found if CHETRD or CHPTRD or CHBTRD has been used to reduce this matrix to tridiagonal form.

ARGUMENTS

COMPZ (input)

= 'N': Compute eigenvalues only.
= 'V': Compute eigenvalues and eigenvectors of the original Hermitian matrix. On entry, Z must contain the unitary matrix used to reduce the original matrix to tridiagonal form. = 'I': Compute eigenvalues and eigenvectors of the tridiagonal matrix. Z is initialized to the identity matrix.

N (input) The order of the matrix. $N \geq 0$.

D (input/output)

On entry, the diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E (input/output)

On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z (input) On entry, if COMPZ = 'V', then Z contains the unitary matrix used in the reduction to tridiagonal form. On exit, if INFO = 0, then if COMPZ = 'V', Z contains the orthonormal eigenvectors of the original Hermitian matrix, and if COMPZ = 'I', Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If COMPZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. $LDZ \geq 1$, and if eigenvectors are desired, then $LDZ \geq \max(1, N)$.

WORK (workspace)

dimension($\max(1, 2*N-2)$) If COMPZ = 'N', then WORK is not referenced.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: the algorithm has failed to find all the eigenvalues in a total of $30*N$ iterations; if INFO = i, then i elements of E have not converged to zero; on exit, D and E contain the elements of a symmetric tridiagonal matrix which is unitarily

similar to the original matrix.

COMPLEX, DIMENSION(:, :) :: B  
INTEGER(8) :: N, NRHS, LDB, INFO  
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cstsv(int n, int nrhs, complex *l, complex *d, complex  
          *subl, complex *b, int ldb, int *ipiv, int *info);
```

```
void cstsv_64(long n, long nrhs, complex *l, complex *d,  
             complex *subl, complex *b, long ldb, long *ipiv,  
             long *info);
```

PURPOSE

cstsv computes the solution to a complex system of linear equations $A * X = B$ where A is a Hermitian tridiagonal matrix.

ARGUMENTS

N (input)
The order of the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides in B.

L (input/output)
COMPLEX array, dimension (N)
On entry, the n-1 subdiagonal elements of the tridiagonal matrix A. On exit, part of the factorization of A.

D (input/output)
REAL array, dimension (N)
On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the factorization of A.

SUBL (output)
COMPLEX array, dimension (N)
On exit, part of the factorization of A.

B (input/output)
The columns of B contain the right hand sides.

LDB (input)
The leading dimension of B as specified in a type or DIMENSION statement.

IPIV (output)
INTEGER array, dimension (N)
On exit, the pivot indices of the factorization.

INFO (output)
INTEGER
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular and division by zero will occur if it is used to solve a system of equations.

```

```
void csstrf_64(long n, complex *l, complex *d, complex  
              *subl, long *ipiv, long *info);
```

PURPOSE

csttrf computes the $L^*D^*L^{**}H$ factorization of a complex Hermitian tridiagonal matrix A.

ARGUMENTS

N (input) INTEGER
The order of the matrix A. $N \geq 0$.

L (input/output)
COMPLEX array, dimension (N)
On entry, the n-1 subdiagonal elements of the tridiagonal matrix A. On exit, part of the factorization of A.

D (input/output)
REAL array, dimension (N)
On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the factorization of A.

SUBL (output)
COMPLEX array, dimension (N)
On exit, part of the factorization of A.

IPIV (output)
INTEGER array, dimension (N)
On exit, the pivot indices of the factorization.

INFO (output)
INTEGER
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular and division by zero will occur if it is used to solve a system of equations.

#include <sunperf.h>
```

```
void csttrs(int n, int nrhs, complex *l, complex *d, complex  
           *subl, complex *b, int ldb, int *ipiv, int *info);
```

```
void csttrs_64(long n, long nrhs, complex *l, complex *d,  
              complex *subl, complex *b, long ldb, long *ipiv,  
              long *info);
```

PURPOSE

csttrs computes the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N symmetric tridiagonal matrix and X and B are N-by-NRHS matrices.

ARGUMENTS

N (input) INTEGER
The order of the matrix A. $N \geq 0$.

NRHS (input) INTEGER
The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

L (input) COMPLEX array, dimension (N-1)
On entry, the subdiagonal elements of LL and DD.

D (input) COMPLEX array, dimension (N)
On entry, the diagonal elements of DD.

SUBL (input) COMPLEX array, dimension (N-2)
On entry, the second subdiagonal elements of LL.

B (input/output) COMPLEX array, dimension (LDB, NRHS)
On entry, the N-by-NRHS right hand side matrix B.
On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

LDB (input) INTEGER
The leading dimension of the array B. $LDB \geq \max(1, N)$

IPIV (output) INTEGER array, dimension (N)
Details of the interchanges and block pivot. If $IPIV(K) > 0$, 1 by 1 pivot, and if $IPIV(K) = K + 1$ an interchange done; If $IPIV(K) < 0$, 2 by 2 pivot, no interchange required.

INFO (output) INTEGER
= 0: successful exit
< 0: if $INFO = -k$, the k-th argument had an illegal value

```
void cswap(int n, complex *x, int incx, complex *y, int  
incy);
```

```
void cswap_64(long n, complex *x, long incx, complex *y,  
long incy);
```

PURPOSE

cswap Exchange x and y where x and y are n-vectors.

ARGUMENTS

- N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.
- X (input/output)
 $(1 + (n - 1) * \text{abs}(\text{INCX}))$. On entry, the incremented array X must contain the vector x. On exit, the y vector.
- INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.
- Y (input/output)
 $(1 + (n - 1) * \text{abs}(\text{INCY}))$. On entry, the incremented array Y must contain the vector y. On exit, the x vector.
- INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: N, LDA, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT  
REAL :: ANORM, RCOND
```

C INTERFACE

```
#include <sunperf.h>
void csycon(char uplo, int n, complex *a, int lda, int
            *ipivot, float anorm, float *rcond, int *info);

void csycon_64(char uplo, long n, complex *a, long lda, long
              *ipivot, float anorm, float *rcond, long *info);
```

PURPOSE

csycon estimates the reciprocal of the condition number (in the 1-norm) of a complex symmetric matrix A using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by CSYTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is $A = U*D*U**T$;
= 'L': Lower triangular, form is $A = L*D*L**T$.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by CSYTRF.

ANORM (input)

The 1-norm of the original matrix A.

RCOND (output)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

WORK (workspace)

dimension(2*N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

C INTERFACE

```
#include <sunperf.h>
```

```
void csymm(char side, char uplo, int m, int n, complex
           *alpha, complex *a, int lda, complex *b, int ldb,
```

```

        complex *beta, complex *c, int ldc);

void csymm_64(char side, char uplo, long m, long n, complex
*alpha, complex *a, long lda, complex *b, long
ldb, complex *beta, complex *c, long ldc);

```

PURPOSE

csymm performs one of the matrix-matrix operations $C := \alpha * A * B + \beta * C$ or $C := \alpha * B * A + \beta * C$ where α and β are scalars, A is a symmetric matrix and B and C are m by n matrices.

ARGUMENTS

SIDE (input)

On entry, SIDE specifies whether the symmetric matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l' $C := \alpha * A * B + \beta * C$,

SIDE = 'R' or 'r' $C := \alpha * B * A + \beta * C$,

Unchanged on exit.

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of the symmetric matrix is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of the symmetric matrix is to be referenced.

Unchanged on exit.

M (input)

On entry, M specifies the number of rows of the matrix C . $M \geq 0$. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix C . $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

A (input)

COMPLEX array of DIMENSION (LDA, ka), where ka is m when SIDE = 'L' or 'l' and is n otherwise.

Before entry with SIDE = 'L' or 'l', the m by m part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading m by m upper triangular part of the array A must contain the upper triangular part

of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading m by m lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

Before entry with SIDE = 'R' or 'r', the n by n part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then $LDA \geq \max(1, m)$, otherwise $LDA \geq \max(1, n)$. Unchanged on exit.

B (input)

COMPLEX array of DIMENSION (LDB, n). Before entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. $LDB \geq \max(1, m)$. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

C (input/output)

COMPLEX array of DIMENSION (LDC, n). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. $LDC \geq \max(1, m)$. Unchanged on exit.

```

C INTERFACE

```
#include <sunperf.h>
```

```
void csyr2k(char uplo, char transa, int n, int k, complex
```

```

        *alpha, complex *a, int lda, complex *b, int ldb,
        complex *beta, complex *c, int ldc);
void csyr2k_64(char uplo, char transa, long n, long k, com-
        plex *alpha, complex *a, long lda, complex *b,
        long ldb, complex *beta, complex *c, long ldc);

```

PURPOSE

csyr2k performs one of the symmetric rank 2k operations $C := \alpha A^*B' + \alpha B^*A' + \beta C$ or $C := \alpha A^*B + \alpha B^*A + \beta C$ where α and β are scalars, C is an n by n symmetric matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $C := \alpha A^*B' + \alpha B^*A' + \beta C$.

TRANSA = 'T' or 't' $C := \alpha A^*B + \alpha B^*A + \beta C$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)

On entry, N specifies the order of the matrix C . N must be at least zero. Unchanged on exit.

K (input)

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrices A and B , and on entry with TRANSA = 'T' or 't', K specifies the number of rows of the matrices A and B . K must be at least zero. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

A (input)

COMPLEX array of DIMENSION (LDA, ka),
where ka is k when TRANSA = 'N' or 'n', and is
n otherwise. Before entry with TRANSA = 'N' or
'n', the leading n by k part of the array A
must contain the matrix A, otherwise the leading
k by n part of the array A must contain the
matrix A. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A
as declared in the calling (sub) program.
When TRANSA = 'N' or 'n' then LDA must be at
least $\max(1, n)$, otherwise LDA must be at
least $\max(1, k)$. Unchanged on exit.

B (input)

COMPLEX array of DIMENSION (LDB, kb),
where kb is k when TRANSA = 'N' or 'n', and is
n otherwise. Before entry with TRANSA = 'N' or
'n', the leading n by k part of the array B
must contain the matrix B, otherwise the leading
k by n part of the array B must contain the
matrix B. Unchanged on exit.

LDB (input)

On entry, LDB specifies the first dimension of B
as declared in the calling (sub) program.
When TRANSA = 'N' or 'n' then LDB must be at
least $\max(1, n)$, otherwise LDB must be at
least $\max(1, k)$. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta.
Unchanged on exit.

C (input/output)

COMPLEX array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the lead-
ing n by n upper triangular part of the array C
must contain the upper triangular part of the
symmetric matrix and the strictly lower triangu-
lar part of C is not referenced. On exit, the
upper triangular part of the array C is overwrit-
ten by the upper triangular part of the updated
matrix.

Before entry with UPLO = 'L' or 'l', the lead-
ing n by n lower triangular part of the array C
must contain the lower triangular part of the
symmetric matrix and the strictly upper triangu-
lar part of C is not referenced. On exit, the
lower triangular part of the array C is overwrit-
ten by the lower triangular part of the updated
matrix.

LDC (input)

On entry, LDC specifies the first dimension of C
as declared in the calling (sub) program.
LDC must be at least $\max(1, n)$. Unchanged
on exit.

               *ferr, float *berr, long *info);

```

PURPOSE

csyrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1, N)$.

AF (input)
 The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^T$ or $A = L*D*L^T$ as computed by CSYTRF.

LDAF (input)
 The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

IPIVOT (input)
 Details of the interchanges and the block struc-

ture of D as determined by CSYTRF.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB \geq
max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by
CSYTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX \geq
max(1,N).

FERR (output)
The estimated forward error bound for each solu-
tion vector X(j) (the j-th column of the solution
matrix X). If XTRUE is the true solution
corresponding to X(j), FERR(j) is an estimated
upper bound for the magnitude of the largest ele-
ment in (X(j) - XTRUE) divided by the magnitude of
the largest element in X(j). The estimate is as
reliable as the estimate for RCOND, and is almost
always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each
solution vector X(j) (i.e., the smallest relative
change in any element of A or B that makes X(j) an
exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-
gal value

                  C, [LDC])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA  
COMPLEX :: ALPHA, BETA  
COMPLEX, DIMENSION(:, :) :: A, C  
INTEGER(8) :: N, K, LDA, LDC
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csyrk(char uplo, char transa, int n, int k, complex  
          *alpha, complex *a, int lda, complex *beta, com-  
          plex *c, int ldc);
```

```
void csyrk_64(char uplo, char transa, long n, long k, complex *alpha, complex *a, long lda, complex *beta, complex *c, long ldc);
```

PURPOSE

csyrk performs one of the symmetric rank k operations $C := \alpha A A^T + \beta C$ or $C := \alpha A^T A + \beta C$ where α and β are scalars, C is an n by n symmetric matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $C := \alpha A A^T + \beta C$.

TRANSA = 'T' or 't' $C := \alpha A^T A + \beta C$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K (input)

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANSA = 'T' or 't', K specifies the number of rows of the matrix A. K must be at least zero. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

COMPLEX array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading

k by n part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDA must be at least $\max(1, n)$, otherwise LDA must be at least $\max(1, k)$. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. Unchanged on exit.

C (input/output)

COMPLEX array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, n)$. Unchanged on exit.

C INTERFACE

```
#include <sunperf.h>
```

```

void csysv(char uplo, int n, int nrhs, complex *a, int lda,
           int *ipiv, complex *b, int ldb, int *info);
void csysv_64(char uplo, long n, long nrhs, complex *a, long
              lda, long *ipiv, complex *b, long ldb, long
              *info);

```

PURPOSE

csysv computes the solution to a complex system of linear equations

$A * X = B$, where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$A = U * D * U^{**T}$, if UPLO = 'U', or

$A = L * D * L^{**T}$, if UPLO = 'L',

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input/output)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U * D * U^{**T}$ or $A = L * D * L^{**T}$ as computed by CSYTRF.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIV (output)

Details of the interchanges and the block structure of D, as determined by CSYTRF. If $IPIV(k) > 0$, then rows and columns k and $IPIV(k)$ were interchanged, and $D(k, k)$ is a 1-by-1 diagonal block. If UPLO = 'U' and $IPIV(k) = IPIV(k-1) < 0$, then rows and columns k-1 and $-IPIV(k)$ were inter-

changed and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIV(k) = IPIV(k+1) < 0$, then rows and columns $k+1$ and $-IPIV(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B.
On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

LWORK (input)

The length of WORK. $LWORK \geq 1$, and for best performance $LWORK \geq N * NB$, where NB is the optimal blocksize for CSYTRF.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value
> 0: if $INFO = i$, $D(i, i)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

C INTERFACE

```

#include <sunperf.h>

void csysvx(char fact, char uplo, int n, int nrhs, complex
 *a, int lda, complex *af, int ldaf, int *ipivot,
 complex *b, int ldb, complex *x, int ldx, float
 *rcond, float *ferr, float *berr, int *info);

void csysvx_64(char fact, char uplo, long n, long nrhs, com-
plex *a, long lda, complex *af, long ldaf, long
 *ipivot, complex *b, long ldb, complex *x, long
 ldx, float *rcond, float *ferr, float *berr, long
 *info);

```

PURPOSE

csysvx uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N symmetric matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the diagonal pivoting method is used to factor A .

The form of the factorization is

$A = U * D * U^{*T}$, if $UPLO = 'U'$, or

$A = L * D * L^{*T}$, if $UPLO = 'L'$,

where U (or L) is a product of permutation and unit upper (lower)

triangular matrices, and D is symmetric and block diagonal with

1-by-1 and 2-by-2 diagonal blocks.

2. If some $D(i,i)=0$, so that D is exactly singular, then the routine

returns with $INFO = i$. Otherwise, the factored form of A is used

to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision,

$INFO = N+1$ is returned as a warning, but the routine still goes on

to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form of A .

4. Iterative refinement is applied to improve the computed solution

matrix and calculate error bounds and backward error estimates for it.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AF and IPIVOT contain the factored form of A. A, AF and IPIVOT will not be modified. = 'N': The matrix A will be copied to AF and factored.

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

AF (input/output)

If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^T$ or $A = L*D*L^T$ as computed by CSYTRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^T$ or $A = L*D*L^T$.

LDAF (input)

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

IPIVOT (input or output)

If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CSYTRF. If $IPIVOT(k) > 0$, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns

$k-1$ and $-IPIVOT(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns $k+1$ and $-IPIVOT(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

If $FACT = 'N'$, then $IPIVOT$ is an output argument and on exit contains details of the interchanges and the block structure of D , as determined by $CSYTRF$.

B (input) The N -by- $NRHS$ right hand side matrix B .

LDB (input)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

X (output)

If $INFO = 0$ or $INFO = N+1$, the N -by- $NRHS$ solution matrix X .

LDX (input)

The leading dimension of the array X . $LDX \geq \max(1, N)$.

RCOND (output)

The estimate of the reciprocal condition number of the matrix A . If $RCOND$ is less than the machine precision (in particular, if $RCOND = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $INFO > 0$.

FERR (output)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If $XTRUE$ is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$.

LDWORK (input)

The length of $WORK$. $LDWORK \geq 2*N$, and for best performance $LDWORK \geq N*NB$, where NB is the optimal blocksize for $CSYTRF$.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LDWORK$ is issued by $XERBLA$.

WORK2 (workspace)
dimension(N)
INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

```

C INTERFACE

```
#include <sunperf.h>
```

```
void csytf2(char uplo, int n, complex *a, int lda, int  
           *ipiv, int *info);
```

```
void csytf2_64(char uplo, long n, complex *a, long lda, long
```

```
*ipiv, long *info);
```

PURPOSE

csytf2 computes the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method:

$A = U^*D^*U'$ or $A = L^*D^*L'$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U' is the transpose of U, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:

= 'U': Upper triangular

= 'L': Lower triangular

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIV (output)

Details of the interchanges and the block structure of D. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k, k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1, k:k+1) is a 2-by-2 diagonal block.

INFO (output)

= 0: successful exit

< 0: if INFO = -k, the k-th argument had an illegal value

> 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

1-96 - Based on modifications by J. Lewis, Boeing Computer Services Company

If UPLO = 'U', then $A = U^*D^*U'$, where

$U = P(n)^*U(n)^* \dots *P(k)^*U(k)^* \dots$,
 i.e., U is a product of terms $P(k)^*U(k)$, where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIV(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

$$U(k) = \begin{pmatrix} I & v & 0 &) & k-s \\ 0 & I & 0 &) & s \\ 0 & 0 & I &) & n-k \\ k-s & s & n-k & & \end{pmatrix}$$

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k). If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then $A = L^*D^*L'$, where

$L = P(1)^*L(1)^* \dots *P(k)^*L(k)^* \dots$,
 i.e., L is a product of terms $P(k)^*L(k)$, where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIV(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

$$L(k) = \begin{pmatrix} I & 0 & 0 &) & k-1 \\ 0 & I & 0 &) & s \\ 0 & v & I &) & n-k-s+1 \\ k-1 & s & n-k-s+1 & & \end{pmatrix}$$

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csytrf(char uplo, int n, complex *a, int lda, int
```

```

        *ipivot, int *info);

void csytrf_64(char uplo, long n, complex *a, long lda, long
        *ipivot, long *info);

```

PURPOSE

csytrf computes the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

$$A = U^*D^*U^{**T} \quad \text{or} \quad A = L^*D^*L^{**T}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (output)

Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k, k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1, k:k+1) is a 2-by-2 diagonal block.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The length of WORK. LDWORK >= 1. For best performance LDWORK >= N*NB, where NB is the block size returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

If UPLO = 'U', then $A = U^*D^*U'$, where

$U = P(n)^*U(n)^* \dots *P(k)^*U(k)^* \dots$,
i.e., U is a product of terms $P(k)^*U(k)$, where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

$$U(k) = \begin{pmatrix} I & v & 0 &) & k-s \\ 0 & I & 0 &) & s \\ 0 & 0 & I &) & n-k \\ k-s & s & n-k & & \end{pmatrix}$$

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k). If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then $A = L^*D^*L'$, where

$L = P(1)^*L(1)^* \dots *P(k)^*L(k)^* \dots$,
i.e., L is a product of terms $P(k)^*L(k)$, where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

$$L(k) = \begin{pmatrix} I & 0 & 0 &) & k-1 \\ 0 & I & 0 &) & s \\ 0 & v & I &) & n-k-s+1 \\ k-1 & s & n-k-s+1 & & \end{pmatrix}$$

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

```

C INTERFACE

```
#include <sunperf.h>
```

```
void csytri(char uplo, int n, complex *a, int lda, int  
            *ipivot, int *info);
```

```
void csytri_64(char uplo, long n, complex *a, long lda, long
               *ipivot, long *info);
```

PURPOSE

csytri computes the inverse of a complex symmetric indefinite matrix A using the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ computed by CSYTRF.

ARGUMENTS

UPLO (input)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is $A = U*D*U^{**T}$;
= 'L': Lower triangular, form is $A = L*D*L^{**T}$.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by CSYTRF.

WORK (workspace)

dimension(2*N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, $D(i,i) = 0$; the matrix is singular and its inverse could not be computed.

```

PURPOSE

csytrs solves a system of linear equations $A \cdot X = B$ with a complex symmetric matrix A using the factorization $A = U \cdot D \cdot U^{**T}$ or $A = L \cdot D \cdot L^{**T}$ computed by CSYTRF.

ARGUMENTS

UPLO (input)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is $A = U \cdot D \cdot U^{**T}$;
= 'L': Lower triangular, form is $A = L \cdot D \cdot L^{**T}$.

N (input) The order of the matrix A . $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

LDA (input)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by CSYTRF.

B (input/output)

On entry, the right hand side matrix B . On exit, the solution matrix X .

LDB (input)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value

REAL, DIMENSION(:) :: WORK2
```

```
SUBROUTINE TBCON_64(NORM, UPLO, DIAG, [N], NDIAG, A, [LDA], RCOND,  
[WORK], [WORK2], [INFO])
```

```
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: N, NDIAG, LDA, INFO  
REAL :: RCOND
```

```
REAL, DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
void ctbcon(char norm, char uplo, char diag, int n, int
            ndiag, complex *a, int lda, float *rcond, int
            *info);

void ctbcon_64(char norm, char uplo, char diag, long n, long
              ndiag, complex *a, long lda, float *rcond, long
              *info);
```

PURPOSE

ctbcon estimates the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

NORM (input)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I': Infinity-norm.

UPLO (input)

= 'U': A is upper triangular;
= 'L': A is lower triangular.

DIAG (input)

= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

NDIAG (input)

The number of superdiagonals or subdiagonals of the triangular band matrix A. $NDIAG \geq 0$.

A (input) The upper or lower triangular band matrix A, stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

LDA (input)

The leading dimension of the array A. $LDA \geq NDIAG+1$.

RCOND (output)

The reciprocal of the condition number of the

matrix A, computed as $RCOND = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

ctbmv - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$

SYNOPSIS

```
SUBROUTINE CTBMV(UPLO, TRANSA, DIAG, N, NDIAG, A, LDA, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
COMPLEX A(LDA,*), Y(*)  
INTEGER N, NDIAG, LDA, INCY
```

```
SUBROUTINE CTBMV_64(UPLO, TRANSA, DIAG, N, NDIAG, A, LDA, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
COMPLEX A(LDA,*), Y(*)  
INTEGER*8 N, NDIAG, LDA, INCY
```

F95 INTERFACE

```
SUBROUTINE TBMV(UPLO, [TRANSA], DIAG, [N], NDIAG, A, [LDA], Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX, DIMENSION(:) :: Y  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER :: N, NDIAG, LDA, INCY
```

```
SUBROUTINE TBMV_64(UPLO, [TRANSA], DIAG, [N], NDIAG, A, [LDA], Y,  
[INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX, DIMENSION(:) :: Y  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: N, NDIAG, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctbmv(char uplo, char transa, char diag, int n, int  
ndiag, complex *a, int lda, complex *y, int incy);
```

```
void ctbmv_64(char uplo, char transa, char diag, long n,  
long ndiag, complex *a, long lda, complex *y, long  
incy);
```

PURPOSE

ctbmv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$ where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with $(\text{ndiag} + 1)$ diagonals.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $x := A*x$.

TRANSA = 'T' or 't' $x := A'*x$.

TRANSA = 'C' or 'c' $x := \text{conjg}(A')*x$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

NDIAG (input)

On entry with UPLO = 'U' or 'u', NDIAG specifies the number of super-diagonals of the matrix A . On entry with UPLO = 'L' or 'l', NDIAG specifies the number of sub-diagonals of the matrix A . $NDIAG \geq 0$. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading $(\text{ndiag} + 1)$ by n part of the array A must contain

the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (ndiag + 1) of the array, the first super-diagonal starting at position 2 in row ndiag, and so on. The top left ndiag by ndiag triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```

      DO 20, J = 1, N
        M = NDIAG + 1 - J
        DO 10, I = MAX( 1, J - NDIAG ), J
          A( M + I, J ) = matrix( I, J )
10      CONTINUE
20      CONTINUE

```

Before entry with UPLO = 'L' or 'l', the leading (ndiag + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right ndiag by ndiag triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```

      DO 20, J = 1, N
        M = 1 - J
        DO 10, I = J, MIN( N, J + NDIAG )
          A( M + I, J ) = matrix( I, J )
10      CONTINUE
20      CONTINUE

```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= (ndiag + 1). Unchanged on exit.

Y (input/output)

(1 + (n - 1) * abs(INCY)). Before entry, the incremented array Y must contain the n element vector x. On exit, Y is overwritten with the transformed vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

              plex *b, long ldb, complex *x, long ldx, float
              *ferr, float *berr, long *info);
```

PURPOSE

ctbrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix.

The solution matrix X must be computed by CTBTRS or some other means before entering this routine. CTBRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

UPLO (input)

= 'U': A is upper triangular;
 = 'L': A is lower triangular.

TRANSA (input)

Specifies the form of the system of equations:
 = 'N': $A * X = B$ (No transpose)
 = 'T': $A^{**T} * X = B$ (Transpose)
 = 'C': $A^{**H} * X = B$ (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

= 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

NDIAG (input)

The number of superdiagonals or subdiagonals of the triangular band matrix A. $NDIAG \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The upper or lower triangular band matrix A, stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

LDA (input)

The leading dimension of the array A. $LDA \geq$

NDIAG+1.

B (input) The right hand side matrix B.

LDB (input)

The leading dimension of the array B. LDB \geq
max(1,N).

X (input) The solution matrix X.

LDX (input)

The leading dimension of the array X. LDX \geq
max(1,N).

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

dimension(2*N)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

[INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX, DIMENSION(:) :: Y  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: N, NDIAG, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctbsv(char uplo, char transa, char diag, int n, int  
ndiag, complex *a, int lda, complex *y, int incy);
```

```
void ctbsv_64(char uplo, char transa, char diag, long n,  
long ndiag, complex *a, long lda, complex *y, long  
incy);
```

PURPOSE

ctbsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, or $\text{conjg}(A)*x = b$ where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with $(\text{ndiag} + 1)$ diagonals.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n' $A*x = b$.

TRANSA = 'T' or 't' $A'*x = b$.

TRANSA = 'C' or 'c' $\text{conjg}(A)*x = b$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

NDIAG (input)

On entry with UPLO = 'U' or 'u', NDIAG specifies the number of super-diagonals of the matrix A . On entry with UPLO = 'L' or 'l', NDIAG specifies the number of sub-diagonals of the matrix A . NDIAG \geq

0. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading (ndiag + 1) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (ndiag + 1) of the array, the first super-diagonal starting at position 2 in row ndiag, and so on. The top left ndiag by ndiag triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
DO 20, J = 1, N
  M = NDIAG + 1 - J
  DO 10, I = MAX( 1, J - NDIAG ), J
    A( M + I, J ) = matrix( I, J )
10 CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (ndiag + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right ndiag by ndiag triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```
DO 20, J = 1, N
  M = 1 - J
  DO 10, I = J, MIN( N, J + NDIAG )
    A( M + I, J ) = matrix( I, J )
10 CONTINUE
20 CONTINUE
```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= (ndiag + 1). Unchanged on exit.

Y (input/output)

(1 + (n - 1) * abs(INCY)). Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

```

```
plex *b, long ldb, long *info);
```

PURPOSE

ctbtrs solves a triangular system of the form

where A is a triangular band matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is non-singular.

ARGUMENTS

UPLO (input)

= 'U': A is upper triangular;
= 'L': A is lower triangular.

TRANS (input)

Specifies the form of the system of equations:
= 'N': $A * X = B$ (No transpose)
= 'T': $A^{**T} * X = B$ (Transpose)
= 'C': $A^{*H} * X = B$ (Conjugate transpose)

DIAG (input)

= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

NDIAG (input)

The number of superdiagonals or subdiagonals of the triangular band matrix A. $NDIAG \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input) The upper or lower triangular band matrix A, stored in the first $kd+1$ rows of A. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

LDA (input)

The leading dimension of the array A. $LDA \geq NDIAG+1$.

B (input/output)

On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-

gal value
> 0: if INFO = i, the i-th diagonal element of A
is zero, indicating that the matrix is singular
and the solutions X have not been computed.

REAL, DIMENSION(:) :: RWORK

C INTERFACE

```
#include <sunperf.h>
void ctgevc(char side, char howmny, int *select, int n, complex *a, int lda, complex *b, int ldb, complex *vl, int ldvl, complex *vr, int ldvr, int mm, int *m, int *info);

void ctgevc_64(char side, char howmny, long *select, long n, complex *a, long lda, complex *b, long ldb, complex *vl, long ldvl, complex *vr, long ldvr, long mm, long *m, long *info);
```

PURPOSE

ctgevc computes some or all of the right and/or left generalized eigenvectors of a pair of complex upper triangular matrices (A,B).

The right generalized eigenvector x and the left generalized eigenvector y of (A,B) corresponding to a generalized eigenvalue w are defined by:

$$(A - wB) * x = 0 \quad \text{and} \quad y^{**H} * (A - wB) = 0$$

where y^{**H} denotes the conjugate transpose of y .

If an eigenvalue w is determined by zero diagonal elements of both A and B , a unit vector is returned as the corresponding eigenvector.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of (A,B), or the products $Z*X$ and/or $Q*Y$, where Z and Q are input unitary matrices. If (A,B) was obtained from the generalized Schur factorization of an original pair of matrices $(A0,B0) = (Q*A*Z^{**H}, Q*B*Z^{**H})$, then $Z*X$ and $Q*Y$ are the matrices of right or left eigenvectors of A .

ARGUMENTS

SIDE (input)

= 'R': compute right eigenvectors only;
= 'L': compute left eigenvectors only;
= 'B': compute both right and left eigenvectors.

HOWMNY (input)

= 'A': compute all right and/or left eigenvectors;
= 'B': compute all right and/or left eigenvectors, and backtransform them using the input matrices supplied in VR and/or VL; = 'S': compute selected right and/or left eigenvectors, specified by the logical array SELECT.

SELECT (input)

If HOWMNY='S', SELECT specifies the eigenvectors to be computed. If HOWMNY='A' or 'B', SELECT is not referenced. To select the eigenvector

corresponding to the j-th eigenvalue, SELECT(j) must be set to .TRUE..

N (input) The order of the matrices A and B. N >= 0.

A (input) The upper triangular matrix A.

LDA (input)
The leading dimension of array A. LDA >= max(1,N).

B (input) The upper triangular matrix B. B must have real diagonal elements.

LDB (input)
The leading dimension of array B. LDB >= max(1,N).

VL (input/output)
On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the unitary matrix Q of left Schur vectors returned by CHGEQZ). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of (A,B); if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of (A,B) specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

LDVL (input)
The leading dimension of array VL. LDVL >= max(1,N) if SIDE = 'L' or 'B'; LDVL >= 1 otherwise.

VR (input/output)
On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the unitary matrix Z of right Schur vectors returned by CHGEQZ). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of (A,B); if HOWMNY = 'B', the matrix Z*X; if HOWMNY = 'S', the right eigenvectors of (A,B) specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

LDVR (input)
The leading dimension of the array VR. LDVR >= max(1,N) if SIDE = 'R' or 'B'; LDVR >= 1 otherwise.

MM (input)
The number of columns in the arrays VL and/or VR. MM >= M.

M (output)
The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected eigenvector occupies one column.

WORK (workspace)
dimension(2*N)

RWORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

  Z, [LDZ], IFST, ILST, [INFO])
```

```
COMPLEX, DIMENSION(:,:) :: A, B, Q, Z
INTEGER(8) :: N, LDA, LDB, LDQ, LDZ, IFST, ILST, INFO
LOGICAL(8) :: WANTQ, WANTZ
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctgexc(int wantq, int wantz, int n, complex *a, int
  lda, complex *b, int ldb, complex *q, int ldq,
```

```

        complex *z, int ldz, int *ifst, int *ilst, int
        *info);

void ctgexc_64(long wantq, long wantz, long n, complex *a,
              long lda, complex *b, long ldb, complex *q, long
              ldq, complex *z, long ldz, long *ifst, long *ilst,
              long *info);

```

PURPOSE

ctgexc reorders the generalized Schur decomposition of a complex matrix pair (A,B), using an unitary equivalence transformation $(A, B) := Q * (A, B) * Z'$, so that the diagonal block of (A, B) with row index IFST is moved to row ILST.

(A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

Optionally, the matrices Q and Z of generalized Schur vectors are updated.

$$Q(\text{in}) * A(\text{in}) * Z(\text{in})' = Q(\text{out}) * A(\text{out}) * Z(\text{out})'$$

$$Q(\text{in}) * B(\text{in}) * Z(\text{in})' = Q(\text{out}) * B(\text{out}) * Z(\text{out})'$$

ARGUMENTS

WANTQ (input)

WANTZ (input)

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)

On entry, the upper triangular matrix A in the pair (A, B). On exit, the updated matrix A.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

B (input/output)

On entry, the upper triangular matrix B in the pair (A, B). On exit, the updated matrix B.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

Q (input/output)

On entry, if WANTQ = .TRUE., the unitary matrix Q. On exit, the updated matrix Q. If WANTQ = .FALSE., Q is not referenced.

LDQ (input)

The leading dimension of the array Q. $LDQ \geq 1$; If WANTQ = .TRUE., $LDQ \geq N$.

Z (input/output)

On entry, if WANTZ = .TRUE., the unitary matrix Z.

On exit, the updated matrix Z. If WANTZ =
.FALSE., Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ >= 1; If
WANTZ = .TRUE., LDZ >= N.

IFST (input/output)

Specify the reordering of the diagonal blocks of
(A, B). The block with row index IFST is moved to
row ILST, by a sequence of swapping between adja-
cent blocks.

ILST (input/output)

See the description of IFST.

INFO (output)

=0: Successful exit.
<0: if INFO = -i, the i-th argument had an ille-
gal value.
=1: The transformed matrix pair (A, B) would be
too far from generalized Schur form; the problem
is ill- conditioned. (A, B) may have been par-
tially reordered, and ILST points to the first row
of the current position of the block being moved.

```

PURPOSE

ctgsen reorders the generalized Schur decomposition of a complex matrix pair (A, B) (in terms of an unitary equivalence trans- formation $Q' * (A, B) * Z$), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the pair (A,B). The leading columns of Q and Z form unitary bases of the corresponding left and right eigenspaces (deflating subspaces). (A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

CTGSSEN also computes the generalized eigenvalues

$$w(j) = \text{ALPHA}(j) / \text{BETA}(j)$$

of the reordered matrix pair (A, B).

Optionally, the routine computes estimates of reciprocal condition numbers for eigenvalues and eigenspaces. These are $\text{Difu}[(A_{11}, B_{11}), (A_{22}, B_{22})]$ and $\text{Difl}[(A_{11}, B_{11}), (A_{22}, B_{22})]$, i.e. the separation(s) between the matrix pairs (A₁₁, B₁₁) and (A₂₂, B₂₂) that correspond to the selected cluster and the eigenvalues outside the cluster, resp., and norms of "projections" onto left and right eigenspaces w.r.t. the

selected cluster in the (1,1)-block.

ARGUMENTS

IJOB (input)

Specifies whether condition numbers are required for the cluster of eigenvalues (PL and PR) or the deflating subspaces (Difu and Difl):
=0: Only reorder w.r.t. SELECT. No extras.
=1: Reciprocal of norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster (PL and PR). =2: Upper bounds on Difu and Difl. F-norm-based estimate (DIF(1:2)).
=3: Estimate of Difu and Difl. 1-norm-based estimate (DIF(1:2)). About 5 times as expensive as IJOB = 2.
=4: Compute PL, PR and DIF (i.e. 0, 1 and 2 above): Economic version to get it all. =5: Compute PL, PR and DIF (i.e. 0, 1 and 3 above)

WANTQ (input)

WANTZ (input)

SELECT (input)

SELECT specifies the eigenvalues in the selected cluster. To select an eigenvalue $w(j)$, SELECT(j) must be set to

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)

On entry, the upper triangular matrix A, in generalized Schur canonical form. On exit, A is overwritten by the reordered matrix A.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

B (input/output)

On entry, the upper triangular matrix B, in generalized Schur canonical form. On exit, B is overwritten by the reordered matrix B.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

ALPHA (output)

The diagonal elements of A and B, respectively, when the pair (A,B) has been reduced to generalized Schur form. $ALPHA(i)/BETA(i)$ $i=1, \dots, N$ are the generalized eigenvalues.

BETA (output)

See the description of ALPHA.

Q (input/output)

On entry, if WANTQ = .TRUE., Q is an N-by-N matrix. On exit, Q has been postmultiplied by the left unitary transformation matrix which reorder

(A, B); The leading M columns of Q form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTQ = .FALSE., Q is not referenced.

LDQ (input)

The leading dimension of the array Q. LDQ \geq 1.
If WANTQ = .TRUE., LDQ \geq N.

Z (input/output)

On entry, if WANTZ = .TRUE., Z is an N-by-N matrix. On exit, Z has been postmultiplied by the left unitary transformation matrix which reorders (A, B); The leading M columns of Z form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTZ = .FALSE., Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ \geq 1.
If WANTZ = .TRUE., LDZ \geq N.

M (output)

The dimension of the specified pair of left and right eigenspaces, (deflating subspaces) $0 \leq M \leq N$.

PL (output)

If IJOB = 1, 4, or 5, PL, PR are lower bounds on the reciprocal of the norm of "projections" onto left and right eigenspace with respect to the selected cluster.
 $0 < PL, PR \leq 1$. If M = 0 or M = N, PL = PR = 1.
If IJOB = 0, 2, or 3 PL, PR are not referenced.

PR (output)

See the description of PL.

DIF (output)

If IJOB \geq 2, DIF(1:2) store the estimates of Difu and Difl.
If IJOB = 2 or 4, DIF(1:2) are F-norm-based upper bounds on
Difu and Difl. If IJOB = 3 or 5, DIF(1:2) are 1-norm-based estimates of Difu and Difl, computed using reversed communication with CLACON. If M = 0 or N, DIF(1:2) = F-norm([A, B]). If IJOB = 0 or 1, DIF is not referenced.

WORK (workspace)

If IJOB = 0, WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK \geq 1
If IJOB = 1, 2 or 4, LWORK \geq $2 * M * (N - M)$
If IJOB = 3 or 5, LWORK \geq $4 * M * (N - M)$

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
 If IJOB = 0, IWORK is not referenced. Otherwise, on exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
 The dimension of the array IWORK. LIWORK >= 1. If IJOB = 1, 2 or 4, LIWORK >= N+2; If IJOB = 3 or 5, LIWORK >= MAX(N+2, 2*M*(N-M));

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
 =0: Successful exit.
 <0: If INFO = -i, the i-th argument had an illegal value.
 =1: Reordering of (A, B) failed because the transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is very ill-conditioned. (A, B) may have been partially reordered. If requested, 0 is returned in DIF(*), PL and PR.

FURTHER DETAILS

CTGSEN first collects the selected eigenvalues by computing unitary U and W that move them to the top left corner of (A, B). In other words, the selected eigenvalues are the eigenvalues of (A11, B11) in

$$U'*(A, B)*W = \begin{pmatrix} (A11 & A12) & (B11 & B12) & n1 \\ (0 & A22) & (0 & B22) & n2 \\ n1 & n2 & n1 & n2 \end{pmatrix}$$

where $N = n1+n2$ and U' means the conjugate transpose of U. The first $n1$ columns of U and W span the specified pair of left and right eigenspaces (deflating subspaces) of (A, B).

If (A, B) has been obtained from the generalized real Schur decomposition of a matrix pair $(C, D) = Q*(A, B)*Z'$, then the reordered generalized Schur form of (C, D) is given by

$$(C, D) = (Q*U)*(U'*(A, B)*W)*(Z*W)',$$

and the first $n1$ columns of $Q*U$ and $Z*W$ span the corresponding deflating subspaces of (C, D) (Q and Z store $Q*U$ and $Z*W$, resp.).

Note that if the selected eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

The reciprocal condition numbers of the left and right eigenspaces spanned by the first $n1$ columns of U and W (or $Q*U$ and $Z*W$) may be returned in DIF(1:2), corresponding to DifU and Difl, resp.

The DifU and Difl are defined as:
 $\text{ifu}[(A11, B11), (A22, B22)] = \text{sigma-min}(Z_u)$

and

where $\sigma_{\min}(Z_u)$ is the smallest singular value of the $(2 \times n_1 \times n_2)$ -by- $(2 \times n_1 \times n_2)$ matrix

$$u = \begin{bmatrix} \text{kron}(In_2, A11) & -\text{kron}(A22', In1) \\ \text{kron}(In2, B11) & -\text{kron}(B22', In1) \end{bmatrix}.$$

Here, In_x is the identity matrix of size n_x and $A22'$ is the transpose of $A22$. $\text{kron}(X, Y)$ is the Kronecker product between the matrices X and Y .

When $\text{DIF}(2)$ is small, small changes in (A, B) can cause large changes in the deflating subspace. An approximate (asymptotic) bound on the maximum angular error in the computed deflating subspaces is $\text{EPS} * \text{norm}((A, B)) / \text{DIF}(2)$,

where EPS is the machine precision.

The reciprocal norm of the projectors on the left and right eigenspaces associated with $(A11, B11)$ may be returned in PL and PR . They are computed as follows. First we compute L and R so that $P*(A, B)*Q$ is block diagonal, where

$$= \begin{pmatrix} I & -L \\ 0 & I \end{pmatrix} \begin{matrix} n1 \\ n2 \\ n1 \ n2 \end{matrix} \quad \text{and} \quad Q = \begin{pmatrix} I & R \\ 0 & I \end{pmatrix} \begin{matrix} n1 \\ n2 \\ n1 \ n2 \end{matrix}$$

and (L, R) is the solution to the generalized Sylvester equation $L1*R - L*A22 = -A12$

Then $PL = (F\text{-norm}(L)**2+1)**(-1/2)$ and $PR = (F\text{-norm}(R)**2+1)**(-1/2)$. An approximate (asymptotic) bound on the average absolute error of the selected eigenvalues is $\text{EPS} * \text{norm}((A, B)) / PL$.

There are also global error bounds which valid for perturbations up to a certain restriction: A lower bound (x) on the smallest $F\text{-norm}(E, F)$ for which an eigenvalue of $(A11, B11)$ may move and coalesce with an eigenvalue of $(A22, B22)$ under perturbation (E, F) , (i.e. $(A + E, B + F)$), is

$$x = \min(\text{Difu}, \text{Difl}) / ((1/(PL*PL) + 1/(PR*PR))**(1/2) + 2*\max(1/PL, 1/PR)).$$

An approximate bound on x can be computed from $\text{DIF}(1:2)$, PL and PR .

If $y = (F\text{-norm}(E, F) / x) \leq 1$, the angles between the perturbed (L', R') and unperturbed (L, R) left and right deflating subspaces associated with the selected cluster in the $(1,1)$ -blocks can be bounded as

$$\begin{aligned} \max\text{-angle}(L, L') &\leq \arctan(y * PL / (1 - y * (1 - PL * PL)**(1/2))) \\ \max\text{-angle}(R, R') &\leq \arctan(y * PR / (1 - y * (1 - PR * PR)**(1/2))) \end{aligned}$$

See LAPACK User's Guide section 4.11 or the following references for more information.

Note that if the default method for computing the Frobenius-norm-based estimate DIF is not wanted (see CLATDF), then the parameter IDIFJB (see below) should be changed from 3 to 4 (routine CLATDF ($\text{IJOB} = 2$ will be used)). See CTGSYL for more details.

```

PURPOSE

ctgsja computes the generalized singular value decomposition (GSVD) of two complex upper triangular (or trapezoidal) matrices A and B.

On entry, it is assumed that matrices A and B have the following forms, which may be obtained by the preprocessing subroutine CCGSVP from a general M-by-N matrix A and P-by-N matrix B:

$$A = \begin{array}{ccc} & \begin{array}{cc} \text{N-K-L} & \text{K} & \text{L} \end{array} \\ \begin{array}{c} \text{K} \\ \text{L} \\ \text{M-K-L} \end{array} & \begin{pmatrix} 0 & \text{A12} & \text{A13} \\ 0 & 0 & \text{A23} \\ 0 & 0 & 0 \end{pmatrix} & \text{if } \text{M-K-L} \geq 0; \end{array}$$

$$A = \begin{array}{ccc} & \begin{array}{cc} \text{N-K-L} & \text{K} & \text{L} \end{array} \\ \begin{array}{c} \text{K} \\ \text{M-K} \end{array} & \begin{pmatrix} 0 & \text{A12} & \text{A13} \\ 0 & 0 & \text{A23} \end{pmatrix} & \text{if } \text{M-K-L} < 0; \end{array}$$

$$B = \begin{array}{ccc} & \begin{array}{cc} \text{N-K-L} & \text{K} & \text{L} \end{array} \\ \begin{array}{c} \text{L} \\ \text{P-L} \end{array} & \begin{pmatrix} 0 & 0 & \text{B13} \\ 0 & 0 & 0 \end{pmatrix} \end{array}$$

where the K-by-K matrix A12 and L-by-L matrix B13 are nonsingular upper triangular; A23 is L-by-L upper triangular if M-K-L ≥ 0, otherwise A23 is (M-K)-by-L upper trapezoidal.

On exit,
 $U' * A * Q = D1 * (0 \ R)$, $V' * B * Q = D2 * (0 \ R)$,

where U, V and Q are unitary matrices, Z' denotes the conjugate transpose of Z, R is a nonsingular upper triangular matrix, and D1 and D2 are ``diagonal'' matrices, which are of the following structures:

If $M-K-L \geq 0$,

$$D1 = \begin{matrix} & & K & L \\ & K & (I & 0) \\ & & L & (0 & C) \\ M-K-L & (0 & 0) \end{matrix}$$

$$D2 = \begin{matrix} & & K & L \\ L & (0 & S) \\ P-L & (0 & 0) \end{matrix}$$

$$(0 R) = \begin{matrix} & N-K-L & K & L \\ K & (0 & R11 & R12) & K \\ L & (0 & 0 & R22) & L \end{matrix}$$

where

$$C = \text{diag}(\text{ALPHA}(K+1), \dots, \text{ALPHA}(K+L)),$$

$$S = \text{diag}(\text{BETA}(K+1), \dots, \text{BETA}(K+L)),$$

$$C^{**2} + S^{**2} = I.$$

R is stored in $A(1:K+L, N-K-L+1:N)$ on exit.

If $M-K-L < 0$,

$$D1 = \begin{matrix} & & K & M-K & K+L-M \\ & K & (I & 0 & 0) \\ M-K & (0 & C & 0) \end{matrix}$$

$$D2 = \begin{matrix} & & K & M-K & K+L-M \\ M-K & (0 & S & 0) \\ K+L-M & (0 & 0 & I) \\ P-L & (0 & 0 & 0) \end{matrix}$$

$$\begin{matrix} & N-K-L & K & M-K & K+L-M \\ M-K & (0 & 0 & R22 & R23) \\ K+L-M & (0 & 0 & 0 & R33) \end{matrix}$$

where

$$C = \text{diag}(\text{ALPHA}(K+1), \dots, \text{ALPHA}(M)),$$

$$S = \text{diag}(\text{BETA}(K+1), \dots, \text{BETA}(M)),$$

$$C^{**2} + S^{**2} = I.$$

$R = (R11 \ R12 \ R13)$ is stored in $A(1:M, N-K-L+1:N)$ and $R33$ is stored

$(0 \ R22 \ R23)$
in $B(M-K+1:L, N+M-K-L+1:N)$ on exit.

The computation of the unitary transformation matrices U, V or Q is optional. These matrices may either be formed explicitly, or they may be postmultiplied into input matrices U1, V1, or Q1.

CTGSJA essentially uses a variant of Kogbetliantz algorithm to reduce $\min(L, M-K)$ -by- L triangular (or trapezoidal) matrix A23 and L -by- L matrix B13 to the form:

$$U1' * A13 * Q1 = C1 * R1; \quad V1' * B13 * Q1 = S1 * R1,$$

where U1, V1 and Q1 are unitary matrix, and Z' is the conjugate transpose of Z. C1 and S1 are diagonal matrices satisfying

$$C1^{**2} + S1^{**2} = I,$$

and R1 is an L -by- L nonsingular upper triangular matrix.

ARGUMENTS

JOBU (input)
= 'U': U must contain a unitary matrix U1 on entry, and the product U1*U is returned; = 'I': U is initialized to the unit matrix, and the unitary matrix U is returned; = 'N': U is not computed.

JOBV (input)
= 'V': V must contain a unitary matrix V1 on entry, and the product V1*V is returned; = 'I': V is initialized to the unit matrix, and the unitary matrix V is returned; = 'N': V is not computed.

JOBQ (input)
= 'Q': Q must contain a unitary matrix Q1 on entry, and the product Q1*Q is returned; = 'I': Q is initialized to the unit matrix, and the unitary matrix Q is returned; = 'N': Q is not computed.

M (input) The number of rows of the matrix A. $M \geq 0$.

P (input) The number of rows of the matrix B. $P \geq 0$.

N (input) The number of columns of the matrices A and B. $N \geq 0$.

K (input) K and L specify the subblocks in the input matrices A and B:
A23 = A(K+1:MIN(K+L,M),N-L+1:N) and B13 = B(1:L,,N-L+1:N) of A and B, whose GSVD is going to be computed by CTGSJA. See the Further Details section below.

L (input) See the description of K.

A (input/output)
On entry, the M-by-N matrix A. On exit, A(N-K+1:N,1:MIN(K+L,M)) contains the triangular matrix R or part of R. See Purpose for details.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1,M)$.

B (input/output)
On entry, the P-by-N matrix B. On exit, if necessary, B(M-K+1:L,N+M-K-L+1:N) contains a part of R. See Purpose for details.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1,P)$.

TOLA (input)
TOLA and TOLB are the convergence criteria for the Jacobi-Kogbetliantz iteration procedure. Generally, they are the same as used in the preprocessing step, say $TOLA = \max(M,N) * \text{norm}(A) * \text{MACHEPS}$, $TOLB = \max(P,N) * \text{norm}(B) * \text{MACHEPS}$.

TOLB (input)

See the description of TOLA.

ALPHA (output)

On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; ALPHA(1:K) = 1, BETA(1:K) = 0, and if $M-K-L \geq 0$, ALPHA(K+1:K+L) = diag(C), BETA(K+1:K+L) = diag(S), or if $M-K-L < 0$, ALPHA(K+1:M) = C, ALPHA(M+1:K+L) = 0, BETA(K+1:M) = S, BETA(M+1:K+L) = 1. Furthermore, if $K+L < N$, ALPHA(K+L+1:N) = 0, BETA(K+L+1:N) = 0.

BETA (output)

See the description of ALPHA.

U (input) On entry, if JOBU = 'U', U must contain a matrix U1 (usually the unitary matrix returned by CGGSVP). On exit, if JOBU = 'I', U contains the unitary matrix U; if JOBU = 'U', U contains the product U1*U. If JOBU = 'N', U is not referenced.

LDU (input)

The leading dimension of the array U. LDU \geq max(1,M) if JOBU = 'U'; LDU \geq 1 otherwise.

V (input) On entry, if JOBV = 'V', V must contain a matrix V1 (usually the unitary matrix returned by CGGSVP). On exit, if JOBV = 'I', V contains the unitary matrix V; if JOBV = 'V', V contains the product V1*V. If JOBV = 'N', V is not referenced.

LDV (input)

The leading dimension of the array V. LDV \geq max(1,P) if JOBV = 'V'; LDV \geq 1 otherwise.

Q (input) On entry, if JOBQ = 'Q', Q must contain a matrix Q1 (usually the unitary matrix returned by CGGSVP). On exit, if JOBQ = 'I', Q contains the unitary matrix Q; if JOBQ = 'Q', Q contains the product Q1*Q. If JOBQ = 'N', Q is not referenced.

LDQ (input)

The leading dimension of the array Q. LDQ \geq max(1,N) if JOBQ = 'Q'; LDQ \geq 1 otherwise.

WORK (workspace)

dimension(2*N)

NCYCLE (output)

The number of cycles required for convergence.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1: the procedure does not converge after MAXIT cycles.

```

PURPOSE

ctgsna estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B).

(A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

ARGUMENTS

JOB (input)
 Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (DIF):
 = 'E': for eigenvalues only (S);
 = 'V': for eigenvectors only (DIF);
 = 'B': for both eigenvalues and eigenvectors (S and DIF).

HOWMNT (input)
 = 'A': compute condition numbers for all eigenpairs;
 = 'S': compute condition numbers for selected eigenpairs specified by the array SELECT.

SELECT (input)
 If HOWMNT = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the corresponding j-th eigenvalue and/or eigenvector, SELECT(j) must be set to .TRUE.. If HOWMNT = 'A', SELECT is not referenced.

N (input) The order of the square matrix pair (A, B). N >= 0.

A (input) The upper triangular matrix A in the pair (A,B).

LDA (input)
 The leading dimension of the array A. LDA >= max(1,N).

B (input) The upper triangular matrix B in the pair (A, B).

LDB (input)
The leading dimension of the array B. LDB \geq max(1,N).

VL (input)
If JOB = 'E' or 'B', VL must contain left eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNT and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by CTGEEV. If JOB = 'V', VL is not referenced.

LDVL (input)
The leading dimension of the array VL. LDVL \geq 1; and If JOB = 'E' or 'B', LDVL \geq N.

VR (input)
If JOB = 'E' or 'B', VR must contain right eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNT and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by CTGEEV. If JOB = 'V', VR is not referenced.

LDVR (input)
The leading dimension of the array VR. LDVR \geq 1; If JOB = 'E' or 'B', LDVR \geq N.

S (output)
If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. If JOB = 'V', S is not referenced.

DIF (output)
If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. If the eigenvalues cannot be reordered to compute DIF(j), DIF(j) is set to 0; this can only occur when the true value would be very small anyway. For each eigenvalue/vector specified by SELECT, DIF stores a Frobenius norm-based estimate of Difl. If JOB = 'E', DIF is not referenced.

MM (input)
The number of elements in the arrays S and DIF. MM \geq M.

M (output)
The number of elements of the arrays S and DIF used to store the specified condition numbers; for each selected eigenvalue one element is used. If HOWMNT = 'A', M is set to N.

WORK (workspace)
If JOB = 'E', WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK >= 1. If JOB = 'V' or 'B', LWORK >= 2*N*N.

IWORK (workspace)
dimension(N+2) If JOB = 'E', IWORK is not referenced.

INFO (output)
= 0: Successful exit
< 0: If INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The reciprocal of the condition number of the i-th generalized eigenvalue $w = (a, b)$ is defined as

$$S(I) = \frac{(|v'Au|^{**2} + |v'Bu|^{**2})^{**}(1/2)}{(\text{norm}(u)*\text{norm}(v))}$$

where u and v are the right and left eigenvectors of (A, B) corresponding to w ; $|z|$ denotes the absolute value of the complex number, and $\text{norm}(u)$ denotes the 2-norm of the vector u . The pair (a, b) corresponds to an eigenvalue $w = a/b$ ($= v'Au/v'Bu$) of the matrix pair (A, B) . If both a and b equal zero, then (A, B) is singular and $S(I) = -1$ is returned.

An approximate error bound on the chordal distance between the i-th computed generalized eigenvalue w and the corresponding exact eigenvalue λ is

$$\text{chord}(w, \lambda) \leq \text{EPS} * \text{norm}(A, B) / S(I),$$

where EPS is the machine precision.

The reciprocal of the condition number of the right eigenvector u and left eigenvector v corresponding to the generalized eigenvalue w is defined as follows. Suppose

$$(A, B) = \begin{pmatrix} a & * & & & 1 \\ 0 & A22 & & & \\ & & & & \\ 1 & n-1 & & & 1 \\ & & & & n-1 \end{pmatrix}$$

Then the reciprocal condition number DIF(I) is

$$\text{Dif1}[(a, b), (A22, B22)] = \text{sigma-min}(Z1)$$

where $\text{sigma-min}(Z1)$ denotes the smallest singular value of

$$Z1 = \begin{bmatrix} \text{kron}(a, In-1) & -\text{kron}(1, A22) \\ \text{kron}(b, In-1) & -\text{kron}(1, B22) \end{bmatrix}.$$

Here $In-1$ is the identity matrix of size $n-1$ and X' is the conjugate transpose of X . $\text{kron}(X, Y)$ is the Kronecker product between the matrices X and Y .

We approximate the smallest singular value of $Z1$ with an upper bound. This is done by CLATDF.

An approximate error bound for a computed eigenvector $VL(i)$ or $VR(i)$ is given by

$$\text{EPS} * \text{norm}(A, B) / \text{DIF}(i).$$

See ref. [2-3] for more details and further references.

C INTERFACE

```
#include <sunperf.h>
```

```
void ctgsyl(char trans, int ijob, int m, int n, complex *a,  
int lda, complex *b, int ldb, complex *c, int ldc,  
complex *d, int ldd, complex *e, int lde, complex  
*f, int ldf, float *scale, float *dif, int *info);
```

```
void ctgsyl_64(char trans, long ijob, long m, long n, com-  
plex *a, long lda, complex *b, long ldb, complex  
*c, long ldc, complex *d, long ldd, complex *e,  
long lde, complex *f, long ldf, float *scale,  
float *dif, long *info);
```

PURPOSE

ctgsyl solves the generalized Sylvester equation:

$$\begin{aligned} A * R - L * B &= \text{scale} * C & (1) \\ D * R - L * E &= \text{scale} * F \end{aligned}$$

where R and L are unknown m-by-n matrices, (A, D), (B, E) and (C, F) are given matrix pairs of size m-by-m, n-by-n and m-by-n, respectively, with complex entries. A, B, D and E are upper triangular (i.e., (A,D) and (B,E) in generalized Schur form).

The solution (R, L) overwrites (C, F). 0 <= SCALE <= 1 is an output scaling factor chosen to avoid overflow.

In matrix notation (1) is equivalent to solve $Zx = \text{scale} * b$, where Z is defined as

$$Z = \begin{bmatrix} \text{kron}(I_n, A) & -\text{kron}(B', I_m) \\ \text{kron}(I_n, D) & -\text{kron}(E', I_m) \end{bmatrix}, \quad (2)$$

Here I_x is the identity matrix of size x and X' is the conjugate transpose of X. $\text{Kron}(X, Y)$ is the Kronecker product between the matrices X and Y.

If TRANS = 'C', y in the conjugate transposed system $Z' * y = \text{scale} * b$ is solved for, which is equivalent to solve for R and L in

$$\begin{aligned} A' * R + D' * L &= \text{scale} * C & (3) \\ R * B' + L * E' &= \text{scale} * -F \end{aligned}$$

This case (TRANS = 'C') is used to compute an one-norm-based estimate of $\text{Dif}[(A,D), (B,E)]$, the separation between the matrix pairs (A,D) and (B,E), using CLACON.

If IJOB >= 1, CTGSYL computes a Frobenius norm-based esti-

mate of $\text{Dif}[(A,D),(B,E)]$. That is, the reciprocal of a lower bound on the reciprocal of the smallest singular value of Z.

This is a level-3 BLAS algorithm.

ARGUMENTS

TRANS (input)
= 'N': solve the generalized sylvester equation (1).
= 'C': solve the "conjugate transposed" system (3).

IJOB (input)
Specifies what kind of functionality to be performed. =0: solve (1) only.
=1: The functionality of 0 and 3.
=2: The functionality of 0 and 4.
=3: Only an estimate of $\text{Dif}[(A,D),(B,E)]$ is computed. (look ahead strategy is used). =4: Only an estimate of $\text{Dif}[(A,D),(B,E)]$ is computed. (CGECON on sub-systems is used). Not referenced if TRANS = 'C'.

M (input) The order of the matrices A and D, and the row dimension of the matrices C, F, R and L.

N (input) The order of the matrices B and E, and the column dimension of the matrices C, F, R and L.

A (input) The upper triangular matrix A.

LDA (input)
The leading dimension of the array A. LDA \geq max(1, M).

B (input) The upper triangular matrix B.

LDB (input)
The leading dimension of the array B. LDB \geq max(1, N).

C (input/output)
On entry, C contains the right-hand-side of the first matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, C has been overwritten by the solution R. If IJOB = 3 or 4 and TRANS = 'N', C holds R, the solution achieved during the computation of the Dif-estimate.

LDC (input)
The leading dimension of the array C. LDC \geq max(1, M).

D (input) The upper triangular matrix D.

LDD (input)
The leading dimension of the array D. LDD \geq max(1, M).

E (input) The upper triangular matrix E.

LDE (input)
 The leading dimension of the array E. LDE \geq max(1, N).

F (input/output)
 On entry, F contains the right-hand-side of the second matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, F has been overwritten by the solution L. If IJOB = 3 or 4 and TRANS = 'N', F holds L, the solution achieved during the computation of the Dif-estimate.

LDF (input)
 The leading dimension of the array F. LDF \geq max(1, M).

DIF (output)
 On exit SCALE is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. SCALE is an upper bound of Dif[(A,D), (B,E)] = $\sigma_{\min}(Z)$, where Z as in (2). If IJOB = 0 or TRANS = 'C', SCALE is not referenced.

SCALE (output)
 On exit SCALE is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. SCALE is an upper bound of Dif[(A,D), (B,E)] = $\sigma_{\min}(Z)$, where Z as in (2). If IJOB = 0 or TRANS = 'C', SCALE is not referenced.

WORK (workspace)
 If IJOB = 0, WORK is not referenced. Otherwise, on exit, if INFO=0 then WORK(1) returns the optimal LWORK.

LWORK (input)
 The dimension of the array WORK. LWORK \geq 1. If IJOB = 1 or 2 and TRANS = 'N', LWORK \geq 2*M*N.

 If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace)
 If IJOB = 0, IWORK is not referenced.

INFO (output)
 =0: successful exit
 <0: If INFO = -i, the i-th argument had an illegal value.
 >0: (A, D) and (B, E) have common or very close eigenvalues.

```

```
SUBROUTINE CTPCON_64(NORM, UPLO, DIAG, N, A, RCOND, WORK, WORK2,  
INFO)
```

```
CHARACTER * 1 NORM, UPLO, DIAG  
COMPLEX A(*), WORK(*)  
INTEGER*8 N, INFO  
REAL RCOND  
REAL WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE TPCON(NORM, UPLO, DIAG, N, A, RCOND, [WORK], [WORK2],  
[INFO])
```

```
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
COMPLEX, DIMENSION(:) :: A, WORK  
INTEGER :: N, INFO  
REAL :: RCOND  
REAL, DIMENSION(:) :: WORK2
```

```
SUBROUTINE TPCON_64(NORM, UPLO, DIAG, N, A, RCOND, [WORK], [WORK2],  
[INFO])
```

```
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
COMPLEX, DIMENSION(:) :: A, WORK  
INTEGER(8) :: N, INFO  
REAL :: RCOND  
REAL, DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>

void ctpcon(char norm, char uplo, char diag, int n, complex
            *a, float *rcond, int *info);
void ctpcon_64(char norm, char uplo, char diag, long n, complex
               *a, float *rcond, long *info);
```

PURPOSE

ctpcon estimates the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))) .$$

ARGUMENTS

NORM (input)
 Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
 = '1' or 'O': 1-norm;
 = 'I': Infinity-norm.

UPLO (input)
 = 'U': A is upper triangular;
 = 'L': A is lower triangular.

DIAG (input)
 = 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

RCOND (output)
 The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

WORK (workspace)
 dimension(2*N)

WORK2 (workspace)
 dimension(N)

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value

NAME

ctpmv - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$

SYNOPSIS

```
SUBROUTINE CTPMV(UPLO, TRANSA, DIAG, N, A, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
COMPLEX A(*), Y(*)  
INTEGER N, INCY
```

```
SUBROUTINE CTPMV_64(UPLO, TRANSA, DIAG, N, A, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
COMPLEX A(*), Y(*)  
INTEGER*8 N, INCY
```

F95 INTERFACE

```
SUBROUTINE TPMV(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX, DIMENSION(:) :: A, Y  
INTEGER :: N, INCY
```

```
SUBROUTINE TPMV_64(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX, DIMENSION(:) :: A, Y  
INTEGER(8) :: N, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctpmv(char uplo, char transa, char diag, int n, complex  
          *a, complex *y, int incy);
```

```
void ctpmv_64(char uplo, char transa, char diag, long n,  
             complex *a, complex *y, long incy);
```

PURPOSE

ctpmv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$ where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $x := A*x$.

TRANSA = 'T' or 't' $x := A'*x$.

TRANSA = 'C' or 'c' $x := \text{conjg}(A')*x$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

A (input)

(($n*(n+1)$) / 2). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular matrix packed sequentially, column by column, so that $A(1)$ contains $a(1,1)$, $A(2)$ and $A(3)$ contain $a(1,2)$ and $a(2,2)$ respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular matrix packed sequentially, column by column, so that $A(1)$ contains $a(1,1)$, $A(2)$

and $A(3)$ contain $a(2, 1)$ and $a(3, 1)$ respectively, and so on. Note that when $DIAG = 'U'$ or $'u'$, the diagonal elements of A are not referenced, but are assumed to be unity. Unchanged on exit.

Y (input/output)

$(1 + (n - 1) * \text{abs}(INCY))$. Before entry, the incremented array Y must contain the n element vector x . On exit, Y is overwritten with the transformed vector x .

$INCY$ (input)

On entry, $INCY$ specifies the increment for the elements of Y . $INCY \neq 0$. Unchanged on exit.

             nrhs, complex *a, complex *b, int ldb, complex *x,
             int ldx, float *ferr, float *berr, int *info);
void ctpfrfs_64(char uplo, char transa, char diag, long n,
                long nrhs, complex *a, complex *b, long ldb, com-
                plex *x, long ldx, float *ferr, float *berr, long
                *info);

```

PURPOSE

ctprfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix.

The solution matrix X must be computed by CTPTRS or some other means before entering this routine. CTPRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

UPLO (input)

= 'U': A is upper triangular;
 = 'L': A is lower triangular.

TRANSA (input)

Specifies the form of the system of equations:
 = 'N': $A * X = B$ (No transpose)
 = 'T': $A^{**T} * X = B$ (Transpose)
 = 'C': $A^{*H} * X = B$ (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

= 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

B (input) The right hand side matrix B.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

X (input) The solution matrix X.

LDX (input)
The leading dimension of the array X. LDX \geq max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

```
void ctpsv(char uplo, char transa, char diag, int n, complex  
          *a, complex *y, int incy);
```

```
void ctpsv_64(char uplo, char transa, char diag, long n,  
             complex *a, complex *y, long incy);
```

PURPOSE

ctpsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, or $\text{conjg}(A)*x = b$ where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANS (input)

On entry, TRANS specifies the equations to be solved as follows:

TRANS = 'N' or 'n' $A*x = b$.

TRANS = 'T' or 't' $A'*x = b$.

TRANS = 'C' or 'c' $\text{conjg}(A)*x = b$.

Unchanged on exit.

TRANS is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

A (input)

(($n*(n+1)$) / 2). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular matrix packed sequentially, column by column, so that $A(1)$ contains $a(1,1)$, $A(2)$ and $A(3)$ contain $a(1,2)$ and $a(2,2)$ respectively, and so on. Before entry with UPLO = 'L'

or 'l', the array A must contain the lower triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity. Unchanged on exit.

Y (input/output)
(1 + (n - 1) * abs(INCY)). Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

           *info);
```

```
void ctptri_64(char uplo, char diag, long n, complex *a,  
              long *info);
```

PURPOSE

ctptri computes the inverse of a complex upper or lower triangular matrix A stored in packed format.

ARGUMENTS

UPLO (input)
= 'U': A is upper triangular;
= 'L': A is lower triangular.

DIAG (input)
= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
On entry, the upper or lower triangular matrix A, stored columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*((2*n-j)/2)) = A(i,j)$ for $j \leq i \leq n$. See below for further details. On exit, the (triangular) inverse of the original matrix, in the same packed storage format.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, A(i,i) is exactly zero. The triangular matrix is singular and its inverse can not be computed.

FURTHER DETAILS

A triangular matrix A can be transferred to packed storage using one of the following program segments:

UPLO = 'U':	UPLO = 'L':
JC = 1	JC = 1
DO 2 J = 1, N	DO 2 J = 1, N
DO 1 I = 1, J	DO 1 I = J, N
A(JC+I-1) = A(I,J)	A(JC+I-J) =
A(I,J)	
1 CONTINUE	1 CONTINUE
JC = JC + J	JC = JC + N - J +
1	
2 CONTINUE	2 CONTINUE

INTEGER*8 N, NRHS, LDB, INFO
```

F95 INTERFACE

```
SUBROUTINE TPTRS(UPLO, TRANSA, DIAG, N, [NRHS], A, B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX, DIMENSION(:) :: A  
COMPLEX, DIMENSION(:, :) :: B  
INTEGER :: N, NRHS, LDB, INFO
```

```
SUBROUTINE TPTRS_64(UPLO, TRANSA, DIAG, N, [NRHS], A, B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX, DIMENSION(:) :: A  
COMPLEX, DIMENSION(:, :) :: B  
INTEGER(8) :: N, NRHS, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctptrs(char uplo, char transa, char diag, int n, int  
           nrhs, complex *a, complex *b, int ldb, int *info);
```

```
void ctptrs_64(char uplo, char transa, char diag, long n,  
              long nrhs, complex *a, complex *b, long ldb, long  
              *info);
```

PURPOSE

ctptrs solves a triangular system of the form

where A is a triangular matrix of order N stored in packed format, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

ARGUMENTS

UPLO (input)

= 'U': A is upper triangular;
= 'L': A is lower triangular.

TRANSA (input)

Specifies the form of the system of equations:
= 'N': $A * X = B$ (No transpose)
= 'T': $A^{**T} * X = B$ (Transpose)
= 'C': $A^{**H} * X = B$ (Conjugate transpose)

DIAG (input)

= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input) The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

B (input/output)

On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

NAME

ctrans - transpose and scale source matrix

SYNOPSIS

```
SUBROUTINE CTRANS(PLACE, SCALE, SOURCE, M, N, DEST)
```

```
CHARACTER * 1 PLACE  
COMPLEX SCALE  
COMPLEX SOURCE(*), DEST(*)  
INTEGER M, N
```

```
SUBROUTINE CTRANS_64(PLACE, SCALE, SOURCE, M, N, DEST)
```

```
CHARACTER * 1 PLACE  
COMPLEX SCALE  
COMPLEX SOURCE(*), DEST(*)  
INTEGER*8 M, N
```

F95 INTERFACE

```
SUBROUTINE TRANS([PLACE], SCALE, SOURCE, M, N, [DEST])
```

```
CHARACTER(LEN=1) :: PLACE  
COMPLEX :: SCALE  
COMPLEX, DIMENSION(:) :: SOURCE, DEST  
INTEGER :: M, N
```

```
SUBROUTINE TRANS_64([PLACE], SCALE, SOURCE, M, N, [DEST])
```

```
CHARACTER(LEN=1) :: PLACE  
COMPLEX :: SCALE  
COMPLEX, DIMENSION(:) :: SOURCE, DEST  
INTEGER(8) :: M, N
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrans(char place, complex *scale, complex *source, int  
            m, int n, complex *dest);
```

```
void ctrans_64(char place, complex *scale, complex *source,  
              long m, long n, complex *dest);
```

PURPOSE

ctrans scales and transposes the source matrix. The $N_2 \times N_1$ result is written into SOURCE when PLACE = 'I' or 'i', and DEST when PLACE = 'O' or 'o'.

PLACE = 'I' or 'i': SOURCE = SCALE * SOURCE'

PLACE = 'O' or 'o': DEST = SCALE * SOURCE'

ARGUMENTS

PLACE (input)

Type of transpose. 'I' or 'i' for in-place, 'O' or 'o' for out-of-place. 'I' is default.

SCALE (input)

Scale factor on the SOURCE matrix.

SOURCE (input/output)

on input. Array of (N, M) on output if in-place transpose.

M (input)

Number of rows in the SOURCE matrix on input.

N (input)

Number of columns in the SOURCE matrix on input.

DEST (output)

Scaled and transposed SOURCE matrix if out-of-place transpose. Not referenced if in-place transpose.

INFO)
```

```
CHARACTER * 1 NORM, UPLO, DIAG  
COMPLEX A(LDA,*), WORK(*)  
INTEGER*8 N, LDA, INFO  
REAL RCOND  
REAL WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE TRCON(NORM, UPLO, DIAG, [N], A, [LDA], RCOND, [WORK],  
[WORK2], [INFO])
```

```
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER :: N, LDA, INFO  
REAL :: RCOND  
REAL, DIMENSION(:) :: WORK2
```

```
SUBROUTINE TRCON_64(NORM, UPLO, DIAG, [N], A, [LDA], RCOND, [WORK],  
[WORK2], [INFO])
```

```
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: N, LDA, INFO  
REAL :: RCOND
```

```
REAL, DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
void ctrcon(char norm, char uplo, char diag, int n, complex
            *a, int lda, float *rcond, int *info);

void ctrcon_64(char norm, char uplo, char diag, long n, com-
               plex *a, long lda, float *rcond, long *info);
```

PURPOSE

ctrcon estimates the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

NORM (input)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I': Infinity-norm.

UPLO (input)

= 'U': A is upper triangular;
= 'L': A is lower triangular.

DIAG (input)

= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

RCOND (output)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

WORK (workspace)

dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)

SUBROUTINE TREVC(SIDE, HOWMNY, SELECT, [N], T, [LDT], VL, [LDVL], VR,  
  [LDVR], MM, M, [WORK], [RWORK], [INFO])
```

```
CHARACTER(LEN=1) :: SIDE, HOWMNY  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:, :) :: T, VL, VR  
INTEGER :: N, LDT, LDVL, LDVR, MM, M, INFO  
LOGICAL, DIMENSION(:) :: SELECT  
REAL, DIMENSION(:) :: RWORK
```

```
SUBROUTINE TREVC_64(SIDE, HOWMNY, SELECT, [N], T, [LDT], VL, [LDVL],  
  VR, [LDVR], MM, M, [WORK], [RWORK], [INFO])
```

```
CHARACTER(LEN=1) :: SIDE, HOWMNY  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:, :) :: T, VL, VR  
INTEGER(8) :: N, LDT, LDVL, LDVR, MM, M, INFO
```

```
LOGICAL(8), DIMENSION(:) :: SELECT
REAL, DIMENSION(:) :: RWORK
```

C INTERFACE

```
#include <sunperf.h>
void ctrevc(char side, char howmny, int *select, int n, complex *t, int ldt, complex *vl, int ldvl, complex *vr, int ldvr, int mm, int *m, int *info);

void ctrevc_64(char side, char howmny, long *select, long n, complex *t, long ldt, complex *vl, long ldvl, complex *vr, long ldvr, long mm, long *m, long *info);
```

PURPOSE

ctrevc computes some or all of the right and/or left eigenvectors of a complex upper triangular matrix T.

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w are defined by:

$$T*x = w*x, \quad y'*T = w*y'$$

where y' denotes the conjugate transpose of the vector y.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of T, or the products Q*X and/or Q*Y, where Q is an input unitary matrix. If T was obtained from the Schur factorization of an original matrix $A = Q*T*Q'$, then Q*X and Q*Y are the matrices of right or left eigenvectors of A.

ARGUMENTS

SIDE (input)

= 'R': compute right eigenvectors only;
= 'L': compute left eigenvectors only;
= 'B': compute both right and left eigenvectors.

HOWMNY (input)

= 'A': compute all right and/or left eigenvectors;
= 'B': compute all right and/or left eigenvectors, and backtransform them using the input matrices supplied in VR and/or VL; = 'S': compute selected right and/or left eigenvectors, specified by the logical array SELECT.

SELECT (input/output)

If HOWMNY = 'S', SELECT specifies the eigenvectors to be computed. If HOWMNY = 'A' or 'B', SELECT is not referenced. To select the eigenvector corresponding to the j-th eigenvalue, SELECT(j) must be set to .TRUE..

N (input) The order of the matrix T. N >= 0.

T (input/output)

The upper triangular matrix T. T is modified, but restored on exit.

LDT (input)

The leading dimension of the array T. LDT \geq max(1,N).

VL (input/output)

On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the unitary matrix Q of Schur vectors returned by CHSEQR). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of T; VL is lower triangular. The i-th column VL(i) of VL is the eigenvector corresponding to T(i,i). if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of T specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

LDVL (input)

The leading dimension of the array VL. LDVL \geq max(1,N) if SIDE = 'L' or 'B'; LDVL \geq 1 otherwise.

VR (input/output)

On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the unitary matrix Q of Schur vectors returned by CHSEQR). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of T; VR is upper triangular. The i-th column VR(i) of VR is the eigenvector corresponding to T(i,i). if HOWMNY = 'B', the matrix Q*X; if HOWMNY = 'S', the right eigenvectors of T specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

LDVR (input)

The leading dimension of the array VR. LDVR \geq max(1,N) if SIDE = 'R' or 'B'; LDVR \geq 1 otherwise.

MM (input)

The number of columns in the arrays VL and/or VR. MM \geq M.

M (output)

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected eigenvector occupies one column.

WORK (workspace)

dimension(2*N)

RWORK (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-

gal value

FURTHER DETAILS

The algorithm used in this program is basically backward (forward) substitution, with scaling to make the code robust against possible overflow.

Each eigenvector is normalized so that the element of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be $|x| + |y|$.

INTEGER*8 N, LDT, LDQ, IFST, ILST, INFO
```

F95 INTERFACE

```
SUBROUTINE TREXC(COMPQ, [N], T, [LDT], Q, [LDQ], IFST, ILST, [INFO])
```

```
CHARACTER(LEN=1) :: COMPQ  
COMPLEX, DIMENSION(:,:) :: T, Q  
INTEGER :: N, LDT, LDQ, IFST, ILST, INFO
```

```
SUBROUTINE TREXC_64(COMPQ, [N], T, [LDT], Q, [LDQ], IFST, ILST, [INFO])
```

```
CHARACTER(LEN=1) :: COMPQ  
COMPLEX, DIMENSION(:,:) :: T, Q  
INTEGER(8) :: N, LDT, LDQ, IFST, ILST, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrexc(char compq, int n, complex *t, int ldt, complex  
           *q, int ldq, int ifst, int ilst, int *info);
```

```
void ctrexc_64(char compq, long n, complex *t, long ldt,  
              complex *q, long ldq, long ifst, long ilst, long  
              *info);
```

PURPOSE

ctrexc reorders the Schur factorization of a complex matrix $A = Q^*T^*Q^{**}H$, so that the diagonal element of T with row index $IFST$ is moved to row $ILST$. The Schur form T is reordered by a unitary similarity transformation $Z^{**}H^*T^*Z$, and optionally the matrix Q of Schur vectors is updated by postmultiplying it with Z .

ARGUMENTS

COMPQ (input)
= 'V': update the matrix Q of Schur vectors;
= 'N': do not update Q .

N (input) The order of the matrix T . $N \geq 0$.

T (input/output)
On entry, the upper triangular matrix T . On exit, the reordered upper triangular matrix.

LDT (input)
The leading dimension of the array T . $LDT \geq \max(1, N)$.

Q (input) On entry, if $COMPQ = 'V'$, the matrix Q of Schur vectors. On exit, if $COMPQ = 'V'$, Q has been postmultiplied by the unitary transformation matrix Z which reorders T . If $COMPQ = 'N'$, Q is not referenced.

LDQ (input)
The leading dimension of the array Q . $LDQ \geq \max(1, N)$.

IFST (input)
Specify the reordering of the diagonal elements of T : The element with row index $IFST$ is moved to row $ILST$ by a sequence of transpositions between adjacent elements. $1 \leq IFST \leq N$; $1 \leq ILST \leq N$.

ILST (input)
See the description of $IFST$.

INFO (output)
= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value

NAME

ctrmm - perform one of the matrix-matrix operations $B := \alpha * \text{op}(A) * B$, or $B := \alpha * B * \text{op}(A)$ where alpha is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and op(A) is one of op(A) = A or op(A) = A' or op(A) = conjg(A')

SYNOPSIS

```
SUBROUTINE CTRMM(SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
                LDB)
```

```
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
COMPLEX ALPHA
COMPLEX A(LDA,*), B(LDB,*)
INTEGER M, N, LDA, LDB
```

```
SUBROUTINE CTRMM_64(SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
                   LDB)
```

```
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
COMPLEX ALPHA
COMPLEX A(LDA,*), B(LDB,*)
INTEGER*8 M, N, LDA, LDB
```

F95 INTERFACE

```
SUBROUTINE TRMM(SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A, [LDA],
                B, [LDB])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
COMPLEX :: ALPHA
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER :: M, N, LDA, LDB
```

```
SUBROUTINE TRMM_64(SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
                  [LDA], B, [LDB])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
COMPLEX :: ALPHA
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER(8) :: M, N, LDA, LDB
```

C INTERFACE

```
#include <sunperf.h>
```

```

void ctrmm(char side, char uplo, char transa, char diag, int
           m, int n, complex *alpha, complex *a, int lda,
           complex *b, int ldb);
void ctrmm_64(char side, char uplo, char transa, char diag,
              long m, long n, complex *alpha, complex *a, long
              lda, complex *b, long ldb);

```

PURPOSE

ctrmm performs one of the matrix-matrix operations $B := \alpha * \text{op}(A) * B$, or $B := \alpha * B * \text{op}(A)$ where alpha is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and $\text{op}(A)$ is one of $\text{op}(A) = A$ or $\text{op}(A) = A'$ or $\text{op}(A) = \text{conjg}(A')$

ARGUMENTS

SIDE (input)

On entry, SIDE specifies whether $\text{op}(A)$ multiplies B from the left or right as follows:

SIDE = 'L' or 'l' $B := \alpha * \text{op}(A) * B$.

SIDE = 'R' or 'r' $B := \alpha * B * \text{op}(A)$.

Unchanged on exit.

UPLO (input)

On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the form of $\text{op}(A)$ to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' $\text{op}(A) = A$.

TRANSA = 'T' or 't' $\text{op}(A) = A'$.

TRANSA = 'C' or 'c' $\text{op}(A) = \text{conjg}(A')$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

M (input)

On entry, M specifies the number of rows of B. $M \geq 0$. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of B. $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

A (input)

COMPLEX array of DIMENSION (LDA, k), where k is m when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'.

Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced.

Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.

Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then $LDA \geq \max(1, M)$, when SIDE = 'R' or 'r' then $LDA \geq \max(1, N)$. Unchanged on exit.

B (input/output)

COMPLEX array of DIMENSION (LDB, n). Before entry, the leading M by N part of the array B must contain the matrix B, and on exit is overwritten by the transformed matrix.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling subprogram. LDB must be at least $\max(1, M)$. Unchanged on exit.

NAME

ctrmv - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$

SYNOPSIS

```
SUBROUTINE CTRMV(UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
COMPLEX A(LDA,*), Y(*)  
INTEGER N, LDA, INCY
```

```
SUBROUTINE CTRMV_64(UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
COMPLEX A(LDA,*), Y(*)  
INTEGER*8 N, LDA, INCY
```

F95 INTERFACE

```
SUBROUTINE TRMV(UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX, DIMENSION(:) :: Y  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER :: N, LDA, INCY
```

```
SUBROUTINE TRMV_64(UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX, DIMENSION(:) :: Y  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: N, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrmv(char uplo, char transa, char diag, int n, complex  
          *a, int lda, complex *y, int incy);
```

```
void ctrmv_64(char uplo, char transa, char diag, long n,  
             complex *a, long lda, complex *y, long incy);
```

PURPOSE

ctrmv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$ where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $x := A*x$.

TRANSA = 'T' or 't' $x := A'*x$.

TRANSA = 'C' or 'c' $x := \text{conjg}(A')*x$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u',

the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, n)$. Unchanged on exit.

Y (input/output)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector x. On exit, Y is overwritten with the transformed vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrrfs(char uplo, char transa, char diag, int n, int
           nrhs, complex *a, int lda, complex *b, int ldb,
           complex *x, int ldx, float *ferr, float *berr, int
           *info);
```

```
void ctrrfs_64(char uplo, char transa, char diag, long n,
              long nrhs, complex *a, long lda, complex *b, long
              ldb, complex *x, long ldx, float *ferr, float
              *berr, long *info);
```

PURPOSE

ctrrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix.

The solution matrix X must be computed by CTRTRS or some other means before entering this routine. CTRRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

UPLO (input)

= 'U': A is upper triangular;
 = 'L': A is lower triangular.

TRANSA (input)

Specifies the form of the system of equations:
 = 'N': $A * X = B$ (No transpose)
 = 'T': $A^{**T} * X = B$ (Transpose)
 = 'C': $A^{**H} * X = B$ (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

= 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB \geq
max(1,N).

X (input) The solution matrix X.

LDX (input)
The leading dimension of the array X. LDX \geq
max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

SUBROUTINE TRSEN_64(JOB, COMPQ, SELECT, [N], T, [LDT], Q, [LDQ], W,  
  M, S, SEP, [WORK], [LWORK], [INFO])
```

```
CHARACTER(LEN=1) :: JOB, COMPQ
COMPLEX, DIMENSION(:) :: W, WORK
COMPLEX, DIMENSION(:, :) :: T, Q
INTEGER(8) :: N, LDT, LDQ, M, LWORK, INFO
LOGICAL(8), DIMENSION(:) :: SELECT
REAL :: S, SEP
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrsen(char job, char compq, int *select, int n, complex *t, int ldt, complex *q, int ldq, complex *w, int *m, float *s, float *sep, int *info);
```

```
void ctrsen_64(char job, char compq, long *select, long n, complex *t, long ldt, complex *q, long ldq, complex *w, long *m, float *s, float *sep, long *info);
```

PURPOSE

ctrsen reorders the Schur factorization of a complex matrix $A = Q^*TQ^{**H}$, so that a selected cluster of eigenvalues appears in the leading positions on the diagonal of the upper triangular matrix T, and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace.

Optionally the routine computes the reciprocal condition numbers of the cluster of eigenvalues and/or the invariant subspace.

ARGUMENTS

JOB (input)

Specifies whether condition numbers are required for the cluster of eigenvalues (S) or the invariant subspace (SEP):

= 'N': none;
= 'E': for eigenvalues only (S);
= 'V': for invariant subspace only (SEP);
= 'B': for both eigenvalues and invariant subspace (S and SEP).

COMPQ (input)

= 'V': update the matrix Q of Schur vectors;
= 'N': do not update Q.

SELECT (input)

SELECT specifies the eigenvalues in the selected cluster. To select the j-th eigenvalue, SELECT(j) must be set to .TRUE..

N (input) The order of the matrix T. $N \geq 0$.

T (input/output)

On entry, the upper triangular matrix T. On exit, T is overwritten by the reordered matrix T, with the selected eigenvalues as the leading diagonal elements.

LDT (input)

The leading dimension of the array T. $LDT \geq \max(1, N)$.

Q (input) On entry, if $COMPQ = 'V'$, the matrix Q of Schur vectors. On exit, if $COMPQ = 'V'$, Q has been postmultiplied by the unitary transformation matrix which reorders T; the leading M columns of Q form an orthonormal basis for the specified invariant subspace. If $COMPQ = 'N'$, Q is not referenced.

LDQ (input)
The leading dimension of the array Q. $LDQ \geq 1$; and if $COMPQ = 'V'$, $LDQ \geq N$.

W (output)
The reordered eigenvalues of T, in the same order as they appear on the diagonal of T.

M (output)
The dimension of the specified invariant subspace. $0 \leq M \leq N$.

S (output)
If $JOB = 'E'$ or $'B'$, S is a lower bound on the reciprocal condition number for the selected cluster of eigenvalues. S cannot underestimate the true reciprocal condition number by more than a factor of \sqrt{N} . If $M = 0$ or N , $S = 1$. If $JOB = 'N'$ or $'V'$, S is not referenced.

SEP (output)
If $JOB = 'V'$ or $'B'$, SEP is the estimated reciprocal condition number of the specified invariant subspace. If $M = 0$ or N , $SEP = \text{norm}(T)$. If $JOB = 'N'$ or $'E'$, SEP is not referenced.

WORK (workspace)
If $JOB = 'N'$, WORK is not referenced. Otherwise, on exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If $JOB = 'N'$, $LWORK \geq 1$; if $JOB = 'E'$, $LWORK = M*(N-M)$; if $JOB = 'V'$ or $'B'$, $LWORK \geq 2*M*(N-M)$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value

FURTHER DETAILS

CTRSEN first collects the selected eigenvalues by computing a unitary transformation Z to move them to the top left corner of T. In other words, the selected eigenvalues are the eigenvalues of T11 in:

$$Z'^*T*Z = \begin{pmatrix} T11 & T12 \\ 0 & T22 \end{pmatrix} \begin{matrix} n1 \\ n2 \end{matrix}$$

where $N = n1+n2$ and Z' means the conjugate transpose of Z . The first $n1$ columns of Z span the specified invariant subspace of T .

If T has been obtained from the Schur factorization of a matrix $A = Q*T*Q'$, then the reordered Schur factorization of A is given by $A = (Q*Z)*(Z'*T*Z)*(Q*Z)'$, and the first $n1$ columns of $Q*Z$ span the corresponding invariant subspace of A .

The reciprocal condition number of the average of the eigenvalues of $T11$ may be returned in S . S lies between 0 (very badly conditioned) and 1 (very well conditioned). It is computed as follows. First we compute R so that

$$P = \begin{pmatrix} I & R \\ 0 & 0 \end{pmatrix} \begin{matrix} n1 \\ n2 \end{matrix}$$

is the projector on the invariant subspace associated with $T11$. R is the solution of the Sylvester equation:

$$T11*R - R*T22 = T12.$$

Let $F\text{-norm}(M)$ denote the Frobenius-norm of M and $2\text{-norm}(M)$ denote the two-norm of M . Then S is computed as the lower bound

$$(1 + F\text{-norm}(R)**2)**(-1/2)$$

on the reciprocal of $2\text{-norm}(P)$, the true reciprocal condition number. S cannot underestimate $1 / 2\text{-norm}(P)$ by more than a factor of \sqrt{N} .

An approximate error bound for the computed average of the eigenvalues of $T11$ is

$$EPS * \text{norm}(T) / S$$

where EPS is the machine precision.

The reciprocal condition number of the right invariant subspace spanned by the first $n1$ columns of Z (or of $Q*Z$) is returned in SEP . SEP is defined as the separation of $T11$ and $T22$:

$$\text{sep}(T11, T22) = \text{sigma-min}(C)$$

where $\text{sigma-min}(C)$ is the smallest singular value of the $n1*n2$ -by- $n1*n2$ matrix

$$C = \text{kprod}(I(n2), T11) - \text{kprod}(\text{transpose}(T22), I(n1))$$

$I(m)$ is an m by m identity matrix, and kprod denotes the Kronecker product. We estimate $\text{sigma-min}(C)$ by the reciprocal of an estimate of the 1-norm of $\text{inverse}(C)$. The true reciprocal 1-norm of $\text{inverse}(C)$ cannot differ from $\text{sigma-min}(C)$ by more than a factor of $\sqrt{n1*n2}$.

When SEP is small, small changes in T can cause large

changes in the invariant subspace. An approximate bound on the maximum angular error in the computed right invariant subspace is

$$\text{EPS} * \text{norm}(T) / \text{SEP}$$

                   LDB)
```

```
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
COMPLEX ALPHA
COMPLEX A(LDA,*), B(LDB,*)
INTEGER*8 M, N, LDA, LDB
```

F95 INTERFACE

```
SUBROUTINE TRSM(SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A, [LDA],
                B, [LDB])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
COMPLEX :: ALPHA
COMPLEX, DIMENSION(:,) :: A, B
INTEGER :: M, N, LDA, LDB
```

```
SUBROUTINE TRSM_64(SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
                  [LDA], B, [LDB])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
COMPLEX :: ALPHA
COMPLEX, DIMENSION(:,) :: A, B
INTEGER(8) :: M, N, LDA, LDB
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrsm(char side, char uplo, char transa, char diag, int
           m, int n, complex *alpha, complex *a, int lda,
```

```

        complex *b, int ldb);

void ctrsm_64(char side, char uplo, char transa, char diag,
              long m, long n, complex *alpha, complex *a, long
              lda, complex *b, long ldb);

```

PURPOSE

ctrsm solves one of the matrix equations $op(A) * X = \alpha * B$, or $X * op(A) = \alpha * B$ where α is a scalar, X and B are m by n matrices, A is a unit, or non-unit, upper or lower triangular matrix and $op(A)$ is one of

$op(A) = A$ or $op(A) = A'$ or $op(A) = conjg(A')$.

The matrix X is overwritten on B .

ARGUMENTS

SIDE (input)

On entry, SIDE specifies whether $op(A)$ appears on the left or right of X as follows:

SIDE = 'L' or 'l' $op(A) * X = \alpha * B$.

SIDE = 'R' or 'r' $X * op(A) = \alpha * B$.

Unchanged on exit.

UPLO (input)

On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the form of $op(A)$ to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' $op(A) = A$.

TRANSA = 'T' or 't' $op(A) = A'$.

TRANSA = 'C' or 'c' $op(A) = conjg(A')$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit tri-

angular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

M (input)

On entry, M specifies the number of rows of B. M \geq 0. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of B. N \geq 0. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

A (input)

COMPLEX array of DIMENSION (LDA, k), where k is m when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'.

Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced.

Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.

Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA \geq max(1,M), when SIDE = 'R' or 'r' then LDA \geq max(1,N). Unchanged on exit.

B (input/output)

COMPLEX array of DIMENSION (LDB, n). Before entry, the leading M by N part of the array B must contain the right-hand side matrix B, and on exit is overwritten by the solution matrix X.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling subprogram. LDB \geq max(1,M). Unchanged on exit.

C INTERFACE

```
#include <sunperf.h>
void ctrsna(char job, char howmny, int *select, int n, complex *t, int ldt, complex *vl, int ldvl, complex *vr, int ldvr, float *s, float *sep, int mm, int *m, int ldwork, int *info);

void ctrsna_64(char job, char howmny, long *select, long n, complex *t, long ldt, complex *vl, long ldvl, complex *vr, long ldvr, float *s, float *sep, long mm, long *m, long ldwork, long *info);
```

PURPOSE

ctrsna estimates reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a complex upper triangular matrix T (or of any matrix $Q^*T^*Q^{*H}$ with Q unitary).

ARGUMENTS

JOB (input)

Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (SEP):
= 'E': for eigenvalues only (S);
= 'V': for eigenvectors only (SEP);
= 'B': for both eigenvalues and eigenvectors (S and SEP).

HOWMNY (input)

= 'A': compute condition numbers for all eigenpairs;
= 'S': compute condition numbers for selected eigenpairs specified by the array SELECT.

SELECT (input)

If HOWMNY = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the j-th eigenpair, SELECT(j) must be set to .TRUE.. If HOWMNY = 'A', SELECT is not referenced.

N (input) The order of the matrix T. $N \geq 0$.

T (input) The upper triangular matrix T.

LDT (input)

The leading dimension of the array T. $LDT \geq \max(1, N)$.

VL (input)

If JOB = 'E' or 'B', VL must contain left eigenvectors of T (or of any $Q^*T^*Q^{*H}$ with Q unitary), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by CHSEIN or CTREVC. If JOB = 'V', VL is not refer-

enced.

LDVL (input)

The leading dimension of the array VL. LDVL \geq 1;
and if JOB = 'E' or 'B', LDVL \geq N.

VR (input)

If JOB = 'E' or 'B', VR must contain right eigenvectors of T (or of any $Q^*T^*Q^*H$ with Q unitary), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by CHSEIN or CTREVC. If JOB = 'V', VR is not referenced.

LDVR (input)

The leading dimension of the array VR. LDVR \geq 1;
and if JOB = 'E' or 'B', LDVR \geq N.

S (output)

If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. Thus S(j), SEP(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If JOB = 'V', S is not referenced.

SEP (output)

If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. If JOB = 'E', SEP is not referenced.

MM (input)

The number of elements in the arrays S (if JOB = 'E' or 'B') and/or SEP (if JOB = 'V' or 'B'). MM \geq M.

M (output)

The number of elements of the arrays S and/or SEP actually used to store the estimated condition numbers. If HOWMNY = 'A', M is set to N.

WORK (workspace)

dimension(LDWORK,N+1) If JOB = 'E', WORK is not referenced.

LDWORK (input)

The leading dimension of the array WORK. LDWORK \geq 1; and if JOB = 'V' or 'B', LDWORK \geq N.

WORK1 (workspace)

dimension(N) If JOB = 'E', WORK1 is not referenced.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The reciprocal of the condition number of an eigenvalue λ is defined as

$$S(\lambda) = |v' * u| / (\text{norm}(u) * \text{norm}(v))$$

where u and v are the right and left eigenvectors of T corresponding to λ ; v' denotes the conjugate transpose of v , and $\text{norm}(u)$ denotes the Euclidean norm. These reciprocal condition numbers always lie between zero (very badly conditioned) and one (very well conditioned). If $n = 1$, $S(\lambda)$ is defined to be 1.

An approximate error bound for a computed eigenvalue $W(i)$ is given by

$$\text{EPS} * \text{norm}(T) / S(i)$$

where EPS is the machine precision.

The reciprocal of the condition number of the right eigenvector u corresponding to λ is defined as follows. Suppose

$$T = \begin{pmatrix} \lambda & c \\ 0 & T_{22} \end{pmatrix}$$

Then the reciprocal condition number is

$$\text{SEP}(\lambda, T_{22}) = \text{sigma-min}(T_{22} - \lambda * I)$$

where sigma-min denotes the smallest singular value. We approximate the smallest singular value by the reciprocal of an estimate of the one-norm of the inverse of $T_{22} - \lambda * I$. If $n = 1$, $\text{SEP}(1)$ is defined to be $\text{abs}(T(1,1))$.

An approximate error bound for a computed right eigenvector $VR(i)$ is given by

$$\text{EPS} * \text{norm}(T) / \text{SEP}(i)$$

NAME

ctrsv - solve one of the systems of equations $A*x = b$, or $A'*x = b$, or $\text{conjg}(A')*x = b$

SYNOPSIS

```
SUBROUTINE CTRSV(UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
COMPLEX A(LDA,*), Y(*)  
INTEGER N, LDA, INCY
```

```
SUBROUTINE CTRSV_64(UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
COMPLEX A(LDA,*), Y(*)  
INTEGER*8 N, LDA, INCY
```

F95 INTERFACE

```
SUBROUTINE TRSV(UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX, DIMENSION(:) :: Y  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER :: N, LDA, INCY
```

```
SUBROUTINE TRSV_64(UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX, DIMENSION(:) :: Y  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: N, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrsv(char uplo, char transa, char diag, int n, complex  
          *a, int lda, complex *y, int incy);
```

```
void ctrsv_64(char uplo, char transa, char diag, long n,  
             complex *a, long lda, complex *y, long incy);
```

PURPOSE

ctrsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, or $\text{conjg}(A)*x = b$ where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANS (input)

On entry, TRANS specifies the equations to be solved as follows:

TRANS = 'N' or 'n' $A*x = b$.

TRANS = 'T' or 't' $A'*x = b$.

TRANS = 'C' or 'c' $\text{conjg}(A)*x = b$.

Unchanged on exit.

TRANS is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the

strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, n)$. Unchanged on exit.

Y (input/output)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

C, [LDC], SCALE, [INFO])
```

```
CHARACTER(LEN=1) :: TRANA, TRANB  
COMPLEX, DIMENSION(:,:) :: A, B, C  
INTEGER(8) :: ISGN, M, N, LDA, LDB, LDC, INFO  
REAL :: SCALE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrsyl(char trana, char tranb, int isgn, int m, int n,  
complex *a, int lda, complex *b, int ldb, complex  
*c, int ldc, float *scale, int *info);
```

```
void ctrsyl_64(char trana, char tranb, long isgn, long m,
               long n, complex *a, long lda, complex *b, long
               ldb, complex *c, long ldc, float *scale, long
               *info);
```

PURPOSE

ctrsyl solves the complex Sylvester matrix equation:

$$\begin{aligned} \text{op}(A)*X + X*\text{op}(B) &= \text{scale}*C \text{ or} \\ \text{op}(A)*X - X*\text{op}(B) &= \text{scale}*C, \end{aligned}$$

where $\text{op}(A) = A$ or A^{**H} , and A and B are both upper triangular. A is M -by- M and B is N -by- N ; the right hand side C and the solution X are M -by- N ; and scale is an output scale factor, set ≤ 1 to avoid overflow in X .

ARGUMENTS

TRANA (input)

Specifies the option $\text{op}(A)$:
 = 'N': $\text{op}(A) = A$ (No transpose)
 = 'C': $\text{op}(A) = A^{**H}$ (Conjugate transpose)

TRANB (input)

Specifies the option $\text{op}(B)$:
 = 'N': $\text{op}(B) = B$ (No transpose)
 = 'C': $\text{op}(B) = B^{**H}$ (Conjugate transpose)

ISGN (input)

Specifies the sign in the equation:
 = +1: solve $\text{op}(A)*X + X*\text{op}(B) = \text{scale}*C$
 = -1: solve $\text{op}(A)*X - X*\text{op}(B) = \text{scale}*C$

M (input) The order of the matrix A , and the number of rows in the matrices X and C . $M \geq 0$.

N (input) The order of the matrix B , and the number of columns in the matrices X and C . $N \geq 0$.

A (input) The upper triangular matrix A .

LDA (input)

The leading dimension of the array A . $LDA \geq \max(1, M)$.

B (input) The upper triangular matrix B .

LDB (input)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

C (input/output)

On entry, the M -by- N right hand side matrix C . On exit, C is overwritten by the solution matrix X .

LDC (input)

The leading dimension of the array C . $LDC \geq \max(1, M)$

SCALE (output)

The scale factor, scale, set ≤ 1 to avoid overflow in X.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

= 1: A and B have common or very close eigenvalues; perturbed values were used to solve the equation (but the matrices A and B are unchanged).

```
SUBROUTINE TRTRI2_64(UPLO, DIAG, [N], A, [LDA], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO, DIAG  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: N, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrtri2(char uplo, char diag, int n, complex *a, int  
            lda, int *info);
```

```
void ctrtri2_64(char uplo, char diag, long n, complex *a,  
               long lda, long *info);
```

PURPOSE

ctrtri2 computes the inverse of a complex upper or lower triangular matrix.

This is the Level 2 BLAS version of the algorithm.

ARGUMENTS

UPLO (input)

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular
= 'L': Lower triangular

DIAG (input)

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular
= 'U': Unit triangular

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the triangular matrix A. If UPLO = 'U', the leading n by n upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

On exit, the (triangular) inverse of the original matrix, in the same storage format.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

INFO (output)

= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value

           lda, int *info);
```

```
void ctrtri_64(char uplo, char diag, long n, complex *a,  
              long lda, long *info);
```

PURPOSE

ctrtri computes the inverse of a complex upper or lower triangular matrix A.

This is the Level 3 BLAS version of the algorithm.

ARGUMENTS

UPLO (input)

= 'U': A is upper triangular;
= 'L': A is lower triangular.

DIAG (input)

= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1. On exit, the (triangular) inverse of the original matrix, in the same storage format.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, A(i,i) is exactly zero. The triangular matrix is singular and its inverse can not be computed.

NAME

ctrtrs - solve a triangular system of the form $A * X = B$,
 $A^{**T} * X = B$, or $A^{**H} * X = B$,

SYNOPSIS

```
SUBROUTINE CTRTRS(UPLO, TRANSA, DIAG, N, NRHS, A, LDA, B, LDB, INFO)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
COMPLEX A(LDA,*), B(LDB,*)  
INTEGER N, NRHS, LDA, LDB, INFO
```

```
SUBROUTINE CTRTRS_64(UPLO, TRANSA, DIAG, N, NRHS, A, LDA, B, LDB,  
INFO)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
COMPLEX A(LDA,*), B(LDB,*)  
INTEGER*8 N, NRHS, LDA, LDB, INFO
```

F95 INTERFACE

```
SUBROUTINE TRTRS(UPLO, [TRANSA], DIAG, [N], [NRHS], A, [LDA], B, [LDB],  
[INFO])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX, DIMENSION(:,) :: A, B  
INTEGER :: N, NRHS, LDA, LDB, INFO
```

```
SUBROUTINE TRTRS_64(UPLO, [TRANSA], DIAG, [N], [NRHS], A, [LDA], B,  
[LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX, DIMENSION(:,) :: A, B  
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrtrs(char uplo, char transa, char diag, int n, int  
nrhs, complex *a, int lda, complex *b, int ldb,  
int *info);
```

```
void ctrtrs_64(char uplo, char transa, char diag, long n,  
long nrhs, complex *a, long lda, complex *b, long  
ldb, long *info);
```

PURPOSE

ctrtrs solves a triangular system of the form where A is a triangular matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is non-singular.

ARGUMENTS

UPLO (input)

= 'U': A is upper triangular;
= 'L': A is lower triangular.

TRANSA (input)

Specifies the form of the system of equations:
= 'N': $A * X = B$ (No transpose)
= 'T': $A^{**T} * X = B$ (Transpose)
= 'C': $A^{*H} * X = B$ (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input) The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,N)$.

B (input/output)

On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element of A

is zero, indicating that the matrix is singular
and the solutions X have not been computed.

NAME

ctzrqf - routine is deprecated and has been replaced by routine CTZRZF

SYNOPSIS

```
SUBROUTINE CTZRQF(M, N, A, LDA, TAU, INFO)
```

```
COMPLEX A(LDA,*), TAU(*)  
INTEGER M, N, LDA, INFO
```

```
SUBROUTINE CTZRQF_64(M, N, A, LDA, TAU, INFO)
```

```
COMPLEX A(LDA,*), TAU(*)  
INTEGER*8 M, N, LDA, INFO
```

F95 INTERFACE

```
SUBROUTINE TZRQF([M], [N], A, [LDA], TAU, [INFO])
```

```
COMPLEX, DIMENSION(:) :: TAU  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER :: M, N, LDA, INFO
```

```
SUBROUTINE TZRQF_64([M], [N], A, [LDA], TAU, [INFO])
```

```
COMPLEX, DIMENSION(:) :: TAU  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctzrqf(int m, int n, complex *a, int lda, complex *tau,  
           int *info);
```

```
void ctzrqf_64(long m, long n, complex *a, long lda, complex  
              *tau, long *info);
```

PURPOSE

ctzrqf routine is deprecated and has been replaced by routine CTZRZF.

CTZRQF reduces the M-by-N ($M \leq N$) complex upper trapezoidal matrix A to upper triangular form by means of unitary transformations.

The upper trapezoidal matrix A is factored as
$$A = \begin{pmatrix} R & 0 \end{pmatrix} * Z,$$

where Z is an N-by-N unitary matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq M$.

A (input/output)

On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the unitary matrix Z as a product of M elementary reflectors.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

TAU (output)

The scalar factors of the elementary reflectors.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The factorization is obtained by Householder's method. The kth transformation matrix, $Z(k)$, whose conjugate transpose is used to introduce zeros into the $(m - k + 1)$ th row of A, is given in the form

$$Z(k) = \begin{pmatrix} I & 0 \\ 0 & T(k) \end{pmatrix},$$

where

$$T(k) = I - \tau * u(k) * u(k)', \quad u(k) = \begin{pmatrix} 1 \\ 0 \\ z(k) \end{pmatrix},$$

τ is a scalar and $z(k)$ is an $(n - m)$ element vector.

τ and $z(k)$ are chosen to annihilate the elements of the k th row of X .

The scalar τ is returned in the k th element of TAU and the vector $u(k)$ in the k th row of A , such that the elements of $z(k)$ are in $a(k, m + 1), \dots, a(k, n)$. The elements of R are returned in the upper triangular part of A .

Z is given by

$$Z = Z(1) * Z(2) * \dots * Z(m).$$

```
void ctzrzf_64(long m, long n, complex *a, long lda, complex  
               *tau, long *info);
```

PURPOSE

ctzrzf reduces the M-by-N ($M \leq N$) complex upper trapezoidal matrix A to upper triangular form by means of unitary transformations.

The upper trapezoidal matrix A is factored as

$$A = \begin{pmatrix} R & 0 \end{pmatrix} * Z,$$

where Z is an N-by-N unitary matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)
On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the unitary matrix Z as a product of M elementary reflectors.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, M)$.

TAU (output)
The scalar factors of the elementary reflectors.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq M * NB$, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

Based on contributions by

A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

The factorization is obtained by Householder's method. The k th transformation matrix, $Z(k)$, which is used to introduce zeros into the $(m - k + 1)$ th row of A , is given in the form

$$Z(k) = \begin{pmatrix} I & 0 \\ 0 & T(k) \end{pmatrix},$$

where

$$T(k) = I - \tau \cdot u(k) \cdot u(k)', \quad u(k) = \begin{pmatrix} 1 \\ 0 \\ z(k) \end{pmatrix},$$

τ is a scalar and $z(k)$ is an $(n - m)$ element vector. τ and $z(k)$ are chosen to annihilate the elements of the k th row of X .

The scalar τ is returned in the k th element of TAU and the vector $u(k)$ in the k th row of A , such that the elements of $z(k)$ are in $a(k, m + 1), \dots, a(k, n)$. The elements of R are returned in the upper triangular part of A .

Z is given by

$$Z = Z(1) * Z(2) * \dots * Z(m).$$

COMPLEX, DIMENSION(:,:) :: A  
INTEGER :: M, N, K, LDA, LWORK, INFO
```

```
SUBROUTINE UNGBR_64(VECT, M, [N], K, A, [LDA], TAU, [WORK], [LWORK],  
[INFO])
```

```
CHARACTER(LEN=1) :: VECT  
COMPLEX, DIMENSION(:) :: TAU, WORK  
COMPLEX, DIMENSION(:,:) :: A  
INTEGER(8) :: M, N, K, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cungbr(char vect, int m, int n, int k, complex *a, int  
lda, complex *tau, int *info);
```

```
void cungbr_64(char vect, long m, long n, long k, complex  
*a, long lda, complex *tau, long *info);
```

PURPOSE

cungbr generates one of the complex unitary matrices Q or P^{*H} determined by CGEBRD when reducing a complex matrix A to bidiagonal form: $A = Q * B * P^{*H}$. Q and P^{*H} are defined as products of elementary reflectors $H(i)$ or $G(i)$ respectively.

If $VECT = 'Q'$, A is assumed to have been an M -by- K matrix, and Q is of order M :

if $m \geq k$, $Q = H(1) H(2) \dots H(k)$ and CUNGBR returns the first n columns of Q , where $m \geq n \geq k$;

if $m < k$, $Q = H(1) H(2) \dots H(m-1)$ and CUNGBR returns Q as an M -by- M matrix.

If $VECT = 'P'$, A is assumed to have been a K -by- N matrix, and P^{*H} is of order N :

if $k < n$, $P^{*H} = G(k) \dots G(2) G(1)$ and CUNGBR returns the first m rows of P^{*H} , where $n \geq m \geq k$;

if $k \geq n$, $P^{*H} = G(n-1) \dots G(2) G(1)$ and CUNGBR returns P^{*H} as an N -by- N matrix.

ARGUMENTS

VECT (input)

Specifies whether the matrix Q or the matrix P^{*H} is required, as defined in the transformation applied by CGEBRD:

= 'Q': generate Q ;

= 'P': generate P^{*H} .

M (input) The number of rows of the matrix Q or P^{*H} to be returned. $M \geq 0$.

N (input) The number of columns of the matrix Q or P^{*H} to be returned. $N \geq 0$. If $VECT = 'Q'$, $M \geq N \geq \min(M,K)$; if $VECT = 'P'$, $N \geq M \geq \min(N,K)$.

K (input) If $VECT = 'Q'$, the number of columns in the original M -by- K matrix reduced by CGEBRD. If $VECT = 'P'$, the number of rows in the original K -by- N matrix reduced by CGEBRD. $K \geq 0$.

A (input/output)

On entry, the vectors which define the elementary reflectors, as returned by CGEBRD. On exit, the M -by- N matrix Q or P^{*H} .

LDA (input)

The leading dimension of the array A . $LDA \geq M$.

TAU (input)

$(\min(M,K))$ if $VECT = 'Q'$ ($\min(N,K)$) if $VECT = 'P'$
 $TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$ or $G(i)$, which determines Q or P^{*H} , as returned by CGEBRD in its array argument $TAUQ$ or $TAUP$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK \geq max(1,min(M,N)). For optimum performance LWORK \geq min(M,N)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

cunghr - generate a complex unitary matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by CGEHRD

SYNOPSIS

```
SUBROUTINE CUNGHR(N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
```

```
COMPLEX A(LDA,*), TAU(*), WORK(*)  
INTEGER N, ILO, IHI, LDA, LWORK, INFO
```

```
SUBROUTINE CUNGHR_64(N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
```

```
COMPLEX A(LDA,*), TAU(*), WORK(*)  
INTEGER*8 N, ILO, IHI, LDA, LWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE UNGHR([N], ILO, IHI, A, [LDA], TAU, [WORK], [LWORK], [INFO])
```

```
COMPLEX, DIMENSION(:) :: TAU, WORK  
COMPLEX, DIMENSION(:,:) :: A  
INTEGER :: N, ILO, IHI, LDA, LWORK, INFO
```

```
SUBROUTINE UNGHR_64([N], ILO, IHI, A, [LDA], TAU, [WORK], [LWORK],  
[INFO])
```

```
COMPLEX, DIMENSION(:) :: TAU, WORK  
COMPLEX, DIMENSION(:,:) :: A  
INTEGER(8) :: N, ILO, IHI, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cunghr(int n, int ilo, int ihi, complex *a, int lda,  
complex *tau, int *info);
```

```
void cunghr_64(long n, long ilo, long ihi, complex *a, long  
lda, complex *tau, long *info);
```

PURPOSE

cunghr generates a complex unitary matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N , as returned by CGEHRD:

$$Q = H(\text{ilo}) H(\text{ilo}+1) \dots H(\text{ihi}-1).$$

ARGUMENTS

N (input) The order of the matrix Q . $N \geq 0$.

ILO (input)
ILO and IHI must have the same values as in the previous call of CGEHRD. Q is equal to the unit matrix except in the submatrix $Q(\text{ilo}+1:\text{ihi}, \text{ilo}+1:\text{ihi})$. $1 \leq \text{ILO} \leq \text{IHI} \leq N$, if $N > 0$; $\text{ILO}=1$ and $\text{IHI}=0$, if $N=0$.

IHI (input)
See the description of IHI.

A (input/output)
On entry, the vectors which define the elementary reflectors, as returned by CGEHRD. On exit, the N -by- N unitary matrix Q .

LDA (input)
The leading dimension of the array A . $\text{LDA} \geq \max(1, N)$.

TAU (input)
 $\text{TAU}(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by CGEHRD.

WORK (workspace)
On exit, if $\text{INFO} = 0$, $\text{WORK}(1)$ returns the optimal LWORK .

LWORK (input)
The dimension of the array WORK . $\text{LWORK} \geq \text{IHI}-\text{ILO}$. For optimum performance $\text{LWORK} \geq (\text{IHI}-\text{ILO}) * \text{NB}$, where NB is the optimal blocksize.

If $\text{LWORK} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if $\text{INFO} = -i$, the i -th argument had an illegal value

```

```
void cungql_64(long m, long n, long k, complex *a, long lda, complex *tau, long *info);
```

PURPOSE

cungql generates an M-by-N complex matrix Q with orthonormal columns, which is defined as the last N columns of a product of K elementary reflectors of order M

$$Q = H(k) \dots H(2) H(1)$$

as returned by CGEQLF.

ARGUMENTS

M (input) The number of rows of the matrix Q. M \geq 0.

N (input) The number of columns of the matrix Q. M \geq N \geq 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. N \geq K \geq 0.

A (input/output)
On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGEQLF in the last k columns of its array argument A. On exit, the M-by-N matrix Q.

LDA (input)
The first dimension of the array A. LDA \geq max(1,M).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQLF.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK \geq max(1,N). For optimum performance LWORK \geq N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument has an illegal value

```

```
void cungqr_64(long m, long n, long k, complex *a, long lda, complex *tau, long *info);
```

PURPOSE

cungqr generates an M-by-N complex matrix Q with orthonormal columns, which is defined as the first N columns of a product of K elementary reflectors of order M

$$Q = H(1) H(2) \dots H(k)$$

as returned by CGEQRF.

ARGUMENTS

M (input) The number of rows of the matrix Q. $M \geq 0$.

N (input) The number of columns of the matrix Q. $M \geq N \geq 0$.

K (input) The number of elementary reflectors whose product defines the matrix Q. $N \geq K \geq 0$.

A (input/output)
On entry, the i-th column must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by CGEQRF in the first k columns of its array argument A. On exit, the M-by-N matrix Q.

LDA (input)
The first dimension of the array A. $LDA \geq \max(1, M)$.

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQRF.

WORKIN (workspace)
On exit, if INFO = 0, WORKIN(1) returns the optimal LWORKIN.

LWORKIN (input)
The dimension of the array WORKIN. $LWORKIN \geq \max(1, N)$. For optimum performance $LWORKIN \geq N * NB$, where NB is the optimal blocksize.

If LWORKIN = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORKIN array, returns this value as the first entry of the WORKIN array, and no error message related to LWORKIN is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument has an illegal value

```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:) :: TAU, WORK  
COMPLEX, DIMENSION(:,:) :: A  
INTEGER(8) :: N, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cungtr(char uplo, int n, complex *a, int lda, complex  
            *tau, int *info);
```

```
void cungtr_64(char uplo, long n, complex *a, long lda, com-  
               plex *tau, long *info);
```

PURPOSE

cungtr generates a complex unitary matrix Q which is defined as the product of $n-1$ elementary reflectors of order N , as returned by CHETRD:

if UPLO = 'U', $Q = H(n-1) \dots H(2) H(1)$,

if UPLO = 'L', $Q = H(1) H(2) \dots H(n-1)$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A contains elementary reflectors from CHETRD; = 'L': Lower triangle of A contains elementary reflectors from CHETRD.

N (input) The order of the matrix Q . $N \geq 0$.

A (input/output)

On entry, the vectors which define the elementary reflectors, as returned by CHETRD. On exit, the N -by- N unitary matrix Q .

LDA (input)

The leading dimension of the array A . $LDA \geq N$.

TAU (input)

TAU(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by CHETRD.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. $LWORK \geq N-1$. For optimum performance $LWORK \geq (N-1)*NB$, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = - i , the i -th argument had an illegal value

```
SUBROUTINE UNMBR_64(VECT, SIDE, [TRANS], [M], [N], K, A, [LDA], TAU,
                   C, [LDC], [WORK], [LWORK], [INFO])
```

```
CHARACTER(LEN=1) :: VECT, SIDE, TRANS
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:,:) :: A, C
INTEGER(8) :: M, N, K, LDA, LDC, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cunmbr(char vect, char side, char trans, int m, int n,
            int k, complex *a, int lda, complex *tau, complex
            *c, int ldc, int *info);
```

```
void cunmbr_64(char vect, char side, char trans, long m,
              long n, long k, complex *a, long lda, complex
              *tau, complex *c, long ldc, long *info);
```

PURPOSE

cunmbr VECT = 'Q', CUNMBR overwrites the general complex M-by-N matrix C with

```

                SIDE = 'L'          SIDE = 'R' TRANS = 'N':
Q * C          C * Q TRANS = 'C':   Q**H * C          C *
Q**H
```

If VECT = 'P', CUNMBR overwrites the general complex M-by-N matrix C with

```

                SIDE = 'L'          SIDE = 'R'
TRANS = 'N':   P * C              C * P
TRANS = 'C':   P**H * C           C * P**H
```

Here Q and P**H are the unitary matrices determined by CGEBRD when reducing a complex matrix A to bidiagonal form: $A = Q * B * P**H$. Q and P**H are defined as products of elementary reflectors H(i) and G(i) respectively.

Let nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Thus nq is the order of the unitary matrix Q or P**H that is applied.

If VECT = 'Q', A is assumed to have been an NQ-by-K matrix:
if nq >= k, Q = H(1) H(2) . . . H(k);
if nq < k, Q = H(1) H(2) . . . H(nq-1).

If VECT = 'P', A is assumed to have been a K-by-NQ matrix:
if k < nq, P = G(1) G(2) . . . G(k);
if k >= nq, P = G(1) G(2) . . . G(nq-1).

ARGUMENTS

VECT (input)
= 'Q': apply Q or Q**H;
= 'P': apply P or P**H.

SIDE (input)
= 'L': apply Q, Q**H, P or P**H from the Left;
= 'R': apply Q, Q**H, P or P**H from the Right.

TRANS (input)
= 'N': No transpose, apply Q or P;
= 'C': Conjugate transpose, apply Q**H or P**H.

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) If VECT = 'Q', the number of columns in the original matrix reduced by CGEBRD. If VECT = 'P', the number of rows in the original matrix reduced by CGEBRD. K >= 0.

A (input) (LDA,min(nq,K)) if VECT = 'Q' (LDA,nq) if

VECT = 'P' The vectors which define the elementary reflectors $H(i)$ and $G(i)$, whose products determine the matrices Q and P , as returned by CGEBRD.

LDA (input)

The leading dimension of the array A . If VECT = 'Q', $LDA \geq \max(1, nq)$; if VECT = 'P', $LDA \geq \max(1, \min(nq, K))$.

TAU (input)

TAU(i) must contain the scalar factor of the elementary reflector $H(i)$ or $G(i)$ which determines Q or P , as returned by CGEBRD in the array argument TAUQ or TAUP.

C (input/output)

On entry, the M -by- N matrix C . On exit, C is overwritten by Q^*C or $Q^{**H}C$ or C^*Q^{**H} or C^*Q or P^*C or $P^{**H}C$ or C^*P or C^*P^{**H} .

LDC (input)

The leading dimension of the array C . $LDC \geq \max(1, M)$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If SIDE = 'L', $LWORK \geq \max(1, N)$; if SIDE = 'R', $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N \cdot NB$ if SIDE = 'L', and $LWORK \geq M \cdot NB$ if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

COMPLEX, DIMENSION(:) :: TAU, WORK  
COMPLEX, DIMENSION(:, :) :: A, C  
INTEGER(8) :: M, N, ILO, IHI, LDA, LDC, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cunmhr(char side, char trans, int m, int n, int ilo,  
           int ihi, complex *a, int lda, complex *tau, com-  
           plex *c, int ldc, int *info);
```

```
void cummhr_64(char side, char trans, long m, long n, long
  ilo, long ihi, complex *a, long lda, complex *tau,
  complex *c, long ldc, long *info);
```

PURPOSE

cummhr overwrites the general complex M-by-N matrix C with
 TRANS = 'C': $Q^{*H} * C$ $C * Q^{*H}$

where Q is a complex unitary matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of IHI-ILO elementary reflectors, as returned by CGEHRD:

$Q = H(ilo) H(ilo+1) . . . H(ihi-1).$

ARGUMENTS

SIDE (input)

= 'L': apply Q or Q^{*H} from the Left;
 = 'R': apply Q or Q^{*H} from the Right.

TRANS (input)

= 'N': apply Q (No transpose)
 = 'C': apply Q^{*H} (Conjugate transpose)

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

ILO (input)

ILO and IHI must have the same values as in the previous call of CGEHRD. Q is equal to the unit matrix except in the submatrix $Q(ilo+1:ihi,ilo+1:ihi)$. If SIDE = 'L', then $1 \leq ILO \leq IHI \leq M$, if $M > 0$, and $ILO = 1$ and $IHI = 0$, if $M = 0$; if SIDE = 'R', then $1 \leq ILO \leq IHI \leq N$, if $N > 0$, and $ILO = 1$ and $IHI = 0$, if $N = 0$.

IHI (input)

See the description of ILO.

A (input) (LDA,M) if SIDE = 'L' (LDA,N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by CGEHRD.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,M)$ if SIDE = 'L'; $LDA \geq \max(1,N)$ if SIDE = 'R'.

TAU (input)

(M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEHRD.

C (input/output)

On entry, the M-by-N matrix C. On exit, C is

overwritten by Q^*C or $Q^{**H}C$ or C^*Q^{**H} or C^*Q .

LDC (input)

The leading dimension of the array C. LDC \geq max(1,M).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If SIDE = 'L', LWORK \geq max(1,N); if SIDE = 'R', LWORK \geq max(1,M). For optimum performance LWORK \geq N*NB if SIDE = 'L', and LWORK \geq M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

```

```

        ldc, int *info);

void cunml2_64(char side, char trans, long m, long n, long
              k, complex *a, long lda, complex *tau, complex *c,
              long ldc, long *info);

```

PURPOSE

cunml2 overwrites the general complex m-by-n matrix C with
 where Q is a complex unitary matrix defined as the product
 of k elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by CGELQF. Q is of order m if SIDE = 'L' and of
 order n if SIDE = 'R'.

ARGUMENTS

SIDE (input)
 = 'L': apply Q or Q' from the Left
 = 'R': apply Q or Q' from the Right

TRANS (input)
 = 'N': apply Q (No transpose)
 = 'C': apply Q' (Conjugate transpose)

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) The number of elementary reflectors whose product
 defines the matrix Q. If SIDE = 'L', M >= K >= 0;
 if SIDE = 'R', N >= K >= 0.

A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The
 i-th row must contain the vector which defines the
 elementary reflector H(i), for i = 1,2,...,k, as
 returned by CGELQF in the first k rows of its
 array argument A. A is modified by the routine
 but restored on exit.

LDA (input)
 The leading dimension of the array A. LDA >=
 max(1,K).

TAU (input)
 TAU(i) must contain the scalar factor of the ele-
 mentary reflector H(i), as returned by CGELQF.

C (input/output)
 On entry, the m-by-n matrix C. On exit, C is
 overwritten by Q*C or Q'*C or C*Q' or C*Q.

LDC (input)
 The leading dimension of the array C. LDC >=
 max(1,M).

COMPLEX, DIMENSION(:) :: TAU, WORK  
COMPLEX, DIMENSION(:,:) :: A, C  
INTEGER(8) :: M, N, K, LDA, LDC, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cunmlq(char side, char trans, int m, int n, int k, com-  
plex *a, int lda, complex *tau, complex *c, int  
ldc, int *info);
```

```
void cunmlq_64(char side, char trans, long m, long n, long
              k, complex *a, long lda, complex *tau, complex *c,
              long ldc, long *info);
```

PURPOSE

cunmlq overwrites the general complex M-by-N matrix C with
 TRANS = 'C': $Q^{*H} * C$ $C * Q^{*H}$

where Q is a complex unitary matrix defined as the product
 of k elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by CGELQF. Q is of order M if SIDE = 'L' and of
 order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)

= 'L': apply Q or Q^{*H} from the Left;
 = 'R': apply Q or Q^{*H} from the Right.

TRANS (input)

= 'N': No transpose, apply Q;
 = 'C': Conjugate transpose, apply Q^{*H} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

K (input) The number of elementary reflectors whose product
 defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$;
 if SIDE = 'R', $N \geq K \geq 0$.

A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The
 i-th row must contain the vector which defines the
 elementary reflector H(i), for $i = 1, 2, \dots, k$, as
 returned by CGELQF in the first k rows of its
 array argument A. A is modified by the routine
 but restored on exit.

LDA (input)

The leading dimension of the array A. $LDA \geq$
 $\max(1, K)$.

TAU (input)

TAU(i) must contain the scalar factor of the ele-
 mentary reflector H(i), as returned by CGELQF.

C (input/output)

On entry, the M-by-N matrix C. On exit, C is
 overwritten by $Q * C$ or $Q^{*H} * C$ or $C * Q^{*H}$ or $C * Q$.

LDC (input)

The leading dimension of the array C. $LDC \geq$
 $\max(1, M)$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If SIDE = 'L', LWORK \geq max(1,N); if SIDE = 'R', LWORK \geq max(1,M). For optimum performance LWORK \geq N*NB if SIDE 'L', and LWORK \geq M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

               k, complex *a, long lda, complex *tau, complex *c,
               long ldc, long *info);
```

PURPOSE

cunmql overwrites the general complex M-by-N matrix C with
 TRANS = 'C': $Q^{*H} * C$ $C * Q^{*H}$

where Q is a complex unitary matrix defined as the product
 of k elementary reflectors

$$Q = H(k) \dots H(2) H(1)$$

as returned by CGEQLF. Q is of order M if SIDE = 'L' and of
 order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
 = 'L': apply Q or Q^{*H} from the Left;
 = 'R': apply Q or Q^{*H} from the Right.

TRANS (input)
 = 'N': No transpose, apply Q;
 = 'C': Transpose, apply Q^{*H} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

K (input) The number of elementary reflectors whose product
 defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$;
 if SIDE = 'R', $N \geq K \geq 0$.

A (input) The i-th column must contain the vector which
 defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$,
 as returned by CGEQLF in the last k columns of its array
 argument A. A is modified by the routine but restored on
 exit.

LDA (input)
 The leading dimension of the array A. If SIDE = 'L',
 $LDA \geq \max(1, M)$; if SIDE = 'R', $LDA \geq \max(1, N)$.

TAU (input)
 TAU(i) must contain the scalar factor of the elementary
 reflector $H(i)$, as returned by CGEQLF.

C (input/output)
 On entry, the M-by-N matrix C. On exit, C is overwritten
 by $Q * C$ or $Q^{*H} * C$ or $C * Q^{*H}$ or $C * Q$.

LDC (input)
 The leading dimension of the array C. $LDC \geq \max(1, M)$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If SIDE = 'L', LWORK \geq max(1,N); if SIDE = 'R', LWORK \geq max(1,M). For optimum performance LWORK \geq N*NB if SIDE = 'L', and LWORK \geq M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

```

PURPOSE

cunmqr overwrites the general complex M-by-N matrix C with
 TRANS = 'C': $Q^{*H} * C$ $C * Q^{*H}$

where Q is a complex unitary matrix defined as the product
 of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by CGEQRF. Q is of order M if SIDE = 'L' and of
 order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)

= 'L': apply Q or Q^{*H} from the Left;
 = 'R': apply Q or Q^{*H} from the Right.

TRANS (input)

= 'N': No transpose, apply Q;
 = 'C': Conjugate transpose, apply Q^{*H} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

K (input) The number of elementary reflectors whose product
 defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$;
 if SIDE = 'R', $N \geq K \geq 0$.

A (input) The i-th column must contain the vector which
 defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by CGEQRF in the first k
 columns of its array argument A. A is modified by
 the routine but restored on exit.

LDA (input)

The leading dimension of the array A. If SIDE =
 'L', $LDA \geq \max(1, M)$; if SIDE = 'R', $LDA \geq$
 $\max(1, N)$.

TAU (input)

TAU(i) must contain the scalar factor of the ele-
 mentary reflector H(i), as returned by CGEQRF.

C (input/output)

On entry, the M-by-N matrix C. On exit, C is
 overwritten by $Q * C$ or $Q^{*H} * C$ or $C * Q^{*H}$ or $C * Q$.

LDC (input)

The leading dimension of the array C. $LDC \geq$
 $\max(1, M)$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If SIDE = 'L', LWORK \geq max(1,N); if SIDE = 'R', LWORK \geq max(1,M). For optimum performance LWORK \geq N*NB if SIDE = 'L', and LWORK \geq M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

PURPOSE

cummr2 overwrites the general complex m-by-n matrix C with where Q is a complex unitary matrix defined as the product of k elementary reflectors

$$Q = H(1)' H(2)' \dots H(k)'$$

as returned by CGERQF. Q is of order m if SIDE = 'L' and of order n if SIDE = 'R'.

ARGUMENTS

SIDE (input)
 = 'L': apply Q or Q' from the Left
 = 'R': apply Q or Q' from the Right

TRANS (input)
 = 'N': apply Q (No transpose)
 = 'C': apply Q' (Conjugate transpose)

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGERQF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

LDA (input)
 The leading dimension of the array A. LDA >= max(1,K).

TAU (input)
 TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGERQF.

C (input/output)
 On entry, the m-by-n matrix C. On exit, C is overwritten by Q*C or Q'*C or C*Q' or C*Q.

LDC (input)
 The leading dimension of the array C. LDC >= max(1,M).

```

PURPOSE

cunmrq overwrites the general complex M-by-N matrix C with
 TRANS = 'C': $Q^{*H} * C$ $C * Q^{*H}$

where Q is a complex unitary matrix defined as the product
 of k elementary reflectors

$$Q = H(1)' H(2)' \dots H(k)'$$

as returned by CGERQF. Q is of order M if SIDE = 'L' and of
 order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)

= 'L': apply Q or Q^{*H} from the Left;
 = 'R': apply Q or Q^{*H} from the Right.

TRANS (input)

= 'N': No transpose, apply Q;
 = 'C': Transpose, apply Q^{*H} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

K (input) The number of elementary reflectors whose product
 defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$;
 if SIDE = 'R', $N \geq K \geq 0$.

A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The
 i-th row must contain the vector which defines the
 elementary reflector H(i), for $i = 1, 2, \dots, k$, as
 returned by CGERQF in the last k rows of its array
 argument A. A is modified by the routine but
 restored on exit.

LDA (input)

The leading dimension of the array A. $LDA \geq$
 $\max(1, K)$.

TAU (input)

TAU(i) must contain the scalar factor of the ele-
 mentary reflector H(i), as returned by CGERQF.

C (input/output)

On entry, the M-by-N matrix C. On exit, C is
 overwritten by $Q * C$ or $Q^{*H} * C$ or $C * Q^{*H}$ or $C * Q$.

LDC (input)

The leading dimension of the array C. $LDC \geq$
 $\max(1, M)$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If SIDE = 'L', LWORK \geq max(1,N); if SIDE = 'R', LWORK \geq max(1,M). For optimum performance LWORK \geq N*NB if SIDE = 'L', and LWORK \geq M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

cunmrz overwrites the general complex M-by-N matrix C with
TRANS = 'C': $Q^{*H} * C$ $C * Q^{*H}$

where Q is a complex unitary matrix defined as the product of k elementary reflectors

$$Q = H(1) H(2) . . . H(k)$$

as returned by CTZRZF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q^{*H} from the Left;
= 'R': apply Q or Q^{*H} from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'C': Conjugate transpose, apply Q^{*H} .

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

K (input) The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$; if SIDE = 'R', $N \geq K \geq 0$.

L (input) The number of columns of the matrix A containing the meaningful part of the Householder reflectors. If SIDE = 'L', $M \geq L \geq 0$, if SIDE = 'R', $N \geq L \geq 0$.

A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by CTZRZF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, K)$.

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CTZRZF.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by $Q * C$ or $Q^{*H} * C$ or $C * Q^{*H}$ or $C * Q$.

LDC (input)
The leading dimension of the array C. LDC \geq max(1,M).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', LWORK \geq max(1,N); if SIDE = 'R', LWORK \geq max(1,M). For optimum performance LWORK \geq N*NB if SIDE = 'L', and LWORK \geq M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>
```

```
void cumtr(char side, char uplo, char trans, int m, int n,  
          complex *a, int lda, complex *tau, complex *c, int  
          ldc, int *info);
```

```

void cummtr_64(char side, char uplo, char trans, long m,
               long n, complex *a, long lda, complex *tau, complex *c, long ldc, long *info);

```

PURPOSE

cummtr overwrites the general complex M-by-N matrix C with
 TRANS = 'C': $Q^{*H} * C$ $C * Q^{*H}$

where Q is a complex unitary matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of nq-1 elementary reflectors, as returned by CHETRD:

```
if UPLO = 'U', Q = H(nq-1) . . . H(2) H(1);
```

```
if UPLO = 'L', Q = H(1) H(2) . . . H(nq-1).
```

ARGUMENTS

SIDE (input)
 = 'L': apply Q or Q**H from the Left;
 = 'R': apply Q or Q**H from the Right.

UPLO (input)
 = 'U': Upper triangle of A contains elementary reflectors from CHETRD; = 'L': Lower triangle of A contains elementary reflectors from CHETRD.

TRANS (input)
 = 'N': No transpose, apply Q;
 = 'C': Conjugate transpose, apply Q**H.

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

A (input) (LDA,M) if SIDE = 'L' (LDA,N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by CHETRD.

LDA (input)
 The leading dimension of the array A. LDA >= max(1,M) if SIDE = 'L'; LDA >= max(1,N) if SIDE = 'R'.

TAU (input)
 (M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CHETRD.

C (input/output)
 On entry, the M-by-N matrix C. On exit, C is overwritten by Q*C or Q**H*C or C*Q**H or C*Q.

LDC (input)
 The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If SIDE = 'L', LWORK \geq max(1,N); if SIDE = 'R', LWORK \geq max(1,M). For optimum performance LWORK \geq N*NB if SIDE = 'L', and LWORK \geq M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

COMPLEX, DIMENSION(:, :) :: Q  
INTEGER(8) :: N, LDQ, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cupgtr(char uplo, int n, complex *ap, complex *tau,  
            complex *q, int ldq, int *info);
```

```
void cupgtr_64(char uplo, long n, complex *ap, complex *tau,  
               complex *q, long ldq, long *info);
```

PURPOSE

cupgtr generates a complex unitary matrix Q which is defined as the product of $n-1$ elementary reflectors $H(i)$ of order n , as returned by CHPTRD using packed storage:

if UPLO = 'U', $Q = H(n-1) \dots H(2) H(1)$,

if UPLO = 'L', $Q = H(1) H(2) \dots H(n-1)$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangular packed storage used in previous call to CHPTRD; = 'L': Lower triangular packed storage used in previous call to CHPTRD.

N (input) The order of the matrix Q . $N \geq 0$.

AP (input)

The vectors which define the elementary reflectors, as returned by CHPTRD.

TAU (input)

TAU(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by CHPTRD.

Q (output)

The N -by- N unitary matrix Q .

LDQ (input)

The leading dimension of the array Q . $LDQ \geq \max(1, N)$.

WORK (workspace)

dimension($N-1$)

INFO (output)

= 0: successful exit

< 0: if INFO = $-i$, the i -th argument had an illegal value

              long n, complex *ap, complex *tau, complex *c,
              long ldc, long *info);
```

PURPOSE

cupmtr overwrites the general complex M-by-N matrix C with
 TRANS = 'C': $Q^{*H} * C$ $C * Q^{*H}$

where Q is a complex unitary matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of nq-1 elementary reflectors, as returned by CHPTRD using packed storage:

if UPLO = 'U', Q = H(nq-1) . . . H(2) H(1);

if UPLO = 'L', Q = H(1) H(2) . . . H(nq-1).

ARGUMENTS

SIDE (input)
 = 'L': apply Q or Q**H from the Left;
 = 'R': apply Q or Q**H from the Right.

UPLO (input)
 = 'U': Upper triangular packed storage used in previous call to CHPTRD; = 'L': Lower triangular packed storage used in previous call to CHPTRD.

TRANS (input)
 = 'N': No transpose, apply Q;
 = 'C': Conjugate transpose, apply Q**H.

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

AP (input)
 (M*(M+1)/2) if SIDE = 'L' (N*(N+1)/2) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by CHPTRD. AP is modified by the routine but restored on exit.

TAU (input)
 or (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CHPTRD.

C (input/output)
 On entry, the M-by-N matrix C. On exit, C is overwritten by Q*C or Q**H*C or C*Q**H or C*Q.

LDC (input)
 The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)
 (N) if SIDE = 'L' (M) if SIDE = 'R'

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

DESCRIPTION

$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$
where ALPHA and BETA are scalar, C and B are matrices,
A is a matrix represented in variable block sparse row format
and $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = A$ or $\operatorname{op}(A) = A'$ or $\operatorname{op}(A) = \operatorname{conjg}(A')$.
(' indicates matrix transpose)

ARGUMENTS

TRANSA Indicates how to operate with the sparse matrix
 0 : operate with matrix
 1 : operate with transpose matrix
 2 : operate with the conjugate transpose of matrix.
 2 is equivalent to 1 if the matrix is real.

MB Number of block rows in matrix A

N Number of columns in matrix C

KB Number of block columns in matrix A

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array
DESCRA(1) matrix structure
 0 : general
 1 : symmetric (A=A')
 2 : Hermitian (A= CONJG(A'))
 3 : Triangular
 4 : Skew(Anti)-Symmetric (A=-A')
 5 : Diagonal
 6 : Skew-Hermitian (A= -CONJG(A'))
DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper
DESCRA(3) main diagonal type
 0 : non-unit
 1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL() scalar array of length NNZ consisting of the block entries
 of A where each block entry is a dense rectangular matrix
 stored column by column.
 NNZ is the total number of point entries in all nonzero
 block entries of a matrix A.

INDX() integer array of length BNNZ+1 where BNNZ is the number of
 block entries of a matrix A such that the I-th element of
 INDX[] points to the location in VAL of the (1,1) element
 of the I-th block entry.

BINDX() integer array of length BNNZ consisting of the block

column indices of the block entries of A where BNNZ is the number block entries of a matrix A.

RPNTR() integer array of length MB+1 such that RPNTR(I)-RPNTR(1)+1 is the row index of the first point row in the I-th block row. RPNTR(MB+1) is set to M+RPNTR(1) where M is the number of rows in matrix A. Thus, the number of point rows in the I-th block row is RPNTR(I+1)-RPNTR(I).

CPNTR() integer array of length KB+1 such that CPNTR(J)-CPNTR(1)+1 is the column index of the first point column in the J-th block column. CPNTR(KB+1) is set to K+CPNTR(1) where K is the number of columns in matrix A. Thus, the number of point columns in the J-th block column is CPNTR(J+1)-CPNTR(J).

BPNTRB() integer array of length MB such that BPNTRB(I)-BPNTRB(1)+1 points to location in BINDX of the first block entry of the I-th block row of A.

BPNTRE() integer array of length MB such that BPNTRE(I)-BPNTRB(1) points to location in BINDX of the last block entry of the I-th block row of A.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK. WORK is not referenced in the current version.

LWORK length of WORK array. LWORK is not referenced in the current version.

NOTES/BUGS

1. For a general matrix (*DESCRA*(1)=0), array CPNTR can be different from RPNTR. For all other matrix types, RPNTR must equal CPNTR and a single array can be passed for both arguments.

2. It is known that there exists another representation of the variable block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS,

DESCRIPTION

```
C <- ALPHA op(A) B + BETA C      C <- ALPHA D op(A) B + BETA C
C <- ALPHA op(A) D B + BETA C
where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a block diagonal matrix, A is a unit, or non-unit, upper or
lower triangular matrix represented in variable block sparse row
format and op( A ) is one of
```

```
op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))
(inv denotes matrix inverse, ' indicates matrix transpose)
```

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real.
MB	Number of block rows in matrix A
N	Number of columns in matrix C
UNITD	Type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row block scaling) 3 : Scale on right (column block scaling)
DV()	Array containing the block entries of the block diagonal matrix D. The size of the J-th block is RPNTR(J+1)-RPNTR(J) and each block contains matrix entries stored column-major. The total length of array DV is given by the formula: sum over J from 1 to MB: ((RPNTR(J+1)-RPNTR(J))*(RPNTR(J+1)-RPNTR(J)))
ALPHA	Scalar parameter
DESCRA()	Descriptor argument. Five element integer array DESCRA(1) matrix structure 0 : general 1 : symmetric (A=A') 2 : Hermitian (A= CONJG(A')) 3 : Triangular 4 : Skew(Anti)-Symmetric (A=-A') 5 : Diagonal 6 : Skew-Hermitian (A= -CONJG(A')) Note: For the routine, DESCRA(1)=3 is only supported. DESCRA(2) upper/lower triangular indicator 1 : lower 2 : upper DESCRA(3) main diagonal type 0 : non-identity blocks on the main diagonal 1 : identity diagonal block 2 : diagonal blocks are dense matrices DESCRA(4) Array base (NOT IMPLEMENTED) 0 : C/C++ compatible 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL() scalar array of length NNZ consisting of the block entries of A where each block entry is a dense rectangular matrix stored column by column. NNZ is the total number of point entries in all nonzero block entries of a matrix A.

INDX() integer array of length BNNZ+1 where BNNZ is the number block entries of a matrix A such that the I-th element of INDX[] points to the location in VAL of the (1,1) element of the I-th block entry.

BINDX() integer array of length BNNZ consisting of the block column indices of the block entries of A where BNNZ is the number block entries of a matrix A. Block column indices MUST be sorted in increasing order for each block row.

RPNTR() integer array of length MB+1 such that RPNTR(I)-RPNTR(1)+1 is the row index of the first point row in the I-th block row. RPNTR(MB+1) is set to M+RPNTR(1) where M is the number of rows in square triangular matrix A. Thus, the number of point rows in the I-th block row is RPNTR(I+1)-RPNTR(I).

NOTE: For the current version CPNTR must equal RPNTR and a single array can be passed for both arguments

CPNTR() integer array of length MB+1 such that CPNTR(J)-CPNTR(1)+1 is the column index of the first point column in the J-th block column. CPNTR(MB+1) is set to M+CPNTR(1). Thus, the number of point columns in the J-th block column is CPNTR(J+1)-CPNTR(J).

NOTE: For the current version CPNTR must equal RPNTR and a single array can be passed for both arguments

BPNTRB() integer array of length MB such that BPNTRB(I)-BPNTRB(1)+1 points to location in BINDX of the first block entry of the I-th block row of A.

BPNTRE() integer array of length MB such that BPNTRE(I)-BPNTRB(1) points to location in BINDX of the last block entry of the I-th block row of A.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK. On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK length of WORK array. LWORK should be at least $M = \text{RPNTR}(\text{MB}+1) - \text{RPNTR}(1)$.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >= M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If *DESCRA*(3)=0, the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).
3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the VBR representation of a sparse matrix. They are not used anyway.
4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. *WORK*(1)=0 on return if the factorization for all diagonal blocks has been completed successfully, otherwise *WORK*(1) = -i where i is the block number for which the LU factorization could not be computed.
5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case. *DESCRA*(2) indicates which triangle will be used.
6. It is known that there exists another representation of the variable block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of six array instead of the seven used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block row in the array BINDX is used instead of two arrays BPNTTB and BPNTRE. To use the routine with this kind of variable block sparse row format the following calling sequence should be used

```
SUBROUTINE CVBRSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,  
* VAL, INDX, BINDX, RPNTR, CPNTR, IA, IA(2),  
* B, LDB, BETA, C, LDC, WORK, LWORK )
```

NAME

cvmul - compute the scaled product of complex vectors

SYNOPSIS

```
SUBROUTINE CVMUL(N, ALPHA, X, INCX, Y, INCY, BETA, Z, INCZ)
```

```
COMPLEX ALPHA, BETA  
COMPLEX X(*), Y(*), Z(*)  
INTEGER N, INCX, INCY, INCZ
```

```
SUBROUTINE CVMUL_64(N, ALPHA, X, INCX, Y, INCY, BETA, Z, INCZ)
```

```
COMPLEX ALPHA, BETA  
COMPLEX X(*), Y(*), Z(*)  
INTEGER*8 N, INCX, INCY, INCZ
```

F95 INTERFACE

```
SUBROUTINE VMUL([N], ALPHA, X, [INCX], Y, [INCY], BETA, Z, [INCZ])
```

```
COMPLEX :: ALPHA, BETA  
COMPLEX, DIMENSION(:) :: X, Y, Z  
INTEGER :: N, INCX, INCY, INCZ
```

```
SUBROUTINE VMUL_64([N], ALPHA, X, [INCX], Y, [INCY], BETA, Z, [INCZ])
```

```
COMPLEX :: ALPHA, BETA  
COMPLEX, DIMENSION(:) :: X, Y, Z  
INTEGER(8) :: N, INCX, INCY, INCZ
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cvmul(int n, complex *alpha, complex *x, int incx, complex *y, int incy, complex *beta, complex *z, int incz);
```

```
void cvmul_64(long n, complex *alpha, complex *x, long incx, complex *y, long incy, complex *beta, complex *z, long incz);
```

PURPOSE

cvmul computes the scaled product of complex vectors:
 $z(i) = \text{ALPHA} * x(i) * y(i) + \text{BETA} * z(i)$
for $1 \leq i \leq N$.

ARGUMENTS

N (input)
Length of the vectors. $N \geq 0$. Returns immediately if $N = 0$.

ALPHA (input)
Scale factor on the multiplicand vectors.

X (input) dimension(*)
Multiplicand vector.

INCX (input)
Stride between elements of the multiplicand vector X. $\text{INCX} > 0$.

Y (input) dimension(*)
Multiplicand vector.

INCY (input)
Stride between elements of the multiplicand vector Y. $\text{INCY} > 0$.

BETA (input)
Scale factor on the product vector.

Z (input/output) dimension(*)
Product vector. On exit, $z(i) = \text{ALPHA} * x(i) * y(i) + \text{BETA} * z(i)$.

INCZ (input)
Stride between elements of Z. $\text{INCZ} > 0$.

NAME

dasum - Return the sum of the absolute values of a vector x.

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DASUM(N, X, INCX)
```

```
INTEGER N, INCX  
DOUBLE PRECISION X(*)
```

```
DOUBLE PRECISION FUNCTION DASUM_64(N, X, INCX)
```

```
INTEGER*8 N, INCX  
DOUBLE PRECISION X(*)
```

F95 INTERFACE

```
REAL(8) FUNCTION ASUM([N], X, [INCX])
```

```
INTEGER :: N, INCX  
REAL(8), DIMENSION(:) :: X
```

```
REAL(8) FUNCTION ASUM_64([N], X, [INCX])
```

```
INTEGER(8) :: N, INCX  
REAL(8), DIMENSION(:) :: X
```

C INTERFACE

```
#include <sunperf.h>
```

```
double dasum(int n, double *x, int incx);
```

```
double dasum_64(long n, double *x, long incx);
```

PURPOSE

dasum Return the sum of the absolute values of x where x is an n-vector.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)

($1 + (n - 1) * \text{abs}(\text{INCX})$). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

NAME

daxpy - compute $y := \alpha * x + y$

SYNOPSIS

```
SUBROUTINE DAXPY(N, ALPHA, X, INCX, Y, INCY)
```

```
INTEGER N, INCX, INCY  
DOUBLE PRECISION ALPHA  
DOUBLE PRECISION X(*), Y(*)
```

```
SUBROUTINE DAXPY_64(N, ALPHA, X, INCX, Y, INCY)
```

```
INTEGER*8 N, INCX, INCY  
DOUBLE PRECISION ALPHA  
DOUBLE PRECISION X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE AXPY([N], ALPHA, X, [INCX], Y, [INCY])
```

```
INTEGER :: N, INCX, INCY  
REAL(8) :: ALPHA  
REAL(8), DIMENSION(:) :: X, Y
```

```
SUBROUTINE AXPY_64([N], ALPHA, X, [INCX], Y, [INCY])
```

```
INTEGER(8) :: N, INCX, INCY  
REAL(8) :: ALPHA  
REAL(8), DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void daxpy(int n, double alpha, double *x, int incx, double  
          *y, int incy);
```

```
void daxpy_64(long n, double alpha, double *x, long incx,  
             double *y, long incy);
```

PURPOSE

daxpy compute $y := \text{alpha} * x + y$ where alpha is a scalar and x and y are n-vectors.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)

($1 + (n - 1) * \text{abs}(\text{INCX})$). Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input/output)

($1 + (n - 1) * \text{abs}(\text{INCY})$). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

daxpyi - Compute $y := \alpha * x + y$

SYNOPSIS

```
SUBROUTINE DAXPYI(NZ, A, X, INDX, Y)

DOUBLE PRECISION A
DOUBLE PRECISION X(*), Y(*)
INTEGER NZ
INTEGER INDX(*)

SUBROUTINE DAXPYI_64(NZ, A, X, INDX, Y)

DOUBLE PRECISION A
DOUBLE PRECISION X(*), Y(*)
INTEGER*8 NZ
INTEGER*8 INDX(*)

F95 INTERFACE
SUBROUTINE AXPYI([NZ], [A], X, INDX, Y)

REAL(8) :: A
REAL(8), DIMENSION(:) :: X, Y
INTEGER :: NZ
INTEGER, DIMENSION(:) :: INDX

SUBROUTINE AXPYI_64([NZ], [A], X, INDX, Y)

REAL(8) :: A
REAL(8), DIMENSION(:) :: X, Y
INTEGER(8) :: NZ
INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

DAXPYI Compute $y := \alpha * x + y$ where α is a scalar, x is a sparse vector, and y is a vector in full storage form

```
do i = 1, n
  y(indx(i)) = alpha * x(i) + y(indx(i))
enddo
```

ARGUMENTS

NZ (input) - INTEGER

Number of elements in the compressed form.
Unchanged on exit.

A (input)

On entry, A(LPHA) specifies the scaling value.
Unchanged on exit. A is defaulted to 1.0D0 for F95
INTERFACE.

X (input)

Vector containing the values of the compressed form.
Unchanged on exit.

INDX (input) - INTEGER

Vector containing the indices of the compressed
form. It is assumed that the elements in INDX are
distinct and greater than zero. Unchanged on exit.

Y (output)

Vector on input which contains the vector Y in full
storage form. On exit, only the elements
corresponding to the indices in INDX have been
modified.

DOUBLE PRECISION, DIMENSION(:, :) :: B, C  
  
SUBROUTINE BCOMM_64(TRANSA,MB,N,KB,ALPHA,DESCRA,VAL,BINDX, BJNDX,  
* BNNZ, LB, B, [LDB], BETA, C,[LDC], [WORK], [LWORK])  
INTEGER*8        TRANSA, MB, N, KB, BNNZ, LB  
INTEGER*8, DIMENSION(:) :: DESCRA, BINDX, BJNDX  
DOUBLE PRECISION ALPHA, BETA  
DOUBLE PRECISION, DIMENSION(:) :: VAL  
DOUBLE PRECISION, DIMENSION(:, :) :: B, C
```

DESCRIPTION

```
C <- alpha op(A) B + beta C
```

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in block coordinate format and
op(A) is one of

```
op( A ) = A    or    op( A ) = A'    or    op( A ) = conjg( A' ).  
                ( ' indicates matrix transpose)
```

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if the matrix is real.
MB	Number of block rows in matrix A
N	Number of columns in matrix C
KB	Number of block columns in matrix A
ALPHA	Scalar parameter
DESCRA()	Descriptor argument. Five element integer array DESCRA(1) matrix structure 0 : general 1 : symmetric (A=A') 2 : Hermitian (A= CONJG(A')) 3 : Triangular 4 : Skew(Anti)-Symmetric (A=-A') 5 : Diagonal 6 : Skew-Hermitian (A= -CONJG(A')) DESCRA(2) upper/lower triangular indicator 1 : lower 2 : upper DESCRA(3) main diagonal type 0 : non-unit 1 : unit DESCRA(4) Array base (NOT IMPLEMENTED) 0 : C/C++ compatible 1 : Fortran compatible DESCRA(5) repeated indices? (NOT IMPLEMENTED) 0 : unknown 1 : no repeated indices
VAL()	scalar array of length LB*LB*BNNZ consisting of the non-zero block entries of A, in any order. Each block is stored in standard column-major form.
BINDX()	integer array of length BNNZ consisting of the block row indices of the block entries of A.
BJNDX()	integer array of length BNNZ consisting of the block column indices of the block entries of A.
BNNZ	number of block entries

LB	dimension of dense blocks composing A.
B() LDB	rectangular array with first dimension LDB. leading dimension of B
BETA	Scalar parameter
C() LDC	rectangular array with first dimension LDC. leading dimension of C
WORK()	scratch array of length LWORK. WORK is not referenced in the current version.
LWORK	length of WORK array. LWORK is not referenced in the current version.

```

DESCRIPTION

```
C <- ALPHA op(A) B + BETA C      C <- ALPHA D op(A) B + BETA C
C <- ALPHA op(A) D B + BETA C
```

where ALPHA and BETA are scalar, C and B are m by n dense matrices, D is a block diagonal matrix, A is a unit, or non-unit, upper or lower triangular matrix represented in block diagonal format and op(A) is one of
op(A) = inv(A) or op(A) = inv(A') or op(A) =inv(conjg(A'))
(inv denotes matrix inverse, ' indicates matrix transpose)

ARGUMENTS

TRANSA Indicates how to operate with the sparse matrix
 0 : operate with matrix
 1 : operate with transpose matrix
 2 : operate with the conjugate transpose of matrix.
 2 is equivalent to 1 if matrix is real.

MB Number of block rows in matrix A

N Number of columns in matrix C

UNITD Type of scaling:
 1 : Identity matrix (argument DV[] is ignored)
 2 : Scale on left (row scaling)
 3 : Scale on right (column scaling)

DV() Array of length MB*LB*LB containing the elements of the diagonal blocks of the matrix D. The size of each square block is LB-by-LB and each block is stored in standard column-major form.

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array
DESCRA(1) matrix structure
 0 : general
 1 : symmetric (A=A')
 2 : Hermitian (A= CONJG(A'))
 3 : Triangular
 4 : Skew(Anti)-Symmetric (A=-A')
 5 : Diagonal
 6 : Skew-Hermitian (A= -CONJG(A'))
Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper

DESCRA(3) main diagonal type
 0 : non-identity blocks on the main diagonal
 1 : identity diagonal blocks
 2 : diagonal blocks are dense matrices

DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL() Two-dimensional LB*LB*BLDA-by-NBDIAG scalar array

consisting of the NBDIAG non-zero block diagonal.
Each dense block is stored in standard column-major form.

BLDA Leading block dimension of VAL(). Should be greater than or equal to MB.

IBDIAG() integer array of length NBDIAG consisting of the corresponding diagonal offsets of the non-zero block diagonals of A in VAL. Lower triangular block diagonals have negative offsets, the main block diagonal has offset 0, and upper triangular block diagonals have positive offset. Elements of IBDIAG MUST be sorted in increasing order.

NBDIAG The number of non-zero block diagonals in A.

LB Dimension of dense blocks composing A.

B() Rectangular array with first dimension LDB.

LDB Leading dimension of B.

BETA Scalar parameter.

C() Rectangular array with first dimension LDC.

LDC Leading dimension of C.

WORK() scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK length of WORK array. LWORK should be at least MB*LB.

For good performance, LWORK should generally be larger.
For optimum performance on multiple processors, LWORK \geq MB*LB*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If *DESCRA*(3)=0, the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).

3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the BDI representation of a sparse matrix. They are not used anyway.

4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. *WORK*(1)=0 on return if the factorization for all diagonal blocks has been completed successfully, otherwise *WORK*(1) = -i where i is the block number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

C INTERFACE

```
#include <sunperf.h>

void dbdsdc(char uplo, char compq, int n, double *d, double
            *e, double *u, int ldu, double *vt, int ldvt,
            double *q, int *iq, int *info);

void dbdsdc_64(char uplo, char compq, long n, double *d,
              double *e, double *u, long ldu, double *vt, long
              ldvt, double *q, long *iq, long *info);
```

PURPOSE

dbdsdc computes the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B: $B = U * S * VT$, using a divide and conquer method, where S is a diagonal matrix with non-negative diagonal elements (the singular values of B), and U and VT are orthogonal matrices of left and right singular vectors, respectively. SBDSDC can be used to compute all singular values, and optionally, singular vectors or singular vectors in compact form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See SLASD3 for details.

The code currently call SLASDQ if singular values only are desired. However, it can be slightly modified to compute singular values using the divide and conquer method.

ARGUMENTS

UPLO (input)

= 'U': B is upper bidiagonal.
= 'L': B is lower bidiagonal.

COMPQ (input)

Specifies whether singular vectors are to be computed as follows:
= 'N': Compute singular values only;
= 'P': Compute singular values and compute singular vectors in compact form; = 'I': Compute singular values and singular vectors.

N (input) The order of the matrix B. $N \geq 0$.

D (input/output)

On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if INFO=0, the singular values of B.

E (input/output)

On entry, the elements of E contain the offdiagonal elements of the bidiagonal matrix whose SVD is desired. On exit, E has been destroyed.

U (output)
 If COMPQ = 'I', then: On exit, if INFO = 0, U contains the left singular vectors of the bidiagonal matrix. For other values of COMPQ, U is not referenced.

LDU (input)
 The leading dimension of the array U. LDU \geq 1. If singular vectors are desired, then LDU \geq max(1, N).

VT (output)
 If COMPQ = 'I', then: On exit, if INFO = 0, VT contains the right singular vectors of the bidiagonal matrix. For other values of COMPQ, VT is not referenced.

LDVT (input)
 The leading dimension of the array VT. LDVT \geq 1. If singular vectors are desired, then LDVT \geq max(1, N).

Q (input) If COMPQ = 'P', then: On exit, if INFO = 0, Q and IQ contain the left and right singular vectors in a compact form, requiring $O(N \log N)$ space instead of $2*N**2$. In particular, Q contains all the REAL data in LDQ $\geq N*(11 + 2*SMLSIZ + 8*INT(LOG_2(N/(SMLSIZ+1))))$ words of memory, where SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25). For other values of COMPQ, Q is not referenced.

IQ (output)
 If COMPQ = 'P', then: On exit, if INFO = 0, Q and IQ contain the left and right singular vectors in a compact form, requiring $O(N \log N)$ space instead of $2*N**2$. In particular, IQ contains all INTEGER data in LDIQ $\geq N*(3 + 3*INT(LOG_2(N/(SMLSIZ+1))))$ words of memory, where SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25). For other values of COMPQ, IQ is not referenced.

WORK (workspace)
 If COMPQ = 'N' then LWORK $\geq (2 * N)$. If COMPQ = 'P' then LWORK $\geq (6 * N)$. If COMPQ = 'I' then LWORK $\geq (3 * N**2 + 4 * N)$.

IWORK (workspace)
 dimension(8*N)

INFO (output)
 = 0: successful exit.
 < 0: if INFO = -i, the i-th argument had an illegal value.
 > 0: The algorithm failed to compute an singular value. The update process of divide and conquer failed.

void dbdsqr_64(char uplo, long n, long ncvt, long nru, long
    ncc, double *d, double *e, double *vt, long ldvt,
    double *u, long ldu, double *c, long ldc, long
    *info);

```

PURPOSE

dbdsqr computes the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B: $B = Q * S * P'$ (P' denotes the transpose of P), where S is a diagonal matrix with non-negative diagonal elements (the singular values of B), and Q and P are orthogonal matrices.

The routine computes S, and optionally computes $U * Q$, $P' * VT$, or $Q' * C$, for given real input matrices U, VT, and C.

See "Computing Small Singular Values of Bidiagonal Matrices With Guaranteed High Relative Accuracy," by J. Demmel and W. Kahan, LAPACK Working Note #3 (or SIAM J. Sci. Statist. Comput. vol. 11, no. 5, pp. 873-912, Sept 1990) and "Accurate singular values and differential qd algorithms," by B. Parlett and V. Fernando, Technical Report CPAM-554, Mathematics Department, University of California at Berkeley, July 1992 for a detailed description of the algorithm.

ARGUMENTS

UPLO (input)
 = 'U': B is upper bidiagonal;
 = 'L': B is lower bidiagonal.

N (input) The order of the matrix B. $N \geq 0$.

NCVT (input)
 The number of columns of the matrix VT. $NCVT \geq 0$.

NRU (input)
 The number of rows of the matrix U. $NRU \geq 0$.

NCC (input)
 The number of columns of the matrix C. $NCC \geq 0$.

D (input/output)
 On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if INFO=0, the singular values of B in decreasing order.

E (input/output)
 On entry, the elements of E contain the offdiagonal elements of the bidiagonal matrix whose SVD is desired. On normal exit (INFO = 0), E is destroyed. If the algorithm does not converge (INFO > 0), D and E will contain the diagonal and superdiagonal elements of a bidiagonal matrix orthogonally equivalent to the one given as input. E(N) is used for workspace.

VT (input/output)
 On entry, an N-by-NCVT matrix VT. On exit, VT is

overwritten by $P' * VT$. VT is not referenced if $NCVT = 0$.

LDVT (input)

The leading dimension of the array VT . $LDVT \geq \max(1, N)$ if $NCVT > 0$; $LDVT \geq 1$ if $NCVT = 0$.

U (input/output)

On entry, an NRU -by- N matrix U . On exit, U is overwritten by $U * Q$. U is not referenced if $NRU = 0$.

LDU (input)

The leading dimension of the array U . $LDU \geq \max(1, NRU)$.

C (input/output)

On entry, an N -by- NCC matrix C . On exit, C is overwritten by $Q' * C$. C is not referenced if $NCC = 0$.

LDC (input)

The leading dimension of the array C . $LDC \geq \max(1, N)$ if $NCC > 0$; $LDC \geq 1$ if $NCC = 0$.

WORK (workspace)

dimension($4*N$)

INFO (output)

= 0: successful exit
< 0: If $INFO = -i$, the i -th argument had an illegal value
> 0: the algorithm did not converge; D and E contain the elements of a bidiagonal matrix which is orthogonally similar to the input matrix B ; if $INFO = i$, i elements of E have not converged to zero.

```

DESCRIPTION

```
C <- alpha op(A) B + beta C
```

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in block Ellpack format and
op(A) is one of

```
op( A ) = A    or    op( A ) = A'    or    op( A ) = conjg( A' ).  
                ( ' indicates matrix transpose)
```

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real.
MB	Number of block rows in matrix A
N	Number of columns in matrix C
KB	Number of block columns in matrix A
ALPHA	Scalar parameter
DESCRA()	Descriptor argument. Five element integer array DESCRA(1) matrix structure 0 : general 1 : symmetric (A=A') 2 : Hermitian (A= CONJG(A')) 3 : Triangular 4 : Skew(Anti)-Symmetric (A=-A') 5 : Diagonal 6 : Skew-Hermitian (A= -CONJG(A')) DESCRA(2) upper/lower triangular indicator 1 : lower 2 : upper DESCRA(3) main diagonal type 0 : non-unit 1 : unit DESCRA(4) Array base (NOT IMPLEMENTED) 0 : C/C++ compatible 1 : Fortran compatible DESCRA(5) repeated indices? (NOT IMPLEMENTED) 0 : unknown 1 : no repeated indices
VAL()	scalar array of length LB*LB*BLDA*MAXBNZ containing matrix entries, stored column-major within each dense block.
BINDX()	two-dimensional integer BLDA-by-MAXBNZ array such BINDX(i,:) consists of the block column indices of the nonzero blocks in block row i, padded by the integer value i if the number of nonzero blocks is less than MAXBNZ.
BLDA	leading dimension of BINDX(:,:).

MAXBNZ	max number of nonzeros blocks per row.
LB	row and column dimension of the dense blocks composing VAL.
B()	rectangular array with first dimension LDB.
LDB	leading dimension of B
BETA	Scalar parameter
C()	rectangular array with first dimension LDC.
LDC	leading dimension of C
WORK()	scratch array of length LWORK. WORK is not referenced in the current version.
LWORK	length of WORK array. LWORK is not referenced in the current version.

```

DESCRIPTION

```
C <- ALPHA op(A) B + BETA C      C <- ALPHA D op(A) B + BETA C
C <- ALPHA op(A) D B + BETA C
```

where ALPHA and BETA are scalar, C and B are m by n dense matrices, D is a block diagonal matrix, A is a unit, or non-unit, upper or lower triangular matrix represented in block Ellpack format and op(A) is one of
op(A) = inv(A) or op(A) = inv(A') or op(A) =inv(conjg(A'))
(inv denotes matrix inverse, ' indicates matrix transpose)

ARGUMENTS

TRANSA Indicates how to operate with the sparse matrix
 0 : operate with matrix
 1 : operate with transpose matrix
 2 : operate with the conjugate transpose of matrix.
 2 is equivalent to 1 if matrix is real.

MB Number of block rows in matrix A

N Number of columns in matrix C

UNITD Type of scaling:
 1 : Identity matrix (argument DV[] is ignored)
 2 : Scale on left (row scaling)
 3 : Scale on right (column scaling)

DV() Array of the length MB*LB*LB consisting of the block
 entries of block diagonal matrix D where each
 block is stored in standard column-major form.

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array
DESCRA(1) matrix structure
 0 : general
 1 : symmetric (A=A')
 2 : Hermitian (A= CONJG(A'))
 3 : Triangular
 4 : Skew(Anti)-Symmetric (A=-A')
 5 : Diagonal
 6 : Skew-Hermitian (A= -CONJG(A'))
Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper

DESCRA(3) main diagonal type
 0 : non-identity blocks on the main diagonal
 1 : identity diagonal blocks
 2 : diagonal blocks are dense matrices

DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL() scalar array of length LB*LB*BLDA*MAXBNZ containing
 matrix entries, stored column-major within each dense

block.

BINDX() two-dimensional integer BLDA-by-MAXBNZ array such BINDX(i,:) consists of the block column indices of the nonzero blocks in block row i, padded by the integer value i if the number of nonzero blocks is less than MAXBNZ. The block column indices MUST be sorted in increasing order for each block row.

BLDA leading dimension of BINDX(:,:).

MAXBNZ max number of nonzeros blocks per row.

LB row and column dimension of the dense blocks composing A.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the minimum size of LWORK.

LWORK length of WORK array. LWORK should be at least MB*LB.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=MB*LB*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If DESCRA(3)=0, the lower or upper triangular part of each

diagonal block is used by the routine depending on *DESCRA(2)*.

3. If *DESCRA(3)=1*, the unit diagonal blocks might or might not be referenced in the BEL representation of a sparse matrix. They are not used anyway.

4. If *DESCRA(3)=2*, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. *WORK(1)=0* on return if the factorization for all diagonal blocks has been completed successfully, otherwise *WORK(1) = -i* where *i* is the block number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix *A* is used. However *DESCRA(1)* must be equal to 3 in this case.

INTEGER*8, DIMENSION(:) :: DESCRA, BINDX, BPNTRB, BPNTRE  
DOUBLE PRECISION ALPHA, BETA  
DOUBLE PRECISION, DIMENSION(:) :: VAL  
DOUBLE PRECISION, DIMENSION(:, :) :: B, C
```

DESCRIPTION

```
C <- alpha op(A) B + beta C
```

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in block sparse column format and
op(A) is one of
op(A) = A or op(A) = A' or op(A) = conjg(A').
(' indicates matrix transpose)

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real.
MB	Number of block rows in matrix A
N	Number of columns in matrix C
KB	Number of block columns in matrix A
ALPHA	Scalar parameter
DESCRA()	Descriptor argument. Five element integer array DESCRA(1) matrix structure 0 : general 1 : symmetric (A=A') 2 : Hermitian (A= CONJG(A')) 3 : Triangular 4 : Skew(Anti)-Symmetric (A=-A') 5 : Diagonal 6 : Skew-Hermitian (A= -CONJG(A')) DESCRA(2) upper/lower triangular indicator 1 : lower 2 : upper DESCRA(3) main diagonal type 0 : non-unit 1 : unit DESCRA(4) Array base (NOT IMPLEMENTED) 0 : C/C++ compatible 1 : Fortran compatible DESCRA(5) repeated indices? (NOT IMPLEMENTED) 0 : unknown 1 : no repeated indices
VAL()	scalar array of length LB*LB*BNNZ consisting of the block entries stored column-major within each dense block.
BINDX()	integer array of length BNNZ consisting of the block row indices of the block entries of A.
BPNTRB()	integer array of length KB such that BPNTRB(J)-BPNTRB(1)+1 points to location in BINDX of the first block entry of the J-th block column of A.
BPNTRE()	integer array of length KB such that BPNTRE(J)-BPNTRB(1) points to location in BINDX

	of the last block entry of the J-th block column of A.
LB	dimension of dense blocks composing A.
B()	rectangular array with first dimension LDB.
LDB	leading dimension of B
BETA	Scalar parameter
C()	rectangular array with first dimension LDC.
LDC	leading dimension of C
WORK()	scratch array of length LWORK. WORK is not referenced in the current version.
LWORK	length of WORK array. LWORK is not referenced in the current version.

NOTES/BUGS

It is known that there exists another representation of the block sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block column in the arrays VAL and BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of block sparse column format the following calling sequence should be used

```
CALL SBSCMM( TRANSA, MB, N, KB, ALPHA, DESCRA,
*           VAL, BINDX, IA, IA(2), LB,
*           B, LDB, BETA, C, LDC, WORK, LWORK )
```

DOUBLE PRECISION, DIMENSION(:, :) :: B, C

SUBROUTINE BSCSM_64(TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA, VAL, BINDX,
*                  BPNTRB, BPNTRE, LB, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
INTEGER*8        TRANSA, MB, N, UNITD, LB
INTEGER*8, DIMENSION(:) :: DESCRA, BINDX, BPNTRB, BPNTRE
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION, DIMENSION(:) :: VAL, DV
DOUBLE PRECISION, DIMENSION(:, :) :: B, C
```

DESCRIPTION

```
C <- ALPHA op(A) B + BETA C      C <- ALPHA D op(A) B + BETA C
C <- ALPHA op(A) D B + BETA C
```

where ALPHA and BETA are scalar, C and B are m by n dense matrices, D is a block diagonal matrix, A is a unit, or non-unit, upper or lower triangular matrix represented in block sparse column format and op(A) is one of
op(A) = inv(A) or op(A) = inv(A') or op(A) =inv(conjg(A'))
(inv denotes matrix inverse, ' indicates matrix transpose)

ARGUMENTS

TRANSA Indicates how to operate with the sparse matrix
 0 : operate with matrix
 1 : operate with transpose matrix
 2 : operate with the conjugate transpose of matrix.
 2 is equivalent to 1 if matrix is real.

MB Number of block rows in matrix A

N Number of columns in matrix C

UNITD Type of scaling:
 1 : Identity matrix (argument DV[] is ignored)
 2 : Scale on left (row block scaling)
 3 : Scale on right (column block scaling)

DV() Array of the length MB*LB*LB consisting of the block entries of block diagonal matrix D where each block is stored in standard column-major form.

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array
DESCRA(1) matrix structure
 0 : general
 1 : symmetric (A=A')
 2 : Hermitian (A= CONJG(A'))
 3 : Triangular
 4 : Skew(Anti)-Symmetric (A=-A')
 5 : Diagonal
 6 : Skew-Hermitian (A= -CONJG(A'))

Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator

 1 : lower

 2 : upper

DESCRA(3) main diagonal type

 0 : non-identity blocks on the main diagonal

 1 : identity diagonal blocks

 2 : diagonal blocks are dense matrices

DESCRA(4) Array base (NOT IMPLEMENTED)

 0 : C/C++ compatible

 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)

 0 : unknown

 1 : no repeated indices

VAL() scalar array of length LB*LB*BNNZ consisting of the block

entries stored column-major within each dense block.

BINDX() integer array of length BNNZ consisting of the block row indices of the block entries of A. The block row indices MUST be sorted in increasing order for each block column.

BPNTRB() integer array of length MB such that $BPNTRB(J) - BPNTRB(1) + 1$ points to location in BINDX of the first block entry of the J-th block column of A.

BPNTRE() integer array of length MB such that $BPNTRE(J) - BPNTRB(1)$ points to location in BINDX of the last block entry of the J-th block column of A.

LB dimension of dense blocks composing A.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK. On exit, if LWORK = -1, WORK(1) returns the optimum size of LWORK.

LWORK length of WORK array. LWORK should be at least $MB * LB$.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, $LWORK \geq MB * LB * N_CPUS$ where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If *DESCRA*(3)=0, the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).

3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the BSC representation of a sparse matrix. They are not used anyway.

4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. *WORK*(1)=0 on return if the factorization for all diagonal blocks has been completed successfully, otherwise *WORK*(1) = -i where i is the block number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

6. It is known that there exists another representation of the block sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block column in the arrays VAL and BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of block sparse column format the following calling sequence should be used

```
CALL SBSCSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,  
*           VAL, BINDX, IA, IA(2), LB,  
*           B, LDB, BETA, C, LDC, WORK, LWORK )
```

NAME

dcnvcor - compute the convolution or correlation of real vectors

SYNOPSIS

```
SUBROUTINE DCNVCOR(CNVCOR, FOUR, NX, X, IFX, INCX, NY, NPRE, M, Y,
  IFY, INC1Y, INC2Y, NZ, K, Z, IFZ, INC1Z, INC2Z, WORK, LWORK)
```

```
CHARACTER * 1 CNVCOR, FOUR
INTEGER NX, IFX, INCX, NY, NPRE, M, IFY, INC1Y, INC2Y, NZ,
K, IFZ, INC1Z, INC2Z, LWORK
DOUBLE PRECISION X(*), Y(*), Z(*), WORK(*)
```

```
SUBROUTINE DCNVCOR_64(CNVCOR, FOUR, NX, X, IFX, INCX, NY, NPRE, M, Y,
  IFY, INC1Y, INC2Y, NZ, K, Z, IFZ, INC1Z, INC2Z, WORK, LWORK)
```

```
CHARACTER * 1 CNVCOR, FOUR
INTEGER*8 NX, IFX, INCX, NY, NPRE, M, IFY, INC1Y, INC2Y, NZ,
K, IFZ, INC1Z, INC2Z, LWORK
DOUBLE PRECISION X(*), Y(*), Z(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE CNVCOR(CNVCOR, FOUR, [NX], X, IFX, [INCX], NY, NPRE, M, Y,
  IFY, INC1Y, INC2Y, NZ, K, Z, IFZ, INC1Z, INC2Z, WORK, [LWORK])
```

```
CHARACTER(LEN=1) :: CNVCOR, FOUR
INTEGER :: NX, IFX, INCX, NY, NPRE, M, IFY, INC1Y, INC2Y,
NZ, K, IFZ, INC1Z, INC2Z, LWORK
REAL(8), DIMENSION(:) :: X, Y, Z, WORK
```

```
SUBROUTINE CNVCOR_64(CNVCOR, FOUR, [NX], X, IFX, [INCX], NY, NPRE, M,
  Y, IFY, INC1Y, INC2Y, NZ, K, Z, IFZ, INC1Z, INC2Z, WORK, [LWORK])
```

```
CHARACTER(LEN=1) :: CNVCOR, FOUR
INTEGER(8) :: NX, IFX, INCX, NY, NPRE, M, IFY, INC1Y, INC2Y,
NZ, K, IFZ, INC1Z, INC2Z, LWORK
REAL(8), DIMENSION(:) :: X, Y, Z, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```

void dcnvcor(char cnvcor, char four, int nx, double *x, int
    ifx, int incx, int ny, int npre, int m, double *y,
    int ify, int inclx, int inc2y, int nz, int k, dou-
    ble *z, int ifz, int inclz, int inc2z, double
    *work, int lwork);
void dcnvcor_64(char cnvcor, char four, long nx, double *x,
    long ifx, long incx, long ny, long npre, long m,
    double *y, long ify, long inclx, long inc2y, long
    nz, long k, double *z, long ifz, long inclz, long
    inc2z, double *work, long lwork);

```

PURPOSE

dcnvcor computes the convolution or correlation of real vectors.

ARGUMENTS

CNVCOR (input)

'V' or 'v' if convolution is desired, 'R' or 'r' if correlation is desired.

FOUR (input)

'T' or 't' if the Fourier transform method is to be used, 'D' or 'd' if the computation should be done directly from the definition. The Fourier transform method is generally faster, but it may introduce noticeable errors into certain results, notably when both the filter and data vectors consist entirely of integers or vectors where elements of either the filter vector or a given data vector differ significantly in magnitude from the 1-norm of the vector.

NX (input)

Length of the filter vector. $NX \geq 0$. DCNVCOR will return immediately if $NX = 0$.

X (input)

Filter vector.

IFX (input)

Index of the first element of X. $NX \geq IFX \geq 1$.

INCX (input)

Stride between elements of the filter vector in X. $INCX > 0$.

NY (input)

Length of the input vectors. $NY \geq 0$. DCNVCOR will return immediately if $NY = 0$.

NPRES (input)

The number of implicit zeros prepended to the Y vectors. $NPRES \geq 0$.

M (input)

Number of input vectors. $M \geq 0$. DCNVCOR will return immediately if $M = 0$.

Y (input)

Input vectors.

IFY (input)

Index of the first element of Y. $NY \geq IFY \geq 1$.

INC1Y (input)

Stride between elements of the input vectors in Y.
 $INC1Y > 0$.

INC2Y (input)

Stride between the input vectors in Y. $INC2Y > 0$.

NZ (input)

Length of the output vectors. $NZ \geq 0$. DCNVCOR will return immediately if $NZ = 0$. See the Notes section below for information about how this argument interacts with NX and NY to control circular versus end-off shifting.

K (input)

Number of Z vectors. $K \geq 0$. If $K = 0$ then DCNVCOR will return immediately. If $K < M$ then only the first K input vectors will be processed. If $K > M$ then M input vectors will be processed.

Z (output)

Result vectors.

IFZ (input)

Index of the first element of Z. $NZ \geq IFZ \geq 1$.

INC1Z (input)

Stride between elements of the output vectors in Z. $INC1Z > 0$.

INC2Z (input)

Stride between the output vectors in Z. $INC2Z > 0$.

WORK (input/output)

Scratch space. Before the first call to DCNVCOR with particular values of the integer arguments the first element of WORK must be set to zero. If WORK is written between calls to DCNVCOR or if DCNVCOR is called with different values of the integer arguments then the first element of WORK must again be set to zero before each call. If WORK has not been written and the same values of the integer arguments are used then the first element of WORK to zero. This can avoid certain initializations that store their results into WORK, and avoiding the initialization can make DCNVCOR run faster.

LWORK (input)

Length of WORK. $LWORK \geq 4*MAX(NX,NY,NZ)+15$.

NOTES

If any vector overlaps a writable vector, either because of argument aliasing or ill-chosen values of the various INC arguments, the results are undefined and may vary from one run to the next.

The most common form of the computation, and the case that executes fastest, is applying a filter vector X to a series of vectors stored in the columns of Y with the result placed into the columns of Z. In that case, INCX = 1, INC1Y = 1, INC2Y >= NY, INC1Z = 1, INC2Z >= NZ. Another common form is applying a filter vector X to a series of vectors stored in the rows of Y and store the result in the row of Z, in which case INCX = 1, INC1Y >= NY, INC2Y = 1, INC1Z >= NZ, and INC2Z = 1.

A common use of convolution is to compute the products of polynomials. The following code uses DCNVCOR to compute the product of $1 + 2x + 3x^2$ and $4 + 5x + 6x^2$:

```

PURPOSE

dcnvcor2 computes the convolution or correlation of real matrices.

ARGUMENTS

CNVCOR (input)
 'V' or 'v' to compute convolution, 'R' or 'r' to compute correlation.

METHOD (input)
 'T' or 't' if the Fourier transform method is to be used, 'D' or 'd' to compute directly from the definition.

TRANSX (input)
 'N' or 'n' if X is the filter matrix, 'T' or 't' if transpose(X) is the filter matrix.

SCRATCHX (input)
 'N' or 'n' if X must be preserved, 'S' or 's' if X can be used as scratch space. The contents of X are undefined after returning from a call in which X is allowed to be used for scratch.

TRANSY (input)
 'N' or 'n' if Y is the input matrix, 'T' or 't' if transpose(Y) is the input matrix.

SCRATCHY (input)
 'N' or 'n' if Y must be preserved, 'S' or 's' if Y can be used as scratch space. The contents of Y are undefined after returning from a call in which Y is allowed to be used for scratch.

MX (input)
 Number of rows in the filter matrix. MX >= 0.

NX (input)
Number of columns in the filter matrix. NX >= 0.

X (input) dimension(LDX,NX)
On entry, the filter matrix. Unchanged on exit if SCRATCHX is 'N' or 'n', undefined on exit if SCRATCHX is 'S' or 's'.

LDX (input)
Leading dimension of the array that contains the filter matrix.

MY (input)
Number of rows in the input matrix. MY >= 0.

NY (input)
Number of columns in the input matrix. NY >= 0.

MPRE (input)
Number of implicit zeros to prepend to each row of the input matrix. MPRE >= 0.

NPRE (input)
Number of implicit zeros to prepend to each column of the input matrix. NPRE >= 0.

Y (input) dimension(LDY,*)
Input matrix. Unchanged on exit if SCRATCHY is 'N' or 'n', undefined on exit if SCRATCHY is 'S' or 's'.

LDY (input)
Leading dimension of the array that contains the input matrix.

MZ (input)
Number of rows in the output matrix. MZ >= 0.
DCNVCOR2 will return immediately if MZ = 0.

NZ (input)
Number of columns in the output matrix. NZ >= 0.
DCNVCOR2 will return immediately if NZ = 0.

Z (output)
dimension(LDZ,*)
Result matrix.

LDZ (input)
Leading dimension of the array that contains the result matrix. LDZ >= MAX(1,MZ).

WORKIN (input/output)
(input/scratch) dimension(LWORK)
On entry for the first call to DCNVCOR2, WORKIN(1) must contain 0.0. After the first call, WORKIN(1) must be set to 0.0 iff WORKIN has been altered since the last call to this subroutine or if the sizes of the arrays have changed.

LWORK (input)
Length of the work vector. If the FFT is to be used then for best performance LWORK should be at least 30 words longer than the amount of memory

needed to hold the trig tables. If the FFT is not used, the value of LWORK is unimportant.

INTEGER*8        TRANSA, M, K, NNZ  
INTEGER*8, DIMENSION(:) :: DESCRA, INDX, JNDX  
DOUBLE PRECISION ALPHA, BETA  
DOUBLE PRECISION, DIMENSION(:) :: VAL  
DOUBLE PRECISION, DIMENSION(:, :) :: B, C
```

DESCRIPTION

```
C <- alpha op(A) B + beta C
```

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in coordinate format and
op(A) is one of
op(A) = A or op(A) = A' or op(A) = conjg(A').
(' indicates matrix transpose)

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real.
M	Number of rows in matrix A
N	Number of columns in matrix C
K	Number of columns in matrix A
ALPHA	Scalar parameter
DESCRA()	Descriptor argument. Five element integer array DESCRA(1) matrix structure 0 : general 1 : symmetric (A=A') 2 : Hermitian (A= CONJG(A')) 3 : Triangular 4 : Skew(Anti)-Symmetric (A=-A') 5 : Diagonal 6 : Skew-Hermitian (A= -CONJG(A')) DESCRA(2) upper/lower triangular indicator 1 : lower 2 : upper DESCRA(3) main diagonal type 0 : non-unit 1 : unit DESCRA(4) Array base (NOT IMPLEMENTED) 0 : C/C++ compatible 1 : Fortran compatible DESCRA(5) repeated indices? (NOT IMPLEMENTED) 0 : unknown 1 : no repeated indices
VAL()	scalar array of length NNZ consisting of the non-zero entries of A, in any order.
INDX()	integer array of length NNZ consisting of the corresponding row indices of the entries of A.
JNDX()	integer array of length NNZ consisting of the corresponding column indices of the entries of A.
NNZ	number of non-zero elements in A.
B()	rectangular array with first dimension LDB.
LDB	leading dimension of B

BETA	Scalar parameter
C()	rectangular array with first dimension LDC.
LDC	leading dimension of C
WORK()	scratch array of length LWORK. WORK is not referenced in the current version.
LWORK	length of WORK array. LWORK is not referenced in the current version.

NAME

dcopy - Copy x to y

SYNOPSIS

```
SUBROUTINE DCOPY(N, X, INCX, Y, INCY)
```

```
INTEGER N, INCX, INCY  
DOUBLE PRECISION X(*), Y(*)
```

```
SUBROUTINE DCOPY_64(N, X, INCX, Y, INCY)
```

```
INTEGER*8 N, INCX, INCY  
DOUBLE PRECISION X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE COPY([N], X, [INCX], Y, [INCY])
```

```
INTEGER :: N, INCX, INCY  
REAL(8), DIMENSION(:) :: X, Y
```

```
SUBROUTINE COPY_64([N], X, [INCX], Y, [INCY])
```

```
INTEGER(8) :: N, INCX, INCY  
REAL(8), DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dcopy(int n, double *x, int incx, double *y, int incy);
```

```
void dcopy_64(long n, double *x, long incx, double *y, long  
incy);
```

PURPOSE

dcopy Copy x to y where x and y are n-vectors.

ARGUMENTS

- N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.
- X (input)
(1 + (n - 1) * abs(INCX)). Before entry, the incremented array X must contain the vector x. Unchanged on exit.
- INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.
- Y (output)
(1 + (m - 1) * abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the vector x.
- INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

dcosqb - synthesize a Fourier sequence from its representation in terms of a cosine series with odd wave numbers. The COSQ operations are unnormalized inverses of themselves, so a call to COSQF followed by a call to COSQB will multiply the input sequence by $4 * N$.

SYNOPSIS

```
SUBROUTINE DCOSQB(N, X, WSAVE)
```

```
INTEGER N  
DOUBLE PRECISION X(*), WSAVE(*)
```

```
SUBROUTINE DCOSQB_64(N, X, WSAVE)
```

```
INTEGER*8 N  
DOUBLE PRECISION X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQB([N], X, WSAVE)
```

```
INTEGER :: N  
REAL(8), DIMENSION(:) :: X, WSAVE
```

```
SUBROUTINE COSQB_64([N], X, WSAVE)
```

```
INTEGER(8) :: N  
REAL(8), DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dcosqb(int n, double *x, double *wsave);
```

```
void dcosqb_64(long n, double *x, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

X (input/output)

On entry, an array of length N containing the sequence to be transformed. On exit, the quarter-wave cosine synthesis of the input.

WSAVE (input)

On entry, an array with dimension of at least $(3 * N + 15)$ that has been initialized by DCOSQI.

NAME

dcosqf - compute the Fourier coefficients in a cosine series representation with only odd wave numbers. The COSQ operations are unnormalized inverses of themselves, so a call to COSQF followed by a call to COSQB will multiply the input sequence by $4 * N$.

SYNOPSIS

```
SUBROUTINE DCOSQF(N, X, WSAVE)
```

```
INTEGER N  
DOUBLE PRECISION X(*), WSAVE(*)
```

```
SUBROUTINE DCOSQF_64(N, X, WSAVE)
```

```
INTEGER*8 N  
DOUBLE PRECISION X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQF([N], X, WSAVE)
```

```
INTEGER :: N  
REAL(8), DIMENSION(:) :: X, WSAVE
```

```
SUBROUTINE COSQF_64([N], X, WSAVE)
```

```
INTEGER(8) :: N  
REAL(8), DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dcosqf(int n, double *x, double *wsave);
```

```
void dcosqf_64(long n, double *x, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

X (input/output)

On entry, an array of length N containing the sequence to be transformed. On exit, the quarter-wave cosine transform of the input.

WSAVE (input)

On entry, an array with dimension of at least (3 * N + 15) that has been initialized by DCOSQI.

Contents

- [NAME](#)
- [SYNOPSIS](#)
 - [F95 INTERFACE](#)
 - [C INTERFACE](#)
- [ARGUMENTS](#)

NAME

dcosqi - initialize the array WSAVE, which is used in both COSQF and COSQB.

SYNOPSIS

```
SUBROUTINE DCOSQI(N, WSAVE)

INTEGER N
DOUBLE PRECISION WSAVE(*)

SUBROUTINE DCOSQI_64(N, WSAVE)

INTEGER*8 N
DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQI(N, WSAVE)

INTEGER :: N
REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE COSQI_64(N, WSAVE)

INTEGER(8) :: N
REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dcosqi(int n, double *wsave);

void dcosqi_64(long n, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. The method is most efficient when N is a product of small primes.

WSAVE (input)
On entry, an array of dimension (3 * N + 15) or greater. DCOSQI needs to be called only once to

initialize WSAVE before calling DCOSQF and/or DCOSQB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

```

```
SUBROUTINE COST_64([N], X, WSAVE)
```

```
INTEGER(8) :: N  
REAL(8), DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dcost(int n, double *x, double *wsave);
```

```
void dcost_64(long n, double *x, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. These subroutines are most efficient when $N - 1$ is a product of small primes. $N \geq 2$.

X (input/output)

On entry, an array of length N containing the sequence to be transformed. On exit, the cosine transform of the input.

WSAVE (input)

On entry, an array with dimension of at least $(3 * N + 15)$, initialized by DCOSTI.

Contents

```

C INTERFACE

```
#include <sunperf.h>

void dcosti(int n, double *wsave);

void dcosti_64(long n, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. The method is most efficient when $N - 1$ is a product of small primes. $N \geq 2$.

WSAVE (input)

On entry, an array of dimension $(3 * N + 15)$ or greater. DCOSTI is called once to initialize WSAVE before calling DCOST and need not be called

again between calls to DCOST if N and WSAVE remain unchanged. Thus, subsequent transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

dcscmm - compressed sparse column format matrix-matrix multiply

SYNOPSIS

```
SUBROUTINE DCSCMM( TRANSA, M, N, K, ALPHA, DESCRA,  
* VAL, INDX, PNTRB, PNTRE,  
* B, LDB, BETA, C, LDC, WORK, LWORK)  
INTEGER TRANSA, M, N, K, DESCRA(5),  
* LDB, LDC, LWORK  
INTEGER INDX(NNZ), PNTRB(K), PNTRE(K)  
DOUBLE PRECISION ALPHA, BETA  
DOUBLE PRECISION VAL(NNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
```

```
SUBROUTINE DCSCMM_64( TRANSA, M, N, K, ALPHA, DESCRA,  
* VAL, INDX, PNTRB, PNTRE,  
* B, LDB, BETA, C, LDC, WORK, LWORK)  
INTEGER*8 TRANSA, M, N, K, DESCRA(5),  
* LDB, LDC, LWORK  
INTEGER*8 INDX(NNZ), PNTRB(K), PNTRE(K)  
DOUBLE PRECISION ALPHA, BETA  
DOUBLE PRECISION VAL(NNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
```

where NNZ = PNTRE(K)-PNTRB(1)

F95 INTERFACE

```
SUBROUTINE CSCMM( TRANSA, M, [N], K, ALPHA, DESCRA, VAL, INDX,  
* PNTRB, PNTRE, B, [LDB], BETA, C, [LDC], [WORK], [LWORK] )  
INTEGER TRANSA, M, K  
INTEGER, DIMENSION(:) :: DESCRA, INDX, PNTRB, PNTRE  
DOUBLE PRECISION ALPHA, BETA  
DOUBLE PRECISION, DIMENSION(:) :: VAL  
DOUBLE PRECISION, DIMENSION(:, :) :: B, C
```

```
SUBROUTINE CSCMM_64( TRANSA, M, [N], K, ALPHA, DESCRA, VAL, INDX,  
* PNTRB, PNTRE, B, [LDB], BETA, C, [LDC], [WORK], [LWORK] )  
INTEGER*8 TRANSA, M, K  
INTEGER*8, DIMENSION(:) :: DESCRA, INDX, PNTRB, PNTRE  
DOUBLE PRECISION ALPHA, BETA  
DOUBLE PRECISION, DIMENSION(:) :: VAL  
DOUBLE PRECISION, DIMENSION(:, :) :: B, C
```

DESCRIPTION

```
C <- alpha op(A) B + beta C
```

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in compressed sparse column format and
op(A) is one of
op(A) = A or op(A) = A' or op(A) = conjg(A').
(' indicates matrix transpose)

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real.
M	Number of rows in matrix A
N	Number of columns in matrix C
K	Number of columns in matrix A
ALPHA	Scalar parameter
DESCRA()	Descriptor argument. Five element integer array DESCRA(1) matrix structure 0 : general 1 : symmetric (A=A') 2 : Hermitian (A= CONJG(A')) 3 : Triangular 4 : Skew(Anti)-Symmetric (A=-A') 5 : Diagonal 6 : Skew-Hermitian (A= -CONJG(A')) DESCRA(2) upper/lower triangular indicator 1 : lower 2 : upper DESCRA(3) main diagonal type 0 : non-unit 1 : unit DESCRA(4) Array base (NOT IMPLEMENTED) 0 : C/C++ compatible 1 : Fortran compatible DESCRA(5) repeated indices? (NOT IMPLEMENTED) 0 : unknown 1 : no repeated indices
VAL()	scalar array of length NNZ consisting of nonzero entries of A.
INDX()	integer array of length NNZ consisting of the row indices of nonzero entries of A.
PNTRB()	integer array of length K such that PNTRB(J)-PNTRB(1)+1 points to location in VAL of the first nonzero element in column J.
PNTRE()	integer array of length K such that PNTRE(J)-PNTRB(1) points to location in VAL of the last nonzero element in column J.

B()	rectangular array with first dimension LDB.
LDB	leading dimension of B
BETA	Scalar parameter
C()	rectangular array with first dimension LDC.
LDC	leading dimension of C
WORK()	scratch array of length LWORK. WORK is not referenced in the current version.
LWORK	length of WORK array. LWORK is not referenced in the current version.

NOTES/BUGS

It is known that there exists another representation of the compressed sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each column in the arrays VAL and INDX is used instead of two arrays PNTRB and PNTRE. To use the routine with this kind of sparse column format the following calling sequence should be used

```

SUBROUTINE SCSCMM( TRANSA, M, N, K, ALPHA, DESCRA,
*                VAL, INDX, IA, IA(2), B, LDB, BETA,
*                C, LDC, WORK, LWORK )

```

DOUBLE PRECISION, DIMENSION(:) :: VAL, DV
DOUBLE PRECISION, DIMENSION(:, :) :: B, C

SUBROUTINE CSCSM_64(TRANSA, M, [N], UNITD, DV, ALPHA, DESCRA, VAL, INDX,
* PNTRB, PNTRE, B, [LDB], BETA, C, [LDC], [WORK], [LWORK] )
INTEGER*8 TRANSA, M, UNITD
INTEGER*8, DIMENSION(:) :: DESCRA, INDX, PNTRB, PNTRE
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION, DIMENSION(:) :: VAL, DV
DOUBLE PRECISION, DIMENSION(:, :) :: B, C
```

DESCRIPTION

```
C <- ALPHA op(A) B + BETA C      C <- ALPHA D op(A) B + BETA C
C <- ALPHA op(A) D B + BETA C
```

where ALPHA and BETA are scalar, C and B are m by n dense matrices, D is a diagonal scaling matrix, A is a unit, or non-unit, upper or lower triangular matrix represented in compressed sparse column format and op(A) is one of
op(A) = inv(A) or op(A) = inv(A') or op(A) = inv(conjg(A'))
(inv denotes matrix inverse, ' indicates matrix transpose)

ARGUMENTS

TRANSA Indicates how to operate with the sparse matrix
 0 : operate with matrix
 1 : operate with transpose matrix
 2 : operate with the conjugate transpose of matrix.
 2 is equivalent to 1 if matrix is real.

M Number of rows in matrix A

N Number of columns in matrix C

UNITD Type of scaling:
 1 : Identity matrix (argument DV[] is ignored)
 2 : Scale on left (row scaling)
 3 : Scale on right (column scaling)
 4 : Automatic column scaling (see section NOTES for
 further details)

DV() Array of length M containing the diagonal entries of the
 scaling diagonal matrix D.

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array
DESCRA(1) matrix structure
 0 : general
 1 : symmetric (A=A')
 2 : Hermitian (A= CONJG(A'))
 3 : Triangular
 4 : Skew(Anti)-Symmetric (A=-A')
 5 : Diagonal
 6 : Skew-Hermitian (A= -CONJG(A'))

Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper

DESCRA(3) main diagonal type
 0 : non-unit
 1 : unit

DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL() scalar array of length NNZ consisting of nonzero entries

of A.

INDX() integer array of length NNZ consisting of the row indices of nonzero entries of A. (Row indices MUST be sorted in increasing order for each column).

PNTRB() integer array of length M such that PNTRB(J)-PNTRB(1)+1 points to location in VAL of the first nonzero element in column J.

PNTRE() integer array of length M such that PNTRE(J)-PNTRB(1) points to location in VAL of the last nonzero element in column J.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK.

On exit, if LWORK = -1, WORK(1) returns the optimum LWORK.

LWORK length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK $\geq M \cdot N_{\text{CPUS}}$ where N_{CPUS} is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If UNITD =4, the routine scales the columns of A such that their 2-norms are one. The scaling may improve the

accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the columns have been scaled. UNITD=3 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise WORK(1) = -i where i is the column number which 2-norm is exactly zero.

3. If DESCRA(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the CSC representation of a sparse matrix. They are not used anyway in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the CSC representation.

4. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However DESCRA(1) must be equal to 3 in this case.

5. It is known that there exists another representation of the compressed sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each column in the arrays VAL and INDX is used instead of two arrays PNTRB and PNTRE. To use the routine with this kind of sparse column format the following calling sequence should be used

```
      SUBROUTINE SCSCSM( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,  
*                   VAL, INDX, IA, IA(2), B, LDB, BETA,  
*                   C, LDC, WORK, LWORK )
```

```

DESCRIPTION

```
C <- alpha op(A) B + beta C
```

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in diagonal format and op(A) is one of

```
op( A ) = A    or    op( A ) = A'    or    op( A ) = conjg( A' ).  
                ( ' indicates matrix transpose)
```

TRANSA Indicates how to operate with the sparse matrix
 0 : operate with matrix
 1 : operate with transpose matrix
 2 : operate with the conjugate transpose of matrix.
 2 is equivalent to 1 if matrix is real.

M Number of rows in matrix A

N Number of columns in matrix C

K Number of columns in matrix A

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array
 0 : general
 1 : symmetric (A=A')
 2 : Hermitian (A= CONJG(A'))
 3 : Triangular
 4 : Skew(Anti)-Symmetric (A=-A')
 5 : Diagonal
 6 : Skew-Hermitian (A= -CONJG(A'))
DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper
DESCRA(3) main diagonal type
 0 : non-unit
 1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL() two-dimensional LDA-by-NDIAG array such that VAL(:,I)
 consists of non-zero elements on diagonal IDIAG(I)
 of A. Diagonals in the lower triangular part of A
 are padded from the top, and those in the upper
 triangular part are padded from the bottom.

LDA leading dimension of VAL, must be .GE. MIN(M,K)

IDIAG() integer array of length NDIAG consisting of the
 corresponding diagonal offsets of the non-zero
 diagonals of A in VAL. Lower triangular diagonals
 have negative offsets, the main diagonal has offset
 0, and upper triangular diagonals have positive offset.

NDIAG number of non-zero diagonals in A.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA	Scalar parameter
C()	rectangular array with first dimension LDC.
LDC	leading dimension of C
WORK()	scratch array of length LWORK. WORK is not referenced in the current version.
LWORK	length of WORK array. LWORK is not referenced in the current version.

INTEGER*8        TRANSA, M, NDIAG
INTEGER*8, DIMENSION(:) :: DESCRA, IDIAG
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION, DIMENSION(:) :: DV
DOUBLE PRECISION, DIMENSION(:, :) :: VAL, B, C
```

DESCRIPTION

```
C <- ALPHA op(A) B + BETA C      C <- ALPHA D op(A) B + BETA C
C <- ALPHA op(A) D B + BETA C
```

where ALPHA and BETA are scalar, C and B are m by n dense matrices, D is a diagonal scaling matrix, A is a unit, or non-unit, upper or lower triangular matrix represented in diagonal format and op(A) is one of

```
op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))
(inv denotes matrix inverse, ' indicates matrix transpose)
```

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real.
M	Number of rows in matrix A
N	Number of columns in matrix C
UNITD	Type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) 4 : Automatic row scaling (see section NOTES for further details)
DV()	Array of length M containing the diagonal entries of the scaling diagonal matrix D.
ALPHA	Scalar parameter
DESCRA()	Descriptor argument. Five element integer array DESCRA(1) matrix structure 0 : general 1 : symmetric (A=A') 2 : Hermitian (A= CONJG(A')) 3 : Triangular 4 : Skew(Anti)-Symmetric (A=-A') 5 : Diagonal 6 : Skew-Hermitian (A= -CONJG(A')) Note: For the routine, only DESCRA(1)=3 is supported. DESCRA(2) upper/lower triangular indicator 1 : lower 2 : upper DESCRA(3) main diagonal type 0 : non-unit 1 : unit DESCRA(4) Array base (NOT IMPLEMENTED) 0 : C/C++ compatible 1 : Fortran compatible DESCRA(5) repeated indices? (NOT IMPLEMENTED) 0 : unknown 1 : no repeated indices
VAL()	two-dimensional LDA-by-NDIAG array such that VAL(:,I)

consists of non-zero elements on diagonal IDIAG(I) of A. Diagonals in the lower triangular part of A are padded from the top, and those in the upper triangular part are padded from the bottom.

LDA leading dimension of VAL, must be .GE. MIN(M,K)

IDIAG() integer array of length NDIAG consisting of the corresponding diagonal offsets of the non-zero diagonals of A in VAL. Lower triangular diagonals have negative offsets, the main diagonal has offset 0, and upper triangular diagonals have positive offset. Elements of IDIAG of MUST be sorted in increasing order.

NDIAG number of non-zero diagonals in A.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK.
On exit, if LWORK = -1, WORK(1) returns the optimum LWORK.

LWORK length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK $\geq M \cdot N_{CPUS}$ where N_{CPUS} is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If UNITD =4, the routine scales the rows of A such that their 2-norms are one. The scaling may improve the accuracy

of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise WORK(1) = -i where i is the row number which 2-norm is exactly zero.

3. If DESCRA(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the DIA representation of a sparse matrix. They are not used anyway in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the DIA representation.

4. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However DESCRA(1) must be equal to 3 in this case.

NAME

ddisna - compute the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m-by-n matrix

SYNOPSIS

```
SUBROUTINE DDISNA(JOB, M, N, D, SEP, INFO)
```

```
CHARACTER * 1 JOB  
INTEGER M, N, INFO  
DOUBLE PRECISION D(*), SEP(*)
```

```
SUBROUTINE DDISNA_64(JOB, M, N, D, SEP, INFO)
```

```
CHARACTER * 1 JOB  
INTEGER*8 M, N, INFO  
DOUBLE PRECISION D(*), SEP(*)
```

F95 INTERFACE

```
SUBROUTINE DISNA(JOB, M, N, D, SEP, [INFO])
```

```
CHARACTER(LEN=1) :: JOB  
INTEGER :: M, N, INFO  
REAL(8), DIMENSION(:) :: D, SEP
```

```
SUBROUTINE DISNA_64(JOB, M, N, D, SEP, [INFO])
```

```
CHARACTER(LEN=1) :: JOB  
INTEGER(8) :: M, N, INFO  
REAL(8), DIMENSION(:) :: D, SEP
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ddisna(char job, int m, int n, double *d, double *sep,  
            int *info);
```

```
void ddisna_64(char job, long m, long n, double *d, double  
               *sep, long *info);
```

PURPOSE

ddisna computes the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m-by-n matrix. The reciprocal condition number is the 'gap' between the corresponding eigenvalue or singular value and the nearest other one.

The bound on the error, measured by angle in radians, in the I-th computed vector is given by

$$\text{SLAMCH}('E') * (\text{ANORM} / \text{SEP}(I))$$

where $\text{ANORM} = 2\text{-norm}(A) = \max(\text{abs}(D(j)))$. $\text{SEP}(I)$ is not allowed to be smaller than $\text{SLAMCH}('E') * \text{ANORM}$ in order to limit the size of the error bound.

SDISNA may also be used to compute error bounds for eigenvectors of the generalized symmetric definite eigenproblem.

ARGUMENTS

JOB (input)

Specifies for which problem the reciprocal condition numbers should be computed:
= 'E': the eigenvectors of a symmetric/Hermitian matrix;
= 'L': the left singular vectors of a general matrix;
= 'R': the right singular vectors of a general matrix.

M (input) The number of rows of the matrix. $M \geq 0$.

N (input) If JOB = 'L' or 'R', the number of columns of the matrix, in which case $N \geq 0$. Ignored if JOB = 'E'.

D (input) dimension ($\min(M,N)$) if JOB = 'L' or 'R' The eigenvalues (if JOB = 'E') or singular values (if JOB = 'L' or 'R') of the matrix, in either increasing or decreasing order. If singular values, they must be non-negative.

SEP (output)

dimension ($\min(M,N)$) if JOB = 'L' or 'R' The reciprocal condition numbers of the vectors.

INFO (output)

= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

NAME

ddot - compute the dot product of two vectors x and y.

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DDOT(N, X, INCX, Y, INCY)
```

```
INTEGER N, INCX, INCY  
DOUBLE PRECISION X(*), Y(*)
```

```
DOUBLE PRECISION FUNCTION DDOT_64(N, X, INCX, Y, INCY)
```

```
INTEGER*8 N, INCX, INCY  
DOUBLE PRECISION X(*), Y(*)
```

F95 INTERFACE

```
REAL(8) FUNCTION DOT([N], X, [INCX], Y, [INCY])
```

```
INTEGER :: N, INCX, INCY  
REAL(8), DIMENSION(:) :: X, Y
```

```
REAL(8) FUNCTION DOT_64([N], X, [INCX], Y, [INCY])
```

```
INTEGER(8) :: N, INCX, INCY  
REAL(8), DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
double ddot(int n, double *x, int incx, double *y, int  
            incy);
```

```
double ddot_64(long n, double *x, long incx, double *y, long  
              incy);
```

PURPOSE

ddot compute the dot product of x and y where x and y are n-vectors.

ARGUMENTS

- N (input)
On entry, N specifies the number of elements in the vector. If N is not positive then the function returns the value 0.0. Unchanged on exit.
- X (input)
($1 + (n - 1) * \text{abs}(\text{INCX})$). On entry, the incremented array X must contain the vector x. Unchanged on exit.
- INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.
- Y (input)
($1 + (n - 1) * \text{abs}(\text{INCY})$). On entry, the incremented array Y must contain the vector y. Unchanged on exit.
- INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

ddoti - Compute the indexed dot product.

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DDOTI(NZ, X, INDX, Y)
```

```
DOUBLE PRECISION X(*), Y(*)  
INTEGER NZ  
INTEGER INDX(*)
```

```
DOUBLE PRECISION FUNCTION DDOTI_64(NZ, X, INDX, Y)
```

```
DOUBLE PRECISION X(*), Y(*)  
INTEGER*8 NZ  
INTEGER*8 INDX(*)
```

```
F95 INTERFACE
```

```
DOUBLE PRECISION FUNCTION DOTI([NZ], X, INDX, Y)
```

```
REAL(8), DIMENSION(:) :: X, Y  
INTEGER :: NZ  
INTEGER, DIMENSION(:) :: INDX
```

```
DOUBLE PRECISION FUNCTION DOTI_64([NZ], X, INDX, Y)
```

```
REAL(8), DIMENSION(:) :: X, Y  
INTEGER(8) :: NZ  
INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

DDOTI Compute the indexed dot product of a real sparse vector *x* stored in compressed form with a real vector *y* in full storage form.

```
dot = 0  
do i = 1, n  
  dot = dot + x(i) * y(indx(i))  
enddo
```

ARGUMENTS

NZ (input)

Number of elements in the compressed form.
Unchanged on exit.

X (input)

Vector in compressed form. Unchanged on exit.

INDX (input)

Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

Y (input)

Vector in full storage form. Only the elements corresponding to the indices in INDX will be accessed.

```

DESCRIPTION

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in Ellpack format format and
op(A) is one of

op(A) = A or op(A) = A' or op(A) = conjg(A').
(' indicates matrix transpose)

ARGUMENTS

TRANSA Indicates how to operate with the sparse matrix
0 : operate with matrix
1 : operate with transpose matrix
2 : operate with the conjugate transpose of matrix.
2 is equivalent to 1 if matrix is real.

M Number of rows in matrix A

N Number of columns in matrix C

K Number of columns in matrix A

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array
DESCRA(1) matrix structure
0 : general
1 : symmetric (A=A')
2 : Hermitian (A= CONJG(A'))
3 : Triangular
4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper
DESCRA(3) main diagonal type
0 : non-unit
1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL() two-dimensional LDA-by-MAXNZ array such that VAL(I,:) consists of non-zero elements in row I of A, padded by zero values if the row contains less than MAXNZ.

INDX() two-dimensional integer LDA-by-MAXNZ array such INDX(I,:) consists of the column indices of the nonzero elements in row I, padded by the integer value I if the number of nonzeros is less than MAXNZ.

LDA leading dimension of VAL and INDX.

MAXNZ max number of nonzeros elements per row.

B() rectangular array with first dimension LDB.

LDB	leading dimension of B
BETA	Scalar parameter
C()	rectangular array with first dimension LDC.
LDC	leading dimension of C
WORK()	scratch array of length LWORK. WORK is not referenced in the current version.
LWORK	length of WORK array. LWORK is not referenced in the current version.

where ALPHA and BETA are scalar, C and B are m by n dense matrices, D is a diagonal scaling matrix, A is a unit, or non-unit, upper or lower triangular matrix represented in Ellpack format and op(A) is one of

```
op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))
(inv denotes matrix inverse, ' indicates matrix transpose)
```

ARGUMENTS

TRANSA Indicates how to operate with the sparse matrix
 0 : operate with matrix
 1 : operate with transpose matrix
 2 : operate with the conjugate transpose of matrix.
 2 is equivalent to 1 if matrix is real.

M Number of rows in matrix A

N Number of columns in matrix C

UNITD Type of scaling:
 1 : Identity matrix (argument DV[] is ignored)
 2 : Scale on left (row scaling)
 3 : Scale on right (column scaling)
 4 : Automatic row scaling (see section NOTES for
 further details)

DV() Array of length M containing the diagonal entries of the
 scaling diagonal matrix D.

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array
DESCRA(1) matrix structure
 0 : general
 1 : symmetric (A=A')
 2 : Hermitian (A= CONJG(A'))
 3 : Triangular
 4 : Skew(Anti)-Symmetric (A=-A')
 5 : Diagonal
 6 : Skew-Hermitian (A= -CONJG(A'))

Note: For the routine, only DESCRA(1)=3 is supported.

DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper

DESCRA(3) main diagonal type
 0 : non-unit
 1 : unit

DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL() two-dimensional LDA-by-MAXNZ array such that VAL(I,:)

consists of non-zero elements in row I of A, padded by zero values if the row contains less than MAXNZ.

INDX() two-dimensional integer LDA-by-MAXNZ array such INDX(I,:) consists of the column indices of the nonzero elements in row I, padded by the integer value I if the number of nonzeros is less than MAXNZ. The column indices MUST be sorted in increasing order for each row.

LDA leading dimension of VAL and INDX.

MAXNZ max number of nonzeros elements per row.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK.

On exit, if LWORK = -1, WORK(1) returns the optimum LWORK.

LWORK length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If UNITD =4, the routine scales the rows of A such that their 2-norms are one. The scaling may improve the accuracy

of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise WORK(1) = -i where i is the row number which 2-norm is exactly zero.

3. If DESCRA(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the ELL representation of a sparse matrix. They are not used anyway in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the ELL representation.

4. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However DESCRA(1) must be equal to 3 in this case.

```
void dezftb(int n, double *r, double azero, double *a, double *b, double *wsave);
```

```
void dezftb_64(long n, double *r, double azero, double *a, double *b, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be synthesized. The method is most efficient when N is the product of small primes. $N \geq 0$.

R (output) On exit, the Fourier synthesis of the inputs.

AZERO (input) On entry, the constant Fourier coefficient A0. Unchanged on exit.

A (input/output) On entry, array that contains the remaining Fourier coefficients. On exit, these arrays are unchanged.

B (input/output) On entry, array that contains the remaining Fourier coefficients. On exit, these arrays are unchanged.

WSAVE (input) On entry, an array with dimension of at least $(3 * N + 15)$, initialized by DEZFTI.

```

```
INTEGER :: N  
REAL(8) :: AZERO  
REAL(8), DIMENSION(:) :: R, A, B, WSAVE
```

```
SUBROUTINE DEZFTF_64(N, R, AZERO, A, B, WSAVE)
```

```
INTEGER(8) :: N  
REAL(8) :: AZERO  
REAL(8), DIMENSION(:) :: R, A, B, WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dezftf(int n, double *r, double azero, double *a, double *b, double *wsave);
```

```
void dezftf_64(long n, double *r, double azero, double *a, double *b, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. The method is most efficient when N is the product of small primes. $N \geq 0$.

R (input/output)
On entry, a real array of length N containing the sequence to be transformed. On exit, R is unchanged.

AZERO (output)
On exit, the sum from $i=1$ to $i=n$ of $r(i)/n$.

A (input/output)
On entry, array that contains the remaining Fourier coefficients. On exit, these arrays are unchanged.

B (input/output)
On entry, array that contains the remaining Fourier coefficients. On exit, these arrays are unchanged.

WSAVE (input)
On entry, an array with dimension of at least $(3 * N + 15)$, initialized by DEZFTI.

Contents

NAME

dezfti - initializes the array WSAVE, which is used in both DEZFTF and DEZFTB.

SYNOPSIS

```
SUBROUTINE DEZFTI(N, WSAVE)

INTEGER N
DOUBLE PRECISION WSAVE(*)

SUBROUTINE DEZFTI_64(N, WSAVE)

INTEGER*8 N
DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE DEZFTI(N, WSAVE)

INTEGER :: N
REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE DEZFTI_64(N, WSAVE)

INTEGER(8) :: N
REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dezfti(int n, double *wsave);

void dezfti_64(long n, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. N >= 0.

WSAVE (input)

On entry, an array with a dimension of at least (3 * N + 15). The same work array can be used for both DEZFTF and DEZFTB as long as N remains unchanged. Different WSAVE arrays are required for different values of N. This initialization

does not have to be repeated between calls to DEZFTF or DEZFTB as long as N and WSAVE remain unchanged, thus subsequent transforms can be obtained faster than the first.

NAME

dffft2b - compute a periodic sequence from its Fourier coefficients. The DFFT operations are unnormalized, so a call of DFFFT2F followed by a call of DFFFT2B will multiply the input sequence by M*N.

SYNOPSIS

```
SUBROUTINE DFFFT2B(PLACE, M, N, A, LDA, B, LDB, WORK, LWORK)
```

```
CHARACTER * 1 PLACE  
INTEGER M, N, LDA, LDB, LWORK  
DOUBLE PRECISION A(LDA,*), B(LDB,*), WORK(*)
```

```
SUBROUTINE DFFFT2B_64(PLACE, M, N, A, LDA, B, LDB, WORK, LWORK)
```

```
CHARACTER * 1 PLACE  
INTEGER*8 M, N, LDA, LDB, LWORK  
DOUBLE PRECISION A(LDA,*), B(LDB,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2B(PLACE, [M], [N], A, [LDA], B, [LDB], WORK, LWORK)
```

```
CHARACTER(LEN=1) :: PLACE  
INTEGER :: M, N, LDA, LDB, LWORK  
REAL(8), DIMENSION(:) :: WORK  
REAL(8), DIMENSION(:,:) :: A, B
```

```
SUBROUTINE FFT2B_64(PLACE, [M], [N], A, [LDA], B, [LDB], WORK, LWORK)
```

```
CHARACTER(LEN=1) :: PLACE  
INTEGER(8) :: M, N, LDA, LDB, LWORK  
REAL(8), DIMENSION(:) :: WORK  
REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dffft2b(char place, int m, int n, double *a, int lda,  
             double *b, int ldb, double *work, int lwork);
```

```
void dffft2b_64(char place, long m, long n, double *a, long  
                lda, double *b, long ldb, double *work, long  
                lwork);
```

ARGUMENTS

PLACE (input)

Character. If PLACE = 'I' or 'i' (for in-place), the input and output data are stored in array A. If PLACE = 'O' or 'o' (for out-of-place), the input data is stored in array B while the output is stored in A.

M (input) Integer specifying the number of rows to be transformed. It is most efficient when M is a product of small primes. $M \geq 0$; when $M = 0$, the subroutine returns immediately without changing any data.

N (input) Integer specifying the number of columns to be transformed. It is most most efficient when N is a product of small primes. $N \geq 0$; when $N = 0$, the subroutine returns immediately without changing any data.

A (input/output)

Real array of dimension (LDA,N). On entry, the two-dimensional array A(LDA,N) contains the input data to be transformed if an in-place transform is requested. Otherwise, it is not referenced. Upon exit, results are stored in A(1:M,1:N).

LDA (input)

Integer specifying the leading dimension of A. If an out-of-place transform is desired $LDA \geq M$. Else if an in-place transform is desired $LDA \geq 2*(M/2+1)$.

B (input/output)

Real array of dimension (2*LDB, N). On entry, if an out-of-place transform is requested B contains the input data. Otherwise, B is not referenced. B is unchanged upon exit.

LDB (input)

Integer. If an out-of-place transform is desired, 2*LDB is the leading dimension of the array B which contains the data to be transformed and $2*LDB \geq 2*(M/2+1)$. Otherwise it is not referenced.

WORK (input/output)

One-dimensional real array of length at least LWORK. On input, WORK must have been initialized by DFFT2I.

LWORK (input)

Integer. $LWORK \geq (M + 2*N + \text{MAX}(M, 2*N) + 30)$

NAME

dffft2f - compute the Fourier coefficients of a periodic sequence. The DFFT operations are unnormalized, so a call of DFFFT2F followed by a call of DFFFT2B will multiply the input sequence by M*N.

SYNOPSIS

```
SUBROUTINE DFFFT2F(PLACE, FULL, M, N, A, LDA, B, LDB, WORK, LWORK)
```

```
CHARACTER * 1 PLACE, FULL  
INTEGER M, N, LDA, LDB, LWORK  
DOUBLE PRECISION A(LDA,*), B(LDB,*), WORK(*)
```

```
SUBROUTINE DFFFT2F_64(PLACE, FULL, M, N, A, LDA, B, LDB, WORK, LWORK)
```

```
CHARACTER * 1 PLACE, FULL  
INTEGER*8 M, N, LDA, LDB, LWORK  
DOUBLE PRECISION A(LDA,*), B(LDB,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2F(PLACE, FULL, [M], [N], A, [LDA], B, [LDB], WORK,  
LWORK)
```

```
CHARACTER(LEN=1) :: PLACE, FULL  
INTEGER :: M, N, LDA, LDB, LWORK  
REAL(8), DIMENSION(:) :: WORK  
REAL(8), DIMENSION(:,:) :: A, B
```

```
SUBROUTINE FFT2F_64(PLACE, FULL, [M], [N], A, [LDA], B, [LDB], WORK,  
LWORK)
```

```
CHARACTER(LEN=1) :: PLACE, FULL  
INTEGER(8) :: M, N, LDA, LDB, LWORK  
REAL(8), DIMENSION(:) :: WORK  
REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dffft2f(char place, char full, int m, int n, double *a,  
int lda, double *b, int ldb, double *work, int  
lwork);
```

```
void dffft2f_64(char place, char full, long m, long n, double  
*a, long lda, double *b, long ldb, double *work,  
long lwork);
```

ARGUMENTS

PLACE (input)

Character. If PLACE = 'I' or 'i' (for in-place) , the input and output data are stored in array A. If PLACE = 'O' or 'o' (for out-of-place), the input data is stored in array B while the output is stored in A.

FULL (input)

Indicates whether or not to generate the full result matrix. 'F' or 'f' will cause DFFT2F to generate the full result matrix. Otherwise only a partial matrix that takes advantage of symmetry will be generated.

M (input) Integer specifying the number of rows to be transformed. It is most efficient when M is a product of small primes. $M \geq 0$; when $M = 0$, the subroutine returns immediately without changing any data.

N (input) Integer specifying the number of columns to be transformed. It is most most efficient when N is a product of small primes. $N \geq 0$; when $N = 0$, the subroutine returns immediately without changing any data.

A (input/output)

On entry, a two-dimensional array A(LDA,N) that contains the data to be transformed. Upon exit, A is unchanged if an out-of-place transform is done. If an in-place transform with partial result is requested, A(1:(M/2+1)*2,1:N) will contain the transformed results. If an in-place transform with full result is requested, A(1:2*M,1:N) will contain complete transformed results.

LDA (input)

Leading dimension of the array containing the data to be transformed. LDA must be even if the transformed sequences are to be stored in A.

If PLACE = ('O' or 'o') LDA \geq M

If PLACE = ('I' or 'i') LDA must be even. If FULL = ('F' or 'f'), LDA \geq 2*M

FULL is not ('F' or 'f'), LDA \geq (M/2+1)*2

B (input/output)

Upon exit, a two-dimensional array B(2*LDB,N) that contains the transformed results if an out-of-place transform is done. Otherwise, B is not used.

If an out-of-place transform is done and FULL is not 'F' or 'f', B(1:(M/2+1)*2,1:N) will contain the partial transformed results. If FULL = 'F' or 'f', B(1:2*M,1:N) will contain the complete transformed results.

LDB (input)

2*LDB is the leading dimension of the array B. If an in-place transform is desired LDB is ignored.

If PLACE is ('O' or 'o') and

FULL is ('F' or 'f'), LDB \geq M

FULL is not ('F' or 'f'), LDB \geq M/2+1

Note that even though LDB is used in the argument list, 2*LDB is the actual leading dimension of B.

WORK (input/output)

One-dimensional real array of length at least LWORK. On input, WORK must have been initialized by DFFT2I.

LWORK (input)

Integer. LWORK \geq (M + 2*N + MAX(M, 2*N) + 30)

NAME

dffft2i - initialize the array WSAVE, which is used in both the forward and backward transforms.

SYNOPSIS

```
SUBROUTINE DFFFT2I(M, N, WORK)
```

```
INTEGER M, N  
DOUBLE PRECISION WORK(*)
```

```
SUBROUTINE DFFFT2I_64(M, N, WORK)
```

```
INTEGER*8 M, N  
DOUBLE PRECISION WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2I(M, N, WORK)
```

```
INTEGER :: M, N  
REAL(8), DIMENSION(:) :: WORK
```

```
SUBROUTINE FFT2I_64(M, N, WORK)
```

```
INTEGER(8) :: M, N  
REAL(8), DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dffft2i(int m, int n, double *work);
```

```
void dffft2i_64(long m, long n, double *work);
```

ARGUMENTS

M (input) Number of rows to be transformed. M >= 0.

N (input) Number of columns to be transformed. N >= 0.

WORK (input/output)

On entry, an array of dimension (M + 2*N + MAX(M, 2*N) + 30) or greater. DFFFT2I needs to be called

only once to initialize array WORK before calling DFFT2F and/or DFFT2B if M, N and WORK remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

lda, double *b, int ldb, double *work, int lwork);
```

```
void dffft3b_64(char place, long m, long n, long k, double  
*a, long lda, double *b, long ldb, double *work,  
long lwork);
```

ARGUMENTS

- PLACE (input)
Select an in-place ('I' or 'i') or out-of-place ('O' or 'o') transform.
- M (input) Integer specifying the number of rows to be transformed. It is most efficient when M is a product of small primes. $M \geq 0$; when $M = 0$, the subroutine returns immediately without changing any data.
- N (input) Integer specifying the number of columns to be transformed. It is most efficient when N is a product of small primes. $N \geq 0$; when $N = 0$, the subroutine returns immediately without changing any data.
- K (input) Integer specifying the number of planes to be transformed. It is most efficient when K is a product of small primes. $K \geq 0$; when $K = 0$, the subroutine returns immediately without changing any data.
- A (input/output)
On entry, the three-dimensional array $A(LDA,N,K)$ contains the data to be transformed if an in-place transform is requested. Otherwise, it is not referenced. Upon exit, results are stored in $A(1:M,1:N,1:K)$.
- LDA (input)
Integer specifying the leading dimension of A. If an out-of-place transform is desired $LDA \geq M$. Else if an in-place transform is desired $LDA \geq 2*(M/2+1)$.
- B (input/output)
Real array of dimension $B(2*LDB,N,K)$. On entry, if an out-of-place transform is requested $B(1:2*(M/2+1),1:N,1:K)$ contains the input data. Otherwise, B is not referenced. B is unchanged upon exit.
- LDB (input)
If an out-of-place transform is desired, $2*LDB$ is the leading dimension of the array B which contains the data to be transformed and $2*LDB \geq 2*(M/2+1)$. Otherwise it is not referenced.
- WORK (input/output)
One-dimensional real array of length at least LWORK. On input, WORK must have been initialized by DFFT3I.
- LWORK (input)
Integer. $LWORK \geq (M + 2*(N + K) + 4*K + 45)$.

int lwork);
```

```
void dffft3f_64(char place, char full, long m, long n, long  
k, double *a, long lda, double *b, long ldb, dou-
```

```
ble *work, long lwork);
```

ARGUMENTS

PLACE (input)

Select an in-place ('I' or 'i') or out-of-place ('O' or 'o') transform.

FULL (input)

Select a full ('F' or 'f') or partial (' ') representation of the results. If the caller selects full representation then an $M \times N \times K$ real array will transform to produce an $M \times N \times K$ complex array. If the caller does not select full representation then an $M \times N \times K$ real array will transform to a $(M/2+1) \times N \times K$ complex array that takes advantage of the symmetry properties of a transformed real sequence.

M (input) Integer specifying the number of rows to be transformed. It is most efficient when M is a product of small primes. $M \geq 0$; when $M = 0$, the subroutine returns immediately without changing any data.

N (input) Integer specifying the number of columns to be transformed. It is most efficient when N is a product of small primes. $N \geq 0$; when $N = 0$, the subroutine returns immediately without changing any data.

K (input) Integer specifying the number of planes to be transformed. It is most efficient when K is a product of small primes. $K \geq 0$; when $K = 0$, the subroutine returns immediately without changing any data.

A (input/output)

On entry, a three-dimensional array $A(LDA, N, K)$ that contains input data to be transformed. On exit, if an in-place transform is done and FULL is not 'F' or 'f', $A(1:2*(M/2+1), 1:N, 1:K)$ will contain the partial transformed results. If FULL = 'F' or 'f', $A(1:2*M, 1:N, 1:K)$ will contain the complete transformed results.

LDA (input)

Leading dimension of the array containing the data to be transformed. LDA must be even if the transformed sequences are to be stored in A.

If PLACE = ('O' or 'o') $LDA \geq M$

If PLACE = ('I' or 'i') LDA must be even. If

FULL = ('F' or 'f'), $LDA \geq 2*M$

FULL is not ('F' or 'f'), $LDA \geq 2*(M/2+1)$

B (input/output)

Upon exit, a three-dimensional array $B(2*LDB, N, K)$ that contains the transformed results if an out-

of-place transform is done. Otherwise, B is not used.

If an out-of-place transform is done and FULL is not 'F' or 'f', B(1:2*(M/2+1),1:N,1:K) will contain the partial transformed results. If FULL = 'F' or 'f', B(1:2*M,1:N,1:K) will contain the complete transformed results.

LDB (input)

2*LDB is the leading dimension of the array B. If an in-place transform is desired LDB is ignored.

If PLACE is ('O' or 'o') and

FULL is ('F' or 'f'), then $LDB \geq M$

FULL is not ('F' or 'f'), then $LDB \geq M/2 + 1$

Note that even though LDB is used in the argument list, 2*LDB is the actual leading dimension of B.

WORK (input/output)

One-dimensional real array of length at least LWORK. WORK must have been initialized by DFFT3I.

LWORK (input)

Integer. $LWORK \geq (M + 2*(N + K) + 4*K + 45)$.

NAME

dffft3i - initialize the array WSAVE, which is used in both DFFT3F and DFFT3B.

SYNOPSIS

```
SUBROUTINE DFFT3I(M, N, K, WORK)
```

```
INTEGER M, N, K  
DOUBLE PRECISION WORK(*)
```

```
SUBROUTINE DFFT3I_64(M, N, K, WORK)
```

```
INTEGER*8 M, N, K  
DOUBLE PRECISION WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT3I(M, N, K, WORK)
```

```
INTEGER :: M, N, K  
REAL(8), DIMENSION(:) :: WORK
```

```
SUBROUTINE FFT3I_64(M, N, K, WORK)
```

```
INTEGER(8) :: M, N, K  
REAL(8), DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dffft3i(int m, int n, int k, double *work);
```

```
void dffft3i_64(long m, long n, long k, double *work);
```

ARGUMENTS

M (input) Number of rows to be transformed. M >= 0.

N (input) Number of columns to be transformed. N >= 0.

K (input) Number of planes to be transformed. K >= 0.

WORK (input/output)

On entry, an array of dimension $(M + 2*(N + K) + 30)$ or greater. DFFT3I needs to be called only once to initialize array WORK before calling DFFT3F and/or DFFT3B if M, N, K and WORK remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

`dfftopt` - compute the length of the closest fast FFT

SYNOPSIS

```
INTEGER FUNCTION DFFTOPT(LEN)
```

```
INTEGER LEN
```

```
INTEGER*8 FUNCTION DFFTOPT_64(LEN)
```

```
INTEGER*8 LEN
```

F95 INTERFACE

```
INTEGER FUNCTION DFFTOPT(LEN)
```

```
INTEGER :: LEN
```

```
INTEGER(8) FUNCTION DFFTOPT_64(LEN)
```

```
INTEGER(8) :: LEN
```

C INTERFACE

```
#include <sunperf.h>
```

```
int dfftopt(int len);
```

```
long dfftopt_64(long len);
```

PURPOSE

`dfftopt` computes the length of the closest fast FFT. Fast Fourier transform algorithms, including those used in Performance Library, work best with vector lengths that are products of small primes. For example, an FFT of length $32=2*5$ will run faster than an FFT of prime length 31 because 32 is a product of small primes and 31 is not. If your application is such that you can taper or zero pad your vector to a larger length then this function may help you select a better length and run your FFT faster.

`DFFTOPT` will return an integer no smaller than the input argument `N` that is the closest number that is the product of

small primes. DFFTOPT will return 16 for an input of $N=16$ and return $18=2*3*3$ for an input of $N=17$.

Note that the length computed here is not guaranteed to be optimal, only to be a

product of small primes. Also, the value returned may change as the underlying

FFTs become capable of handling larger primes. For example, passing in $N=51$ to day will return $52=2*2*13$ rather than $51=3*17$ because the FFTs in Performance Library do not have fast radix 17 code. In the future, radix 17 code may be added

and then $N=51$ will return 51.

REAL(8), INTENT(IN), DIMENSION(:) :: X  
COMPLEX(8), INTENT(OUT), DIMENSION(:) :: Y  
REAL(8), INTENT(INOUT), DIMENSION(:) :: TRIGS  
INTEGER(8), INTENT(INOUT), DIMENSION(:) :: IFAC  
REAL(8), INTENT(OUT), DIMENSION(:) :: WORK  
INTEGER(8), INTENT(OUT) :: IERR
```

C INTERFACE

```
#include <sunperf.h>

void dffftz_ (int *iopt, int *n, double *scale, double *x,
             doublecomplex *y, double *trigs, int *ifac, double
             *work, int *lwork, int *ierr);

void dffftz_64_ (long *iopt, long *n, double *scale, double
                *x, doublecomplex *y, double *trigs, long *ifac,
                double *work, long *lwork, long *ierr);
```

PURPOSE

dffftz initializes the trigonometric weight and factor tables or computes the forward Fast Fourier Transform of a double precision sequence as follows:

$$Y(k) = \text{scale} * \sum_{j=0}^{N-1} W^j X(j)$$

where

k ranges from 0 to N-1

i = sqrt(-1)

isign = -1 for forward transform

$W = \exp(isign * i * j * k * 2 * \pi / N)$

In real-to-complex transform of length N, the (N/2+1) complex output data points stored are the positive-frequency half of the spectrum of the Discrete Fourier Transform. The other half can be obtained through complex conjugation and therefore is not stored.

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = -1 computes forward FFT

N (input)

Integer specifying length of the input sequence X. N is most efficient when it is a product of small primes. N >= 0. Unchanged on exit.

SCALE (input)

Double precision scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0D0 for F95 INTERFACE.

X (input) On entry, X is a real array whose first N elements contain the sequence to be transformed.

Y (output)

Double complex array whose first (N/2+1) elements contain the transform results. X and Y may be the same array starting at the same memory location, in which case the dimension of X must be at least 2*(N/2+1). Otherwise, it is assumed that there is

no overlap between X and Y in memory.

TRIGS (input/output)

Double precision array of length $2*N$ that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

IFAC (input/output)

Integer array of dimension at least 128 that contains the factors of N. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls where IOPT = -1. Unchanged on exit.

WORK (workspace)

Double precision array of dimension at least N. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)

Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)

On exit, integer IERR has one of the following values:

- 0 = normal return
- 1 = IOPT is not 0 or -1
- 2 = $N < 0$
- 3 = (LWORK is not 0) and (LWORK is less than N)
- 4 = memory allocation for workspace failed

```
#include <sunperf.h>
void dffftz2_(int *iopt, int *n1, int *n2, double *scale,
             double *x, int *ldx, doublecomplex *y, int *ldy,
             double *trigs, int *ifac, double *work, int
             *lwork, int *ierr);

void dffftz2_64_(long *iopt, long *n1, long *n2, double
                *scale, double *x, long *ldx, doublecomplex *y,
```

```

long *ldy, double *trigs, long *ifac, double
*work, long *lwork, long *ierr);

```

PURPOSE

dffftz2 initializes the trigonometric weight and factor tables or computes the two-dimensional forward Fast Fourier Transform of a two-dimensional double precision array. In computing the two-dimensional FFT, one-dimensional FFTs are computed along the columns of the input array. One-dimensional FFTs are then computed along the rows of the intermediate results.

$$Y(k_1, k_2) = \text{scale} * \sum_{j_2=0}^{N_2-1} \sum_{j_1=0}^{N_1-1} W_2 * W_1 * X(j_1, j_2)$$

where

k_1 ranges from 0 to N_1-1 and k_2 ranges from 0 to N_2-1

$i = \sqrt{-1}$

isign = -1 for forward transform

$W_1 = \exp(\text{isign} * i * j_1 * k_1 * 2 * \pi / N_1)$

$W_2 = \exp(\text{isign} * i * j_2 * k_2 * 2 * \pi / N_2)$

In real-to-complex transform of length N_1 , the $(N_1/2+1)$ complex output data points stored are the positive-frequency half of the spectrum of the Discrete Fourier Transform. The other half can be obtained through complex conjugation and therefore is not stored.

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:
 IOPT = 0 computes the trigonometric weight table and factor table
 IOPT = -1 computes forward FFT

N1 (input)

Integer specifying length of the transform in the first dimension. N_1 is most efficient when it is a product of small primes. $N_1 \geq 0$. Unchanged on exit.

N2 (input)

Integer specifying length of the transform in the second dimension. N_2 is most efficient when it is a product of small primes $N_2 \geq 0$. Unchanged on exit.

SCALE (input)

Double precision scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0D0 for F95 INTERFACE.

X (input) X is a double complex array of dimensions (LDX, N_2) that contains input data to be transformed. X and Y can be the same array.

LDX (input)

Leading dimension of X. $LDX \geq N_1$ if X is not the same array as Y. Else, $LDX = 2 * LDY$. Unchanged on exit.

Y (output)

Y is a double complex array of dimensions (LDY, N_2) that contains the transform results. X and Y can be the same array starting at the same memory location, in which case the input data are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY (input)
 Leading dimension of Y. LDY >= N1/2+1 Unchanged on exit.

TRIGS (input/output)
 Double precision array of length 2*(N1+N2) that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

IFAC (input/output)
 Integer array of dimension at least 2*128 that contains the factors of N1 and N2. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

WORK (workspace)
 Double precision array of dimension at least MAX(N1, 2*N2) where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
 Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
 On exit, integer IERR has one of the following values:
 0 = normal return
 -1 = IOPT is not 0 or -1
 -2 = N1 < 0
 -3 = N2 < 0
 -4 = (LDX < N1) or (LDX not equal 2*LDY when X and Y are same array)
 -5 = (LDY < N1/2+1)
 -6 = (LWORK not equal 0) and (LWORK < MAX(N1, 2*N2))
 -7 = memory allocation failed

SEE ALSO

fft

CAUTIONS

On exit, output array Y(1:LDY, 1:N2) is overwritten.

$W_1 = \exp(\text{isign} * i * j_1 * k_1 * 2 * \pi / N_1)$

$W_2 = \exp(\text{isign} * i * j_2 * k_2 * 2 * \pi / N_2)$

$W_3 = \exp(\text{isign} * i * j_3 * k_3 * 2 * \pi / N_3)$

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = -1 computes forward FFT

N1 (input)

Integer specifying length of the transform in the first dimension. N1 is most efficient when it is a product of small primes. $N_1 \geq 0$. Unchanged on exit.

N2 (input)

Integer specifying length of the transform in the second dimension. N2 is most efficient when it is a product of small primes. $N_2 \geq 0$. Unchanged on exit.

N3 (input)

Integer specifying length of the transform in the third dimension. N3 is most efficient when it is a product of small primes. $N_3 \geq 0$. Unchanged on exit.

SCALE (input)

Double precision scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0D0 for F95 INTERFACE.

X (input) X is a double precision array of dimensions (LDX1, LDX2, N3) that contains input data to be transformed. X can be same array as Y.

LDX1 (input)

first dimension of X. If X is not same array as Y, $LDX1 \geq N_1$ Else, $LDX1 = 2 * LDY1$ Unchanged on exit.

LDX2 (input)

second dimension of X. $LDX2 \geq N_2$ Unchanged on exit.

Y (output)

Y is a double complex array of dimensions (LDY1, LDY2, N3) that contains the transform results. X and Y can be the same array starting at the same memory location, in which case the input data are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY1 (input)

first dimension of Y. $LDY1 \geq N_1/2+1$ Unchanged on exit.

LDY2 (input)

second dimension of Y. If X and Y are the same array, $LDY2 = LDX2$ Else $LDY2 \geq N_2$ Unchanged on exit.

TRIGS (input/output)

Double precision array of length $2 * (N_1 + N_2 + N_3)$ that contains the trigonometric weights. The weights

are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

IFAC (input/output)

Integer array of dimension at least 3*128 that contains the factors of N1, N2 and N3. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

WORK (workspace)

Double precision array of dimension at least $(\text{MAX}(N, 2*N2, 2*N3) + 16*N3) * \text{NCPUS}$ where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)

Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)

On exit, integer IERR has one of the following values:

- 0 = normal return
- 1 = IOPT is not 0 or -1
- 2 = N1 < 0
- 3 = N2 < 0
- 4 = N3 < 0
- 5 = (LDX1 < N1) or (LDX not equal 2*LDY when X and Y are same array)
- 6 = (LDX2 < N2)
- 7 = (LDY1 < N1/2+1)
- 8 = (LDY2 < N2) or (LDY2 not equal LDX2 when X and Y are same array)
- 9 = (LWORK not equal 0) and (LWORK < $(\text{MAX}(N, 2*N2, 2*N3) + 16*N3)$)
- 10 = memory allocation failed

SEE ALSO

fft

CAUTIONS

On exit, output subarray Y(1:LDY1, 1:N2, 1:N3) is overwritten.

*scale, double *x, long *ldx, doublecomplex *y,
```

```
long *ldy, double *trigs, long *ifac, double
*work, long *lwork, long *ierr);
```

PURPOSE

dffftzm initializes the trigonometric weight and factor tables or computes the one-dimensional forward Fast Fourier Transform of a set of double precision data sequences stored in a two-dimensional array:

$$Y(k,l) = \text{scale} * \sum_{j=0}^{N1-1} W * X(j,l)$$

where

k ranges from 0 to N1-1 and l ranges from 0 to N2-1

i = sqrt(-1)

isign = -1 for forward transform

W = exp(isign*i*j*k*2*pi/N1)

In real-to-complex transform of length N1, the (N1/2+1) complex output data points stored are the positive-frequency half of the spectrum of the discrete Fourier transform. The other half can be obtained through complex conjugation and therefore is not stored.

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = -1 computes forward FFT

N1 (input)

Integer specifying length of the input sequences. N1 is most efficient when it is a product of small primes. N1 >= 0. Unchanged on exit.

N2 (input)

Integer specifying number of input sequences. N2 >= 0. Unchanged on exit.

SCALE (input)

Double precision scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0D0 for F95 INTERFACE.

X (input) X is a double precision array of dimensions (LDX, N2) that contains the sequences to be transformed stored in its columns.

LDX (input)

Leading dimension of X. If X and Y are the same array, LDX = 2*LDY Else LDX >= N1 Unchanged on exit.

Y (output)

Y is a double complex array of dimensions (LDY, N2) that contains the transform results of the input sequences. X and Y can be the same array starting at the same memory location, in which case the input sequences are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY (input)

Leading dimension of Y. LDY >= N1/2 + 1 Unchanged on exit.

TRIGS (input/output)

Double precision array of length 2*N1 that contains the trigonometric weights. The weights are

computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

IFAC (input/output)

Integer array of dimension at least 128 that contains the factors of N1. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

WORK (workspace)

Double precision array of dimension at least N1. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)

Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)

On exit, integer IERR has one of the following values:

- 0 = normal return
- 1 = IOPT is not 0 or -1
- 2 = N1 < 0
- 3 = N2 < 0
- 4 = (LDX < N1) or (LDX not equal 2*LDY when X and Y are same array)
- 4 = (LDY < N1/2 + 1)
- 6 = (LWORK not equal 0) and (LWORK < N1)
- 7 = memory allocation failed

C INTERFACE

```
#include <sunperf.h>
```

```
void dgbbbrd(char vect, int m, int n, int ncc, int kl, int  
ku, double *ab, int ldab, double *d, double *e,
```

```

        double *q, int ldq, double *pt, int ldpt, double
        *c, int ldc, int *info);
void dgbbrd_64(char vect, long m, long n, long ncc, long kl,
long ku, double *ab, long ldab, double *d, double
*e, double *q, long ldq, double *pt, long ldpt,
double *c, long ldc, long *info);

```

PURPOSE

dgbbrd reduces a real general m-by-n band matrix A to upper bidiagonal form B by an orthogonal transformation: $Q' * A * P = B$.

The routine computes B, and optionally forms Q or P', or computes $Q'*C$ for a given matrix C.

ARGUMENTS

VECT (input)

Specifies whether or not the matrices Q and P' are to be formed. = 'N': do not form Q or P';
= 'Q': form Q only;
= 'P': form P' only;
= 'B': form both.

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

NCC (input)

The number of columns of the matrix C. $NCC \geq 0$.

KL (input)

The number of subdiagonals of the matrix A. $KL \geq 0$.

KU (input)

The number of superdiagonals of the matrix A. $KU \geq 0$.

AB (input/output)

On entry, the m-by-n band matrix A, stored in rows 1 to $KL+KU+1$. The j-th column of A is stored in the j-th column of the array AB as follows:
 $AB(ku+1+i-j, j) = A(i, j)$ for $\max(1, j-ku) \leq i \leq \min(m, j+kl)$. On exit, A is overwritten by values generated during the reduction.

LDAB (input)

The leading dimension of the array A. $LDAB \geq KL+KU+1$.

D (output)

The diagonal elements of the bidiagonal matrix B.

E (output)

The superdiagonal elements of the bidiagonal matrix B.

Q (output)

If VECT = 'Q' or 'B', the m-by-m orthogonal matrix

Q. If VECT = 'N' or 'P', the array Q is not referenced.

LDQ (input)

The leading dimension of the array Q. LDQ \geq max(1,M) if VECT = 'Q' or 'B'; LDQ \geq 1 otherwise.

PT (output)

If VECT = 'P' or 'B', the n-by-n orthogonal matrix P'. If VECT = 'N' or 'Q', the array PT is not referenced.

LDPT (input)

The leading dimension of the array PT. LDPT \geq max(1,N) if VECT = 'P' or 'B'; LDPT \geq 1 otherwise.

C (input/output)

On entry, an m-by-ncc matrix C. On exit, C is overwritten by Q'*C. C is not referenced if NCC = 0.

LDC (input)

The leading dimension of the array C. LDC \geq max(1,M) if NCC > 0; LDC \geq 1 if NCC = 0.

WORK (workspace)

dimension(MAX(M,N))

INFO (output)

= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

DOUBLE PRECISION A(LDA,*), WORK(*)
```

```
SUBROUTINE DGBCON_64(NORM, N, NSUB, NSUPER, A, LDA, IPIVOT, ANORM,
                    RCOND, WORK, WORK2, INFO)
```

```
CHARACTER * 1 NORM
INTEGER*8 N, NSUB, NSUPER, LDA, INFO
INTEGER*8 IPIVOT(*), WORK2(*)
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GBCON(NORM, [N], NSUB, NSUPER, A, [LDA], IPIVOT, ANORM,
                RCOND, [WORK], [WORK2], [INFO])
```

```
CHARACTER(LEN=1) :: NORM
INTEGER :: N, NSUB, NSUPER, LDA, INFO
INTEGER, DIMENSION(:) :: IPIVOT, WORK2
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,) :: A
```

```
SUBROUTINE GBCON_64(NORM, [N], NSUB, NSUPER, A, [LDA], IPIVOT, ANORM,
                   RCOND, [WORK], [WORK2], [INFO])
```

```
CHARACTER(LEN=1) :: NORM
INTEGER(8) :: N, NSUB, NSUPER, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT, WORK2
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK
```

```
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
void dgbcon(char norm, int n, int nsub, int nsuper, double
            *a, int lda, int *ipivot, double anorm, double
            *rcond, int *info);

void dgbcon_64(char norm, long n, long nsub, long nsuper,
              double *a, long lda, long *ipivot, double anorm,
              double *rcond, long *info);
```

PURPOSE

dgbcon estimates the reciprocal of the condition number of a real general band matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by SGBTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

NORM (input)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I': Infinity-norm.

N (input) The order of the matrix A. $N \geq 0$.

NSUB (input)

The number of subdiagonals within the band of A.
 $\text{NSUB} \geq 0$.

NSUPER (input)

The number of superdiagonals within the band of A.
 $\text{NSUPER} \geq 0$.

A (input) Details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with $\text{NSUB} + \text{NSUPER}$ superdiagonals in rows 1 to $\text{NSUB} + \text{NSUPER} + 1$, and the multipliers used during the factorization are stored in rows $\text{NSUB} + \text{NSUPER} + 2$ to $2 * \text{NSUB} + \text{NSUPER} + 1$.

LDA (input)

The leading dimension of the array A. $\text{LDA} \geq 2 * \text{NSUB} + \text{NSUPER} + 1$.

IPIVOT (input)

The pivot indices; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

ANORM (input)

If $\text{NORM} = '1'$ or $'O'$, the 1-norm of the original matrix A. If $\text{NORM} = 'I'$, the infinity-norm of the original matrix A.

RCOND (output)

The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

WORK (workspace)

dimension(3*N)

WORK2 (workspace)

dimension (N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

void dgbequ(int m, int n, int nsub, int nsuper, double *a,  
           int lda, double *rowsc, double *colsc, double  
           *rowcn, double *colcn, double *amax, int *info);
```

```

void dgbequ_64(long m, long n, long nsub, long nsuper, double
    *a, long lda, double *rowsc, double *colsc,
    double *rowcn, double *colcn, double *amax, long
    *info);

```

PURPOSE

dgbequ computes row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements $B(i,j)=R(i)*A(i,j)*C(j)$ have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

NSUB (input)
The number of subdiagonals within the band of A.
 $NSUB \geq 0$.

NSUPER (input)
The number of superdiagonals within the band of A.
 $NSUPER \geq 0$.

A (input) The band matrix A, stored in rows 1 to $NSUB+NSUPER+1$. The j-th column of A is stored in the j-th column of the array A as follows:

$$A(ku+1+i-j,j) = A(i,j) \quad \text{for } \max(1,j-ku) \leq i \leq \min(m,j+kl).$$

LDA (input)
The leading dimension of the array A. $LDA \geq NSUB+NSUPER+1$.

ROWSC (output)
If $INFO = 0$, or $INFO > M$, ROWSC contains the row scale factors for A.

COLSC (output)
If $INFO = 0$, COLSC contains the column scale factors for A.

ROWCN (output)
If $INFO = 0$ or $INFO > M$, ROWCN contains the ratio of the smallest ROWSC(i) to the largest ROWSC(i).
If $ROWCN \geq 0.1$ and AMAX is neither too large nor too small, it is not worth scaling by ROWSC.

COLCN (output)
If $INFO = 0$, COLCN contains the ratio of the smallest COLSC(i) to the largest COLSC(i). If COLCN

≥ 0.1 , it is not worth scaling by COLSC.

AMAX (output)

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= M: the i-th row of A is exactly zero
> M: the (i-M)-th column of A is exactly zero

           double alpha, double *a, int lda, double *x, int
           incx, double beta, double *y, int incy);
void dgbmv_64(char transa, long m, long n, long nsub, long
              nsuper, double alpha, double *a, long lda, double
              *x, long incx, double beta, double *y, long incy);

```

PURPOSE

dgbmv performs one of the matrix-vector operations $y := \alpha A x + \beta y$ or $y := \alpha A' x + \beta y$, where α and β are scalars, x and y are vectors and A is an m by n band matrix, with $nsub$ sub-diagonals and $nsuper$ super-diagonals.

ARGUMENTS

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $y := \alpha A x + \beta y$.

TRANSA = 'T' or 't' $y := \alpha A' x + \beta y$.

TRANSA = 'C' or 'c' $y := \alpha A' x + \beta y$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input)

On entry, M specifies the number of rows of the matrix A. $M \geq 0$. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix A. $N \geq 0$. Unchanged on exit.

NSUB (input)

On entry, NSUB specifies the number of sub-diagonals of the matrix A. $NSUB \geq 0$. Unchanged on exit.

NSUPER (input)

On entry, NSUPER specifies the number of super-diagonals of the matrix A. $NSUPER \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

A (input)

Before entry, the leading $(nsub + nsuper + 1)$ by n part of the array A must contain the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row $(nsuper + 1)$ of the array, the first super-diagonal starting at position 2 in row $nsuper$, the first sub-diagonal starting at position 1 in row $(nsuper +$

2), and so on. Elements in the array A that do not correspond to elements in the band matrix (such as the top left nsuper by nsuper triangle) are not referenced. The following program segment will transfer a band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        K = NSUPER + 1 - J
        DO 10, I = MAX( 1, J - NSUPER ), MIN( M, J +
NSUB )
          A( K + I, J ) = matrix( I, J )
10      CONTINUE
20      CONTINUE
```

Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA \geq (nsub + nsuper + 1). Unchanged on exit.

X (input)

(1 + (n - 1) * abs(INCX)) when TRANSA = 'N' or 'n' and at least (1 + (m - 1) * abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX \neq 0. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)

(1 + (m - 1) * abs(INCY)) when TRANSA = 'N' or 'n' and at least (1 + (n - 1) * abs(INCY)) otherwise. Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY \neq 0. Unchanged on exit.

  *info);

```

PURPOSE

dgbrfs improves the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

TRANSA (input)
 Specifies the form of the system of equations:
 = 'N': $A * X = B$ (No transpose)
 = 'T': $A^{**T} * X = B$ (Transpose)
 = 'C': $A^{**H} * X = B$ (Conjugate transpose = Transpose)
 TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

NSUB (input)
 The number of subdiagonals within the band of A.
 $NSUB \geq 0$.

NSUPER (input)
 The number of superdiagonals within the band of A.
 $NSUPER \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The original band matrix A, stored in rows 1 to $NSUB+NSUPER+1$. The j-th column of A is stored in the j-th column of the array A as follows:
 $A(ku+1+i-j, j) = A(i, j)$ for $\max(1, j-ku) \leq i \leq \min(n, j+kl)$.

LDA (input)
 The leading dimension of the array A. $LDA \geq NSUB+NSUPER+1$.

AF (input)
 Details of the LU factorization of the band matrix

A, as computed by SGBTRF. U is stored as an upper triangular band matrix with NSUB+NSUPER superdiagonals in rows 1 to NSUB+NSUPER+1, and the multipliers used during the factorization are stored in rows NSUB+NSUPER+2 to 2*NSUB+NSUPER+1.

LDAF (input)

The leading dimension of the array AF. LDAF \geq 2*NSUB*NSUPER+1.

IPIVOT (input)

The pivot indices from SGBTRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

B (input) The right hand side matrix B.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,N).

X (input/output)

On entry, the solution matrix X, as computed by SGBTRS. On exit, the improved solution matrix X.

LDX (input)

The leading dimension of the array X. LDX \geq max(1,N).

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

dimension(3*N)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```
#include <sunperf.h>
```

```
void dgbsv(int n, int nsub, int nsuper, int nrhs, double *a,  
int lda, int *ipivot, double *b, int ldb, int  
*info);
```

```
void dgbsv_64(long n, long nsub, long nsuper, long nrhs,
             double *a, long lda, long *ipivot, double *b, long
             ldb, long *info);
```

PURPOSE

dgbsv computes the solution to a real system of linear equations $A * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as $A = L * U$, where L is a product of permutation and unit lower triangular matrices with KL subdiagonals, and U is upper triangular with KL+KU superdiagonals. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NSUB (input)
The number of subdiagonals within the band of A. $NSUB \geq 0$.

NSUPER (input)
The number of superdiagonals within the band of A. $NSUPER \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input/output)
On entry, the matrix A in band storage, in rows NSUB+1 to $2*NSUB+NSUPER+1$; rows 1 to NSUB of the array need not be set. The j-th column of A is stored in the j-th column of the array A as follows: $A(NSUB+NSUPER+1+i-j,j) = A(i,j)$ for $\max(1,j-NSUPER) \leq i \leq \min(N,j+NSUB)$ On exit, details of the factorization: U is stored as an upper triangular band matrix with NSUB+NSUPER superdiagonals in rows 1 to NSUB+NSUPER+1, and the multipliers used during the factorization are stored in rows NSUB+NSUPER+2 to $2*NSUB+NSUPER+1$. See below for further details.

LDA (input)
The leading dimension of the array A. $LDA \geq 2*NSUB+NSUPER+1$.

IPIVOT (output)
The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIVOT(i).

B (input/output)

On entry, the N-by-NRHS right hand side matrix B.
 On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and the solution has not been computed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when M = N = 6, NSUB = 2, NSUPER = 1:

On entry:

On exit:

	*	*	*	+	+	+		*	*	*	u14	u25	
u36	*	*	+	+	+	+		*	*		u13	u24	u35
u46	*	a12	a23	a34	a45	a56		*	u12	u23	u34	u45	
u56	a11	a22	a33	a44	a55	a66		u11	u22	u33	u44	u55	
u66	a21	a32	a43	a54	a65	*		m21	m32	m43	m54	m65	
*	a31	a42	a53	a64	*	*		m31	m42	m53	m64	*	
*													

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U because of fill-in resulting from the row interchanges.

```

PURPOSE

dgbsvx uses the LU factorization to compute the solution to a real system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed by this subroutine:

1. If FACT = 'E', real scaling factors are computed to equilibrate

the system:

TRANS = 'N': $\text{diag}(R) * A * \text{diag}(C) * \text{inv}(\text{diag}(C)) * X = \text{diag}(R) * B$

TRANS = 'T': $(\text{diag}(R) * A * \text{diag}(C))^{**T} * \text{inv}(\text{diag}(R)) * X = \text{diag}(C) * B$

TRANS = 'C': $(\text{diag}(R) * A * \text{diag}(C))^{**H} * \text{inv}(\text{diag}(R)) * X = \text{diag}(C) * B$

Whether or not the system will be equilibrated depends on the

scaling of the matrix A, but if equilibration is used, A

is overwritten by $\text{diag}(R) * A * \text{diag}(C)$ and B by $\text{diag}(R) * B$ (if TRANS='N')

or $\text{diag}(C) * B$ (if TRANS = 'T' or 'C').

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the

matrix A (after equilibration if FACT = 'E') as

$A = L * U$,

where L is a product of permutation and unit lower triangular

matrices with KL subdiagonals, and U is upper triangular

with
 KL+KU superdiagonals.

3. If some $U(i,i)=0$, so that U is exactly singular, then the routine returns with $INFO = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $INFO = N+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A .

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(C)$ (if $TRANS = 'N'$) or $\text{diag}(R)$ (if $TRANS = 'T'$ or $'C'$) so that it solves the original system before equilibration.

ARGUMENTS

FACT (input)
 Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and $IPIVOT$ contain the factored form of A . If $EQUED$ is not 'N', the matrix A has been equilibrated with scaling factors given by $ROWSC$ and $COLSC$. A , AF , and $IPIVOT$ are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

TRANS (input)
 Specifies the form of the system of equations. = 'N': $A * X = B$ (No transpose)
 = 'T': $A^{**T} * X = B$ (Transpose)
 = 'COLSC': $A^{**H} * X = B$ (Transpose)

$TRANS$ is defaulted to 'N' for F95 INTERFACE.

N (input) The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

NSUB (input)
 The number of subdiagonals within the band of A . $NSUB \geq 0$.

NSUPER (input)

The number of superdiagonals within the band of A.
NSUPER >= 0.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input/output)

On entry, the matrix A in band storage, in rows 1 to NSUB+NSUPER+1. The j-th column of A is stored in the j-th column of the array A as follows:
 $A(NSUPER+1+i-j, j) = A(i, j)$ for $\max(1, j-NSUPER) \leq i \leq \min(N, j+kl)$

If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in ROWSC and/or COLSC. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows:
EQUED = 'ROWSC': A := diag(ROWSC) * A
EQUED = 'COLSC': A := A * diag(COLSC)
EQUED = 'B': A := diag(ROWSC) * A * diag(COLSC).

LDA (input)

The leading dimension of the array A. LDA >= NSUB+NSUPER+1.

AF (input/output)

If FACT = 'F', then AF is an input argument and on entry contains details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with NSUB+NSUPER superdiagonals in rows 1 to NSUB+NSUPER+1, and the multipliers used during the factorization are stored in rows NSUB+NSUPER+2 to 2*NSUB+NSUPER+1. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns details of the LU factorization of A.

If FACT = 'E', then AF is an output argument and on exit returns details of the LU factorization of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)

The leading dimension of the array AF. LDAF >= 2*NSUB+NSUPER+1.

IPIVOT (input)

If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the factorization $A = L*U$ as computed by SGBTRF; row i of the matrix was interchanged with row IPIVOT(i).

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = L*U$ of the original matrix A.

If FACT = 'E', then IPIVOT is an output argument

and on exit contains the pivot indices from the factorization $A = L*U$ of the equilibrated matrix A.

EQUED (input)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'ROWSC': Row equilibration, i.e., A has been premultiplied by $\text{diag}(\text{ROWSC})$.
= 'COLSC': Column equilibration, i.e., A has been postmultiplied by $\text{diag}(\text{COLSC})$.
= 'B': Both row and column equilibration, i.e., A has been replaced by $\text{diag}(\text{ROWSC}) * A * \text{diag}(\text{COLSC})$.
EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

ROWSC (input/output)

The row scale factors for A. If EQUED = 'ROWSC' or 'B', A is multiplied on the left by $\text{diag}(\text{ROWSC})$; if EQUED = 'N' or 'COLSC', ROWSC is not accessed. ROWSC is an input argument if FACT = 'F'; otherwise, ROWSC is an output argument. If FACT = 'F' and EQUED = 'ROWSC' or 'B', each element of ROWSC must be positive.

COLSC (input/output)

The column scale factors for A. If EQUED = 'COLSC' or 'B', A is multiplied on the right by $\text{diag}(\text{COLSC})$; if EQUED = 'N' or 'ROWSC', COLSC is not accessed. COLSC is an input argument if FACT = 'F'; otherwise, COLSC is an output argument. If FACT = 'F' and EQUED = 'COLSC' or 'B', each element of COLSC must be positive.

B (input/output)

On entry, the right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANS = 'N' and EQUED = 'ROWSC' or 'B', B is overwritten by $\text{diag}(\text{ROWSC}) * B$; if TRANS = 'T' or 'COLSC' and EQUED = 'COLSC' or 'B', B is overwritten by $\text{diag}(\text{COLSC}) * B$.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED = 'N', and the solution to the equilibrated system is $\text{inv}(\text{diag}(\text{COLSC})) * X$ if TRANS = 'N' and EQUED = 'COLSC' or 'B', or $\text{inv}(\text{diag}(\text{ROWSC})) * X$ if TRANS = 'T' or 'COLSC' and EQUED = 'ROWSC' or 'B'.

LDX (input)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in par-

ticular, if $RCOND = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $INFO > 0$.

FERR (output)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If $XTRUE$ is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

dimension($3*N$) On exit, $WORK(1)$ contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$. The "max absolute element" norm is used. If $WORK(1)$ is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X , condition estimator $RCOND$, and forward error bound $FERR$ could be unreliable. If factorization fails with $0 < INFO \leq N$, then $WORK(1)$ contains the reciprocal pivot growth factor for the leading $INFO$ columns of A .

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value
> 0: if $INFO = i$, and i is
 $\leq N$: $U(i,i)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. $RCOND = 0$ is returned. = $N+1$: U is nonsingular, but $RCOND$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $RCOND$ would suggest.

dgbtbf2 - compute an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges

SYNOPSIS

```
SUBROUTINE DGBTF2(M, N, KL, KU, AB, LDAB, IPIV, INFO)
```

```
INTEGER M, N, KL, KU, LDAB, INFO  
INTEGER IPIV(*)  
DOUBLE PRECISION AB(LDAB,*)
```

```
SUBROUTINE DGBTF2_64(M, N, KL, KU, AB, LDAB, IPIV, INFO)
```

```
INTEGER*8 M, N, KL, KU, LDAB, INFO  
INTEGER*8 IPIV(*)  
DOUBLE PRECISION AB(LDAB,*)
```

F95 INTERFACE

```
SUBROUTINE GBTf2([M], [N], KL, KU, AB, [LDAB], IPIV, [INFO])
```

```
INTEGER :: M, N, KL, KU, LDAB, INFO  
INTEGER, DIMENSION(:) :: IPIV  
REAL(8), DIMENSION(:, :) :: AB
```

```
SUBROUTINE GBTf2_64([M], [N], KL, KU, AB, [LDAB], IPIV, [INFO])
```

```
INTEGER(8) :: M, N, KL, KU, LDAB, INFO  
INTEGER(8), DIMENSION(:) :: IPIV  
REAL(8), DIMENSION(:, :) :: AB
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgbtbf2(int m, int n, int kl, int ku, double *ab, int  
            ldab, int *ipiv, int *info);
```

```
void dgbtbf2_64(long m, long n, long kl, long ku, double *ab,  
               long ldab, long *ipiv, long *info);
```

PURPOSE

dgbtbf2 computes an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

KL (input)
The number of subdiagonals within the band of A.
 $KL \geq 0$.

KU (input)
The number of superdiagonals within the band of A.
 $KU \geq 0$.

AB (input/output)
On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows:
$$AB(kl+ku+1+i-j,j) = A(i,j) \quad \text{for} \quad \max(1,j-ku) \leq i \leq \min(m,j+kl)$$

On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB (input)
The leading dimension of the array AB. $LDAB \geq 2*KL+KU+1$.

IPIV (output)
The pivot indices; for $1 \leq i \leq \min(M,N)$, row i of the matrix was interchanged with row IPIV(i).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = +i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when $M = N = 6$, $KL = 2$, $KU = 1$:

On entry:

On exit:

	*	*	*	+	+	+		*	*	*	u14	u25	
u36	*	*	+	+	+	+		*	*		u13	u24	u35
u46	*	a12	a23	a34	a45	a56		*	u12	u23	u34	u45	
u56	a11	a22	a33	a44	a55	a66		u11	u22	u33	u44	u55	
u66	a21	a32	a43	a54	a65	*		m21	m32	m43	m54	m65	
*	a31	a42	a53	a64	*	*		m31	m42	m53	m64	*	
*													

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U , because of fill-in resulting from the row interchanges.

C INTERFACE

```
#include <sunperf.h>
```

```
void dgbtrf(int m, int n, int nsub, int nsuper, double *a,  
           int lda, int *ipivot, int *info);
```

```
void dgbtrf_64(long m, long n, long nsub, long nsuper, dou-  
              ble *a, long lda, long *ipivot, long *info);
```

PURPOSE

dgbtrf computes an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

NSUB (input)
The number of subdiagonals within the band of A.
 $NSUB \geq 0$.

NSUPER (input)
The number of superdiagonals within the band of A.
 $NSUPER \geq 0$.

A (input/output)
On entry, the matrix A in band storage, in rows NSUB+1 to $2*NSUB+NSUPER+1$; rows 1 to NSUB of the array need not be set. The j-th column of A is stored in the j-th column of the array A as follows: $A(kl+ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(m,j+kl)$

On exit, details of the factorization: U is stored as an upper triangular band matrix with NSUB+NSUPER superdiagonals in rows 1 to NSUB+NSUPER+1, and the multipliers used during the factorization are stored in rows NSUB+NSUPER+2 to $2*NSUB+NSUPER+1$. See below for further details.

LDA (input)
The leading dimension of the array A. $LDA \geq 2*NSUB+NSUPER+1$.

IPIVOT (output)
The pivot indices; for $1 \leq i \leq \min(M,N)$, row i of the matrix was interchanged with row IPIVOT(i).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = +i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when $M = N = 6$, $NSUB = 2$, $NSUPER = 1$:

On entry:

On exit:

	*	*	*	+	+	+		*	*	*	u14	u25
u36								*	*			
	*	*	+	+	+	+		*	*	u13	u24	u35
u46												
	*	a12	a23	a34	a45	a56		*	u12	u23	u34	u45
u56												
	a11	a22	a33	a44	a55	a66		u11	u22	u33	u44	u55
u66												
	a21	a32	a43	a54	a65	*		m21	m32	m43	m54	m65
*												
	a31	a42	a53	a64	*	*		m31	m42	m53	m64	*
*												

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U because of fill-in resulting from the row interchanges.

INTEGER*8 N, NSUB, NSUPER, NRHS, LDA, LDB, INFO
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE GBTRS([TRANSA], [N], NSUB, NSUPER, [NRHS], A, [LDA],
  IPIVOT, B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: TRANSA
INTEGER :: N, NSUB, NSUPER, NRHS, LDA, LDB, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL(8), DIMENSION(:, :) :: A, B
```

```
SUBROUTINE GBTRS_64([TRANSA], [N], NSUB, NSUPER, [NRHS], A, [LDA],
  IPIVOT, B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: TRANSA
INTEGER(8) :: N, NSUB, NSUPER, NRHS, LDA, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8), DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgbtrs(char transa, int n, int nsub, int nsuper, int
```

```

        nrhs, double *a, int lda, int *ipivot, double *b,
        int ldb, int *info);
void dgbtrs_64(char transa, long n, long nsub, long nsuper,
        long nrhs, double *a, long lda, long *ipivot, dou-
        ble *b, long ldb, long *info);

```

PURPOSE

dgbtrs solves a system of linear equations
 $A * X = B$ or $A' * X = B$ with a general band matrix A
using the LU factorization computed by SGBTRF.

ARGUMENTS

TRANSA (input)
Specifies the form of the system of equations. =
'N': $A * X = B$ (No transpose)
= 'T': $A' * X = B$ (Transpose)
= 'C': $A' * X = B$ (Conjugate transpose = Tran-
spose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

NSUB (input)
The number of subdiagonals within the band of A.
NSUB ≥ 0 .

NSUPER (input)
The number of superdiagonals within the band of A.
NSUPER ≥ 0 .

NRHS (input)
The number of right hand sides, i.e., the number
of columns of the matrix B. NRHS ≥ 0 .

A (input) Details of the LU factorization of the band matrix
A, as computed by SGBTRF. U is stored as an upper
triangular band matrix with NSUB+NSUPER superdiag-
onals in rows 1 to NSUB+NSUPER+1, and the multi-
pliers used during the factorization are stored in
rows NSUB+NSUPER+2 to 2*NSUB+NSUPER+1.

LDA (input)
The leading dimension of the array A. LDA \geq
2*NSUB+NSUPER+1.

IPIVOT (input)
The pivot indices; for $1 \leq i \leq N$, row i of the
matrix was interchanged with row IPIVOT(i).

B (input/output)
On entry, the right hand side matrix B. On exit,
the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB \geq
max(1,N).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

REAL(8), DIMENSION(:, :) :: V
```

```
SUBROUTINE GEBAK_64(JOB, SIDE, [N], ILO, IHI, SCALE, [M], V, [LDV],  
[INFO])
```

```
CHARACTER(LEN=1) :: JOB, SIDE  
INTEGER(8) :: N, ILO, IHI, M, LDV, INFO  
REAL(8), DIMENSION(:) :: SCALE  
REAL(8), DIMENSION(:, :) :: V
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgebak(char job, char side, int n, int ilo, int ihi,  
double *scale, int m, double *v, int ldv, int  
*info);
```

```
void dgebak_64(char job, char side, long n, long ilo, long
```

```
ihi, double *scale, long m, double *v, long ldv,  
long *info);
```

PURPOSE

dgebak forms the right or left eigenvectors of a real general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by SGEBAL.

ARGUMENTS

JOB (input)

Specifies the type of backward transformation required: = 'N', do nothing, return immediately; = 'P', do backward transformation for permutation only; = 'S', do backward transformation for scaling only; = 'B', do backward transformations for both permutation and scaling. JOB must be the same as the argument JOB supplied to SGEBAL.

SIDE (input)

= 'R': V contains right eigenvectors;
= 'L': V contains left eigenvectors.

N (input) The number of rows of the matrix V. $N \geq 0$.

ILO (input)

The integers ILO and IHI determined by SGEBAL. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

IHI (input)

See the description for ILO.

SCALE (input)

Details of the permutation and scaling factors, as returned by SGEBAL.

M (input) The number of columns of the matrix V. $M \geq 0$.

V (input/output)

On entry, the matrix of right or left eigenvectors to be transformed, as returned by SHSEIN or STREVC. On exit, V is overwritten by the transformed eigenvectors.

LDV (input)

The leading dimension of the array V. $LDV \geq \max(1,N)$.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value.

NAME

dgebal - balance a general real matrix A

SYNOPSIS

```
SUBROUTINE DGEBAL(JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
```

```
CHARACTER * 1 JOB  
INTEGER N, LDA, ILO, IHI, INFO  
DOUBLE PRECISION A(LDA,*), SCALE(*)
```

```
SUBROUTINE DGEBAL_64(JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
```

```
CHARACTER * 1 JOB  
INTEGER*8 N, LDA, ILO, IHI, INFO  
DOUBLE PRECISION A(LDA,*), SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE GEBAL(JOB, [N], A, [LDA], ILO, IHI, SCALE, [INFO])
```

```
CHARACTER(LEN=1) :: JOB  
INTEGER :: N, LDA, ILO, IHI, INFO  
REAL(8), DIMENSION(:) :: SCALE  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE GEBAL_64(JOB, [N], A, [LDA], ILO, IHI, SCALE, [INFO])
```

```
CHARACTER(LEN=1) :: JOB  
INTEGER(8) :: N, LDA, ILO, IHI, INFO  
REAL(8), DIMENSION(:) :: SCALE  
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgebal(char job, int n, double *a, int lda, int *ilo,  
            int *ihi, double *scale, int *info);
```

```
void dgebal_64(char job, long n, double *a, long lda, long  
               *ilo, long *ihi, double *scale, long *info);
```

PURPOSE

dgebal balances a general real matrix A. This involves, first, permuting A by a similarity transformation to isolate eigenvalues in the first 1 to ILO-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

ARGUMENTS

JOB (input)

Specifies the operations to be performed on A:
= 'N': none: simply set ILO = 1, IHI = N,
SCALE(I) = 1.0 for i = 1,...,N; = 'P': permute
only;
= 'S': scale only;
= 'B': both permute and scale.

N (input) The order of the matrix A. N >= 0.

A (input/output)

On entry, the input matrix A. On exit, A is
overwritten by the balanced matrix. If JOB = 'N',
A is not referenced. See Further Details.

LDA (input)

The leading dimension of the array A. LDA >=
max(1,N).

ILO (output)

ILO and IHI are set to integers such that on exit
A(i,j) = 0 if i > j and j = 1,...,ILO-1 or I =
IHI+1,...,N. If JOB = 'N' or 'S', ILO = 1 and IHI
= N.

IHI (output)

See the description for ILO.

SCALE (output)

Details of the permutations and scaling factors
applied to A. If P(j) is the index of the row and
column interchanged with row and column j and D(j)
is the scaling factor applied to row and column j,
then SCALE(j) = P(j) for j = 1,...,ILO-1 = D(j)
for j = ILO,...,IHI = P(j) for j = IHI+1,...,N.
The order in which the interchanges are made is N
to IHI+1, then 1 to ILO-1.

INFO (output)

= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an ille-
gal value.

FURTHER DETAILS

The permutations consist of row and column interchanges which put the matrix in the form

$$P A P = \begin{pmatrix} T1 & X & Y \\ 0 & B & Z \\ 0 & 0 & T2 \end{pmatrix}$$

where T1 and T2 are upper triangular matrices whose eigenvalues lie along the diagonal. The column indices ILO and IHI mark the starting and ending columns of the submatrix B. Balancing consists of applying a diagonal similarity transformation $\text{inv}(D) * B * D$ to make the 1-norms of each row of B and its corresponding column nearly equal. The output matrix is

$$\begin{pmatrix} T1 & X*D & Y \\ 0 & \text{inv}(D)*B*D & \text{inv}(D)*Z \\ 0 & 0 & T2 \end{pmatrix}$$

Information about the permutations P and the diagonal matrix D is returned in the vector SCALE.

This subroutine is based on the EISPACK routine BALANC.

SUBROUTINE DGEBRD_64(M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK,  
INFO)
```

```
INTEGER*8 M, N, LDA, LWORK, INFO  
DOUBLE PRECISION A(LDA,*), D(*), E(*), TAUQ(*), TAUP(*),  
WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEBRD([M], [N], A, [LDA], D, E, TAUQ, TAUP, [WORK], [LWORK],  
[INFO])
```

```
INTEGER :: M, N, LDA, LWORK, INFO  
REAL(8), DIMENSION(:) :: D, E, TAUQ, TAUP, WORK  
REAL(8), DIMENSION(:,:) :: A
```

```
SUBROUTINE GEBRD_64([M], [N], A, [LDA], D, E, TAUQ, TAUP, [WORK],  
[LWORK], [INFO])
```

```
INTEGER(8) :: M, N, LDA, LWORK, INFO  
REAL(8), DIMENSION(:) :: D, E, TAUQ, TAUP, WORK  
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgebrd(int m, int n, double *a, int lda, double *d,  
double *e, double *tauq, double *taup, int *info);
```

```
void dgebrd_64(long m, long n, double *a, long lda, double  
*d, double *e, double *tauq, double *taup, long
```

```
*info);
```

PURPOSE

dgebrd reduces a general real M-by-N matrix A to upper or lower bidiagonal form B by an orthogonal transformation:
 $Q^{*T} * A * P = B$.

If $m \geq n$, B is upper bidiagonal; if $m < n$, B is lower bidiagonal.

ARGUMENTS

M (input) The number of rows in the matrix A. $M \geq 0$.

N (input) The number of columns in the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N general matrix to be reduced. On exit, if $m \geq n$, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors; if $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors. See Further Details.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

D (output)

The diagonal elements of the bidiagonal matrix B:
 $D(i) = A(i, i)$.

E (output)

The off-diagonal elements of the bidiagonal matrix B:
if $m \geq n$, $E(i) = A(i, i+1)$ for $i = 1, 2, \dots, n-1$;
if $m < n$, $E(i) = A(i+1, i)$ for $i = 1, 2, \dots, m-1$.

TAUQ (output)

The scalar factors of the elementary reflectors which represent the orthogonal matrix Q. See Further Details.

TAUP (output)

The scalar factors of the elementary reflectors which represent the orthogonal matrix P. See Further Details.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The length of the array WORK. LWORK \geq max(1,M,N). For optimum performance LWORK \geq (M+N)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrices Q and P are represented as products of elementary reflectors:

If $m \geq n$,

$$Q = H(1) H(2) \dots H(n) \quad \text{and} \quad P = G(1) G(2) \dots G(n-1)$$

Each H(i) and G(i) has the form:

$$H(i) = I - \tau_{iH} v v' \quad \text{and} \quad G(i) = I - \tau_{iG} u u'$$

where τ_{iH} and τ_{iG} are real scalars, and v and u are real vectors; $v(1:i-1) = 0$, $v(i) = 1$, and $v(i+1:m)$ is stored on exit in A(i+1:m,i); $u(1:i) = 0$, $u(i+1) = 1$, and $u(i+2:n)$ is stored on exit in A(i,i+2:n); τ_{iH} is stored in TAUQ(i) and τ_{iG} in TAUP(i).

If $m < n$,

$$Q = H(1) H(2) \dots H(m-1) \quad \text{and} \quad P = G(1) G(2) \dots G(m)$$

Each H(i) and G(i) has the form:

$$H(i) = I - \tau_{iH} v v' \quad \text{and} \quad G(i) = I - \tau_{iG} u u'$$

where τ_{iH} and τ_{iG} are real scalars, and v and u are real vectors; $v(1:i) = 0$, $v(i+1) = 1$, and $v(i+2:m)$ is stored on exit in A(i+2:m,i); $u(1:i-1) = 0$, $u(i) = 1$, and $u(i+1:n)$ is stored on exit in A(i,i+1:n); τ_{iH} is stored in TAUQ(i) and τ_{iG} in TAUP(i).

The contents of A on exit are illustrated by the following examples:

$m = 6$ and $n = 5$ ($m > n$):

```
( d  e  u1 u1 u1 )
u1 )
( v1 d  e  u2 u2 )
u2 )
( v1 v2 d  e  u3 )
u3 )
( v1 v2 v3 d  e )
```

$m = 5$ and $n = 6$ ($m < n$):

```
( d  u1  u1  u1  u1
( e  d  u2  u2  u2
( v1 e  d  u3  u3
( v1 v2 e  d  u4
```

$$\begin{array}{l}
 u_4 \) \\
 (\ v_1 \ v_2 \ v_3 \ v_4 \ d \) \qquad (\ v_1 \ v_2 \ v_3 \ e \ d \\
 u_5 \) \\
 (\ v_1 \ v_2 \ v_3 \ v_4 \ v_5 \)
 \end{array}$$

where d and e denote diagonal and off-diagonal elements of B , v_i denotes an element of the vector defining $H(i)$, and u_i an element of the vector defining $G(i)$.

REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
void dgecon(char norm, int n, double *a, int lda, double
            anorm, double *rcond, int *info);

void dgecon_64(char norm, long n, double *a, long lda, dou-
              ble anorm, double *rcond, long *info);
```

PURPOSE

dgecon estimates the reciprocal of the condition number of a general real matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by SGETRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))) .$$

ARGUMENTS

NORM (input)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I': Infinity-norm.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The factors L and U from the factorization $A = P*L*U$ as computed by SGETRF.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

ANORM (input)

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND (output)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

WORK (workspace)

dimension(4*N)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

REAL(8) :: ROWCN, COLCN, AMAX
REAL(8), DIMENSION(:) :: ROWSC, COLSC
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE GEEQU_64([M], [N], A, [LDA], ROWSC, COLSC, ROWCN, COLCN,
                  AMAX, [INFO])
```

```
INTEGER(8) :: M, N, LDA, INFO
REAL(8) :: ROWCN, COLCN, AMAX
REAL(8), DIMENSION(:) :: ROWSC, COLSC
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgeequ(int m, int n, double *a, int lda, double *rowsc,
           double *colsc, double *rowcn, double *colcn, double *amax, int *info);
```

```
void dgeequ_64(long m, long n, double *a, long lda, double
    *rowsc, double *colsc, double *rowcn, double
    *colcn, double *amax, long *info);
```

PURPOSE

dgeequ computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements $B(i,j)=R(i)*A(i,j)*C(j)$ have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input) The M-by-N matrix whose equilibration factors are to be computed.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1,M)$.

ROWSC (output)
If INFO = 0 or INFO > M, ROWSC contains the row scale factors for A.

COLSC (output)
If INFO = 0, COLSC contains the column scale factors for A.

ROWCN (output)
If INFO = 0 or INFO > M, ROWCN contains the ratio of the smallest ROWSC(i) to the largest ROWSC(i).
If ROWCN ≥ 0.1 and AMAX is neither too large nor too small, it is not worth scaling by ROWSC.

COLCN (output)
If INFO = 0, COLCN contains the ratio of the smallest COLSC(i) to the largest COLSC(i). If COLCN ≥ 0.1 , it is not worth scaling by COLSC.

AMAX (output)
Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
 $\leq M$: the i-th row of A is exactly zero

> M: the $(i-M)$ -th column of A is exactly zero

                   long lda, long *nout, double *wr, double *wi, dou-
                   ble *z, long ldz, long *info);
```

PURPOSE

dgees computes for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization $A = Z^*T^*(Z^{**}T)$.

Optionally, it also orders the eigenvalues on the diagonal of the real Schur form so that selected eigenvalues are at the top left. The leading columns of Z then form an orthonormal basis for the invariant subspace corresponding to the selected eigenvalues.

A matrix is in real Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

$$\begin{bmatrix} a & b \\ c & a \end{bmatrix}$$

where $b*c < 0$. The eigenvalues of such a block are $a \pm \sqrt{bc}$.

ARGUMENTS

JOBZ (input)

= 'N': Schur vectors are not computed;
= 'V': Schur vectors are computed.

SORTEV (input)

Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. = 'N': Eigenvalues are not ordered;
= 'S': Eigenvalues are ordered (see SELECT).

SELECT (input)

SELECT must be declared EXTERNAL in the calling subroutine. If SORTEV = 'S', SELECT is used to select eigenvalues to sort to the top left of the Schur form. If SORTEV = 'N', SELECT is not referenced. An eigenvalue $WR(j)+\sqrt{-1}*WI(j)$ is selected if $SELECT(WR(j),WI(j))$ is true; i.e., if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected. Note that a selected complex eigenvalue may no longer satisfy $SELECT(WR(j),WI(j)) = .TRUE.$ after ordering, since ordering may change

the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case INFO is set to N+2 (see INFO below).

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
On entry, the N-by-N matrix A. On exit, A has been overwritten by its real Schur form T.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, N)$.

NOUT (output)
If SORTEV = 'N', NOUT = 0. If SORTEV = 'S', NOUT = number of eigenvalues (after sorting) for which SELECT is true. (Complex conjugate pairs for which SELECT is true for either eigenvalue count as 2.)

WR (output)
WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues in the same order that they appear on the diagonal of the output Schur form T. Complex conjugate pairs of eigenvalues will appear consecutively with the eigenvalue having the positive imaginary part first.

WI (output)
See the description for WR.

Z (output)
If JOBZ = 'V', Z contains the orthogonal matrix Z of Schur vectors. If JOBZ = 'N', Z is not referenced.

LDZ (input)
The leading dimension of the array Z. $LDZ \geq 1$; if JOBZ = 'V', $LDZ \geq N$.

WORK (workspace)
On exit, if INFO = 0, WORK(1) contains the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. $LDWORK \geq \max(1, 3*N)$. For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK3 (workspace)
dimension(N) Not referenced if SORTEV = 'N'.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, and i is
 $\leq N$: the QR algorithm failed to compute all the

eigenvalues; elements 1:ILO-1 and i+1:N of WR and WI contain those eigenvalues which have converged; if JOBZ = 'V', Z contains the matrix which reduces A to its partially converged Schur form. = N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned); = N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT=.TRUE. This could also be caused by underflow due to scaling.

```

PURPOSE

dgeesx computes for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization $A = Z^*T^*(Z^{**}T)$.

Optionally, it also orders the eigenvalues on the diagonal of the real Schur form so that selected eigenvalues are at the top left; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right invariant subspace corresponding to the selected eigenvalues (RCONDV). The leading columns of Z form an orthonormal basis for this invariant subspace.

For further explanation of the reciprocal condition numbers RCONDE and RCONDV, see Section 4.10 of the LAPACK Users' Guide (where these quantities are called s and sep respectively).

A real matrix is in real Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

$$\begin{bmatrix} a & b \\ c & a \end{bmatrix}$$

where $b*c < 0$. The eigenvalues of such a block are $a \pm \sqrt{bc}$.

ARGUMENTS

JOBZ (input)

= 'N': Schur vectors are not computed;
= 'V': Schur vectors are computed.

SORTEV (input)

Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. = 'N': Eigenvalues are not ordered;
= 'S': Eigenvalues are ordered (see SELECT).

SELECT (input)

SELECT must be declared EXTERNAL in the calling subroutine. If SORTEV = 'S', SELECT is used to select eigenvalues to sort to the top left of the Schur form. If SORTEV = 'N', SELECT is not referenced. An eigenvalue $WR(j)+\sqrt{-1}*WI(j)$ is selected if $SELECT(WR(j),WI(j))$ is true; i.e., if either one of a complex conjugate pair of eigenvalues is selected, then both are. Note that a selected complex eigenvalue may no longer satisfy $SELECT(WR(j),WI(j)) = .TRUE.$ after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case INFO may be set to N+3 (see INFO below).

SENSE (input)

Determines which reciprocal condition numbers are computed. = 'N': None are computed;
= 'E': Computed for average of selected eigenvalues only;
= 'V': Computed for selected right invariant subspace only;
= 'B': Computed for both. If SENSE = 'E', 'V' or 'B', SORTEV must equal 'S'.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the N-by-N matrix A. On exit, A is overwritten by its real Schur form T.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,N)$.

NOUT (output)

If SORTEV = 'N', NOUT = 0. If SORTEV = 'S', NOUT = number of eigenvalues (after sorting) for which SELECT is true. (Complex conjugate pairs for which SELECT is true for either eigenvalue count as 2.)

WR (output)

WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues, in the same order that they appear on the diagonal of the output Schur form T. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having the positive imaginary part first.

WI (output)

See the description for WR.

Z (output)
 If JOBZ = 'V', Z contains the orthogonal matrix Z of Schur vectors. If JOBZ = 'N', Z is not referenced.

LDZ (input)
 The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= N.

SRCONE (output)
 If SENSE = 'E' or 'B', SRCONE contains the reciprocal condition number for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

RCONV (output)
 If SENSE = 'V' or 'B', RCONV contains the reciprocal condition number for the selected right invariant subspace. Not referenced if SENSE = 'N' or 'E'.

WORK (workspace)
 On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
 The dimension of the array WORK. LDWORK >= max(1,3*N). Also, if SENSE = 'E' or 'V' or 'B', LDWORK >= N+2*NOU*(N-NOU), where NOU is the number of selected eigenvalues computed by this routine. Note that N+2*NOU*(N-NOU) <= N+N*N/2. For good performance, LDWORK must generally be larger.

IWORK2 (workspace/output)
 Not referenced if SENSE = 'N' or 'E'. On exit, if INFO = 0, IWORK2(1) returns the optimal LDWRK2.

LDWRK2 (input)
 The dimension of the array IWORK2. LDWRK2 >= 1; if SENSE = 'V' or 'B', LDWRK2 >= NOU*(N-NOU).

BWORK3 (workspace)
 dimension(N) Not referenced if SORTEV = 'N'.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value.
 > 0: if INFO = i, and i is
 <= N: the QR algorithm failed to compute all the eigenvalues; elements 1:ILO-1 and i+1:N of WR and WI contain those eigenvalues which have converged; if JOBZ = 'V', Z contains the transformation which reduces A to its partially converged Schur form.
 = N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned);
 = N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT=.TRUE. This could also be caused by underflow due to scaling.

```

PURPOSE

dgeev computes for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

The right eigenvector $v(j)$ of A satisfies

$$A * v(j) = \text{lambda}(j) * v(j)$$

where $\text{lambda}(j)$ is its eigenvalue.

The left eigenvector $u(j)$ of A satisfies

$$u(j)**H * A = \text{lambda}(j) * u(j)**H$$

where $u(j)**H$ denotes the conjugate transpose of $u(j)$.

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

ARGUMENTS

JOBVL (input)

= 'N': left eigenvectors of A are not computed;
 = 'V': left eigenvectors of A are computed.

JOBVR (input)

= 'N': right eigenvectors of A are not computed;
 = 'V': right eigenvectors of A are computed.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the N-by-N matrix A. On exit, A has been overwritten.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

WR (output)

WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having the positive imaginary part first.

WI (output)

See the description for WR.

VL (output)

If JOBVL = 'V', the left eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. If JOBVL = 'N', VL is not referenced. If the j-th eigenvalue is real, then $u(j) = VL(:, j)$, the j-th column of VL. If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then $u(j) = VL(:, j) + i*VL(:, j+1)$ and

$u(j+1) = VL(:,j) - i*VL(:,j+1).$

LDVL (input)

The leading dimension of the array VL. LDVL ≥ 1 ;
if JOBVL = 'V', LDVL $\geq N$.

VR (input)

If JOBVR = 'V', the right eigenvectors $v(j)$ are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. If the j -th eigenvalue is real, then $v(j) = VR(:,j)$, the j -th column of VR. If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $v(j) = VR(:,j) + i*VR(:,j+1)$ and $v(j+1) = VR(:,j) - i*VR(:,j+1).$

LDVR (input)

The leading dimension of the array VR. LDVR ≥ 1 ;
if JOBVR = 'V', LDVR $\geq N$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK $\geq \max(1,3*N)$, and if JOBVL = 'V' or JOBVR = 'V', LDWORK $\geq 4*N$. For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i -th argument had an illegal value.
> 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors have been computed; elements $i+1:N$ of WR and WI contain eigenvalues which have converged.

```

PURPOSE

dgeevx computes for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, SCALE, and ABNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

The right eigenvector $v(j)$ of A satisfies

$$A * v(j) = \text{lambda}(j) * v(j)$$

where $\text{lambda}(j)$ is its eigenvalue.

The left eigenvector $u(j)$ of A satisfies

$$u(j)**H * A = \text{lambda}(j) * u(j)**H$$

where $u(j)**H$ denotes the conjugate transpose of $u(j)$.

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation $D * A * D^{(-1)}$, where D is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.10.2 of the LAPACK Users' Guide.

ARGUMENTS

BALANC (input)

Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues. = 'N': Do not diagonally scale or permute;
= 'P': Perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale; = 'S': Diagonally scale the matrix, i.e. replace A by $D*A*D^{*(-1)}$, where D is a diagonal matrix chosen to make the rows and columns of A more equal in norm. Do not permute; = 'B': Both diagonally scale and permute A.

Computed reciprocal condition numbers will be for the matrix after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL (input)

= 'N': left eigenvectors of A are not computed;
= 'V': left eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVL must = 'V'.

JOBVR (input)

= 'N': right eigenvectors of A are not computed;
= 'V': right eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVR must = 'V'.

SENSE (input)

Determines which reciprocal condition numbers are computed. = 'N': None are computed;
= 'E': Computed for eigenvalues only;
= 'V': Computed for right eigenvectors only;
= 'B': Computed for eigenvalues and right eigenvectors.

If SENSE = 'E' or 'B', both left and right eigenvectors must also be computed (JOBVL = 'V' and JOBVR = 'V').

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the N-by-N matrix A. On exit, A has been overwritten. If JOBVL = 'V' or JOBVR = 'V', A contains the real Schur form of the balanced version of the input matrix A.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

WR (output)

WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues will appear consecutively with the eigenvalue having the positive imaginary part first.

WI (output)

See the description for WR.

VL (output)

If `JOBVL = 'V'`, the left eigenvectors $u(j)$ are stored one after another in the columns of `VL`, in the same order as their eigenvalues. If `JOBVL = 'N'`, `VL` is not referenced. If the j -th eigenvalue is real, then $u(j) = VL(:,j)$, the j -th column of `VL`. If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $u(j) = VL(:,j) + i*VL(:,j+1)$ and $u(j+1) = VL(:,j) - i*VL(:,j+1)$.

`LDVL` (input)

The leading dimension of the array `VL`. `LDVL` ≥ 1 ; if `JOBVL = 'V'`, `LDVL` $\geq N$.

`VR` (output)

If `JOBVR = 'V'`, the right eigenvectors $v(j)$ are stored one after another in the columns of `VR`, in the same order as their eigenvalues. If `JOBVR = 'N'`, `VR` is not referenced. If the j -th eigenvalue is real, then $v(j) = VR(:,j)$, the j -th column of `VR`. If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $v(j) = VR(:,j) + i*VR(:,j+1)$ and $v(j+1) = VR(:,j) - i*VR(:,j+1)$.

`LDVR` (input)

The leading dimension of the array `VR`. `LDVR` ≥ 1 , and if `JOBVR = 'V'`, `LDVR` $\geq N$.

`ILO` (output)

`ILO` and `IHI` are integer values determined when `A` was balanced. The balanced $A(i,j) = 0$ if $I > J$ and $J = 1, \dots, ILO-1$ or $I = IHI+1, \dots, N$.

`IHI` (output)

See the description of `ILO`.

`SCALE` (output)

Details of the permutations and scaling factors applied when balancing `A`. If $P(j)$ is the index of the row and column interchanged with row and column j , and $D(j)$ is the scaling factor applied to row and column j , then $SCALE(J) = P(J)$, for $J = 1, \dots, ILO-1 = D(J)$, for $J = ILO, \dots, IHI = P(J)$ for $J = IHI+1, \dots, N$. The order in which the interchanges are made is N to $IHI+1$, then 1 to $ILO-1$.

`ABNRM` (output)

The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).

`RCONE` (output)

`RCONE(j)` is the reciprocal condition number of the j -th eigenvalue.

`RCONV` (output)

`RCONV(j)` is the reciprocal condition number of the j -th right eigenvector.

`WORK` (workspace)

On exit, if `INFO = 0`, `WORK(1)` returns the optimal `LDWORK`.

LDWORK (input)

The dimension of the array WORK. If SENSE = 'N' or 'E', LDWORK $\geq \max(1, 2*N)$, and if JOBVL = 'V' or JOBVR = 'V', LDWORK $\geq 3*N$. If SENSE = 'V' or 'B', LDWORK $\geq N*(N+6)$. For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

IWORK2 (workspace)

dimension($2*N-2$) If SENSE = 'N' or 'E', not referenced.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors or condition numbers have been computed; elements 1:ILO-1 and i+1:N of WR and WI contain eigenvalues which have converged.

```

PURPOSE

dgegs routine is deprecated and has been replaced by routine SGGES.

SGEGS computes for a pair of N-by-N real nonsymmetric matrices A, B: the generalized eigenvalues (alpha +/- alpha*i, beta), the real Schur form (A, B), and optionally left and/or right Schur vectors (VSL and VSR).

(If only the generalized eigenvalues are needed, use the driver SGEGV instead.)

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

The (generalized) Schur form of a pair of matrices is the result of multiplying both matrices on the left by one orthogonal matrix and both on the right by another orthogonal matrix, these two orthogonal matrices being chosen so as to bring the pair of matrices into (real) Schur form.

A pair of matrices A, B is in generalized real Schur form if B is upper triangular with non-negative diagonal and A is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of A will be "standardized" by making the corresponding elements of B have the form:

$$\begin{bmatrix} a & 0 \\ 0 & b \end{bmatrix}$$

and the pair of corresponding 2-by-2 blocks in A and B will have a complex conjugate pair of generalized eigenvalues.

The left and right Schur vectors are the columns of VSL and VSR, respectively, where VSL and VSR are the orthogonal matrices which reduce A and B to Schur form:

Schur form of (A,B) = ((VSL)**T A (VSR), (VSL)**T B (VSR))

ARGUMENTS

JOBVSL (input)
 = 'N': do not compute the left Schur vectors;
 = 'V': compute the left Schur vectors.

JOBVSR (input)
 = 'N': do not compute the right Schur vectors;

= 'V': compute the right Schur vectors.

N (input) The order of the matrices A, B, VSL, and VSR. N
>= 0.

A (input/output)
On entry, the first of the pair of matrices whose generalized eigenvalues and (optionally) Schur vectors are to be computed. On exit, the generalized Schur form of A. Note: to avoid overflow, the Frobenius norm of the matrix A should be less than the overflow threshold.

LDA (input)
The leading dimension of A. LDA >= max(1,N).

B (input/output)
On entry, the second of the pair of matrices whose generalized eigenvalues and (optionally) Schur vectors are to be computed. On exit, the generalized Schur form of B. Note: to avoid overflow, the Frobenius norm of the matrix B should be less than the overflow threshold.

LDB (input)
The leading dimension of B. LDB >= max(1,N).

ALPHAR (output)
On exit, $(\text{ALPHAR}(j) + \text{ALPHAI}(j)*i)/\text{BETA}(j)$, $j=1,\dots,N$, will be the generalized eigenvalues. $\text{ALPHAR}(j) + \text{ALPHAI}(j)*i$, $j=1,\dots,N$ and $\text{BETA}(j)$, $j=1,\dots,N$ are the diagonals of the complex Schur form (A,B) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A,B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If $\text{ALPHAI}(j)$ is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with $\text{ALPHAI}(j+1)$ negative.

Note: the quotients $\text{ALPHAR}(j)/\text{BETA}(j)$ and $\text{ALPHAI}(j)/\text{BETA}(j)$ may easily over- or underflow, and $\text{BETA}(j)$ may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta . However, ALPHAR and ALPHAI will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and BETA always less than and usually comparable with $\text{norm}(B)$.

ALPHAI (output)
See the description for ALPHAR.

BETA (output)
See the description for ALPHAR.

VSL (input)
If $\text{JOBVSL} = 'V'$, VSL will contain the left Schur vectors. (See "Purpose", above.) Not referenced if $\text{JOBVSL} = 'N'$.

LDVSL (input)
The leading dimension of the matrix VSL. LDVSL >= 1, and if $\text{JOBVSL} = 'V'$, LDVSL >= N.

VSR (input)

If JOBVSR = 'V', VSR will contain the right Schur vectors. (See "Purpose", above.) Not referenced if JOBVSR = 'N'.

LDVSR (input)

The leading dimension of the matrix VSR. LDVSR \geq 1, and if JOBVSR = 'V', LDVSR \geq N.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK \geq max(1,4*N). For good performance, LDWORK must generally be larger. To compute the optimal value of LDWORK, call ILAENV to get blocksizes (for SGEQRF, SORMQR, and SORGQR.) Then compute: NB -- MAX of the blocksizes for SGEQRF, SORMQR, and SORGQR The optimal LDWORK is $2*N + N*(NB+1)$.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1,...,N: The QZ iteration failed. (A,B) are not in Schur form, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for $j=INFO+1, \dots, N$.
> N: errors that usually indicate LAPACK problems:
=N+1: error return from SGBAL
=N+2: error return from SGEQRF
=N+3: error return from SORMQR
=N+4: error return from SORGQR
=N+5: error return from SGGHRD
=N+6: error return from SHGEQZ (other than failed iteration) =N+7: error return from SGGBAK (computing VSL)
=N+8: error return from SGGBAK (computing VSR)
=N+9: error return from SLASCL (various places)

    double *alphai, double *beta, double *vl, long
    ldvl, double *vr, long ldvr, long *info);

```

PURPOSE

dgegv routine is deprecated and has been replaced by routine SGGEV.

SGEGV computes for a pair of n-by-n real nonsymmetric matrices A and B, the generalized eigenvalues (alphan +/− alphai*i, beta), and optionally, the left and/or right generalized eigenvectors (VL and VR).

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

A right generalized eigenvector corresponding to a generalized eigenvalue w for a pair of matrices (A,B) is a vector r such that (A - w B) r = 0. A left generalized eigenvector is a vector l such that l**H * (A - w B) = 0, where l**H is the conjugate-transpose of l.

Note: this routine performs "full balancing" on A and B -- see "Further Details", below.

ARGUMENTS

JOBVL (input)
 = 'N': do not compute the left generalized eigenvectors;
 = 'V': compute the left generalized eigenvectors.

JOBVR (input)
 = 'N': do not compute the right generalized eigenvectors;
 = 'V': compute the right generalized eigenvectors.

N (input) The order of the matrices A, B, VL, and VR. N >= 0.

A (input/output)
 On entry, the first of the pair of matrices whose generalized eigenvalues and (optionally) generalized eigenvectors are to be computed. On exit, the contents will have been destroyed. (For a description of the contents of A on exit, see "Further Details", below.)

LDA (input)

The leading dimension of A. $LDA \geq \max(1,N)$.

B (input/output)

On entry, the second of the pair of matrices whose generalized eigenvalues and (optionally) generalized eigenvectors are to be computed. On exit, the contents will have been destroyed. (For a description of the contents of B on exit, see "Further Details", below.)

LDB (input)

The leading dimension of B. $LDB \geq \max(1,N)$.

ALPHAR (output)

On exit, $(ALPHAR(j) + ALPHAI(j)*i)/BETA(j)$, $j=1,\dots,N$, will be the generalized eigenvalues. If $ALPHAI(j)$ is zero, then the j -th eigenvalue is real; if positive, then the j -th and $(j+1)$ -st eigenvalues are a complex conjugate pair, with $ALPHAI(j+1)$ negative.

Note: the quotients $ALPHAR(j)/BETA(j)$ and $ALPHAI(j)/BETA(j)$ may easily over- or underflow, and $BETA(j)$ may even be zero. Thus, the user should avoid naively computing the ratio α/β . However, $ALPHAR$ and $ALPHAI$ will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and $BETA$ always less than and usually comparable with $\text{norm}(B)$.

ALPHAI (output)

See the description of $ALPHAR$.

BETA (output)

See the description of $ALPHAR$.

VL (output)

If $JOBVL = 'V'$, the left generalized eigenvectors. (See "Purpose", above.) Real eigenvectors take one column, complex take two columns, the first for the real part and the second for the imaginary part. Complex eigenvectors correspond to an eigenvalue with positive imaginary part. Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$, *except* that for eigenvalues with $\alpha=\beta=0$, a zero vector will be returned as the corresponding eigenvector. Not referenced if $JOBVL = 'N'$.

LDVL (input)

The leading dimension of the matrix VL. $LDVL \geq 1$, and if $JOBVL = 'V'$, $LDVL \geq N$.

VR (output)

If $JOBVR = 'V'$, the right generalized eigenvectors. (See "Purpose", above.) Real eigenvectors take one column, complex take two columns, the first for the real part and the second for the imaginary part. Complex eigenvectors correspond to an eigenvalue with positive imaginary part. Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$, *except* that for eigenvalues with

alpha=beta=0, a zero vector will be returned as the corresponding eigenvector. Not referenced if JOBVR = 'N'.

LDVR (input)

The leading dimension of the matrix VR. LDVR \geq 1, and if JOBVR = 'V', LDVR \geq N.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK \geq max(1,8*N). For good performance, LDWORK must generally be larger. To compute the optimal value of LDWORK, call ILAENV to get blocksizes (for SGEQRF, SORMQR, and SORGQR.) Then compute: NB -- MAX of the blocksizes for SGEQRF, SORMQR, and SORGQR; The optimal LDWORK is: $2*N + \text{MAX}(6*N, N*(NB+1))$.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N.
> N: errors that usually indicate LAPACK problems:
=N+1: error return from SGBAL
=N+2: error return from SGEQRF
=N+3: error return from SORMQR
=N+4: error return from SORGQR
=N+5: error return from SGGHRD
=N+6: error return from SHGEQZ (other than failed iteration)
=N+7: error return from STGEVC
=N+8: error return from SGGBAK (computing VL)
=N+9: error return from SGGBAK (computing VR)
=N+10: error return from SLASCL (various calls)

FURTHER DETAILS

Balancing

This driver calls SGBAL to both permute and scale rows and columns of A and B. The permutations PL and PR are chosen so that PL*A*PR and PL*B*PR will be upper triangular except for the diagonal blocks A(i:j,i:j) and B(i:j,i:j), with i and j as close together as possible. The diagonal scaling matrices DL and DR are chosen so that the pair DL*PL*A*PR*DR, DL*PL*B*PR*DR have elements close to one (except for the elements that start out zero.)

After the eigenvalues and eigenvectors of the balanced

matrices have been computed, SGGBAK transforms the eigenvectors back to what they would have been (in perfect arithmetic) if they had not been balanced.

Contents of A and B on Exit

If any eigenvectors are computed (either JOBVL='V' or JOBVR='V' or both), then on exit the arrays A and B will contain the real Schur form[*] of the "balanced" versions of A and B. If no eigenvectors are computed, then only the diagonal blocks will be correct.

[*] See SHGEQZ, SGEQS, or read the book "Matrix Computations",

by Golub & van Loan, pub. by Johns Hopkins U. Press.

[INFO])
```

```
INTEGER :: N, ILO, IHI, LDA, LWORKIN, INFO  
REAL(8), DIMENSION(:) :: TAU, WORKIN  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE GEHRD_64([N], ILO, IHI, A, [LDA], TAU, [WORKIN], [LWORKIN],  
[INFO])
```

```
INTEGER(8) :: N, ILO, IHI, LDA, LWORKIN, INFO  
REAL(8), DIMENSION(:) :: TAU, WORKIN  
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgehrd(int n, int ilo, int ihi, double *a, int lda,  
double *tau, int *info);
```

```
void dgehrd_64(long n, long ilo, long ihi, double *a, long  
lda, double *tau, long *info);
```

PURPOSE

dgehrd reduces a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation: $Q' * A * Q = H$.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

ILO (input)

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to SGEBAL; otherwise they should be set to 1 and N respectively. See Further Details.

IHI (input)

See the description of ILO.

A (input/output)

On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details). Elements 1:ILO-1 and IHI:N-1 of TAU are set to zero.

WORKIN (workspace)

On exit, if INFO = 0, WORKIN(1) returns the optimal LWORKIN.

LWORKIN (input)

The length of the array WORKIN. $LWORKIN \geq \max(1, N)$. For optimum performance $LWORKIN \geq N * NB$, where NB is the optimal blocksize.

If $LWORKIN = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORKIN array, returns this value as the first entry of the WORKIN array, and no error message related to LWORKIN is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of $(ihi-ilo)$ elementary reflectors

$$Q = H(ilo) H(ilo+1) \dots H(ihi-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a real scalar, and v is a real vector with $v(1:i) = 0$, $v(i+1) = 1$ and $v(ihi+1:n) = 0$; $v(i+2:ihi)$ is stored on exit in $A(i+2:ihi,i)$, and τ in $TAU(i)$.

The contents of A are illustrated by the following example, with $n = 7$, $ilo = 2$ and $ihi = 6$:

on entry,

on exit,

```
( a  a  a  a  a  a  a ) ( a  a  h  h  h  h
a ) (      a  a  a  a  a  a ) (      a  h  h  h
h  a ) (      a  a  a  a  a  a ) (      h  h  h
h  h  h ) (      a  a  a  a  a  a ) (      v2 h
h  h  h  h ) (      a  a  a  a  a  a ) (      v2
v3  h  h  h  h ) (      a  a  a  a  a  a ) (
v2 v3 v4 h  h  h ) (      a ) (
a )
```

where a denotes an element of the original matrix A , h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(i)$.

NAME

dgelqf - compute an LQ factorization of a real M-by-N matrix
A

SYNOPSIS

```
SUBROUTINE DGELQF(M, N, A, LDA, TAU, WORK, LDWORK, INFO)
```

```
INTEGER M, N, LDA, LDWORK, INFO  
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE DGELQF_64(M, N, A, LDA, TAU, WORK, LDWORK, INFO)
```

```
INTEGER*8 M, N, LDA, LDWORK, INFO  
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GELQF([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
INTEGER :: M, N, LDA, LDWORK, INFO  
REAL(8), DIMENSION(:) :: TAU, WORK  
REAL(8), DIMENSION(:,:) :: A
```

```
SUBROUTINE GELQF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
INTEGER(8) :: M, N, LDA, LDWORK, INFO  
REAL(8), DIMENSION(:) :: TAU, WORK  
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgelqf(int m, int n, double *a, int lda, double *tau,  
           int *info);
```

```
void dgelqf_64(long m, long n, double *a, long lda, double  
              *tau, long *info);
```

PURPOSE

dgelqf computes an LQ factorization of a real M-by-N matrix
A: $A = L * Q$.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the m-by-min(m,n) lower trapezoidal matrix L (L is lower triangular if $m \leq n$); the elements above the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. $LDWORK \geq \max(1, M)$. For optimum performance $LDWORK \geq M * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(k) \dots H(2) H(1), \text{ where } k = \min(m, n).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a real scalar, and v is a real vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:n)$ is stored on exit in $A(i, i+1:n)$, and τ in $TAU(i)$.

SUBROUTINE DGELS_64(TRANSA, M, N, NRHS, A, LDA, B, LDB, WORK, LDWORK,  
INFO)
```

```
CHARACTER * 1 TRANSA  
INTEGER*8 M, N, NRHS, LDA, LDB, LDWORK, INFO  
DOUBLE PRECISION A(LDA,*), B(LDB,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GELS([TRANSA], [M], [N], [NRHS], A, [LDA], B, [LDB], [WORK],  
LDWORK, [INFO])
```

```
CHARACTER(LEN=1) :: TRANSA  
INTEGER :: M, N, NRHS, LDA, LDB, LDWORK, INFO  
REAL(8), DIMENSION(:) :: WORK  
REAL(8), DIMENSION(:, :) :: A, B
```

```
SUBROUTINE GELS_64([TRANSA], [M], [N], [NRHS], A, [LDA], B, [LDB],  
[WORK], LDWORK, [INFO])
```

```
CHARACTER(LEN=1) :: TRANSA  
INTEGER(8) :: M, N, NRHS, LDA, LDB, LDWORK, INFO  
REAL(8), DIMENSION(:) :: WORK  
REAL(8), DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgels (char, int, int, int, double*, int, double*, int,  
int*);
```

```
void dgels_64 (char, long, long, long, double*, long, double*, long, long*);
```

PURPOSE

dgels solves overdetermined or underdetermined real linear systems involving an M-by-N matrix A, or its transpose, using a QR or LQ factorization of A. It is assumed that A has full rank.

The following options are provided:

1. If TRANS = 'N' and $m \geq n$: find the least squares solution of an overdetermined system, i.e., solve the least squares problem

$$\text{minimize } \| B - A * X \|^2.$$

2. If TRANS = 'N' and $m < n$: find the minimum norm solution of an underdetermined system $A * X = B$.

3. If TRANS = 'T' and $m \geq n$: find the minimum norm solution of an undetermined system $A^{**T} * X = B$.

4. If TRANS = 'T' and $m < n$: find the least squares solution of an overdetermined system, i.e., solve the least squares problem

$$\text{minimize } \| B - A^{**T} * X \|^2.$$

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

ARGUMENTS

TRANSA (input)

= 'N': the linear system involves A;
= 'T': the linear system involves A^{**T} .

TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS ≥ 0 .

A (input/output)

On entry, the M-by-N matrix A. On exit, if $M \geq N$, A is overwritten by details of its QR factorization as returned by SGEQRF; if $M < N$, A is overwritten by details of its LQ factorization as returned by SGELQF.

LDA (input)

The leading dimension of the array A. LDA \geq max(1,M).

B (input/output)

On entry, the matrix B of right hand side vectors, stored columnwise; B is M-by-NRHS if TRANSA = 'N', or N-by-NRHS if TRANSA = 'T'. On exit, B is overwritten by the solution vectors, stored columnwise: if TRANSA = 'N' and $m \geq n$, rows 1 to n of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements N+1 to M in that column; if TRANSA = 'N' and $m < n$, rows 1 to N of B contain the minimum norm solution vectors; if TRANSA = 'T' and $m \geq n$, rows 1 to M of B contain the minimum norm solution vectors; if TRANSA = 'T' and $m < n$, rows 1 to M of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements M+1 to N in that column.

LDB (input)

The leading dimension of the array B. LDB \geq MAX(1,M,N).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (output)

The dimension of the array WORK. LDWORK \geq max(1, MN + max(MN, NRHS)). For optimal performance, LDWORK \geq max(1, MN + max(MN, NRHS)*NB). where MN = min(M,N) and NB is the optimum block size.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

                   RANK, [WORK], [LWORK], [IWORK], [INFO])
```

```
INTEGER(8) :: M, N, NRHS, LDA, LDB, RANK, LWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL(8) :: RCOND
REAL(8), DIMENSION(:) :: S, WORK
REAL(8), DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void dgelsd(int m, int n, int nrhs, double *a, int lda, double
           *b, int ldb, double *s, double rcond, int
           *rank, int *info);
void dgelsd_64(long m, long n, long nrhs, double *a, long
              lda, double *b, long ldb, double *s, double rcond,
              long *rank, long *info);
```

PURPOSE

dgelsd computes the minimum-norm solution to a real linear least squares problem:

$$\text{minimize } 2\text{-norm}(|b - A*x|)$$

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The problem is solved in three steps:

- (1) Reduce the coefficient matrix A to bidiagonal form with Householder transformations, reducing the original problem into a "bidiagonal least squares problem" (BLS)
- (2) Solve the BLS using a divide and conquer approach.
- (3) Apply back all the Householder transformations to solve the original least squares problem.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

M (input) The number of rows of A. M >= 0.

N (input) The number of columns of A. N >= 0.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input/output)

On entry, the M-by-N matrix A. On exit, A has been destroyed.

LDA (input)

The leading dimension of the array A. LDA >= max(1,M).

B (input/output)

On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If $m \geq n$ and $RANK = n$, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements $n+1:m$ in that column.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, \max(M, N))$.

S (output)

The singular values of A in decreasing order. The condition number of A in the 2-norm = $S(1)/S(\min(m, n))$.

RCOND (input)

RCOND is used to determine the effective rank of A. Singular values $S(i) \leq RCOND * S(1)$ are treated as zero. If $RCOND < 0$, machine precision is used instead.

RANK (output)

The effective rank of A, i.e., the number of singular values which are greater than $RCOND * S(1)$.

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. $LWORK \geq 1$. The exact minimum amount of workspace needed depends on M, N and NRHS. As long as LWORK is at least $12 * N + 2 * N * SMLSIZ + 8 * N * NLVL + N * NRHS * (SMLSIZ + 1) ** 2$, if M is greater than or equal to N or $12 * M + 2 * M * SMLSIZ + 8 * M * NLVL + M * NRHS + (SMLSIZ + 1) ** 2$, if M is less than N, the code will execute correctly. SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25), and $NLVL = \text{INT}(\text{LOG}_2(\text{MIN}(M, N) / (SMLSIZ + 1))) + 1$. For good performance, LWORK should generally be larger.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace)

$LIWORK \geq 3 * \text{MINMN} * NLVL + 11 * \text{MINMN}$, where $\text{MINMN} = \text{MIN}(M, N)$.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value.
> 0: the algorithm for computing the SVD failed to converge; if $INFO = i$, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

```

PURPOSE

dgelss computes the minimum norm solution to a real linear least squares problem:

Minimize 2-norm($| b - A*x |$).

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, the first $\min(m,n)$ rows of A are overwritten with its right singular vectors, stored rowwise.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,M)$.

B (input/output)

On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If $m \geq n$ and $IRANK = n$, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements $n+1:m$ in that column.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1,\max(M,N))$.

SING (output)

The singular values of A in decreasing order. The condition number of A in the 2-norm = $SING(1)/SING(\min(m,n))$.

RCOND (input)

RCOND is used to determine the effective rank of

A. Singular values $SING(i) \leq RCOND * SING(1)$ are treated as zero. If $RCOND < 0$, machine precision is used instead.

IRANK (output)

The effective rank of A, i.e., the number of singular values which are greater than $RCOND * SING(1)$.

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. $LDWORK \geq 1$, and also: $LDWORK \geq 3 * \min(M,N) + \max(2 * \min(M,N), \max(M,N), NRHS)$ For good performance, LDWORK should generally be larger.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value.
> 0: the algorithm for computing the SVD failed to converge; if $INFO = i$, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

void dgelsx_64(long m, long n, long nrhs, double *a, long
    lda, double *b, long ldb, long *jpivot, double
    rcond, long *irank, long *info);

```

PURPOSE

dgelsx routine is deprecated and has been replaced by routine SGELSY.

SGELSX computes the minimum-norm solution to a real linear least squares problem:

minimize $\|A * X - B\|$
 using a complete orthogonal factorization of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The routine first computes a QR factorization with column pivoting:

$$A * P = Q * \begin{bmatrix} R11 & R12 \\ 0 & R22 \end{bmatrix}$$

with R11 defined as the largest leading submatrix whose estimated condition number is less than 1/RCOND. The order of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihilated by orthogonal transformations from the right, arriving at the complete orthogonal factorization:

$$A * P = Q * \begin{bmatrix} T11 & 0 \\ 0 & 0 \end{bmatrix} * Z$$

The minimum-norm solution is then

$$X = P * Z' \begin{bmatrix} \text{inv}(T11) * Q1' * B \\ 0 \end{bmatrix}$$

where Q1 consists of the first RANK columns of Q.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of matrices B and X. $NRHS \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, A has been overwritten by details of its complete orthogonal factorization.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input/output)

On entry, the M-by-NRHS right hand side matrix B.
On exit, the N-by-NRHS solution matrix X. If $m \geq n$ and $IRANK = n$, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements N+1:M in that column.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, M, N)$.

JPIVOT (input/output)

On entry, if $JPIVOT(i) \neq 0$, the i-th column of A is an initial column, otherwise it is a free column. Before the QR factorization of A, all initial columns are permuted to the leading positions; only the remaining free columns are moved as a result of column pivoting during the factorization. On exit, if $JPIVOT(i) = k$, then the i-th column of A^*P was the k-th column of A.

RCOND (input)

RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number $< 1/RCOND$.

IRANK (output)

The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

WORK (workspace)

$(\max(\min(M, N) + 3 * N, 2 * \min(M, N) + NRHS))$,

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value

void dgelsy(int m, int n, int nrhs, double *a, int lda, double
            *b, int ldb, int *jpvt, double rcond, int
            *rank, int *info);
void dgelsy_64(long m, long n, long nrhs, double *a, long
              lda, double *b, long ldb, long *jpvt, double
              rcond, long *rank, long *info);
```

PURPOSE

dgelsy computes the minimum-norm solution to a real linear least squares problem:

minimize $\|A * X - B\|$
 using a complete orthogonal factorization of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The routine first computes a QR factorization with column pivoting:

$$A * P = Q * \begin{bmatrix} R11 & R12 \\ 0 & R22 \end{bmatrix}$$

with R11 defined as the largest leading submatrix whose estimated condition number is less than 1/RCOND. The order of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihilated by orthogonal transformations from the right, arriving at the complete orthogonal factorization:

$$A * P = Q * \begin{bmatrix} T11 & 0 \\ 0 & 0 \end{bmatrix} * Z$$

The minimum-norm solution is then

$$X = P * Z' \begin{bmatrix} \text{inv}(T11) * Q1' * B \\ 0 \end{bmatrix}$$

where Q1 consists of the first RANK columns of Q.

This routine is basically identical to the original xGELSX except three differences:

- o The call to the subroutine xGEQPF has been substituted by the call to the subroutine xGEQP3. This subroutine is a Blas-3 version of the QR factorization with column pivoting.
- o Matrix B (the right hand side) is updated with Blas-3.
- o The permutation of matrix B (the right hand side) is faster and more simple.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

NRHS (input)

The number of right hand sides, i.e., the number of columns of matrices B and X. NRHS >= 0.

A (input/output)
 On entry, the M-by-N matrix A. On exit, A has been overwritten by details of its complete orthogonal factorization.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input/output)
 On entry, the M-by-NRHS right hand side matrix B. On exit, the N-by-NRHS solution matrix X.

LDB (input)
 The leading dimension of the array B. $LDB \geq \max(1, M, N)$.

JPVT (input/output)
 On entry, if JPVT(i) .ne. 0, the i-th column of A is permuted to the front of AP, otherwise column i is a free column. On exit, if JPVT(i) = k, then the i-th column of AP was the k-th column of A.

RCOND (input)
 RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number $< 1/RCOND$.

RANK (output)
 The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

WORK (workspace)
 On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
 The dimension of the array WORK. The unblocked strategy requires that: $LWORK \geq \max(MN+3*N+1, 2*MN+NRHS)$, where $MN = \min(M, N)$. The block algorithm requires that: $LWORK \geq \max(MN+2*N+NB*(N+1), 2*MN+NB*NRHS)$, where NB is an upper bound on the blocksize returned by ILAENV for the routines SGEQP3, STZRZF, STZRQF, SORMQR, and SORMRZ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
 = 0: successful exit
 < 0: If INFO = -i, the i-th argument had an illegal value.

REAL(8), DIMENSION(:, :) :: A, B, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgemm(char transa, char transb, int m, int n, int k,
  double alpha, double *a, int lda, double *b, int
```

```

        ldb, double beta, double *c, int ldc);

void dgemm_64(char transa, char transb, long m, long n, long
        k, double alpha, double *a, long lda, double *b,
        long ldb, double beta, double *c, long ldc);

```

PURPOSE

dgemm performs one of the matrix-matrix operations $C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C$ where $\text{op}(X)$ is one of

$\text{op}(X) = X$ or $\text{op}(X) = X'$,

alpha and beta are scalars, and A, B and C are matrices, with $\text{op}(A)$ an m by k matrix, $\text{op}(B)$ a k by n matrix and C an m by n matrix.

ARGUMENTS

TRANSA (input)

On entry, TRANSA specifies the form of $\text{op}(A)$ to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n', $\text{op}(A) = A$.

TRANSA = 'T' or 't', $\text{op}(A) = A'$.

TRANSA = 'C' or 'c', $\text{op}(A) = A'$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

TRANSB (input)

On entry, TRANSB specifies the form of $\text{op}(B)$ to be used in the matrix multiplication as follows:

TRANSB = 'N' or 'n', $\text{op}(B) = B$.

TRANSB = 'T' or 't', $\text{op}(B) = B'$.

TRANSB = 'C' or 'c', $\text{op}(B) = B'$.

Unchanged on exit.

TRANSB is defaulted to 'N' for F95 INTERFACE.

M (input)

On entry, M specifies the number of rows of the matrix $\text{op}(A)$ and of the matrix C. M must be at least zero. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix $\text{op}(B)$ and the number of columns of the matrix C. N must be at least zero. Unchanged on exit.

K (input)

On entry, K specifies the number of columns of the matrix $\text{op}(A)$ and the number of rows of the

matrix $op(B)$. K must be at least zero.
Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha.
Unchanged on exit.

A (input)

DOUBLE PRECISION array of DIMENSION (LDA, ka),
where ka is k when TRANSA = 'N' or 'n', and is
 m otherwise. Before entry with TRANSA = 'N' or
'n', the leading m by k part of the array A
must contain the matrix A, otherwise the leading
 k by m part of the array A must contain the
matrix A. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A
as declared in the calling (sub) program. When
TRANSA = 'N' or 'n' then $LDA \geq \max(1, m)$, oth-
erwise $LDA \geq \max(1, k)$. Unchanged on exit.

B (input)

DOUBLE PRECISION array of DIMENSION (LDB, kb),
where kb is n when TRANSB = 'N' or 'n', and is
 k otherwise. Before entry with TRANSB = 'N' or
'n', the leading k by n part of the array B
must contain the matrix B, otherwise the leading
 n by k part of the array B must contain the
matrix B. Unchanged on exit.

LDB (input)

On entry, LDB specifies the first dimension of B
as declared in the calling (sub) program. When
TRANSB = 'N' or 'n' then $LDB \geq \max(1, k)$, oth-
erwise $LDB \geq \max(1, n)$. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When
BETA is supplied as zero then C need not be set
on input. Unchanged on exit.

C (input/output)

DOUBLE PRECISION array of DIMENSION (LDC, n).
Before entry, the leading m by n part of the
array C must contain the matrix C, except when
beta is zero, in which case C need not be set on
entry. On exit, the array C is overwritten by
the m by n matrix ($\alpha * op(A) * op(B) +$
 $\beta * C$).

LDC (input)

On entry, LDC specifies the first dimension of C
as declared in the calling (sub) program. LDC
 $\geq \max(1, m)$. Unchanged on exit.

```
CHARACTER * 1 TRANSA  
INTEGER*8 M, N, LDA, INCX, INCY  
DOUBLE PRECISION ALPHA, BETA  
DOUBLE PRECISION A(LDA,*), X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE GEMV([TRANSA], [M], [N], ALPHA, A, [LDA], X, [INCX], BETA,  
Y, [INCY])
```

```
CHARACTER(LEN=1) :: TRANSA  
INTEGER :: M, N, LDA, INCX, INCY  
REAL(8) :: ALPHA, BETA  
REAL(8), DIMENSION(:) :: X, Y  
REAL(8), DIMENSION(:,) :: A
```

```
SUBROUTINE GEMV_64([TRANSA], [M], [N], ALPHA, A, [LDA], X, [INCX],  
BETA, Y, [INCY])
```

```
CHARACTER(LEN=1) :: TRANSA  
INTEGER(8) :: M, N, LDA, INCX, INCY  
REAL(8) :: ALPHA, BETA  
REAL(8), DIMENSION(:) :: X, Y  
REAL(8), DIMENSION(:,) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgemv(char transa, int m, int n, double alpha, double
```

```

        *a, int lda, double *x, int incx, double beta,
        double *y, int incy);
void dgemv_64(char transa, long m, long n, double alpha,
        double *a, long lda, double *x, long incx, double
        beta, double *y, long incy);

```

PURPOSE

dgemv performs one of the matrix-vector operations $y := \alpha A x + \beta y$, or $y := \alpha A' x + \beta y$, where α and β are scalars, x and y are vectors and A is an m by n matrix.

ARGUMENTS

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $y := \alpha A x + \beta y$.

TRANSA = 'T' or 't' $y := \alpha A' x + \beta y$.

TRANSA = 'C' or 'c' $y := \alpha A' x + \beta y$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input)

On entry, M specifies the number of rows of the matrix A. $M \geq 0$. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix A. $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

A (input)

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, m)$. Unchanged on exit.

X (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$ when TRANSA = 'N' or 'n' and at least $(1 + (m - 1) * \text{abs}(\text{INCX}))$ otherwise. Before entry, the incremented array X must contain the vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. $\text{INCX} \neq 0$. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)

($1 + (m - 1) * \text{abs}(\text{ INCY })$) when TRANSA = 'N' or 'n' and at least ($1 + (n - 1) * \text{abs}(\text{ INCY })$) otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY \neq 0. Unchanged on exit.

NAME

dgeqlf - compute a QL factorization of a real M-by-N matrix
A

SYNOPSIS

```
SUBROUTINE DGEQLF(M, N, A, LDA, TAU, WORK, LDWORK, INFO)
```

```
INTEGER M, N, LDA, LDWORK, INFO  
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE DGEQLF_64(M, N, A, LDA, TAU, WORK, LDWORK, INFO)
```

```
INTEGER*8 M, N, LDA, LDWORK, INFO  
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEQLF([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
INTEGER :: M, N, LDA, LDWORK, INFO  
REAL(8), DIMENSION(:) :: TAU, WORK  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE GEQLF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
INTEGER(8) :: M, N, LDA, LDWORK, INFO  
REAL(8), DIMENSION(:) :: TAU, WORK  
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgeqlf(int m, int n, double *a, int lda, double *tau,  
           int *info);
```

```
void dgeqlf_64(long m, long n, double *a, long lda, double  
              *tau, long *info);
```

PURPOSE

dgeqlf computes a QL factorization of a real M-by-N matrix
A: $A = Q * L$.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, if $m \geq n$, the lower triangle of the subarray $A(m-n+1:m, 1:n)$ contains the N-by-N lower triangular matrix L; if $m < n$, the elements on and below the (n-m)-th superdiagonal contain the M-by-N lower trapezoidal matrix L; the remaining elements, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. $LDWORK \geq \max(1, N)$. For optimum performance $LDWORK \geq N * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$Q = H(k) \dots H(2) H(1)$, where $k = \min(m, n)$.
Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a real scalar, and v is a real vector with

$v(m-k+i+1:m) = 0$ and $v(m-k+i) = 1$; $v(1:m-k+i-1)$ is stored on
exit in $A(1:m-k+i-1, n-k+i)$, and tau in $TAU(i)$.

NAME

dgeqp3 - compute a QR factorization with column pivoting of a matrix A

SYNOPSIS

```
SUBROUTINE DGEQP3(M, N, A, LDA, JPVT, TAU, WORK, LWORK, INFO)

INTEGER M, N, LDA, LWORK, INFO
INTEGER JPVT(*)
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)

SUBROUTINE DGEQP3_64(M, N, A, LDA, JPVT, TAU, WORK, LWORK, INFO)

INTEGER*8 M, N, LDA, LWORK, INFO
INTEGER*8 JPVT(*)
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEQP3([M], [N], A, [LDA], JPVT, TAU, [WORK], [LWORK],
  [INFO])

INTEGER :: M, N, LDA, LWORK, INFO
INTEGER, DIMENSION(:) :: JPVT
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:, :) :: A

SUBROUTINE GEQP3_64([M], [N], A, [LDA], JPVT, TAU, [WORK], [LWORK],
  [INFO])

INTEGER(8) :: M, N, LDA, LWORK, INFO
INTEGER(8), DIMENSION(:) :: JPVT
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dgeqp3(int m, int n, double *a, int lda, int *jpvt,
  double *tau, int *info);

void dgeqp3_64(long m, long n, double *a, long lda, long
```

```
*jpvt, double *tau, long *info);
```

PURPOSE

dgeqp3 computes a QR factorization with column pivoting of a matrix A: $A^*P = Q^*R$ using Level 3 BLAS.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)
On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the $\min(M,N)$ -by-N upper trapezoidal matrix R; the elements below the diagonal, together with the array TAU, represent the orthogonal matrix Q as a product of $\min(M,N)$ elementary reflectors.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1,M)$.

JPVT (input/output)
On entry, if $JPVT(J) \neq 0$, the J-th column of A is permuted to the front of A*P (a leading column); if $JPVT(J)=0$, the J-th column of A is a free column. On exit, if $JPVT(J)=K$, then the J-th column of A*P was the the K-th column of A.

TAU (output)
The scalar factors of the elementary reflectors.

WORK (workspace)
On exit, if $INFO=0$, $WORK(1)$ returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. $LWORK \geq 3*N+1$. For optimal performance $LWORK \geq 2*N+(N+1)*NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit.
< 0: if $INFO = -i$, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(k), \text{ where } k = \min(m,n).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(i+1:m,i)$, and τ in $TAU(i)$.

SUBROUTINE GEQPF_64([M], [N], A, [LDA], JPIVOT, TAU, [WORK], [INFO])
```

```
INTEGER(8) :: M, N, LDA, INFO  
INTEGER(8), DIMENSION(:) :: JPIVOT  
REAL(8), DIMENSION(:) :: TAU, WORK  
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgeqpf(int m, int n, double *a, int lda, int *jpivot,  
           double *tau, int *info);
```

```
void dgeqpf_64(long m, long n, double *a, long lda, long  
              *jpivot, double *tau, long *info);
```

PURPOSE

dgeqpf routine is deprecated and has been replaced by routine SGEQP3.

SGEQPF computes a QR factorization with column pivoting of a real M-by-N matrix A: $A^*P = Q^*R$.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$

A (input/output)

On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the $\min(M,N)$ -by-N upper triangular matrix R; the elements below the diagonal, together with the array TAU, represent the orthogonal matrix Q as a product of $\min(m,n)$ elementary reflectors.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,M)$.

JPIVOT (input/output)

On entry, if $JPIVOT(i) \neq 0$, the i-th column of A is permuted to the front of A^*P (a leading column); if $JPIVOT(i) = 0$, the i-th column of A is a free column. On exit, if $JPIVOT(i) = k$, then the i-th column of A^*P was the k-th column of A.

TAU (output)

The scalar factors of the elementary reflectors.

WORK (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(n)$$

Each $H(i)$ has the form

$$H = I - \tau * v * v'$$

where τ is a real scalar, and v is a real vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(i+1:m,i)$.

The matrix P is represented in `jpvt` as follows: If

$jpvt(j) = i$
then the j th column of P is the i th canonical unit vector.

NAME

dgeqrf - compute a QR factorization of a real M-by-N matrix
A

SYNOPSIS

```
SUBROUTINE DGEQRF(M, N, A, LDA, TAU, WORK, LDWORK, INFO)
```

```
INTEGER M, N, LDA, LDWORK, INFO  
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE DGEQRF_64(M, N, A, LDA, TAU, WORK, LDWORK, INFO)
```

```
INTEGER*8 M, N, LDA, LDWORK, INFO  
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEQRF([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
INTEGER :: M, N, LDA, LDWORK, INFO  
REAL(8), DIMENSION(:) :: TAU, WORK  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE GEQRF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
INTEGER(8) :: M, N, LDA, LDWORK, INFO  
REAL(8), DIMENSION(:) :: TAU, WORK  
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgeqrf(int m, int n, double *a, int lda, double *tau,  
           int *info);
```

```
void dgeqrf_64(long m, long n, double *a, long lda, double  
              *tau, long *info);
```

PURPOSE

dgeqrf computes a QR factorization of a real M-by-N matrix
A: $A = Q * R$.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M,N)-by-N upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of min(m,n) elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,M)$.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. $LDWORK \geq \max(1,N)$. For optimum performance $LDWORK \geq N * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(k), \text{ where } k = \min(m,n).$$

Each H(i) has the form

$$H(i) = I - \tau * v * v'$$

where tau is a real scalar, and v is a real vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(i+1:m,i)$, and tau in TAU(i).

NAME

dger - perform the rank 1 operation $A := \alpha * x * y' + A$

SYNOPSIS

```
SUBROUTINE DGER(M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
```

```
INTEGER M, N, INCX, INCY, LDA  
DOUBLE PRECISION ALPHA  
DOUBLE PRECISION X(*), Y(*), A(LDA,*)
```

```
SUBROUTINE DGER_64(M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
```

```
INTEGER*8 M, N, INCX, INCY, LDA  
DOUBLE PRECISION ALPHA  
DOUBLE PRECISION X(*), Y(*), A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE GER([M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
```

```
INTEGER :: M, N, INCX, INCY, LDA  
REAL(8) :: ALPHA  
REAL(8), DIMENSION(:) :: X, Y  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE GER_64([M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
```

```
INTEGER(8) :: M, N, INCX, INCY, LDA  
REAL(8) :: ALPHA  
REAL(8), DIMENSION(:) :: X, Y  
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dger(int m, int n, double alpha, double *x, int incx,  
          double *y, int incy, double *a, int lda);
```

```
void dger_64(long m, long n, double alpha, double *x, long  
            incx, double *y, long incy, double *a, long lda);
```

PURPOSE

dger performs the rank 1 operation $A := \alpha x y' + A$, where α is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

ARGUMENTS

- M (input)
On entry, M specifies the number of rows of the matrix A. $M \geq 0$. Unchanged on exit.
- N (input)
On entry, N specifies the number of columns of the matrix A. $N \geq 0$. Unchanged on exit.
- ALPHA (input)
On entry, ALPHA specifies the scalar α . Unchanged on exit.
- X (input)
($1 + (m - 1) * \text{abs}(\text{INCX})$). Before entry, the incremented array X must contain the m element vector x . Unchanged on exit.
- INCX (input)
On entry, INCX specifies the increment for the elements of X. $\text{INCX} \neq 0$. Unchanged on exit.
- Y (input)
($1 + (n - 1) * \text{abs}(\text{INCY})$). Before entry, the incremented array Y must contain the n element vector y . Unchanged on exit.
- INCY (input)
On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.
- A (input/output)
Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.
- LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $\text{LDA} \geq \max(1, m)$. Unchanged on exit.

               double *b, long ldb, double *x, long ldx, double
               *ferr, double *berr, long *info);
```

PURPOSE

dgerfs improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

ARGUMENTS

TRANSA (input)

Specifies the form of the system of equations:
= 'N': $A * X = B$ (No transpose)
= 'T': $A^{*T} * X = B$ (Transpose)
= 'C': $A^{*H} * X = B$ (Conjugate transpose = Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The original N-by-N matrix A.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

AF (input)

The factors L and U from the factorization $A = P * L * U$ as computed by SGETRF.

LDAF (input)

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

IPIVOT (input)

The pivot indices from SGETRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

B (input) The right hand side matrix B.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

X (input/output)

On entry, the solution matrix X, as computed by SGETRS. On exit, the improved solution matrix X.

LDX (input)

The leading dimension of the array X. LDX \geq max(1,N).

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

dimension(3*N)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

NAME

dgerqf - compute an RQ factorization of a real M-by-N matrix
A

SYNOPSIS

```
SUBROUTINE DGERQF(M, N, A, LDA, TAU, WORK, LDWORK, INFO)
```

```
INTEGER M, N, LDA, LDWORK, INFO  
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE DGERQF_64(M, N, A, LDA, TAU, WORK, LDWORK, INFO)
```

```
INTEGER*8 M, N, LDA, LDWORK, INFO  
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GERQF([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
INTEGER :: M, N, LDA, LDWORK, INFO  
REAL(8), DIMENSION(:) :: TAU, WORK  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE GERQF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
INTEGER(8) :: M, N, LDA, LDWORK, INFO  
REAL(8), DIMENSION(:) :: TAU, WORK  
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgerqf(int m, int n, double *a, int lda, double *tau,  
           int *info);
```

```
void dgerqf_64(long m, long n, double *a, long lda, double  
              *tau, long *info);
```

PURPOSE

dgerqf computes an RQ factorization of a real M-by-N matrix
A: $A = R * Q$.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, if $m \leq n$, the upper triangle of the subarray A(1:m,n-m+1:n) contains the M-by-M upper triangular matrix R; if $m > n$, the elements on and above the (m-n)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAU, represent the orthogonal matrix Q as a product of $\min(m,n)$ elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,M)$.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)

On exit, if $INFO = 0$, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. $LDWORK \geq \max(1,M)$. For optimum performance $LDWORK \geq M * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$Q = H(1) H(2) \dots H(k)$, where $k = \min(m,n)$.
Each H(i) has the form

$$H(i) = I - \tau * v * v'$$

where tau is a real scalar, and v is a real vector with

$v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ is stored on
exit in $A(m-k+i, 1:n-k+i-1)$, and tau in $TAU(i)$.

```

```
REAL(8), DIMENSION(:, :) :: A, U, VT
```

C INTERFACE

```
#include <sunperf.h>
void dgesdd(char jobz, int m, int n, double *a, int lda,
            double *s, double *u, int ldu, double *vt, int
            ldvt, int *info);

void dgesdd_64(char jobz, long m, long n, double *a, long
              lda, double *s, double *u, long ldu, double *vt,
              long ldvt, long *info);
```

PURPOSE

dgesdd computes the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and right singular vectors. If singular vectors are desired, it uses a divide-and-conquer algorithm.

The SVD is written
= U * SIGMA * transpose(V)

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and V is an N-by-N orthogonal matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns VT = V**T, not V.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)

Specifies options for computing all or part of the matrix U:

= 'A': all M columns of U and all N rows of V**T are returned in the arrays U and VT; = 'S': the first min(M,N) columns of U and the first min(M,N) rows of V**T are returned in the arrays U and VT; = 'O': If M >= N, the first N columns of U are overwritten on the array A and all rows of V**T are returned in the array VT; otherwise, all columns of U are returned in the array U and the first M rows of V**T are overwritten in the array VT; = 'N': no columns of U or rows of V**T are computed.

M (input) The number of rows of the input matrix A. M >= 0.

N (input) The number of columns of the input matrix A. N >=

0.

A (input/output)

On entry, the M-by-N matrix A. On exit, if JOBZ = 'O', A is overwritten with the first N columns of U (the left singular vectors, stored columnwise) if $M \geq N$; A is overwritten with the first M rows of $V^{*}T$ (the right singular vectors, stored rowwise) otherwise. If JOBZ \neq 'O', the contents of A are destroyed.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

S (output)

The singular values of A, sorted so that $S(i) \geq S(i+1)$.

U (output)

UCOL = M if JOBZ = 'A' or JOBZ = 'O' and $M < N$; UCOL = $\min(M, N)$ if JOBZ = 'S'. If JOBZ = 'A' or JOBZ = 'O' and $M < N$, U contains the M-by-M orthogonal matrix U; if JOBZ = 'S', U contains the first $\min(M, N)$ columns of U (the left singular vectors, stored columnwise); if JOBZ = 'O' and $M \geq N$, or JOBZ = 'N', U is not referenced.

LDU (input)

The leading dimension of the array U. $LDU \geq 1$; if JOBZ = 'S' or 'A' or JOBZ = 'O' and $M < N$, $LDU \geq M$.

VT (output)

If JOBZ = 'A' or JOBZ = 'O' and $M \geq N$, VT contains the N-by-N orthogonal matrix $V^{*}T$; if JOBZ = 'S', VT contains the first $\min(M, N)$ rows of $V^{*}T$ (the right singular vectors, stored rowwise); if JOBZ = 'O' and $M < N$, or JOBZ = 'N', VT is not referenced.

LDVT (input)

The leading dimension of the array VT. $LDVT \geq 1$; if JOBZ = 'A' or JOBZ = 'O' and $M \geq N$, $LDVT \geq N$; if JOBZ = 'S', $LDVT \geq \min(M, N)$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK;

LWORK (input)

The dimension of the array WORK. $LWORK \geq 1$. If JOBZ = 'N', $LWORK \geq 3 * \min(M, N) + \max(\max(M, N), 6 * \min(M, N))$. If JOBZ = 'O', $LWORK \geq 3 * \min(M, N) * \min(M, N) + \max(\max(M, N), 5 * \min(M, N) * \min(M, N) + 4 * \min(M, N))$. If JOBZ = 'S' or 'A' $LWORK \geq 3 * \min(M, N) * \min(M, N) + \max(\max(M, N), 4 * \min(M, N) * \min(M, N) + 4 * \min(M, N))$. For good performance, LWORK should generally be larger. If $LWORK < 0$ but other input arguments are legal, WORK(1) returns optimal LWORK.

IWORK (workspace)

dimension(8*MIN(M,N))

INFO (output)

= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: SBSDSC did not converge, updating process failed.

SUBROUTINE GESV([N], [NRHS], A, [LDA], IPIVOT, B, [LDB], [INFO])
```

```
INTEGER :: N, NRHS, LDA, LDB, INFO  
INTEGER, DIMENSION(:) :: IPIVOT  
REAL(8), DIMENSION(:, :) :: A, B
```

```
SUBROUTINE GESV_64([N], [NRHS], A, [LDA], IPIVOT, B, [LDB], [INFO])
```

```
INTEGER(8) :: N, NRHS, LDA, LDB, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT  
REAL(8), DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgesv(int n, int nrhs, double *a, int lda, int *ipivot,  
          double *b, int ldb, int *info);
```

```
void dgesv_64(long n, long nrhs, double *a, long lda, long  
             *ipivot, double *b, long ldb, long *info);
```

PURPOSE

dgesv computes the solution to a real system of linear equations

$A * X = B$, where A is an N -by- N matrix and X and B are N -by- $NRHS$ matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as

$$A = P * L * U,$$

where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

N (input) The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

$NRHS$ (input)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input/output)

On entry, the N -by- N coefficient matrix A . On exit, the factors L and U from the factorization $A = P*L*U$; the unit diagonal elements of L are not stored.

LDA (input)

The leading dimension of the array A . $LDA \geq \max(1,N)$.

$IPIVOT$ (output)

The pivot indices that define the permutation matrix P ; row i of the matrix was interchanged with row $IPIVOT(i)$.

B (input/output)

On entry, the N -by- $NRHS$ matrix of right hand side matrix B . On exit, if $INFO = 0$, the N -by- $NRHS$ solution matrix X .

LDB (input)

The leading dimension of the array B . $LDB \geq \max(1,N)$.

$INFO$ (output)

= 0: successful exit

< 0: if $INFO = -i$, the i -th argument had an illegal value

> 0: if $INFO = i$, $U(i,i)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.

        *a, long lda, double *sing, double *u, long ldu,
        double *vt, long ldvt, long *info);

```

PURPOSE

dgesvd computes the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and/or right singular vectors. The SVD is written

$$= U * SIGMA * transpose(V)$$

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and V is an N-by-N orthogonal matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns V**T, not V.

ARGUMENTS

JOBU (input)

Specifies options for computing all or part of the matrix U:

- = 'A': all M columns of U are returned in array U;
- = 'S': the first min(m,n) columns of U (the left singular vectors) are returned in the array U; = 'O': the first min(m,n) columns of U (the left singular vectors) are overwritten on the array A;
- = 'N': no columns of U (no left singular vectors) are computed.

JOBVT (input)

Specifies options for computing all or part of the matrix V**T:

- = 'A': all N rows of V**T are returned in the array VT;
- = 'S': the first min(m,n) rows of V**T (the right singular vectors) are returned in the array VT; = 'O': the first min(m,n) rows of V**T (the right singular vectors) are overwritten on the array A;
- = 'N': no rows of V**T (no right singular vectors) are computed.

JOBVT and JOBVT cannot both be 'O'.

M (input) The number of rows of the input matrix A. M >= 0.

N (input) The number of columns of the input matrix A. N >= 0.

A (input/output)

On entry, the M-by-N matrix A. On exit, if JOBVT = 'O', A is overwritten with the first min(m,n) columns of U (the left singular vectors, stored columnwise); if JOBVT = 'O', A is overwritten with

the first $\min(m,n)$ rows of V^{**T} (the right singular vectors, stored rowwise); if `JOBU` .ne. 'O' and `JOBVT` .ne. 'O', the contents of `A` are destroyed.

`LDA` (input)

The leading dimension of the array `A`. `LDA` \geq $\max(1,M)$.

`SING` (output)

The singular values of `A`, sorted so that `SING(i)` \geq `SING(i+1)`.

`U` (input) (`LDU,M`) if `JOBU` = 'A' or (`LDU,min(M,N)`) if `JOBU` = 'S'. If `JOBU` = 'A', `U` contains the M -by- M orthogonal matrix `U`; if `JOBU` = 'S', `U` contains the first $\min(m,n)$ columns of `U` (the left singular vectors, stored columnwise); if `JOBU` = 'N' or 'O', `U` is not referenced.

`LDU` (input)

The leading dimension of the array `U`. `LDU` \geq 1; if `JOBU` = 'S' or 'A', `LDU` \geq M .

`VT` (input)

If `JOBVT` = 'A', `VT` contains the N -by- N orthogonal matrix V^{**T} ; if `JOBVT` = 'S', `VT` contains the first $\min(m,n)$ rows of V^{**T} (the right singular vectors, stored rowwise); if `JOBVT` = 'N' or 'O', `VT` is not referenced.

`LDVT` (input)

The leading dimension of the array `VT`. `LDVT` \geq 1; if `JOBVT` = 'A', `LDVT` \geq N ; if `JOBVT` = 'S', `LDVT` \geq $\min(M,N)$.

`WORK` (workspace)

On exit, if `INFO` = 0, `WORK(1)` returns the optimal `LDWORK`; if `INFO` > 0, `WORK(2:MIN(M,N))` contains the unconverged superdiagonal elements of an upper bidiagonal matrix `B` whose diagonal is in `SING` (not necessarily sorted). `B` satisfies $A = U * B * VT$, so it has the same singular values as `A`, and singular vectors related by `U` and `VT`.

`LDWORK` (input)

The dimension of the array `WORK`. `LDWORK` \geq 1. `LDWORK` \geq $\max(3 * \min(M,N) + \max(M,N), 5 * \min(M,N))$. For good performance, `LDWORK` should generally be larger.

If `LDWORK` = -1, then a workspace query is assumed; the routine only calculates the optimal size of the `WORK` array, returns this value as the first entry of the `WORK` array, and no error message related to `LDWORK` is issued by `XERBLA`.

`INFO` (output)

= 0: successful exit.
< 0: if `INFO` = - i , the i -th argument had an illegal value.
> 0: if `SBDSQR` did not converge, `INFO` specifies how many superdiagonals of an intermediate bidiagonal form `B` did not converge to zero. See the description of `WORK` above for details.

```

PURPOSE

dgesvx uses the LU factorization to compute the solution to a real system of linear equations

$A * X = B$, where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to equilibrate

the system:

TRANS = 'N': $\text{diag}(R) * A * \text{diag}(C) * \text{inv}(\text{diag}(C)) * X = \text{diag}(R) * B$

TRANS = 'T': $(\text{diag}(R) * A * \text{diag}(C)) ** T * \text{inv}(\text{diag}(R)) * X = \text{diag}(C) * B$

TRANS = 'C': $(\text{diag}(R) * A * \text{diag}(C)) ** H * \text{inv}(\text{diag}(R)) * X = \text{diag}(C) * B$

Whether or not the system will be equilibrated depends on the

scaling of the matrix A, but if equilibration is used, A is

overwritten by $\text{diag}(R) * A * \text{diag}(C)$ and B by $\text{diag}(R) * B$ (if TRANS='N')

or $\text{diag}(C) * B$ (if TRANS = 'T' or 'C').

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the

matrix A (after equilibration if FACT = 'E') as

$A = P * L * U$,

where P is a permutation matrix, L is a unit lower triangular

matrix, and U is upper triangular.

3. If some $U(i,i)=0$, so that U is exactly singular, then the routine

returns with INFO = i. Otherwise, the factored form of A is used

to estimate the condition number of the matrix A. If the

reciprocal of the condition number is less than machine precision,

INFO = N+1 is returned as a warning, but the routine still goes on

to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution

matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by

diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so

that it solves the original system before equilibration.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIVOT contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by ROWSC and COLSC. A, AF, and IPIVOT are not modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

TRANSA (input)

Specifies the form of the system of equations:
= 'N': $A * X = B$ (No transpose)
= 'T': $A^{**T} * X = B$ (Transpose)
= 'COLSC': $A^{*H} * X = B$ (Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output)

On entry, the N-by-N matrix A. If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in ROWSC and/or COLSC. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows:
EQUED = 'ROWSC': $A := \text{diag}(\text{ROWSC}) * A$
EQUED = 'COLSC': $A := A * \text{diag}(\text{COLSC})$

EQUED = 'B': $A := \text{diag}(\text{ROWSC}) * A * \text{diag}(\text{COLSC})$.

LDA (input)

The leading dimension of the array A. LDA \geq max(1,N).

AF (input/output)

If FACT = 'F', then AF is an input argument and on entry contains the factors L and U from the factorization $A = P*L*U$ as computed by SGETRF. If EQUED \neq 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization $A = P*L*U$ of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization $A = P*L*U$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)

The leading dimension of the array AF. LDAF \geq max(1,N).

IPIVOT (input or output)

If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the factorization $A = P*L*U$ as computed by SGETRF; row i of the matrix was interchanged with row IPIVOT(i).

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = P*L*U$ of the original matrix A.

If FACT = 'E', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = P*L*U$ of the equilibrated matrix A.

EQUED (input)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'ROWSC': Row equilibration, i.e., A has been premultiplied by diag(ROWSC).
= 'COLSC': Column equilibration, i.e., A has been postmultiplied by diag(COLSC).
= 'B': Both row and column equilibration, i.e., A has been replaced by $\text{diag}(\text{ROWSC}) * A * \text{diag}(\text{COLSC})$.
EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

ROWSC (input/output)

The row scale factors for A. If EQUED = 'ROWSC' or 'B', A is multiplied on the left by diag(ROWSC); if EQUED = 'N' or 'COLSC', ROWSC is not accessed. ROWSC is an input argument if FACT = 'F'; otherwise, ROWSC is an output argument. If FACT = 'F' and EQUED = 'ROWSC' or 'B', each element of ROWSC must be positive.

COLSC (input/output)

The column scale factors for A. If EQUED = 'COLSC' or 'B', A is multiplied on the right by $\text{diag}(\text{COLSC})$; if EQUED = 'N' or 'ROWSC', COLSC is not accessed. COLSC is an input argument if FACT = 'F'; otherwise, COLSC is an output argument. If FACT = 'F' and EQUED = 'COLSC' or 'B', each element of COLSC must be positive.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANSA = 'N' and EQUED = 'ROWSC' or 'B', B is overwritten by $\text{diag}(\text{ROWSC}) * B$; if TRANSA = 'T' or 'COLSC' and EQUED = 'COLSC' or 'B', B is overwritten by $\text{diag}(\text{COLSC}) * B$.

LDB (input)

The leading dimension of the array B. $\text{LDB} \geq \max(1, N)$.

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is $\text{inv}(\text{diag}(\text{COLSC})) * X$ if TRANSA = 'N' and EQUED = 'COLSC' or 'B', or $\text{inv}(\text{diag}(\text{ROWSC})) * X$ if TRANSA = 'T' or 'COLSC' and EQUED = 'ROWSC' or 'B'.

LDX (input)

The leading dimension of the array X. $\text{LDX} \geq \max(1, N)$.

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

$\text{dimension}(4 * N)$ On exit, WORK(1) contains the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$. The "max absolute element" norm is used. If WORK(1) is much less than 1, then the stability of

the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with $0 < \text{INFO} \leq N$, then WORK(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

```

```
INTEGER :: M, N, LDA, INFO  
INTEGER, DIMENSION(:) :: IPIV  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE GETF2_64([M], [N], A, [LDA], IPIV, [INFO])
```

```
INTEGER(8) :: M, N, LDA, INFO  
INTEGER(8), DIMENSION(:) :: IPIV  
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgetf2(int m, int n, double *a, int lda, int *ipiv, int  
          *info);
```

```
void dgetf2_64(long m, long n, double *a, long lda, long  
             *ipiv, long *info);
```

PURPOSE

dgetf2 computes an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges.

The factorization has the form

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$).

This is the right-looking Level 2 BLAS version of the algorithm.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the m by n matrix to be factored. On exit, the factors L and U from the factorization $A = P*L*U$; the unit diagonal elements of L are not stored.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,M)$.

IPIV (output)

The pivot indices; for $1 \leq i \leq \min(M,N)$, row i of the matrix was interchanged with row IPIV(i).

INFO (output)

= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

```

```
void dgetrf(int m, int n, double *a, int lda, int *ipivot,  
           int *info);
```

```
void dgetrf_64(long m, long n, double *a, long lda, long  
              *ipivot, long *info);
```

PURPOSE

dgetrf computes an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges.

The factorization has the form

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$).

This is the right-looking Level 3 BLAS version of the algorithm.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix to be factored. On exit, the factors L and U from the factorization $A = P*L*U$; the unit diagonal elements of L are not stored.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,M)$.

IPIVOT (output)

The pivot indices; for $1 \leq i \leq \min(M,N)$, row i of the matrix was interchanged with row IPIVOT(i).

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value
> 0: if $INFO = i$, $U(i,i)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NAME

dgetri - compute the inverse of a matrix using the LU factorization computed by SGETRF

SYNOPSIS

```
SUBROUTINE DGETRI(N, A, LDA, IPIVOT, WORK, LDWORK, INFO)
```

```
INTEGER N, LDA, LDWORK, INFO
INTEGER IPIVOT(*)
DOUBLE PRECISION A(LDA,*), WORK(*)
```

```
SUBROUTINE DGETRI_64(N, A, LDA, IPIVOT, WORK, LDWORK, INFO)
```

```
INTEGER*8 N, LDA, LDWORK, INFO
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GETRI([N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])
```

```
INTEGER :: N, LDA, LDWORK, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE GETRI_64([N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])
```

```
INTEGER(8) :: N, LDA, LDWORK, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgetri(int n, double *a, int lda, int *ipivot, int
            *info);
```

```
void dgetri_64(long n, double *a, long lda, long *ipivot,
               long *info);
```

PURPOSE

dgetri computes the inverse of a matrix using the LU factorization computed by SGETRF.

This method inverts U and then computes $\text{inv}(A)$ by solving the system $\text{inv}(A)*L = \text{inv}(U)$ for $\text{inv}(A)$.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
On entry, the factors L and U from the factorization $A = P*L*U$ as computed by SGETRF. On exit, if $\text{INFO} = 0$, the inverse of the original matrix A.

LDA (input)
The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

IPIVOT (input)
The pivot indices from SGETRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

WORK (workspace)
On exit, if $\text{INFO} = 0$, then $\text{WORK}(1)$ returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. $\text{LDWORK} \geq \max(1, N)$. For optimal performance $\text{LDWORK} \geq N*NB$, where NB is the optimal blocksize returned by ILAENV.

If $\text{LDWORK} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if $\text{INFO} = -i$, the i-th argument had an illegal value
> 0: if $\text{INFO} = i$, $U(i, i)$ is exactly zero; the matrix is singular and its inverse could not be computed.

```
void dgetrs_64(char transa, long n, long nrhs, double *a,
               long lda, long *ipivot, double *b, long ldb, long
               *info);
```

PURPOSE

dgetrs solves a system of linear equations
 $A * X = B$ or $A' * X = B$ with a general N-by-N matrix A
using the LU factorization computed by SGETRF.

ARGUMENTS

TRANSA (input)
Specifies the form of the system of equations:
= 'N': $A * X = B$ (No transpose)
= 'T': $A' * X = B$ (Transpose)
= 'C': $A' * X = B$ (Conjugate transpose = Trans-
pose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number
of columns of the matrix B. $NRHS \geq 0$.

A (input) The factors L and U from the factorization $A =$
 $P * L * U$ as computed by SGETRF.

LDA (input)
The leading dimension of the array A. $LDA \geq$
 $\max(1, N)$.

IPIVOT (input)
The pivot indices from SGETRF; for $1 \leq i \leq N$, row i
of the matrix was interchanged with row IPIVOT(i).

B (input/output)
On entry, the right hand side matrix B. On exit,
the solution matrix X.

LDB (input)
The leading dimension of the array B. $LDB \geq$
 $\max(1, N)$.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-
gal value

```

C INTERFACE

```
#include <sunperf.h>
```

```

void dggbak(char job, char side, int n, int ilo, int ihi,
            double *lscale, double *rscale, int m, double *v,
            int ldv, int *info);

void dggbak_64(char job, char side, long n, long ilo, long
              ihi, double *lscale, double *rscale, long m,
              double *v, long ldv, long *info);

```

PURPOSE

dggbak forms the right or left eigenvectors of a real generalized eigenvalue problem $A*x = \lambda*B*x$, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by SGGBAL.

ARGUMENTS

JOB (input)
 Specifies the type of backward transformation required:
 = 'N': do nothing, return immediately;
 = 'P': do backward transformation for permutation only;
 = 'S': do backward transformation for scaling only;
 = 'B': do backward transformations for both permutation and scaling. JOB must be the same as the argument JOB supplied to SGGBAL.

SIDE (input)
 = 'R': V contains right eigenvectors;
 = 'L': V contains left eigenvectors.

N (input) The number of rows of the matrix V. $N \geq 0$.

ILO (input)
 The integers ILO and IHI determined by SGGBAL. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

IHI (input)
 See the description for ILO.

LSCALE (input)
 Details of the permutations and/or scaling factors applied to the left side of A and B, as returned by SGGBAL.

RSCALE (input)
 Details of the permutations and/or scaling factors applied to the right side of A and B, as returned by SGGBAL.

M (input) The number of columns of the matrix V. $M \geq 0$.

V (input/output)
 On entry, the matrix of right or left eigenvectors to be transformed, as returned by STGEVC. On exit, V is overwritten by the transformed eigenvectors.

LDV (input)

The leading dimension of the matrix V. LDV \geq
max(1,N).

INFO (output)

= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an ille-
gal value.

FURTHER DETAILS

See R.C. Ward, Balancing the generalized eigenvalue problem,
SIAM J. Sci. Stat. Comp. 2 (1981), 141-152.

```

```
SUBROUTINE GGBAL_64(JOB, [N], A, [LDA], B, [LDB], ILO, IHI, LSCALE,
                   RSCALE, [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: JOB
INTEGER(8) :: N, LDA, LDB, ILO, IHI, INFO
REAL(8), DIMENSION(:) :: LSCALE, RSCALE, WORK
REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dggbal(char job, int n, double *a, int lda, double *b,
```

```

        int ldb, int *ilo, int *ihi, double *lscale, double
        *rscale, int *info);

void dggbal_64(char job, long n, double *a, long lda, double
        *b, long ldb, long *ilo, long *ihi, double
        *lscale, double *rscale, long *info);

```

PURPOSE

dggbal balances a pair of general real matrices (A,B). This involves, first, permuting A and B by similarity transformations to isolate eigenvalues in the first 1 to ILO-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem $A*x = \lambda*B*x$.

ARGUMENTS

JOB (input)

Specifies the operations to be performed on A and B:
 = 'N': none: simply set ILO = 1, IHI = N, LSCALE(I) = 1.0 and RSCALE(I) = 1.0 for i = 1,...,N.
 = 'P': permute only;
 = 'S': scale only;
 = 'B': both permute and scale.

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)

On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,N)$.

B (input) On entry, the input matrix B. On exit, B is overwritten by the balanced matrix. If JOB = 'N', B is not referenced.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

ILO (output)

ILO and IHI are set to integers such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i = IHI+1, \dots, N$. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

IHI (output)

See the description for ILO.

LSCALE (input)

Details of the permutations and scaling factors applied to the left side of A and B. If $P(j)$ is the index of the row interchanged with row j , and $D(j)$ is the scaling factor applied to row j , then
LSCALE(j) = $P(j)$ for $J = 1, \dots, ILO-1 = D(j)$
for $J = ILO, \dots, IHI = P(j)$ for $J = IHI+1, \dots, N$.
The order in which the interchanges are made is N to $IHI+1$, then 1 to $ILO-1$.

RSCALE (input)

Details of the permutations and scaling factors applied to the right side of A and B. If $P(j)$ is the index of the column interchanged with column j , and $D(j)$ is the scaling factor applied to column j , then LSCALE(j) = $P(j)$ for $J = 1, \dots, ILO-1 = D(j)$ for $J = ILO, \dots, IHI = P(j)$ for $J = IHI+1, \dots, N$. The order in which the interchanges are made is N to $IHI+1$, then 1 to $ILO-1$.

WORK (workspace)

dimension(6*N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

              long *info);

```

PURPOSE

dgges computes for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized real Schur form (S,T), optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization

$$(A,B) = ((VSL)*S*(VSR)**T, (VSL)*T*(VSR)**T)$$

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T. The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver SGGEV instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0 or both being zero.

A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

$$\begin{bmatrix} a & 0 \\ 0 & b \end{bmatrix}$$

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues.

ARGUMENTS

JOBVSL (input)
= 'N': do not compute the left Schur vectors;
= 'V': compute the left Schur vectors.

JOBVSR (input)
= 'N': do not compute the right Schur vectors;
= 'V': compute the right Schur vectors.

SORT (input)
Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. =
'N': Eigenvalues are not ordered;
= 'S': Eigenvalues are ordered (see DELCTG);

DELCTG (input)
DELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', DELCTG is not referenced. If SORT = 'S', DELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue $(\text{ALPHAR}(j) + \text{ALPHAI}(j)i) / \text{BETA}(j)$ is selected if $\text{DELCTG}(\text{ALPHAR}(j), \text{ALPHAI}(j), \text{BETA}(j))$ is true; i.e. if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy $\text{DELCTG}(\text{ALPHAR}(j), \text{ALPHAI}(j), \text{BETA}(j)) = \text{.TRUE.}$ after ordering. INFO is to be set to N+2 in this case.

N (input) The order of the matrices A, B, VSL, and VSR. N ≥ 0 .

A (input/output)
On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA (input)
The leading dimension of A. LDA $\geq \max(1, N)$.

B (input/output)
On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB (input)
The leading dimension of B. LDB $\geq \max(1, N)$.

SDIM (output)
If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which DELCTG is true. (Complex conjugate pairs for which DELCTG is true for either eigenvalue count as 2.)

ALPHAR (output)
On exit, $(\text{ALPHAR}(j) + \text{ALPHAI}(j)i) / \text{BETA}(j)$, $j=1, \dots, N$, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)i, and BETA(j), $j=1, \dots, N$ are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of

the real Schur form of (A,B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

ALPHAI (output)

See the description for ALPHAR.

BETA (output)

See the description for ALPHAR.

VSL (input)

If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL (input)

The leading dimension of the matrix VSL. LDVSL ≥ 1 , and if JOBVSL = 'V', LDVSL $\geq N$.

VSR (input)

If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR (input)

The leading dimension of the matrix VSR. LDVSR ≥ 1 , and if JOBVSR = 'V', LDVSR $\geq N$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK $\geq 8*N+16$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

BWORK (workspace)

dimension(N) Not referenced if SORT = 'N'.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1,...,N: The QZ iteration failed. (A,B) are not in Schur form, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for $j=INFO+1, \dots, N$.
> N: =N+1: other than QZ iteration failed in SHGEQZ.
=N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigen-

values in the Generalized Schur form no longer satisfy DELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in STGSEN.

```

PURPOSE

dggesx computes for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the real Schur form (S,T), and, optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization

$$A, B = ((VSL) S (VSR)**T, (VSL) T (VSR)**T)$$

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues (RCONDV). The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for

beta=0 or for both being zero.

A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

$$\begin{bmatrix} a & 0 \\ 0 & b \end{bmatrix}$$

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues.

ARGUMENTS

JOBVSL (input)

= 'N': do not compute the left Schur vectors;
= 'V': compute the left Schur vectors.

JOBVSR (input)

= 'N': do not compute the right Schur vectors;
= 'V': compute the right Schur vectors.

SORT (input)

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered;
= 'S': Eigenvalues are ordered (see DELCTG).

DELCTG (input)

DELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', DELCTG is not referenced. If SORT = 'S', DELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue $(\text{ALPHAR}(j)+\text{ALPHAI}(j))/\text{BETA}(j)$ is selected if $\text{DELCTG}(\text{ALPHAR}(j),\text{ALPHAI}(j),\text{BETA}(j))$ is true; i.e. if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected. Note that a selected complex eigenvalue may no longer satisfy $\text{DELCTG}(\text{ALPHAR}(j),\text{ALPHAI}(j),\text{BETA}(j)) = \text{.TRUE.}$ after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+3.

SENSE (input)

Determines which reciprocal condition numbers are computed. = 'N' : None are computed;
= 'E' : Computed for average of selected eigenvalues only;
= 'V' : Computed for selected deflating subspaces only;
= 'B' : Computed for both. If SENSE = 'E', 'V', or 'B', SORT must equal 'S'.

N (input) The order of the matrices A, B, VSL, and VSR. N >= 0.

A (input/output)

On entry, the first of the pair of matrices. On

exit, A has been overwritten by its generalized Schur form S.

LDA (input)

The leading dimension of A. LDA \geq max(1,N).

B (input/output)

On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB (input)

The leading dimension of B. LDB \geq max(1,N).

SDIM (output)

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which DELCTG is true. (Complex conjugate pairs for which DELCTG is true for either eigenvalue count as 2.)

ALPHAR (output)

On exit, $(\text{ALPHAR}(j) + \text{ALPHAI}(j)*i)/\text{BETA}(j)$, $j=1,\dots,N$, will be the generalized eigenvalues. $\text{ALPHAR}(j) + \text{ALPHAI}(j)*i$ and $\text{BETA}(j)$, $j=1,\dots,N$ are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A,B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If $\text{ALPHAI}(j)$ is zero, then the j -th eigenvalue is real; if positive, then the j -th and $(j+1)$ -st eigenvalues are a complex conjugate pair, with $\text{ALPHAI}(j+1)$ negative.

Note: the quotients $\text{ALPHAR}(j)/\text{BETA}(j)$ and $\text{ALPHAI}(j)/\text{BETA}(j)$ may easily over- or underflow, and $\text{BETA}(j)$ may even be zero. Thus, the user should avoid naively computing the ratio. However, ALPHAR and ALPHAI will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and BETA always less than and usually comparable with $\text{norm}(B)$.

ALPHAI (output)

See the description for ALPHAR.

BETA (output)

See the description for ALPHAR.

VSL (input)

If $\text{JOBVSL} = 'V'$, VSL will contain the left Schur vectors. Not referenced if $\text{JOBVSL} = 'N'$.

LDVSL (input)

The leading dimension of the matrix VSL. LDVSL ≥ 1 , and if $\text{JOBVSL} = 'V'$, LDVSL $\geq N$.

VSR (input)

If $\text{JOBVSR} = 'V'$, VSR will contain the right Schur vectors. Not referenced if $\text{JOBVSR} = 'N'$.

LDVSR (input)

The leading dimension of the matrix VSR. LDVSR ≥ 1 , and if $\text{JOBVSR} = 'V'$, LDVSR $\geq N$.

RCONDE (output)
 If SENSE = 'E' or 'B', RCONDE(1) and RCONDE(2) contain the reciprocal condition numbers for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

RCONDV (output)
 If SENSE = 'V' or 'B', RCONDV(1) and RCONDV(2) contain the reciprocal condition numbers for the selected deflating subspaces. Not referenced if SENSE = 'N' or 'E'.

WORK (workspace)
 On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
 The dimension of the array WORK. LWORK \geq $8*(N+1)+16$. If SENSE = 'E', 'V', or 'B', LWORK \geq $\text{MAX}(8*(N+1)+16, 2*SDIM*(N-SDIM))$.

IWORK (workspace)
 Not referenced if SENSE = 'N'.

LIWORK (input)
 The dimension of the array WORK. LIWORK \geq N+6.

BWORK (workspace)
 dimension(N) Not referenced if SORT = 'N'.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value.
 = 1,...,N: The QZ iteration failed. (A,B) are not in Schur form, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for $j=\text{INFO}+1,\dots,N$.
 > N: =N+1: other than QZ iteration failed in SHGEQZ
 =N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy DELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in STGSEN.

Further details =====
 An approximate (asymptotic) bound on the average absolute error of the selected eigenvalues is

$$\text{EPS} * \text{norm}((A, B)) / \text{RCONDE}(1).$$

An approximate (asymptotic) bound on the maximum angular error in the computed deflating subspaces is

$$\text{EPS} * \text{norm}((A, B)) / \text{RCONDV}(2).$$

See LAPACK User's Guide, section 4.11 for more information.

void dggev(char jobvl, char jobvr, int n, double *a, int  
          lda, double *b, int ldb, double *alphar, double
```

```

        *alphai, double *beta, double *vl, int ldvl, double
        *vr, int ldvr, int *info);
void dggev_64(char jobvl, char jobvr, long n, double *a,
              long lda, double *b, long ldb, double *alphan,
              double *alphai, double *beta, double *vl, long
              ldvl, double *vr, long ldvr, long *info);

```

PURPOSE

dggev computes for a pair of N-by-N real nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar λ or a ratio $\alpha/\beta = \lambda$, such that $A - \lambda B$ is singular. It is usually represented as the pair (α, β) , as there is a reasonable interpretation for $\beta=0$, and even for both being zero.

The right eigenvector $v(j)$ corresponding to the eigenvalue $\lambda(j)$ of (A,B) satisfies

$$A * v(j) = \lambda(j) * B * v(j).$$

The left eigenvector $u(j)$ corresponding to the eigenvalue $\lambda(j)$ of (A,B) satisfies

$$u(j)**H * A = \lambda(j) * u(j)**H * B .$$

where $u(j)**H$ is the conjugate-transpose of $u(j)$.

ARGUMENTS

JOBVL (input)
 = 'N': do not compute the left generalized eigenvectors;
 = 'V': compute the left generalized eigenvectors.

JOBVR (input)
 = 'N': do not compute the right generalized eigenvectors;
 = 'V': compute the right generalized eigenvectors.

N (input) The order of the matrices A, B, VL, and VR. $N \geq 0$.

A (input/output)
 On entry, the matrix A in the pair (A,B). On exit, A has been overwritten.

LDA (input)
 The leading dimension of A. $LDA \geq \max(1, N)$.

B (input/output)
 On entry, the matrix B in the pair (A,B). On exit, B has been overwritten.

LDB (input)
 The leading dimension of B. $LDB \geq \max(1, N)$.

ALPHAR (output)

On exit, $(\text{ALPHAR}(j) + \text{ALPHAI}(j)*i)/\text{BETA}(j)$, $j=1,\dots,N$, will be the generalized eigenvalues. If $\text{ALPHAI}(j)$ is zero, then the j -th eigenvalue is real; if positive, then the j -th and $(j+1)$ -st eigenvalues are a complex conjugate pair, with $\text{ALPHAI}(j+1)$ negative.

Note: the quotients $\text{ALPHAR}(j)/\text{BETA}(j)$ and $\text{ALPHAI}(j)/\text{BETA}(j)$ may easily over- or underflow, and $\text{BETA}(j)$ may even be zero. Thus, the user should avoid naively computing the ratio α/β . However, ALPHAR and ALPHAI will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and BETA always less than and usually comparable with $\text{norm}(B)$.

ALPHAI (output)

See the description for ALPHAR .

BETA (output)

See the description for ALPHAR .

VL (input)

If $\text{JOBVL} = 'V'$, the left eigenvectors $u(j)$ are stored one after another in the columns of VL , in the same order as their eigenvalues. If the j -th eigenvalue is real, then $u(j) = \text{VL}(:,j)$, the j -th column of VL . If the j -th and $(j+1)$ -th eigenvalues form a complex conjugate pair, then $u(j) = \text{VL}(:,j) + i*\text{VL}(:,j+1)$ and $u(j+1) = \text{VL}(:,j) - i*\text{VL}(:,j+1)$. Each eigenvector will be scaled so the largest component have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$. Not referenced if $\text{JOBVL} = 'N'$.

LDVL (input)

The leading dimension of the matrix VL . $\text{LDVL} \geq 1$, and if $\text{JOBVL} = 'V'$, $\text{LDVL} \geq N$.

VR (input)

If $\text{JOBVR} = 'V'$, the right eigenvectors $v(j)$ are stored one after another in the columns of VR , in the same order as their eigenvalues. If the j -th eigenvalue is real, then $v(j) = \text{VR}(:,j)$, the j -th column of VR . If the j -th and $(j+1)$ -th eigenvalues form a complex conjugate pair, then $v(j) = \text{VR}(:,j) + i*\text{VR}(:,j+1)$ and $v(j+1) = \text{VR}(:,j) - i*\text{VR}(:,j+1)$. Each eigenvector will be scaled so the largest component have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$. Not referenced if $\text{JOBVR} = 'N'$.

LDVR (input)

The leading dimension of the matrix VR . $\text{LDVR} \geq 1$, and if $\text{JOBVR} = 'V'$, $\text{LDVR} \geq N$.

WORK (workspace)

On exit, if $\text{INFO} = 0$, $\text{WORK}(1)$ returns the optimal LWORK .

LWORK (input)

The dimension of the array WORK . $\text{LWORK} \geq$

max(1,8*N). For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in SHGEQZ.
=N+2: error return from STGEVC.

```

PURPOSE

dggevxx computes for a pair of N-by-N real nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, LSCALE, RSCALE, ABNRM, and BBNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right eigenvector v(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

$$A * v(j) = lambda(j) * B * v(j) .$$

The left eigenvector u(j) corresponding to the eigenvalue

lambda(j) of (A,B) satisfies

$$u(j)**H * A = lambda(j) * u(j)**H * B.$$

where $u(j)**H$ is the conjugate-transpose of $u(j)$.

ARGUMENTS

BALANC (input)

Specifies the balance option to be performed. =
= 'N': do not diagonally scale or permute;
= 'P': permute only;
= 'S': scale only;
= 'B': both permute and scale. Computed reciprocal condition numbers will be for the matrices after permuting and/or balancing. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL (input)

= 'N': do not compute the left generalized eigenvectors;
= 'V': compute the left generalized eigenvectors.

JOBVR (input)

= 'N': do not compute the right generalized eigenvectors;
= 'V': compute the right generalized eigenvectors.

SENSE (input)

Determines which reciprocal condition numbers are computed. = 'N': none are computed;
= 'E': computed for eigenvalues only;
= 'V': computed for eigenvectors only;
= 'B': computed for eigenvalues and eigenvectors.

N (input) The order of the matrices A, B, VL, and VR. N >= 0.

A (input/output)

On entry, the matrix A in the pair (A,B). On exit, A has been overwritten. If JOBVL='V' or JOBVR='V' or both, then A contains the first part of the real Schur form of the "balanced" versions of the input A and B.

LDA (input)

The leading dimension of A. LDA >= max(1,N).

B (input/output)

On entry, the matrix B in the pair (A,B). On exit, B has been overwritten. If JOBVL='V' or JOBVR='V' or both, then B contains the second part of the real Schur form of the "balanced" versions of the input A and B.

LDB (input)

The leading dimension of B. LDB >= max(1,N).

ALPHAR (output)

On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues.

If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio ALPHA/BETA. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

ALPHAI (output)

See the description of ALPHAR.

BETA (output)

See the description of ALPHAR.

VL (output)

If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If the j-th eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then u(j) = VL(:,j)+i*VL(:,j+1) and u(j+1) = VL(:,j)-i*VL(:,j+1). Each eigenvector will be scaled so the largest component have abs(real part) + abs(imag. part) = 1. Not referenced if JOBVL = 'N'.

LDVL (input)

The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR (output)

If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If the j-th eigenvalue is real, then v(j) = VR(:,j), the j-th column of VR. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then v(j) = VR(:,j)+i*VR(:,j+1) and v(j+1) = VR(:,j)-i*VR(:,j+1). Each eigenvector will be scaled so the largest component have abs(real part) + abs(imag. part) = 1. Not referenced if JOBVR = 'N'.

LDVR (input)

The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

ILO (output)

ILO and IHI are integer values such that on exit A(i,j) = 0 and B(i,j) = 0 if i > j and j = 1,...,ILO-1 or i = IHI+1,...,N. If BALANC = 'N' or 'S', ILO = 1 and IHI = N.

IHI (output)

See the description of ILO.

LSCALE (output)

Details of the permutations and scaling factors applied to the left side of A and B. If PL(j) is the index of the row interchanged with row j, and DL(j) is the scaling factor applied to row j, then LSCALE(j) = PL(j) for j = 1,...,ILO-1 = DL(j) for j = ILO,...,IHI = PL(j) for j = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

RSCALE (output)

Details of the permutations and scaling factors applied to the right side of A and B. If PR(j) is the index of the column interchanged with column j, and DR(j) is the scaling factor applied to column j, then RSCALE(j) = PR(j) for j = 1,...,ILO-1 = DR(j) for j = ILO,...,IHI = PR(j) for j = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

ABNRM (output)

The one-norm of the balanced matrix A.

BBNRM (output)

The one-norm of the balanced matrix B.

RCONDE (output)

If SENSE = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of RCONDE are set to the same value. Thus RCONDE(j), RCONDV(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If SENSE = 'V', RCONDE is not referenced.

RCONDV (output)

If SENSE = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of RCONDV are set to the same value. If the eigenvalues cannot be reordered to compute RCONDV(j), RCONDV(j) is set to 0; this can only occur when the true value would be very small anyway. If SENSE = 'E', RCONDV is not referenced.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK \geq max(1,6*N). If SENSE = 'E', LWORK \geq 12*N. If SENSE = 'V' or 'B', LWORK \geq 2*N*N+12*N+16.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace)

dimension(N+6) If SENSE = 'E', IWORK is not referenced.

BWORK (workspace)
dimension(N) If SENSE = 'N', BWORK is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in SHGEQZ.
=N+2: error return from STGEVC.

FURTHER DETAILS

Balancing a matrix pair (A,B) includes, first, permuting rows and columns to isolate eigenvalues, second, applying diagonal similarity transformation to the rows and columns to make the rows and columns as close in norm as possible. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.11.1.2 of LAPACK Users' Guide.

An approximate error bound on the chordal distance between the i-th computed generalized eigenvalue w and the corresponding exact eigenvalue λ is
 $\text{hord}(w, \lambda) \leq \text{EPS} * \text{norm}(\text{ABNRM}, \text{BBNRM}) / \text{RCONDE}(i)$
An approximate error bound for the angle between the i-th computed eigenvector VL(i) or VR(i) is given by
 $\text{PS} * \text{norm}(\text{ABNRM}, \text{BBNRM}) / \text{DIF}(i)$.

For further explanation of the reciprocal condition numbers RCONDE and RCONDV, see section 4.11 of LAPACK User's Guide.

  *info);
```

```
void dgglm_64(long n, long m, long p, double *a, long lda,
  double *b, long ldb, double *d, double *x, double
```

```
*y, long *info);
```

PURPOSE

dgglm solves a general Gauss-Markov linear model (GLM) problem:

$$\underset{x}{\text{minimize}} \quad || y ||_2 \quad \text{subject to} \quad d = A*x + B*y$$

where A is an N-by-M matrix, B is an N-by-P matrix, and d is a given N-vector. It is assumed that $M \leq N \leq M+P$, and

$$\text{rank}(A) = M \quad \text{and} \quad \text{rank}(\begin{matrix} A & B \end{matrix}) = N.$$

Under these assumptions, the constrained equation is always consistent, and there is a unique solution x and a minimal 2-norm solution y, which is obtained using a generalized QR factorization of A and B.

In particular, if matrix B is square nonsingular, then the problem GLM is equivalent to the following weighted linear least squares problem

$$\underset{x}{\text{minimize}} \quad || \text{inv}(B)*(d-A*x) ||_2$$

where inv(B) denotes the inverse of B.

ARGUMENTS

N (input) The number of rows of the matrices A and B. $N \geq 0$.

M (input) The number of columns of the matrix A. $0 \leq M \leq N$.

P (input) The number of columns of the matrix B. $P \geq N-M$.

A (input/output)
On entry, the N-by-M matrix A. On exit, A is destroyed.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1,N)$.

B (input/output)
On entry, the N-by-P matrix B. On exit, B is destroyed.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1,N)$.

D (input/output)
On entry, D is the left hand side of the GLM equation. On exit, D is destroyed.

X (output)

On exit, X and Y are the solutions of the GLM problem.

Y (output)

See the description of X.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK \geq $\max(1, N+M+P)$. For optimum performance, LDWORK $\geq M + \min(N, P) + \max(N, P) * NB$, where NB is an upper bound for the optimal blocksizes for SGEQRF, SGERQF, SORMQR and SORMRQ.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value.

void dgghrd_64(char compq, char compz, long n, long ilo,
               long ihi, double *a, long lda, double *b, long
               ldb, double *q, long ldq, double *z, long ldz,
               long *info);

```

PURPOSE

dgghrd reduces a pair of real matrices (A,B) to generalized upper Hessenberg form using orthogonal transformations, where A is a general matrix and B is upper triangular: $Q' * A * Z = H$ and $Q' * B * Z = T$, where H is upper Hessenberg, T is upper triangular, and Q and Z are orthogonal, and ' ' means transpose.

The orthogonal matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q1 and Z1, so that

$$1 * A * Z1' = (Q1*Q) * H * (Z1*Z)'$$

ARGUMENTS

COMPQ (input)

= 'N': do not compute Q;
 = 'I': Q is initialized to the unit matrix, and the orthogonal matrix Q is returned; = 'V': Q must contain an orthogonal matrix Q1 on entry, and the product Q1*Q is returned.

COMPZ (input)

= 'N': do not compute Z;
 = 'I': Z is initialized to the unit matrix, and the orthogonal matrix Z is returned; = 'V': Z must contain an orthogonal matrix Z1 on entry, and the product Z1*Z is returned.

N (input) The order of the matrices A and B. $N \geq 0$.

ILO (input)

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to SGBAL; otherwise they should be set to 1 and N respectively. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; ILO=1 and IHI=0, if $N=0$.

IHI (input)

See the description of ILO.

A (input/output)

On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the rest is set to zero.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,N)$.

B (input/output)
On entry, the N-by-N upper triangular matrix B.
On exit, the upper triangular matrix $T = Q' B Z$.
The elements below the diagonal are set to zero.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, N)$.

Q (input/output)
If COMPQ='N': Q is not referenced.
If COMPQ='I': on entry, Q need not be set, and on exit it contains the orthogonal matrix Q, where Q' is the product of the Givens transformations which are applied to A and B on the left. If COMPQ='V': on entry, Q must contain an orthogonal matrix Q1, and on exit this is overwritten by $Q1*Q$.

LDQ (input)
The leading dimension of the array Q. $LDQ \geq N$ if COMPQ='V' or 'I'; $LDQ \geq 1$ otherwise.

Z (input/output)
If COMPZ='N': Z is not referenced.
If COMPZ='I': on entry, Z need not be set, and on exit it contains the orthogonal matrix Z, which is the product of the Givens transformations which are applied to A and B on the right. If COMPZ='V': on entry, Z must contain an orthogonal matrix Z1, and on exit this is overwritten by $Z1*Z$.

LDZ (input)
The leading dimension of the array Z. $LDZ \geq N$ if COMPZ='V' or 'I'; $LDZ \geq 1$ otherwise.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

This routine reduces A to Hessenberg and B to triangular form by an unblocked reduction, as described in Matrix Computations, by Golub and Van Loan (Johns Hopkins Press.)

[LDWORK], [INFO])
```

```
INTEGER(8) :: M, N, P, LDA, LDB, LDWORK, INFO  
REAL(8), DIMENSION(:) :: C, D, X, WORK  
REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgglse(int m, int n, int p, double *a, int lda, double  
*b, int ldb, double *c, double *d, double *x, int  
*info);
```

```
void dgglse_64(long m, long n, long p, double *a, long lda,  
double *b, long ldb, double *c, double *d, double
```

```
*x, long *info);
```

PURPOSE

dgglse solves the linear equality-constrained least squares (LSE) problem:

$$\text{minimize } \| c - A*x \|_2 \quad \text{subject to } B*x = d$$

where A is an M-by-N matrix, B is a P-by-N matrix, c is a given M-vector, and d is a given P-vector. It is assumed that
P <= N <= M+P, and

$$\text{rank}(B) = P \text{ and } \text{rank} \begin{pmatrix} A \\ B \end{pmatrix} = N.$$

These conditions ensure that the LSE problem has a unique solution, which is obtained using a GRQ factorization of the matrices B and A.

ARGUMENTS

- M (input) The number of rows of the matrix A. M >= 0.
- N (input) The number of columns of the matrices A and B. N >= 0.
- P (input) The number of rows of the matrix B. 0 <= P <= N <= M+P.
- A (input/output)
On entry, the M-by-N matrix A. On exit, A is destroyed.
- LDA (input)
The leading dimension of the array A. LDA >= max(1,M).
- B (input/output)
On entry, the P-by-N matrix B. On exit, B is destroyed.
- LDB (input)
The leading dimension of the array B. LDB >= max(1,P).
- C (input/output)
On entry, C contains the right hand side vector for the least squares part of the LSE problem. On exit, the residual sum of squares for the solution is given by the sum of squares of elements N-P+1 to M of vector C.
- D (input/output)
On entry, D contains the right hand side vector for the constrained equation. On exit, D is destroyed.
- X (output)
On exit, X is the solution of the LSE problem.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK \geq $\max(1, M+N+P)$. For optimum performance LDWORK \geq $P + \min(M, N) + \max(M, N) * NB$, where NB is an upper bound for the optimal blocksizes for SGEQRF, SGERQF, SORMQR and SORMRQ.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value.

#include <sunperf.h>
```

```
void dggqrf(int n, int m, int p, double *a, int lda, double  
*taua, double *b, int ldb, double *taub, int  
*info);
```

```
void dggqrf_64(long n, long m, long p, double *a, long lda,
              double *taua, double *b, long ldb, double *taub,
              long *info);
```

PURPOSE

dggqrf computes a generalized QR factorization of an N -by- M matrix A and an N -by- P matrix B :

$$A = Q \cdot R, \quad B = Q \cdot T \cdot Z,$$

where Q is an N -by- N orthogonal matrix, Z is a P -by- P orthogonal matrix, and R and T assume one of the forms:

$$\text{if } N \geq M, \quad R = \begin{pmatrix} R_{11} & & \\ & & \\ & & \\ & & \\ & 0 & \dots & \end{pmatrix} \begin{matrix} M \\ \\ \\ \\ N-M \\ M \end{matrix}, \quad \text{or if } N < M, \quad R = \begin{pmatrix} R_{11} & R_{12} \\ & \\ & \\ & \\ & \\ & \\ & \\ & \\ & \\ & \\ & \\ & \\ & \\ & \\ & \\ & \\ & \\ & \\ & \end{pmatrix} \begin{matrix} N \\ M-N \\ \end{matrix}$$

where R_{11} is upper triangular, and

$$\text{if } N \leq P, \quad T = \begin{pmatrix} 0 & T_{12} \\ & \end{pmatrix} \begin{matrix} N \\ P-N \\ N \\ \end{matrix}, \quad \text{or if } N > P, \quad T = \begin{pmatrix} T_{11} & \\ & \end{pmatrix} \begin{matrix} P \\ \end{matrix}$$

where T_{12} or T_{21} is upper triangular.

In particular, if B is square and nonsingular, the GQR factorization of A and B implicitly gives the QR factorization of $\text{inv}(B) \cdot A$:

$$\text{inv}(B) \cdot A = Z' \cdot (\text{inv}(T) \cdot R)$$

where $\text{inv}(B)$ denotes the inverse of the matrix B , and Z' denotes the transpose of the matrix Z .

ARGUMENTS

N (input) The number of rows of the matrices A and B . $N \geq 0$.

M (input) The number of columns of the matrix A . $M \geq 0$.

P (input) The number of columns of the matrix B . $P \geq 0$.

A (input/output)

On entry, the N -by- M matrix A . On exit, the elements on and above the diagonal of the array contain the $\min(N,M)$ -by- M upper trapezoidal matrix R (R is upper triangular if $N \geq M$); the elements below the diagonal, with the array $TAUA$, represent the orthogonal matrix Q as a product of $\min(N,M)$ elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A . $LDA \geq \max(1,N)$.

$TAUA$ (output)

The scalar factors of the elementary reflectors which represent the orthogonal matrix Q (see Further Details).

B (input/output)

On entry, the N -by- P matrix B . On exit, if $N \leq P$, the upper triangle of the subarray $B(1:N, P-N+1:P)$ contains the N -by- N upper triangular matrix T ; if $N > P$, the elements on and above the $(N-P)$ -th subdiagonal contain the N -by- P upper trapezoidal matrix T ; the remaining elements, with the array $TAUB$, represent the orthogonal matrix Z as a product of elementary reflectors (see Further Details).

LDB (input)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

TAUB (output)

The scalar factors of the elementary reflectors which represent the orthogonal matrix Z (see Further Details).

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

LWORK (input)

The dimension of the array $WORK$. $LWORK \geq \max(1, N, M, P)$. For optimum performance $LWORK \geq \max(N, M, P) * \max(NB1, NB2, NB3)$, where $NB1$ is the optimal blocksize for the QR factorization of an N -by- M matrix, $NB2$ is the optimal blocksize for the RQ factorization of an N -by- P matrix, and $NB3$ is the optimal blocksize for a call of $SORMQR$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by $XERBLA$.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(k), \text{ where } k = \min(n, m).$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v'$$

where τ is a real scalar, and v is a real vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:n)$ is stored on exit in $A(i+1:n, i)$, and τ in $TAUA(i)$.

To form Q explicitly, use LAPACK subroutine $SORMQR$.

To use Q to update another matrix, use LAPACK subroutine SORMQR.

The matrix Z is represented as a product of elementary reflectors

$$Z = H(1) H(2) \dots H(k), \text{ where } k = \min(n,p).$$

Each H(i) has the form

$$H(i) = I - \text{taub} * v * v'$$

where taub is a real scalar, and v is a real vector with $v(p-k+i+1:p) = 0$ and $v(p-k+i) = 1$; $v(1:p-k+i-1)$ is stored on exit in $B(n-k+i,1:p-k+i-1)$, and taub in $\text{TAUB}(i)$.

To form Z explicitly, use LAPACK subroutine SORGRQ.

To use Z to update another matrix, use LAPACK subroutine SORMRQ.

              double *taua, double *b, long ldb, double *taub,
              long *info);
```

PURPOSE

dggrqf computes a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B:

$$A = R*Q, \quad B = Z*T*Q,$$

where Q is an N-by-N orthogonal matrix, Z is a P-by-P orthogonal matrix, and R and T assume one of the forms:

$$\text{if } M \leq N, \quad R = \begin{pmatrix} 0 & R_{12} \\ & \end{pmatrix} \begin{matrix} M \\ M-N \end{matrix}, \quad \text{or if } M > N, \quad R = \begin{pmatrix} R_{11} \\ & \end{pmatrix} \begin{matrix} M \\ N \end{matrix}$$

where R12 or R21 is upper triangular, and

$$\text{if } P \geq N, \quad T = \begin{pmatrix} T_{11} \\ & \end{pmatrix} \begin{matrix} N \\ P \end{matrix}, \quad \text{or if } P < N, \quad T = \begin{pmatrix} T_{11} & T_{12} \\ & \end{pmatrix} \begin{matrix} P \\ N-P \end{matrix}$$

where T11 is upper triangular.

In particular, if B is square and nonsingular, the GRQ factorization of A and B implicitly gives the RQ factorization of A*inv(B):

$$A*inv(B) = (R*inv(T))*Z'$$

where inv(B) denotes the inverse of the matrix B, and Z' denotes the transpose of the matrix Z.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

P (input) The number of rows of the matrix B. P >= 0.

N (input) The number of columns of the matrices A and B. N >= 0.

A (input/output)

On entry, the M-by-N matrix A. On exit, if M <= N, the upper triangle of the subarray A(1:M,N-M+1:N) contains the M-by-M upper triangular matrix R; if M > N, the elements on and above the (M-N)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAUA, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. LDA >= max(1,M).

TAUA (output)

The scalar factors of the elementary reflectors which represent the orthogonal matrix Q (see Further Details).

B (input/output)

On entry, the P-by-N matrix B. On exit, the elements on and above the diagonal of the array contain the min(P,N)-by-N upper trapezoidal matrix T (T is upper triangular if P >= N); the elements below the diagonal, with the array TAUB, represent the orthogonal matrix Z as a product of elementary reflectors (see Further Details).

LDB (input)

The leading dimension of the array B. LDB >= max(1,P).

TAUB (output)

The scalar factors of the elementary reflectors which represent the orthogonal matrix Z (see Further Details).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK >= max(1,N,M,P). For optimum performance LWORK >= max(N,M,P)*max(NB1,NB2,NB3), where NB1 is the optimal blocksize for the RQ factorization of an M-by-N matrix, NB2 is the optimal blocksize for the QR factorization of a P-by-N matrix, and NB3 is the optimal blocksize for a call of SORMRQ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(k), \text{ where } k = \min(m,n).$$

Each H(i) has the form

$$H(i) = I - \text{taua} * v * v'$$

where taua is a real scalar, and v is a real vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ is stored on exit in $A(m-k+i,1:n-k+i-1)$, and taua in TAUA(i).

To form Q explicitly, use LAPACK subroutine SORGRQ.

To use Q to update another matrix, use LAPACK subroutine SORMRQ.

The matrix Z is represented as a product of elementary reflectors

$$Z = H(1) H(2) \dots H(k), \text{ where } k = \min(p,n).$$

Each H(i) has the form

$$H(i) = I - \text{taub} * v * v'$$

where taub is a real scalar, and v is a real vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:p)$ is stored on exit in $B(i+1:p,i)$, and taub in $TAUB(i)$.

To form Z explicitly, use LAPACK subroutine SORGQR.

To use Z to update another matrix, use LAPACK subroutine SORMQR.

```

PURPOSE

dggsvd computes the generalized singular value decomposition (GSVD) of an M-by-N real matrix A and P-by-N real matrix B:

$$U^*A^*Q = D1^*(\begin{matrix} 0 & R \end{matrix}), \quad V^*B^*Q = D2^*(\begin{matrix} 0 & R \end{matrix})$$

where U, V and Q are orthogonal matrices, and Z' is the transpose of Z. Let K+L = the effective numerical rank of the matrix (A',B')', then R is a K+L-by-K+L nonsingular upper triangular matrix, D1 and D2 are M-by-(K+L) and P-by-(K+L) "diagonal" matrices and of the following structures, respectively:

If M-K-L >= 0,

$$D1 = \begin{matrix} & & & K & L \\ & & & K & (I & 0) \\ & & & L & (0 & C) \\ & & & M-K-L & (0 & 0) \end{matrix}$$

$$D2 = \begin{matrix} & & & K & L \\ & & & L & (0 & S) \\ & & & P-L & (0 & 0) \end{matrix}$$

$$\begin{matrix} & & & N-K-L & K & L \\ (0 R) = & K & (0 & R11 & R12) \\ & L & (0 & 0 & R22) \end{matrix}$$

where

$$\begin{aligned} C &= \text{diag}(\text{ALPHA}(K+1), \dots, \text{ALPHA}(K+L)), \\ S &= \text{diag}(\text{BETA}(K+1), \dots, \text{BETA}(K+L)), \\ C^{**2} + S^{**2} &= I. \end{aligned}$$

R is stored in A(1:K+L,N-K-L+1:N) on exit.

If M-K-L < 0,

$$D1 = \begin{matrix} & & & K & M-K & K+L-M \\ & & & K & (I & 0 & 0) \\ & & & M-K & (0 & C & 0) \end{matrix}$$

$$D2 = \begin{matrix} & & & K & M-K & K+L-M \\ & & & M-K & (0 & S & 0) \\ & & & K+L-M & (0 & 0 & I) \end{matrix}$$

$$P-L \begin{pmatrix} 0 & 0 & 0 \end{pmatrix}$$

$$\begin{pmatrix} 0 & R \end{pmatrix} = \begin{matrix} & N-K-L & K & M-K & K+L-M \\ K & \begin{pmatrix} 0 & R11 & R12 & R13 \end{pmatrix} \\ M-K & \begin{pmatrix} 0 & 0 & R22 & R23 \end{pmatrix} \\ K+L-M & \begin{pmatrix} 0 & 0 & 0 & R33 \end{pmatrix} \end{matrix}$$

where

$$C = \text{diag}(\text{ALPHA}(K+1), \dots, \text{ALPHA}(M)),$$

$$S = \text{diag}(\text{BETA}(K+1), \dots, \text{BETA}(M)),$$

$$C^{**2} + S^{**2} = I.$$

(R11 R12 R13) is stored in A(1:M, N-K-L+1:N), and R33 is stored

$$\begin{pmatrix} 0 & R22 & R23 \end{pmatrix}$$

in B(M-K+1:L, N+M-K-L+1:N) on exit.

The routine computes C, S, R, and optionally the orthogonal transformation matrices U, V and Q.

In particular, if B is an N-by-N nonsingular matrix, then the GSVD of A and B implicitly gives the SVD of A*inv(B):

$$A \cdot \text{inv}(B) = U \cdot (D1 \cdot \text{inv}(D2)) \cdot V'$$

If (A', B')' has orthonormal columns, then the GSVD of A and B is also equal to the CS decomposition of A and B. Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem:

$$A' \cdot A \cdot x = \text{lambda} \cdot B' \cdot B \cdot x.$$

In some literature, the GSVD of A and B is presented in the form

$$U' \cdot A \cdot X = \begin{pmatrix} 0 & D1 \end{pmatrix}, \quad V' \cdot B \cdot X = \begin{pmatrix} 0 & D2 \end{pmatrix}$$

where U and V are orthogonal and X is nonsingular, D1 and D2 are ``diagonal''. The former GSVD form can be converted to the latter form by taking the nonsingular matrix X as

$$X = Q \cdot \begin{pmatrix} I & 0 \\ 0 & \text{inv}(R) \end{pmatrix}.$$

ARGUMENTS

JOBU (input)

= 'U': Orthogonal matrix U is computed;
= 'N': U is not computed.

JOBV (input)

= 'V': Orthogonal matrix V is computed;
= 'N': V is not computed.

JOBQ (input)

= 'Q': Orthogonal matrix Q is computed;
= 'N': Q is not computed.

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrices A and B. N >= 0.

P (input) The number of rows of the matrix B. P >= 0.

K (output)

On exit, K and L specify the dimension of the sub-blocks described in the Purpose section. K + L =

effective numerical rank of (A',B')'.

L (output)

See the description of K.

A (input/output)

On entry, the M-by-N matrix A. On exit, A contains the triangular matrix R, or part of R. See Purpose for details.

LDA (input)

The leading dimension of the array A. LDA \geq max(1,M).

B (input/output)

On entry, the P-by-N matrix B. On exit, B contains the triangular matrix R if M-K-L < 0. See Purpose for details.

LDB (input)

The leading dimension of the array B. LDA \geq max(1,P).

ALPHA (output)

On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; ALPHA(1:K) = 1, BETA(1:K) = 0, and if M-K-L \geq 0, ALPHA(K+1:K+L) = C, BETA(K+1:K+L) = S, or if M-K-L < 0, ALPHA(K+1:M)=C, ALPHA(M+1:K+L)=0, BETA(K+1:M) = S, BETA(M+1:K+L) = 1 and ALPHA(K+L+1:N) = 0, BETA(K+L+1:N) = 0

BETA (output)

See the description of ALPHA.

U (output)

If JOBU = 'U', U contains the M-by-M orthogonal matrix U. If JOBU = 'N', U is not referenced.

LDU (input)

The leading dimension of the array U. LDU \geq max(1,M) if JOBU = 'U'; LDU \geq 1 otherwise.

V (output)

If JOBV = 'V', V contains the P-by-P orthogonal matrix V. If JOBV = 'N', V is not referenced.

LDV (input)

The leading dimension of the array V. LDV \geq max(1,P) if JOBV = 'V'; LDV \geq 1 otherwise.

Q (output)

If JOBQ = 'Q', Q contains the N-by-N orthogonal matrix Q. If JOBQ = 'N', Q is not referenced.

LDQ (input)

The leading dimension of the array Q. LDQ \geq max(1,N) if JOBQ = 'Q'; LDQ \geq 1 otherwise.

WORK (workspace)

dimension (max(3*N,M,P)+N)

IWORK3 (output)

dimension(N) On exit, IWORK3 stores the sorting information. More precisely, the following loop will sort ALPHA for $I = K+1, \min(M, K+L)$ swap ALPHA(I) and ALPHA(IWORK3(I)) endfor such that ALPHA(1) >= ALPHA(2) >= ... >= ALPHA(N).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = 1, the Jacobi-type procedure failed to converge. For further details, see subroutine STGSJA.

               double *u, long ldu, double *v, long ldv, double
               *q, long ldq, long *info);

```

PURPOSE

dggsvp computes orthogonal matrices U, V and Q such that

$$\begin{array}{r}
 \begin{array}{ccc}
 L & (& 0 & 0 & A23 &) \\
 M-K-L & (& 0 & 0 & 0 &)
 \end{array} \\
 \\
 = & \begin{array}{ccc}
 & N-K-L & K & L \\
 K & (& 0 & A12 & A13 &) \\
 M-K & (& 0 & 0 & A23 &)
 \end{array} \text{ if } M-K-L < 0; \\
 \\
 V' * B * Q = & \begin{array}{ccc}
 & N-K-L & K & L \\
 L & (& 0 & 0 & B13 &) \\
 P-L & (& 0 & 0 & 0 &)
 \end{array}
 \end{array}$$

where the K-by-K matrix A12 and L-by-L matrix B13 are non-singular upper triangular; A23 is L-by-L upper triangular if $M-K-L \geq 0$, otherwise A23 is (M-K)-by-L upper trapezoidal. $K+L$ = the effective numerical rank of the (M+P)-by-N matrix (A',B')'. Z' denotes the transpose of Z.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see subroutine SGGSD.

ARGUMENTS

```

JOBV (input)
    = 'U': Orthogonal matrix U is computed;
    = 'N': U is not computed.

JOBV (input)
    = 'V': Orthogonal matrix V is computed;
    = 'N': V is not computed.

JOBQ (input)
    = 'Q': Orthogonal matrix Q is computed;
    = 'N': Q is not computed.

M (input) The number of rows of the matrix A. M >= 0.

```

P (input) The number of rows of the matrix B. $P \geq 0$.

N (input) The number of columns of the matrices A and B. $N \geq 0$.

A (input/output)
On entry, the M-by-N matrix A. On exit, A contains the triangular (or trapezoidal) matrix described in the Purpose section.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input/output)
On entry, the P-by-N matrix B. On exit, B contains the triangular matrix described in the Purpose section.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, P)$.

TOLA (input)
TOLA and TOLB are the thresholds to determine the effective numerical rank of matrix B and a sub-block of A. Generally, they are set to $TOLA = \text{MAX}(M, N) * \text{norm}(A) * \text{MACHEPS}$, $TOLB = \text{MAX}(P, N) * \text{norm}(B) * \text{MACHEPS}$. The size of TOLA and TOLB may affect the size of backward errors of the decomposition.

TOLB (input)
See the description of TOLA.

K (output)
On exit, K and L specify the dimension of the sub-blocks described in Purpose. $K + L =$ effective numerical rank of (A', B') .

L (output)
See the description of K.

U (input) If $JOB_U = 'U'$, U contains the orthogonal matrix U. If $JOB_U = 'N'$, U is not referenced.

LDU (input)
The leading dimension of the array U. $LDU \geq \max(1, M)$ if $JOB_U = 'U'$; $LDU \geq 1$ otherwise.

V (input) If $JOB_V = 'V'$, V contains the orthogonal matrix V. If $JOB_V = 'N'$, V is not referenced.

LDV (input)
The leading dimension of the array V. $LDV \geq \max(1, P)$ if $JOB_V = 'V'$; $LDV \geq 1$ otherwise.

Q (input) If $JOB_Q = 'Q'$, Q contains the orthogonal matrix Q. If $JOB_Q = 'N'$, Q is not referenced.

LDQ (input)
The leading dimension of the array Q. $LDQ \geq \max(1, N)$ if $JOB_Q = 'Q'$; $LDQ \geq 1$ otherwise.

IWORK (workspace)
dimension(N)

TAU (workspace)
dimension(N)

WORK (workspace)
dimension(MAX(3*N,M,P))

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The subroutine uses LAPACK subroutine SGEQPF for the QR factorization with column pivoting to detect the effective numerical rank of the a matrix. It may be replaced by a better rank determination strategy.

NAME

dgssco - General sparse solver condition number estimate.

SYNOPSIS

```
SUBROUTINE DGSSCO ( COND, HANDLE, IER )  
  
INTEGER          IER  
DOUBLE PRECISION COND  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSCO - Condition number estimate.

PARAMETERS

COND - DOUBLE PRECISION
On exit, an estimate of the condition number of the factored matrix. Must be called after the numerical factorization subroutine, *DGSSFA()*.

HANDLE(150) - DOUBLE PRECISION array
On entry, *HANDLE(*)* is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-700 : Invalid calling sequence - need to call *DGSSFA* first.
-710 : Condition number estimate not available (not implemented for this *HANDLE*'s matrix type).

NAME

dgssda - Deallocate working storage for the general sparse solver.

SYNOPSIS

```
SUBROUTINE ZGSSDA ( HANDLE, IER )  
  
INTEGER          IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

ZGSSDA - Deallocate dynamically allocated working storage.

PARAMETERS

HANDLE(150) - DOUBLE PRECISION array
On entry, *HANDLE*(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine.
Modified on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

none

NAME

dgssfa - General sparse solver numeric factorization.

SYNOPSIS

```
SUBROUTINE DGSSFA ( NEQNS, COLSTR, ROWIND, VALUES, HANDLE, IER )  
  
INTEGER          NEQNS, COLSTR(*), ROWIND(*), IER  
DOUBLE PRECISION VALUES(*)  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSFA - Numeric factorization of a sparse matrix.

PARAMETERS

NEQNS - INTEGER
On entry, **NEQNS** specifies the number of equations in coefficient matrix. Unchanged on exit.

COLSTR(*) - INTEGER array
On entry, **COLSTR(*)** is an array of size (NEQNS+1), containing the pointers of the matrix structure. Unchanged on exit.

ROWIND(*) - INTEGER array
On entry, **ROWIND(*)** is an array of size COLSTR(NEQNS+1)-1, containing the indices of the matrix structure. Unchanged on exit.

VALUES(*) - DOUBLE PRECISION array
On entry, **VALUES(*)** is an array of size COLSTR(NEQNS+1)-1, containing the numeric values of the sparse matrix to be factored. Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array
On entry, **HANDLE(*)** is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on

exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- 300 : Invalid calling sequence - need to call DGSSOR first.
- 301 : Failure to dynamically allocate memory.
- 666 : Internal error.

NAME

dgssfs - General sparse solver one call interface.

SYNOPSIS

```
SUBROUTINE DGSSFS ( MTXTYP, PIVOT , NEQNS, COLSTR, ROWIND,
                   VALUES, NRHS , RHS , LDRHS , ORDMTHD,
                   OUTUNT, MSGGLVL, HANDLE, IER )

CHARACTER*2      MTXTYP
CHARACTER*1      PIVOT
INTEGER          NEQNS, COLSTR(*), ROWIND(*), NRHS, LDRHS,
                OUTUNT, MSGGLVL, IER
CHARACTER*3      ORDMTHD
DOUBLE PRECISION VALUES(*), RHS(*)
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSFS - General sparse solver one call interface.

PARAMETERS

MTXTYP - CHARACTER*2
On entry, MTXTYP specifies the coefficient matrix type. Specifically, the valid options are:

- 'sp' or 'SP' - symmetric structure, positive-definite values
- 'ss' or 'SS' - symmetric structure, symmetric values
- 'su' or 'SU' - symmetric structure, unsymmetric values
- 'uu' or 'UU' - unsymmetric structure, unsymmetric values

Unchanged on exit.

PIVOT - CHARACTER*1
On entry, pivot specifies whether or not pivoting is used in the course of the numeric factorization. The valid options are:

- 'n' or 'N' - no pivoting is used (Pivoting is not supported for this release).

Unchanged on exit.

NEQNS - INTEGER

On entry, *NEQNS* specifies the number of equations in the coefficient matrix. *NEQNS* must be at least one. Unchanged on exit.

COLSTR(*) - INTEGER array

On entry, *COLSTR*(*) is an array of size (*NEQNS*+1), containing the pointers of the matrix structure. Unchanged on exit.

ROWIND(*) - INTEGER array

On entry, *ROWIND*(*) is an array of size *COLSTR*(*NEQNS*+1)-1, containing the indices of the matrix structure. Unchanged on exit.

VALUES(*) - DOUBLE PRECISION array

On entry, *VALUES*(*) is an array of size *COLSTR*(*NEQNS*+1)-1, containing the non-zero numeric values of the sparse matrix to be factored. Unchanged on exit.

NRHS - INTEGER

On entry, *NRHS* specifies the number of right hand sides to solve for. Unchanged on exit.

RHS(*) - DOUBLE PRECISION array

On entry, *RHS*(*LDRHS*,*NRHS*) contains the *NRHS* right hand sides. On exit, it contains the solutions.

LDRHS - INTEGER

On entry, *LDRHS* specifies the leading dimension of the *RHS* array. Unchanged on exit.

ORDMTHD - CHARACTER*3

On entry, *ORDMTHD* specifies the fill-reducing ordering to be used by the sparse solver. Specifically, the valid options are:

'nat' or 'NAT' - natural ordering (no ordering)
'mmd' or 'MMD' - multiple minimum degree
'gnd' or 'GND' - general nested dissection
'uso' or 'USO' - user specified ordering (see *DGSSUO*)

Unchanged on exit.

OUTUNT - INTEGER

Output unit. Unchanged on exit.

MSGLVL - INTEGER

Message level.

0 - no output from solver.
(No messages supported for this release.)

Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, *HANDLE*(*) is an array of containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-101 : Failure to dynamically allocate memory.
-102 : Invalid matrix type.
-103 : Invalid pivot option.
-104 : Number of nonzeros is less than NEQNS.
-105 : NEQNS < 1
-201 : Failure to dynamically allocate memory.
-301 : Failure to dynamically allocate memory.
-401 : Failure to dynamically allocate memory.
-402 : NRHS < 1
-403 : NEQNS > LDRHS
-666 : Internal error.

Contents

- [NAME](#)
- [SYNOPSIS](#)
- [PURPOSE](#)

NAME

dgssin - Initialize the general sparse solver.

SYNOPSIS

```
SUBROUTINE DGSSIN ( MTXTYP, PIVOT, NEQNS, COLSTR, ROWIND, OUTUNT,  
                  MSGLVL, HANDLE, IER )
```

```
CHARACTER*2      MTXTYP  
CHARACTER*1      PIVOT  
INTEGER          NEQNS, COLSTR(*), ROWIND(*), OUTUNT, MSGLVL, IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSIN - Initialize the sparse solver and input the matrix structure.

PARAMETERS

MTXTYP - CHARACTER*2
On entry, MTXTYP specifies the coefficient matrix type. Specifically, the valid options are:

- 'sp' or 'SP' - symmetric structure, positive-definite values
- 'ss' or 'SS' - symmetric structure, symmetric values
- 'su' or 'SU' - symmetric structure, unsymmetric values
- 'uu' or 'UU' - unsymmetric structure, unsymmetric values

Unchanged on exit.

PIVOT - CHARACTER*1
On entry, PIVOT specifies whether or not pivoting is used in the course of the numeric factorization. The valid options are:

- 'n' or 'N' - no pivoting is used
(Pivoting is not supported for this release).

Unchanged on exit.

NEQNS - INTEGER
On entry, NEQNS specifies the number of equations in the coefficient matrix. NEQNS must be at least one. Unchanged on exit.

COLSTR(*) - INTEGER array
On entry, *COLSTR*(*) is an array of size (NEQNS+1),
containing the pointers of the matrix structure.
Unchanged on exit.

ROWIND(*) - INTEGER array
On entry, *ROWIND*(*) is an array of size
COLSTR(NEQNS+1)-1, containing the indices of the
matrix structure. Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array
On entry, *HANDLE*(*) is an array containing
information needed by the solver, and must be passed
unchanged to each sparse solver subroutine.
Modified on exit.

OUTUNT - INTEGER
Output unit. Unchanged on exit.

MSGLVL - INTEGER
Message level.

0 - no output from solver.
(No messages supported for this release.)

Unchanged on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on
exit. If error encountered, it is set to a non-zero
integer. Error numbers set by this subroutine:

-101 : Failure to dynamically allocate memory.
-102 : Invalid matrix type.
-103 : Invalid pivot option.
-104 : Number of nonzeros less than NEQNS.
-105 : NEQNS < 1

```
SUBROUTINE DGSSOR ( ORDMTHD, HANDLE, IER )
```

```
CHARACTER*3      ORDMTHD
INTEGER          IER
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSOR - Orders and symbolically factors a sparse matrix.

PARAMETERS

ORDMTHD - CHARACTER*3
On entry, ORDMTHD specifies the fill-reducing ordering to be used by the sparse solver. Specifically, the valid options are:

- 'nat' or 'NAT' - natural ordering (no ordering)
- 'mmd' or 'MMD' - multiple minimum degree
- 'gnd' or 'GND' - general nested dissection
- 'uso' or 'USO' - user specified ordering (see DGSSUO)

Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array
On entry, HANDLE(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- 200 : Invalid calling sequence - need to call DGSSIN first.
- 201 : Failure to dynamically allocate memory.
- 666 : Internal error.

dgssps - Print general sparse solver statics.

SYNOPSIS

```
SUBROUTINE DGSSPS ( HANDLE, IER )  
  
INTEGER          IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSPS - Print solver statistics.

PARAMETERS

HANDLE(150) - DOUBLE PRECISION array
On entry, *HANDLE*(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- 800 : Invalid calling sequence - need to call DGSSSL first.
- 899 : Printed solver statistics not supported this release.

Contents

NAME

dgssrp - Return permutation used by the general sparse solver.

SYNOPSIS

```
SUBROUTINE DGSSRP ( PERM, HANDLE, IER )
```

```
INTEGER          PERM(*), IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSRP - Returns the permutation used by the solver for the fill-reducing ordering.

PARAMETERS

PERM(NEQNS) - INTEGER array

Undefined on entry. PERM(NEQNS) is the permutation array used by the sparse solver for the fill-reducing ordering. Modified on exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, HANDLE(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-600 : Invalid calling sequence - need to call DGSSOR first.

NAME

dgsssl - Solve routine for the general sparse solver.

SYNOPSIS

```
SUBROUTINE DGSSSL ( NRHS, RHS, LDRHS, HANDLE, IER )  
  
INTEGER          NRHS, LDRHS, IER  
DOUBLE PRECISION RHS(LDRHS,NRHS)  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSSL - Triangular solve of a factored sparse matrix.

PARAMETERS

NRHS - INTEGER
On entry, NRHS specifies the number of right hand sides to solve for. Unchanged on exit.

RHS(LDRHS,*) - DOUBLE PRECISION array
On entry, RHS(LDRHS,NRHS) contains the NRHS right hand sides. On exit, it contains the solutions.

LDRHS - INTEGER
On entry, LDRHS specifies the leading dimension of the RHS array. Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array
On entry, HANDLE(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- 400 : Invalid calling sequence - need to call DGSSFA first.
- 401 : Failure to dynamically allocate memory.
- 402 : NRHS < 1
- 403 : NEQNS > LDRHS

NAME

dgssuo - User supplied permutation for ordering used in the general sparse solver.

SYNOPSIS

```
SUBROUTINE DGSSUO ( PERM, HANDLE, IER )
```

```
INTEGER          PERM(*), IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSUO - User supplied permutation for ordering. Must be called after *DGSSIN()* (sparse solver initialization) and before *DGSSOR()* (sparse solver ordering).

PARAMETERS

PERM(NEQNS) - INTEGER array
On entry, PERM(NEQNS) is a permutation array supplied by the user for the fill-reducing ordering. Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array
On entry, *HANDLE(*)* is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-500 : Invalid calling sequence - need to call DGSSIN first.

NAME

dgicon - estimate the reciprocal of the condition number of a real tridiagonal matrix A using the LU factorization as computed by SGTTRF

SYNOPSIS

```
SUBROUTINE DGICON(NORM, N, LOW, DIAG, UP1, UP2, IPIVOT, ANORM, RCOND,
                  WORK, IWORK2, INFO)
```

```
CHARACTER * 1 NORM
INTEGER N, INFO
INTEGER IPIVOT(*), IWORK2(*)
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION LOW(*), DIAG(*), UP1(*), UP2(*), WORK(*)
```

```
SUBROUTINE DGICON_64(NORM, N, LOW, DIAG, UP1, UP2, IPIVOT, ANORM,
                    RCOND, WORK, IWORK2, INFO)
```

```
CHARACTER * 1 NORM
INTEGER*8 N, INFO
INTEGER*8 IPIVOT(*), IWORK2(*)
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION LOW(*), DIAG(*), UP1(*), UP2(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GTCON(NORM, [N], LOW, DIAG, UP1, UP2, IPIVOT, ANORM,
                RCOND, [WORK], [IWORK2], [INFO])
```

```
CHARACTER(LEN=1) :: NORM
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IPIVOT, IWORK2
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: LOW, DIAG, UP1, UP2, WORK
```

```
SUBROUTINE GTCON_64(NORM, [N], LOW, DIAG, UP1, UP2, IPIVOT, ANORM,
                   RCOND, [WORK], [IWORK2], [INFO])
```

```
CHARACTER(LEN=1) :: NORM
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT, IWORK2
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: LOW, DIAG, UP1, UP2, WORK
```

C INTERFACE

```
#include <sunperf.h>
void dgtcon(char norm, int n, double *low, double *diag,
            double *up1, double *up2, int *ipivot, double
            anorm, double *rcond, int *info);

void dgtcon_64(char norm, long n, double *low, double *diag,
              double *up1, double *up2, long *ipivot, double
              anorm, double *rcond, long *info);
```

PURPOSE

dgtcon estimates the reciprocal of the condition number of a real tridiagonal matrix A using the LU factorization as computed by SGTTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

NORM (input)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I': Infinity-norm.

N (input) The order of the matrix A. $N \geq 0$.

LOW (input)

The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by SGTTRF.

DIAG (input)

The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UP1 (input)

The (n-1) elements of the first superdiagonal of U.

UP2 (input)

The (n-2) elements of the second superdiagonal of U.

IPIVOT (input)

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

ANORM (input)

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND (output)

The reciprocal of the condition number of the

matrix A, computed as $RCOND = 1/(ANORM * AINVNM)$,
where AINVNM is an estimate of the 1-norm of
inv(A) computed in this routine.

WORK (workspace)
dimension(2*N)

IWORK2 (workspace)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

dgthr - Gathers specified elements from y into x.

SYNOPSIS

```
SUBROUTINE DGTHR(NZ, Y, X, INDX)

DOUBLE PRECISION Y(*), X(*)
INTEGER NZ
INTEGER INDX(*)

SUBROUTINE DGTHR_64(NZ, Y, X, INDX)

DOUBLE PRECISION Y(*), X(*)
INTEGER*8 NZ
INTEGER*8 INDX(*)

F95 INTERFACE
SUBROUTINE GTHR([NZ], Y, X, INDX)

REAL(8), DIMENSION(:) :: Y, X
INTEGER :: NZ
INTEGER, DIMENSION(:) :: INDX

SUBROUTINE GTHR_64([NZ], Y, X, INDX)

REAL(8), DIMENSION(:) :: Y, X
INTEGER(8) :: NZ
INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

DGTHR - Gathers the specified elements from a vector y in full storage form into a vector x in compressed form. Only the elements of y whose indices are listed in indx are referenced.

```
do i = 1, n
  x(i) = y(indx(i))
enddo
```

ARGUMENTS

NZ (input) - INTEGER

Number of elements in the compressed form.
Unchanged on exit.

Y (input)

Vector in full storage form. Unchanged on exit.

X (output)

Vector in compressed form. Contains elements of y
whose indices are listed in indx on exit.

INDX (input) - INTEGER

Vector containing the indices of the compressed
form. It is assumed that the elements in INDX are
distinct and greater than zero. Unchanged on exit.

INTEGER, DIMENSION(:) :: INDX

SUBROUTINE GTHRZ_64([NZ], Y, X, INDX)

REAL(8), DIMENSION(:) :: Y, X
INTEGER(8) :: NZ
INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

DGTHRZ - Gathers the specified elements from a vector y in full storage form into a vector x in compressed form. The gathered elements of y are set to zero. Only the elements of y whose indices are listed in indx are referenced.

```
do i = 1, n
  x(i) = y(indx(i))
  y(indx(i)) = 0
enddo
```

ARGUMENTS

NZ (input) - INTEGER

Number of elements in the compressed form.
Unchanged on exit.

Y (input/output)

Vector in full storage form. Gathered elements are
set to zero.

X (output)

Vector in compressed form. Contains elements of y
whose indices are listed in indx on exit.

INDX (input) - INTEGER

Vector containing the indices of the compressed
form. It is assumed that the elements in INDX are
distinct and greater than zero. Unchanged on exit.

 double *b, long ldb, double *x, long ldx, double
 *ferr, double *berr, long *info);

```

PURPOSE

dgtrfs improves the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

TRANSA (input)

Specifies the form of the system of equations:
= 'N': $A * X = B$ (No transpose)
= 'T': $A^{*T} * X = B$ (Transpose)
= 'C': $A^{*H} * X = B$ (Conjugate transpose = Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

LOW (input)

The (n-1) subdiagonal elements of A.

DIAG (input)

The diagonal elements of A.

UP (input)

The (n-1) superdiagonal elements of A.

LOWF (input)

The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by SGTTRF.

DIAGF (input)
 The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UPF1 (input)
 The (n-1) elements of the first superdiagonal of U.

UPF2 (input)
 The (n-2) elements of the second superdiagonal of U.

IPIVOT (input)
 The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

B (input) The right hand side matrix B.

LDB (input)
 The leading dimension of the array B. $LDB \geq \max(1, N)$.

X (input/output)
 On entry, the solution matrix X, as computed by SGTTRS. On exit, the improved solution matrix X.

LDX (input)
 The leading dimension of the array X. $LDX \geq \max(1, N)$.

FERR (output)
 The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
 The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
 dimension(3*N)

WORK2 (workspace)
 dimension(N)

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value

SUBROUTINE GTSV([N], [NRHS], LOW, DIAG, UP, B, [LDB], [INFO])
```

```
INTEGER :: N, NRHS, LDB, INFO  
REAL(8), DIMENSION(:) :: LOW, DIAG, UP  
REAL(8), DIMENSION(:, :) :: B
```

```
SUBROUTINE GTSV_64([N], [NRHS], LOW, DIAG, UP, B, [LDB], [INFO])
```

```
INTEGER(8) :: N, NRHS, LDB, INFO  
REAL(8), DIMENSION(:) :: LOW, DIAG, UP  
REAL(8), DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgtsv(int n, int nrhs, double *low, double *diag, double *up, double *b, int ldb, int *info);
```

```
void dgtsv_64(long n, long nrhs, double *low, double *diag, double *up, double *b, long ldb, long *info);
```

PURPOSE

dgtsv solves the equation

where A is an n by n tridiagonal matrix, by Gaussian elimination with partial pivoting.

Note that the equation $A'X = B$ may be solved by interchanging the order of the arguments DU and DL.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

LOW (input/output)

On entry, LOW must contain the (n-1) sub-diagonal elements of A.

On exit, LOW is overwritten by the (n-2) elements of the second super-diagonal of the upper triangular matrix U from the LU factorization of A, in $LOW(1), \dots, LOW(n-2)$.

DIAG (input/output)

On entry, DIAG must contain the diagonal elements of A.

On exit, DIAG is overwritten by the n diagonal elements of U.

UP (input/output)

On entry, UP must contain the (n-1) super-diagonal elements of A.

On exit, UP is overwritten by the (n-1) elements of the first super-diagonal of U.

B (input/output)

On entry, the N by NRHS matrix of right hand side matrix B. On exit, if $INFO = 0$, the N by NRHS solution matrix X.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

INFO (output)

= 0: successful exit

< 0: if $INFO = -i$, the i-th argument had an illegal value

> 0: if $INFO = i$, $U(i,i)$ is exactly zero, and the solution has not been computed. The factorization has not been completed unless $i = N$.

```

PURPOSE

dgtsvx uses the LU factorization to compute the solution to a real system of linear equations $A * X = B$ or $A^{**T} * X = B$, where A is a tridiagonal matrix of order N and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the LU decomposition is used to factor the matrix A
as $A = L * U$, where L is a product of permutation and unit lower
bidiagonal matrices and U is upper triangular with nonzeros in
only the main diagonal and first two superdiagonals.
2. If some $U(i,i)=0$, so that U is exactly singular, then the routine
returns with INFO = i. Otherwise, the factored form of A
is used
to estimate the condition number of the matrix A. If the
reciprocal of the condition number is less than machine
precision,
INFO = N+1 is returned as a warning, but the routine
still goes on
to solve for X and compute error bounds as described
below.
3. The system of equations is solved for X using the fac-
tored form

of A.

4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of A has been supplied on entry. = 'F': LOWF, DIAGF, UPF1, UPF2, and IPIVOT contain the factored form of A; LOW, DIAG, UP, LOWF, DIAGF, UPF1, UPF2 and IPIVOT will not be modified. = 'N': The matrix will be copied to LOWF, DIAGF, and UPF1 and factored.

TRANSA (input)

Specifies the form of the system of equations:
= 'N': $A * X = B$ (No transpose)
= 'T': $A^{**T} * X = B$ (Transpose)
= 'C': $A^{**H} * X = B$ (Conjugate transpose = Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

LOW (input)

The (n-1) subdiagonal elements of A.

DIAG (input)

The n diagonal elements of A.

UP (input/output)

The (n-1) superdiagonal elements of A.

LOWF (input/output)

If FACT = 'F', then LOWF is an input argument and on entry contains the (n-1) multipliers that define the matrix L from the LU factorization of A as computed by SGTTRF.

If FACT = 'N', then LOWF is an output argument and on exit contains the (n-1) multipliers that define the matrix L from the LU factorization of A.

DIAGF (input/output)

If FACT = 'F', then DIAGF is an input argument and on entry contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

If FACT = 'N', then DIAGF is an output argument and on exit contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UPF1 (input/output)

If FACT = 'F', then UPF1 is an input argument and on entry contains the (n-1) elements of the first superdiagonal of U.

If FACT = 'N', then UPF1 is an output argument and on exit contains the (n-1) elements of the first superdiagonal of U.

UPF2 (input/output)

If FACT = 'F', then UPF2 is an input argument and on entry contains the (n-2) elements of the second superdiagonal of U.

If FACT = 'N', then UPF2 is an output argument and on exit contains the (n-2) elements of the second superdiagonal of U.

IPIVOT (input/output)

If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the LU factorization of A as computed by SGTRF.

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the LU factorization of A; row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,N).

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)

The leading dimension of the array X. LDX \geq max(1,N).

RCOND (output)

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO $>$ 0.

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: $U(i,i)$ is exactly zero. The factorization has not been completed unless $i = N$, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

NAME

dgtrrf - compute an LU factorization of a real tridiagonal matrix A using elimination with partial pivoting and row interchanges

SYNOPSIS

```
SUBROUTINE DGTRRF(N, LOW, DIAG, UP1, UP2, IPIVOT, INFO)
```

```
INTEGER N, INFO  
INTEGER IPIVOT(*)  
DOUBLE PRECISION LOW(*), DIAG(*), UP1(*), UP2(*)
```

```
SUBROUTINE DGTRRF_64(N, LOW, DIAG, UP1, UP2, IPIVOT, INFO)
```

```
INTEGER*8 N, INFO  
INTEGER*8 IPIVOT(*)  
DOUBLE PRECISION LOW(*), DIAG(*), UP1(*), UP2(*)
```

F95 INTERFACE

```
SUBROUTINE GTTRF([N], LOW, DIAG, UP1, UP2, IPIVOT, [INFO])
```

```
INTEGER :: N, INFO  
INTEGER, DIMENSION(:) :: IPIVOT  
REAL(8), DIMENSION(:) :: LOW, DIAG, UP1, UP2
```

```
SUBROUTINE GTTRF_64([N], LOW, DIAG, UP1, UP2, IPIVOT, [INFO])
```

```
INTEGER(8) :: N, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT  
REAL(8), DIMENSION(:) :: LOW, DIAG, UP1, UP2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgtrrf(int n, double *low, double *diag, double *up1,  
           double *up2, int *ipivot, int *info);
```

```
void dgtrrf_64(long n, double *low, double *diag, double  
              *up1, double *up2, long *ipivot, long *info);
```

PURPOSE

dgtrrf computes an LU factorization of a real tridiagonal matrix A using elimination with partial pivoting and row interchanges.

The factorization has the form

$$A = L * U$$

where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.

ARGUMENTS

N (input) The order of the matrix A.

LOW (input/output)

On entry, LOW must contain the (n-1) sub-diagonal elements of A.

On exit, LOW is overwritten by the (n-1) multipliers that define the matrix L from the LU factorization of A.

DIAG (input/output)

On entry, DIAG must contain the diagonal elements of A.

On exit, DIAG is overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UP1 (input/output)

On entry, UP1 must contain the (n-1) super-diagonal elements of A.

On exit, UP1 is overwritten by the (n-1) elements of the first super-diagonal of U.

UP2 (output)

On exit, UP2 is overwritten by the (n-2) elements of the second super-diagonal of U.

IPIVOT (output)

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

INFO (output)

= 0: successful exit

< 0: if INFO = -k, the k-th argument had an illegal value

> 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

                *ipivot, double *b, long ldb, long *info);

```

PURPOSE

dgtrtrs solves one of the systems of equations
 $A * X = B$ or $A' * X = B$, with a tridiagonal matrix A using
the LU factorization computed by SGTTRF.

ARGUMENTS

TRANSA (input)
Specifies the form of the system of equations. =
'N': $A * X = B$ (No transpose)
= 'T': $A' * X = B$ (Transpose)
= 'C': $A' * X = B$ (Conjugate transpose = Trans-
pose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A.

NRHS (input)
The number of right hand sides, i.e., the number
of columns of the matrix B. NRHS \geq 0.

LOW (input)
The (n-1) multipliers that define the matrix L
from the LU factorization of A.

DIAG (input)
The n diagonal elements of the upper triangular
matrix U from the LU factorization of A.

UP1 (input)
The (n-1) elements of the first super-diagonal of
U.

UP2 (input)
The (n-2) elements of the second super-diagonal of
U.

IPIVOT (input)
The pivot indices; for $1 \leq i \leq n$, row i of the
matrix was interchanged with row IPIVOT(i).
IPIVOT(i) will always be either i or i+1;
IPIVOT(i) = i indicates a row interchange was not
required.

B (input/output)
On entry, the matrix of right hand side vectors B.
On exit, B is overwritten by the solution vectors
X.

LDB (input)
The leading dimension of the array B. LDB \geq

max(1,N).
