Use *passwd* as the password for authentication to the directory. When you use `-w passwd` to specify the password to be used for authentication, the password is visible to other users of the system by means of the `ps` command, in script files or in shell history. If you use either the `ldapmodify` command or the `ldapadd` command without this option, the command will prompt for the password and read it from standard in. When used without the `-w` option, the password will not be visible to other users.

`-Y proxyid`

Specify the proxy DN (proxied authorization id) to use for the modify operation, usually in double quotes ("") for the shell.

`-Z`

Specify that SSL be used to provide certificate-based client authentication. This option requires the `-N` and SSL password and any other of the SSL options needed to identify the certificate and the key database.

### EXIT STATUS

The following exit values are returned:

0	Successful completion.
Non-zero	An error occurred. A diagnostic message is written to standard error.

### EXAMPLES

The format of the content of *file* (or standard input if no `-f` option is specified) is illustrated in the following examples.

**EXAMPLE 1** Modifying an Entry

The file /tmp/entrymods contains the following modification instructions:

```
dn: cn=Modify Me, o=XYZ, c=US
changetype: modify
replace: mail
mail: modme@atlanta.xyz.com
-
add: title
title: System Manager
-
add: jpegPhoto
jpegPhoto:< file:///tmp/modme.jpeg
-
delete: description
-
```

The command:

```
example% ldapmodify -r -f /tmp/entrymods
```

modifies the Modify Me entry as follows:

1. The current value of the mail attribute is replaced with the value, modme@atlanta.xyz.com.
2. A title attribute with the value, System Manager, is added.
3. A jpegPhoto attribute is added, using the contents of the file, /tmp/modme.jpeg, as the attribute value.
4. The description attribute is removed.

**EXAMPLE 2** Creating a New Entry

The file, /tmp/newentry, contains the following information for creating a new entry:

```
dn: cn=Ann Jones, o=XYZ, c=US
objectClass: person
cn: Ann Jones
cn: Annie Jones
sn: Jones
title: Director of Research and Development
mail: ajones@londonrd.xyz.us.com
uid: ajones
```

The command

```
example% ldapadd -f /tmp/newentry
```

adds a new entry for Ann Jones, using the information in the file.

## ldapmodify(1)

### EXAMPLE 3 Creating a New Entry on an IPv6 Server

The file, /tmp/newentry, contains the following information for creating a new entry: on an IPv6 server.

```
dn: cn=Ann Jones, o=XYZ, c=US
objectClass: person
cn: Ann Jones
cn: Annie Jones
sn: Jones
title: Director of Research and Development
mail: ajones@londonrd.xyz.us.com
uid: ajones
```

The command

```
example% ldapadd -c -v -h '['fec0::111:a00:20ff:feaa:a364']':389 \
-D cn=Directory Manager -w secret \
-f /tmp/entry
```

adds a new entry for Directory Manager, using the information in the file.

### EXAMPLE 4 Deleting an Entry

The file, /tmp/badentry, contains the following information about an entry to be deleted:

```
dn: cn=Ann Jones, o=XYZ, c=US
changetype: delete
```

The command:

```
example% ldapmodify -f /tmp/badentry
```

removes Ann Jones' entry.

## ATTRIBUTES

See [attributes\(5\)](#) for a description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Stability Level	Evolving

## SEE ALSO

<b>NAME</b>	ldapmodrdn – ldap modify entry RDN tool										
<b>SYNOPSIS</b>	<pre> <b>ldapmodrdn</b> [-r] [-n] [-v] [-c] [-E] [-H] [-?] [-M] [-R] [-Z] [-V <i>version</i>] [-d <i>debuglevel</i>] [-D <i>bindDN</i>] [-w <i>passwd</i>] [-h <i>ldaphost</i>] [-i <i>locale</i>] [-j <i>filename</i>] [-J [:<i>criticality</i>]] [-k <i>path</i>] [-N <i>certificate</i>] [-O <i>hopLimit</i>] [-P <i>path</i>] [-W <i>password</i>] [-p <i>ldapport</i>] [-o <i>attributename=value</i>] [-f <i>file</i>] [-Y <i>proxyDN</i>] [ <i>dn rdn</i>] </pre>										
<b>DESCRIPTION</b>	ldapmodrdn opens a connection to an LDAP server, binds, and modifies the RDN of entries. The entry information is read from standard input, from <i>file</i> through the use of the <i>-f</i> option, or from the command-line pair <i>dn</i> and <i>rdn</i> .										
<b>OPTIONS</b>	<p><b>-c</b> Continuous operation mode. Errors are reported, but ldapmodify continues with modifications. The default is to exit after reporting an error.</p> <p><b>-D <i>bindDN</i></b> Use the distinguished name <i>binddn</i> to bind to the directory.</p> <p><b>-d <i>debuglevel</i></b> Set the LDAP debugging level. Useful values of <i>debuglevel</i> for ldapmodrdn are:</p> <table> <tr> <td>1</td> <td>Trace</td> </tr> <tr> <td>2</td> <td>Packets</td> </tr> <tr> <td>4</td> <td>Arguments</td> </tr> <tr> <td>32</td> <td>Filters</td> </tr> <tr> <td>128</td> <td>Access control</td> </tr> </table> <p>To request more than one category of debugging information, add the masks. For example, to request trace and filter information, specify a <i>debuglevel</i> of 33.</p> <p><b>-E</b> Ask server to expose (report) bind identity by means of authentication response control.</p> <p><b>-f <i>file</i></b> Read the entry modification information from <i>file</i> instead of from standard input or the command-line.</p> <p><b>-?</b> Display the usage help text that briefly describes all options.</p> <p><b>-H</b> Display the usage help text that briefly describes all options.</p> <p><b>-h <i>ldaphost</i></b> Specify an alternate host on which the LDAP server is running.</p>	1	Trace	2	Packets	4	Arguments	32	Filters	128	Access control
1	Trace										
2	Packets										
4	Arguments										
32	Filters										
128	Access control										

## ldapmodrdn(1)

- i *locale*  
Specify the character set to use for the -f *LDIFfile* or standard input. The default is the character set specified in the LANG environment variable. You might choose to use this option to perform the conversion from the specified character set to UTF8, thus overriding the LANG setting.
- J *[:criticality[:value | :b64value | b64value | :fileurl]]*  
Criticality is a boolean value (default is `false`).
- j *filename*  
Specify a file containing the password for the bind DN or the password for the SSL client's key database. To protect the password, use this option in scripts and place the password in a secure file. This option is mutually exclusive of the -w and -W options.
- k *path*  
Specify the path to a directory containing conversion routines. These routines are used if you want to specify a locale that is not supported by default by your directory server. This is for NLS support.
- M  
Manage smart referrals. When they are the target of the operation, modify the entry containing the referral instead of the entry obtained by following the referral.
- n  
Previews modifications, but makes no changes to entries. Useful in conjunction with -v and -d for debugging.
- N *certificate*  
Specify the certificate name to use for certificate-based client authentication. For example: -N "Directory-Cert".
- n  
Show what would be done, but do not actually change entries. Useful in conjunction with -v for debugging.
- o *attributename=value*  
For SASL mechanisms and other options such as security properties, mode of operation, authorization ID, authentication ID, and so forth.  
  
The different attribute names and their values are as follows:  
  
*secProp="number"*  
For defining SASL security properties.  
  
*realm="value"*  
Specifies SASL realm (default is `realm=none`).  
  
*authzid="value"*  
Specify the authorization ID name for SASL bind.  
  
*authid="value"*  
Specify the authentication ID for SASL bind.

*mech="value"*

Specifies the various SASL mechanisms.

**-O** *hopLimit*

Specify the maximum number of referral hops to follow while finding an entry to modify. By default, there is no limit.

**-P** *path*

Specify the path and filename of the client's certificate database. For example:

```
-P /home/uid/.netscape/cert7.db
```

When using the command on the same host as the directory server, you can use the server's own certificate database. For example:

```
-P installDir/lapd-serverID/alias/cert7.db
```

Use the **-P** option alone to specify server authentication only.

**-p** *ldapport*

Specify an alternate TCP port where the secure LAPD server is listening.

**-R**

Do not automatically follow referrals returned while searching.

**-r**

Remove old RDN values from the entry. By default, old values are kept.

**-V** *version*

Specify the LDAP protocol version number to be used for the delete operation, either 2 or 3. LDAP v3 is the default. Specify LDAP v2 when connecting to servers that do not support v3.

**-v**

Use verbose mode, with diagnostics written to standard output.

**-W** *password*

Specify the password for the client's key database given in the **-P** option. This option is required for certificate-based client authentication. Specifying *password* on the command line has security issues because the password can be seen by others on the system by means of the `ps` command. Use the **-j** instead to specify the password from the file. This option is mutually exclusive of **-j**.

**-w** *passwd*

Use *passwd* as the password for authentication to the directory. When you use **-w** *passwd* to specify the password to be used for authentication, the password is visible to other users of the system by means of the `ps` command, in script files or in shell history. If you use the `ldapmodrdn` command without this option, the command will prompt for the password and read it from standard in. When used without the **-w** option, the password will not be visible to other users.

**-Y** *proxyid*

Specify the proxy DN (proxied authorization id) to use for the modify operation, usually in double quotes ("") for the shell.

## ldapmodrdn(1)

-Z

Specify that SSL be used to provide certificate-based client authentication. This option requires the `-N` and SSL password and any other of the SSL options needed to identify the certificate and the key database.

**Input Format** If the command-line arguments `dn` and `rdn` are given, `rdn` replaces the RDN of the entry specified by the DN, `dn`.

Otherwise, the contents of `file` (or standard input if the `-f` option is not specified) must consist of one or more pair of lines:

```
Distinguished Name (DN)
Relative Distinguished Name (RDN)
```

Use one or more blank lines to separate each DN/RDN pair.

**EXAMPLES** The file `/tmp/entrymods` contains:

```
cn=Modify Me, o=XYZ, c=US
cn=The New Me
```

The command:

```
example% ldapmodify -r -f /tmp/entrymods
```

changes the RDN of the "Modify Me" entry from "Modify Me" to "The New Me" and the old cn, "Modify Me" is removed.

**ATTRIBUTES** See `attributes(5)` for a description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Stability Level	Evolving

**SEE ALSO** `ldapadd(1)`, `ldapdelete(1)`, `ldapmodify(1)`, `ldapsearch(1)`, `attributes(5)`

**DIAGNOSTICS** Exit status is 0 if no errors occur. Errors result in a non-zero exit status and a diagnostic message being written to standard error.

<b>NAME</b>	ldapsearch – ldap search tool
<b>SYNOPSIS</b>	<pre> <b>ldapsearch</b> [-n] [-u] [-v] [-t] [-A] [-B] [-L] [-R] [-H] [-?] [-t]   [-T] [-B] [-E] [-J] [-e] [-l] [-Z] [-r] [-M] [-d <i>debuglevel</i>]   [-F <i>sep</i>] [-f <i>file</i>] [-D <i>bindDN</i>] [-j <i>filename</i>] [-V <i>version</i>] [-Y <i>proxyDN</i>]   [-O <i>hopLimit</i>] [-i <i>locale</i>] [-k <i>path</i>] [-S [-] <i>attribute</i>] [-C <i>pattern</i>]   [-c <i>authzid</i>] [-P <i>path</i>] [-N <i>certificate</i>] [-w <i>passwd</i>] [-h <i>ldaphost</i>]   [-p <i>ldapport</i>] [-o <i>attributename=value</i>] [-b <i>searchbase</i>] [-s <i>scope</i>]   [-a <i>deref</i>] [-l <i>timelimit</i>] [-z <i>sizelimit</i>] <i>filter</i> [<i>attrs...</i>] </pre>
<b>DESCRIPTION</b>	<p>The <code>ldapsearch</code> utility opens a connection to an LDAP server, binds, and performs a search using the filter <i>filter</i>.</p> <p>If <code>ldapsearch</code> finds one or more entries, the attributes specified by <i>attrs</i> are retrieved and the entries and values are printed to standard output. If no <i>attrs</i> are listed, all attributes are returned.</p>
<b>Output Format</b>	<p>If one or more entries are found, each entry is written to standard output in the form:</p> <pre> Distinguished Name (DN)   User Friendly Name (if the -u option is used)   attributename=value   attributename=value   attributename=value   ... </pre> <p>Multiple entries are separated with a single blank line. If the <code>-F</code> option is used to specify a different separator character, this character will be used instead of the '=' character. If the <code>-t</code> option is used, the name of a temporary file is returned in place of the actual value. If the <code>-A</code> option is given, only the "attributename" is returned and not the attribute value.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-A</code> Retrieve attributes only (no values). This is useful when you just want to see whether an attribute is present in an entry and are not interested in the specific value.</li> <li><code>-a <i>deref</i></code> Specify how aliases dereferencing is done. The possible values for <i>deref</i> are <i>never</i>, <i>always</i>, <i>search</i>, or <i>find</i> to specify respectively that aliases are never dereferenced, always dereferenced, dereferenced when searching, or dereferenced only when finding the base object for the search. The default is to never dereference aliases.</li> <li><code>-B</code> Do not suppress display of non-ASCII values. This is useful when dealing with values that appear in alternate character sets such as ISO-8859.1. This option is automatically set by the <code>-L</code> option.</li> <li><code>-b <i>searchbase</i></code> Use <i>searchbase</i> as the starting point for the search instead of the default.</li> </ul>

## ldapsearch(1)

- C *pattern*  
Persistent search. Perform a search that keeps the connection open and displays results whenever entries matching the scope and filter of the search are added, modified, or removed. With this option, the `ldapsearch` tool runs indefinitely; you must type Control-c to stop it. The pattern has the following format:  

```
ps:changeType[:changesOnly[:entryChangeControls]]
```
- c *authzid*  
Specifies the `getEffectiveRights` control *authzid*. For example:  

```
dn:uid=bjensen,dc=example,dc=com
```
- D *bindDN*  
Use the distinguished name *bindDN* to bind to the directory.
- d *debuglevel*  
Set the LDAP debugging level. Useful levels of debugging for `ldapsearch` are:  

1	Trace
2	Packets
4	Arguments
32	Filters
128	Access control

  
To request more than one category of debugging information, add the masks. For example, to request trace and filter information, specify a debuglevel of 33.
- E  
Ask server to expose (report) bind identity by means of authentication response control.
- e  
Minimize base-64 encoding of values.
- F *sep*  
Use *sep* as the field separator between attribute names and values. The default separator is '='. If -L option has been specified, this option is ignored.
- f *file*  
Read a series of lines from *file*, performing one LDAP search for each line. In this case, the *filter* given on the command line is treated as a pattern where the first occurrence of %s is replaced with a line from *file*. If *file* is a single - character, then the lines are read from standard input.
- G *pattern*  
Virtual list view. Retrieve only a portion of all results, as determined by the index or value of the search target and the number of entries to be returned before and after the target. This option always requires the -S and -x options to specify the sorting order on the server.

- ?
  - Display the usage help text that briefly describes all options.
- H
  - Display the usage help text that briefly describes all options.
- h *ldaphost*
  - Specify an alternate host on which the secure LDAP server is running.
- i *locale*
  - Specify the character set to use for command-line input. The default is the character set specified in the `LANG` environment variable. You might want to use this option to perform the conversion from the specified character set to UTF8, thus overriding the `LANG` setting. Using this argument, you can input the bind DN, base DN, and the search filter pattern in the specified character set. The `ldapsearch` tool converts the input from these arguments before it processes the search request. For example, `-i no` indicates that the bind DN, base DN, and search filter are provided in Norwegian. This argument only affects the command-line input. If you specify a file containing a search filter (with the `-f` option), `ldapsearch` will not convert the data in the file.
- j *filename*
  - Specify a file containing the password for the bind DN or the password for the SSL client's key database. To protect the password, use this option in scripts and place the password in a secure file. This option is mutually exclusive of the `-w` and `-W` options.
- J *[:criticality[:value|::b64value|b64value|:fileurl!]]*
  - Criticality is a boolean value (default is `false`).
- k *path*
  - Specify the path to a directory containing conversion routines. These routines are used if you want to specify a locale that is not supported by default by your directory server. This is for NLS support.
- L
  - Display search results in a modified format. This option also turns on the `-B` option, and causes the `-F` option to be ignored. This behavior is the default.
- l *timelimit*
  - Wait at most *timelimit* seconds for a search to complete.
- M
  - Manage smart referrals. When they are the target of the operation, search the entry containing the referral instead of the entry obtained by following the referral.
- N *certificate*
  - Specify the certificate name to use for certificate-based client authentication. For example: `-N "Directory-Cert"`.
- n
  - Show what would be done, but do not actually perform the search. Useful in conjunction with `-v` and `-d` for debugging.

## ldapsearch(1)

- O *hopLimit*  
Specify the maximum number of referral hops to follow while finding an entry to modify. By default, there is no limit.
- o *attributename=value*  
For SASL mechanisms and other options such as security properties, mode of operation, authorization ID, authentication ID, and so forth.  
  
The different attribute names and their values are as follows:  
*secProp="number"*  
For defining SASL security properties.  
*realm="value"*  
Specifies SASL realm (default is *realm=none*).  
*authzid="value"*  
Specify the authorization ID name for SASL bind.  
*authid="value"*  
Specify the authentication ID for SASL bind.  
*mech="value"*  
Specifies the various SASL mechanisms.
- P *path*  
Specify the path and filename of the client's certificate database. For example:  
  
`-P /home/uid/.netscape/cert7.db`  
  
When using the command on the same host as the directory server, you can use the server's own certificate database. For example:  
  
`-P installDir/lapd-serverID/alias/cert7.db`  
  
Use the `-P` option alone to specify server authentication only.
- p *ldapport*  
Specify an alternate TCP port where the secure LDAP server is listening.
- R  
Do not automatically follow referrals returned while searching.
- r  
Display the output of the `ldapsearch` command in the old format.
- S [-]*attribute*  
Specify an attribute for sorting the entries returned by the search. The sort criteria is alphabetical on the attribute's value or reverse alphabetical with the form `-attribute`. You can give multiple `-S` options to refine the sorting, For example:  
  
`-S sn -S givenname`  
  
By default, the entries are not sorted. Use the `-x` option to perform server-side sorting.

- s** *scope*  
Specify the scope of the search. The possible values of *scope* are *base*, *one*, or *sub* to specify respectively a base object, one-level, or subtree search. The default is *sub*.
- T**  
Format the output of search results so that no line breaks are used within individual attribute values.
- t**  
Write retrieved values to a set of temporary files. This is useful for dealing with non-ASCII values such as *jpegPhoto* or *audio*.
- U**  
URL format (valid only with the **-t** option). When using temporary file output, the standard output of the tool will include the URL of the file instead of the attributes value. For example:

```
jpegPhoto:< file:/tmp/ldapsearch-jpegPhoto-YzaOMh
```
- u**  
Include the user-friendly form of the Distinguished Name (DN) in the output.
- V** *version*  
Specify the LDAP protocol version number to be used for the delete operation, either 2 or 3. LDAP v3 is the default. Specify LDAP v2 when connecting to servers that do not support v3.
- v**  
Run in verbose mode, with diagnostics written to standard output.
- W** *password*  
Specify the password for the client's key database given in the **-P** option. This option is required for certificate-based client authentication. Specifying *password* on the command line has security issues because the password can be seen by others on the system by means of the *ps* command. Use the **-j** instead to specify the password from the file. This option is mutually exclusive of **-j**.
- w** *passwd*  
Use *passwd* as the password for authentication to the directory. When you use **-w** *passwd* to specify the password to be used for authentication, the password is visible to other users of the system by means of the *ps* command, in script files or in shell history. If you use the *ldapsearch* command without this option, the command will prompt for the password and read it from standard in. When used without the **-w** option, the password will not be visible to other users.
- x**  
Use with the **-S** option to specify that search results be sorted on the server rather than by the *ldapsearch* command running on the client. This is useful if you want to sort according to a matching rule, as with an international search. It is usually faster to sort on the server, if that is supported, rather than on the client.
- Y** *proxyDN*  
Specify the proxy DN (proxied authorization id) to use for the modify operation, usually in double quotes (" ") for the shell.

## ldapsearch(1)

-Z

Specify that SSL be used to provide certificate-based client authentication. This option requires the -N and SSL password and any other of the SSL options needed to identify the certificate and the key database.

-z *sizelimit*

Retrieve at most *sizelimit* entries for a search to complete.

### EXAMPLES

#### EXAMPLE 1 Performing a Subtree Search

The following command performs a subtree search (using the default search base) for entries with a commonName of "mark smith". The commonName and telephoneNumber values will be retrieved and printed to standard output. Use the -r option to display this output in the old format.

```
example% ldapsearch "cn=mark smith" cn telephoneNumber
```

The output looks something like this:

```
cn=Mark D Smith, ou=Sales, ou=Atlanta, ou=People, o=XYZ, c=US
cn=Mark Smith
cn=Mark David Smith
cn=Mark D Smith 1
cn=Mark D Smith
telephoneNumber=+1 123 456-7890
cn=Mark C Smith, ou=Distribution, ou=Atlanta, ou=People, o=XYZ, c=US
cn=Mark Smith
cn=Mark C Smith 1
cn=Mark C Smith
telephoneNumber=+1 123 456-9999
```

#### EXAMPLE 2 Performing a Subtree Search Using the Default Search Base

The following command performs a subtree search using the default search base for entries with user id of "mcs". The user-friendly form of the entry's DN will be output after the line that contains the DN itself, and the jpegPhoto and audio values will be retrieved and written to temporary files.

```
example% ldapsearch -u -t "uid=mcs" -r jpegPhoto audio
```

The output might look like this if one entry with one value for each of the requested attributes is found:

```
cn=Mark C Smith, ou=Distribution, ou=Atlanta, ou=People, o=XYZ, c=US
Mark C Smith, Distribution, Atlanta, People, XYZ, US
audio=/tmp/ldapsearch-audio-a19924
jpegPhoto=/tmp/ldapsearch-jpegPhoto-a19924
```

#### EXAMPLE 3 Performing a One-Level Search

The following command performs a one-level search at the c=US level for all organizations whose organizationName begins with XY.

```
example% ldapsearch -s one -b "c=US" "o=XY*" o description
```

**EXAMPLE 3** Performing a One-Level Search (Continued)

Search results are displayed in the LDIF format, which is the default. The organizationName and description attribute values will be retrieved and printed to standard output, resulting in output similar to this:

```
dn: o=XYZ, c=US
o: XYZ
description: XYZ Corporation
dn: o="XY Trading Company", c=US
o: XY Trading Company
description: Import and export specialists

dn: o=XYInternational, c=US
o: XYInternational
o: XYI
o: XY International
```

**EXAMPLE 4** Performing a Subtree Search on an IPv6 Server

The following command performs a subtree search using the default search base for entries with a user id of mcs on an IPv6 (that is, -h) server:

```
example% ldapsearch -u -h '['fec0::111:a00:20ff:fea3:edcf']' \
-t "uid=mcs" jpegPhoto audio
```

**EXIT STATUS** The following exit values are returned:

```
0                Successful completion.
>0              An error occurred. A diagnostic message is written to standard
                error.
```

**ATTRIBUTES** See `attributes(5)` for a description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Stability Level	Evolving

**SEE ALSO** `ldapadd(1)`, `ldapdelete(1)`, `ldapmodify(1)`, `ldapmodrdn(1)`, `attributes(5)`

## ldd(1)

<b>NAME</b>	ldd – list dynamic dependencies of executable files or shared objects
<b>SYNOPSIS</b>	<b>ldd</b> [-d   -r] [-c] [-e <i>envvar</i> ] [-f] [-i] [-L] [-l] [-s] [-U   -u] [-v] <i>filename</i> ...
<b>DESCRIPTION</b>	<p>The <code>ldd</code> utility lists the dynamic dependencies of executable files or shared objects. <code>ldd</code> uses the runtime linker, <code>ld.so.1</code>, to generate the diagnostics. The runtime linker takes the object being inspected and prepares the object as would occur in a running process. By default, <code>ldd</code> triggers the loading of any lazy dependencies.</p> <p><code>ldd</code> lists the path names of all shared objects that would be loaded when <i>filename</i> is loaded. <code>ldd</code> expects the shared objects that are being inspected to have execute permission. If a shared object does not have execute permission, <code>ldd</code> issues a warning before attempting to process the file.</p> <p><code>ldd</code> processes its input one file at a time. For each file, <code>ldd</code> performs one of the following:</p> <ul style="list-style-type: none"><li>■ Lists the object dependencies if the dependencies exist.</li><li>■ Succeeds quietly if dependencies do not exist.</li><li>■ Prints an error message if processing fails.</li></ul>
<b>OPTIONS</b>	<p><code>ldd</code> can also check the compatibility of <i>filename</i> with the shared objects <i>filename</i> uses. With each of the following options, <code>ldd</code> prints warnings for any unresolved symbol references that would occur when <i>filename</i> is loaded.</p> <p>-d           Check <i>immediate</i> references.</p> <p>-r           Check both <i>immediate</i> references and <i>lazy</i> references.</p> <p>Only one of the options <code>-d</code> or <code>-r</code> can be specified during any single invocation of <code>ldd</code>. <i>immediate</i> references are typically to data items used by the executable or shared object code. <i>immediate</i> references are also pointers to functions, and even calls to functions made from a position <i>dependent</i> shared object. <i>lazy</i> references are typically calls to global functions made from a position <i>independent</i> shared object, or calls to external functions made from an executable. For more information on these types of reference, see “When Relocations Are Performed” in the <i>Linker and Libraries Guide</i>. Object loading can also be affected by relocation processing. See <i>Lazy Loading</i> under <i>USAGE</i> for more details.</p> <p><code>ldd</code> can also check dependency use. With each of the following options, <code>ldd</code> prints warnings for any unreferenced, or unused dependencies that are loaded when <i>filename</i> is loaded. Only when a symbol reference is bound to a dependency, is that dependency deemed used. These options are therefore only useful when symbol references are being checked. If the <code>-r</code> option is not in effect, the <code>-d</code> option is enabled.</p> <p>A dependency that is defined by an object but is not bound to from that object is an unreferenced dependency. A dependency that is not bound to by any other object when <i>filename</i> is loaded is an unused object.</p> <p>-U           Displays any unreferenced, or unused dependencies. If an unreferenced dependency is not bound to by other objects loaded with <i>filename</i>, the</p>

dependency is also flagged as unused. Cyclic dependencies that are not bound to from objects outside of the cycle are also deemed unreferenced.

**-u** Displays any unused objects.

Only one of the options **-U** or **-u** can be specified during any single invocation of `ldd`, although **-U** is a superset of **-u**. Objects that are found to be unreferenced, or unused when using the **-r** option, should be removed as dependencies. These objects provide no references, but result in unnecessary overhead when *filename* is loaded. When using the **-d** option, any objects that are found to be unreferenced, or unused are not immediately required when *filename* is loaded. These objects are candidates for lazy loading. See *Lazy Loading* under *USAGE* for more details.

The removal of unused dependencies reduces runtime-linking overhead. The removal of unreferenced dependencies reduces runtime-linking overhead to a lesser degree. However, the removal of unreferenced dependencies guards against a dependency being unused when combined with different objects, or as the other object dependencies evolve.

The following additional options are supported:

- c** Disables any configuration file use. Configuration files can be employed to alter default search paths, and provide alternative object dependencies. See `crle(1)`.
- e *envvar*** Sets the environment variable *envvar*. This option is useful for experimenting with environment variables that are recognized by the runtime linker, that can adversely affect `ldd`.
- f** Forces `ldd` to check for an executable file that is not secure. When `ldd` is invoked by a superuser, by default `ldd` does not process any executable that is not secure. An executable is not considered secure if the interpreter that the executable specifies does not reside under `/lib`, `/usr/lib` or `/etc/lib`. An executable is also not considered secure if the interpreter cannot be determined. See *Security* under *USAGE*.
- i** Displays the order of execution of initialization sections. The order that is discovered can be affected by use of the **-d** or **-r** options. See *Initialization Order* under *USAGE*.
- L** Enables lazy loading. Lazy loading is the default mode of operation when the object under inspection is loaded as part of a process. In this case, any lazy dependencies, or filters, are only loaded into the process when reference is made to a symbol that is defined within the lazy object. The **-d** or **-r** options, together with the **-L** option, can be used to inspect the dependencies, and their order of loading as would occur in a running process.

## ldd(1)

- l Forces the immediate processing of any filters so that all filtees, and their dependencies, are listed. The immediate processing of filters is now the default mode of operation for `ldd`. However, under this default any auxiliary filtees that cannot be found are silently ignored. Under the `-l` option, missing auxiliary filtees generate an error message.
- s Displays the search path used to locate shared object dependencies.
- v Displays all dependency relationships incurred when processing *filename*. This option also displays any dependency version requirements. See [pvs\(1\)](#).

### USAGE

#### Security

A superuser should use the `-f` option only if the executable to be examined is known to be trustworthy. The use of `-f` on an untrustworthy executable while superuser can compromise system security. If an executables trustworthyness is unknown, a superuser should temporarily become a regular user. Then invoke `ldd` as this regular user.

Untrustworthy objects can be safely examined with [dump\(1\)](#) and with [mdb\(1\)](#), as long as the `:r` subcommand is not used. In addition, a non-superuser can use either the `:r` subcommand of `mdb`, or [truss\(1\)](#) to examine an untrustworthy executable without too much risk of compromise. To minimize risk when using `ldd`, `adb :r`, or `truss` on an untrustworthy executable, use the UID "nobody".

#### Lazy Loading

Lazy loading can be applied directly by specified lazy dependencies. See the `-z lazyload` option of [ld\(1\)](#). Lazy loading can also be applied indirectly through filters. See the `-f` option and `-F` option of [ld\(1\)](#). Objects that employ lazy loading techniques can experience variations in `ldd` output due to the options used. If an object expresses all its dependencies as lazy, the default operation of `ldd` lists all dependencies in the order in which the dependencies are recorded in that object:

```
example% ldd main
libelf.so.1 => /lib/libelf.so.1
libnsl.so.1 => /lib/libnsl.so.1
libc.so.1 => /lib/libc.so.1
```

The lazy loading behavior that occurs when this object is used at runtime can be enabled using the `-L` option. In this mode, lazy dependencies are loaded when reference is made to a symbol that is defined within the lazy object. Therefore, combining the `-L` option with use of the `-d` and `-r` options reveals the dependencies that are needed to satisfy the immediate, and lazy references respectively:

```
example% ldd -L main
example% ldd -d main
libc.so.1 => /lib/libc.so.1
example% ldd -r main
libc.so.1 => /lib/libc.so.1
```

```
libelf.so.1 => /lib/libelf.so.1
```

Notice that in this example, the order of the dependencies that are listed is not the same as displayed from `ldd` with no options. Even with the `-r` option, the lazy reference to dependencies might not occur in the same order as would occur in a running program.

Observing lazy loading can also reveal objects that are not required to satisfy any references. These objects, in this example, `libnsl.so.1`, are candidates for removal from the link-line used to build the object being inspected.

### Initialization Order

Objects that do not explicitly define their required dependencies might observe variations in the initialization section order displayed by `ldd` due to the options used. For example, a simple application might reveal:

```
example% ldd -i main
libA.so.1 => ./libA.so.1
libc.so.1 => /lib/libc.so.1
libB.so.1 => ./libB.so.1

init object=./libB.so.1
init object=./libA.so.1
init object=/lib/libc.so.1
```

whereas, when relocations are applied, the initialization section order is:

```
example% ldd -ir main
.....

init object=/lib/libc.so.1
init object=./libB.so.1
init object=./libA.so.1
```

In this case, `libB.so.1` makes reference to a function in `/usr/lib/libc.so.1`. However, `libB.so.1` has no explicit dependency on this library. Only after a relocation is discovered is a dependency then established. This implicit dependency affects the initialization section order.

Typically, the initialization section order established when an application is executed, is equivalent to `ldd` with the `-d` option. The optimum order can be obtained if all objects fully define their dependencies. Use of the `ld(1)` options `-z defs` and `-z ignore` when building dynamic objects is recommended.

Cyclic dependencies can result when one or more dynamic objects reference each other. Cyclic dependencies should be avoided, as a unique initialization sort order for these dependencies can not be established.

Users that prefer a more static analysis of object files can inspect dependencies using tools such as `dump(1)` and `elfdump(1)`.

<b>FILES</b>	<code>/usr/lib/lddstub</code>	Fake 32-bit executable loaded to check the dependencies of shared objects.
--------------	-------------------------------	--

## ldd(1)

`/usr/lib/64/lddstub` Fake 64-bit executable loaded to check the dependencies of shared objects.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWtoo

**SEE ALSO** `mdb(1)`, `crle(1)`, `dump(1)`, `elfdump(1)`, `ld(1)`, `ld.so.1(1)`, `pvs(1)`, `truss(1)`, `dlopen(3C)`, `attributes(5)`

*Linker and Libraries Guide*

**DIAGNOSTICS** `ldd` prints the record of shared object path names to `stdout`. The optional list of symbol resolution problems is printed to `stderr`. If *filename* is not an executable file or a shared object, or if *filename* cannot be opened for reading, a non-zero exit status is returned.

**NOTES** `ldd` does not list shared objects explicitly attached using `dlopen(3C)`.

Use of the `-d` or `-r` option with shared objects can give misleading results. `ldd` does a "worst case" analysis of the shared objects. However, in practice, the symbols reported as unresolved might be resolved by the executable file referencing the shared object. The runtime linker's preloading mechanism can be employed to add dependencies to the object being inspected. See `LD_PRELOAD`.

`ldd` uses the same algorithm as the runtime linker to locate shared objects.

<b>NAME</b>	ld.so.1 – runtime linker for dynamic objects
<b>SYNOPSIS</b>	<code>/lib/ld.so.1</code>
<b>DESCRIPTION</b>	<p>Dynamic applications consist of one or more dynamic objects. A dynamic application is typically a dynamic executable and one or more shared object dependencies. As part of the initialization and execution of a dynamic application, an <i>interpreter</i> is called. This interpreter completes the binding of the application to its shared object dependencies. In Solaris, this interpreter is referred to as the runtime linker.</p> <p>During the link-editing of a dynamic executable, a special <code>.interp</code> section, together with an associated program header, is created. This section contains a pathname specifying the program's interpreter. An interpreter pathname can be specified when the executable is constructed using the <code>-I</code> option to <code>ld(1)</code>, the link-editor. The default name supplied by the link-editor is the name of the runtime linker, <code>ld.so.1</code>.</p> <p>During the process of executing a dynamic executable, the kernel maps the file, and locates the required interpreter. See <code>exec(2)</code> and <code>mmap(2)</code>. The kernel maps in, and transfers control to, this interpreter. Sufficient information is passed to the interpreter to allow the interpreter to continue to bind, and then execute the application.</p> <p>In addition to initializing an application, the runtime linker provides services that allow the application to extend its address space. Additional shared objects can be mapped, and symbols within the shared objects can be bound to.</p> <p>The runtime linker performs the following functions:</p> <ul style="list-style-type: none"> <li>■ A configuration file, if in existence, is processed. Configuration files can be employed to alter default search paths, provide a directory cache, and provide alternative object dependencies. See <code>crle(1)</code>. By default, for 32-bit objects, the configuration file <code>/var/ld/ld.config</code> is used. For 64-bit objects, the default configuration file <code>/var/ld/64/ld.config</code> is used. Alternative configuration files can be specified with the <code>LD_CONFIG</code> environment variable. Alternative configuration files can also be encoded within a dynamic executable by using the <code>-c</code> option of <code>ld(1)</code>.</li> <li>■ The runtime linker analyzes the application's dynamic information section, <code>.dynamic</code>, to determine which shared object dependencies are required.</li> <li>■ The runtime linker then locates and maps in these dependencies. The dynamic information section of each dependency is then analyzed to determine if any additional dependencies are required.</li> <li>■ Once all the shared object dependencies are loaded, the runtime linker performs any necessary relocations. These relocations bind the shared objects in preparation for process execution.</li> <li>■ Any initialization functions provided by the shared object dependencies and, possibly, by the dynamic executable are called. The functions are called in the reverse order of the topologically sorted dependencies. If cyclic dependencies exist, the initialization functions are called using the sorted order with the cycle removed. <code>ldd(1)</code> can be used to display the initialization order of shared object dependencies.</li> </ul>

ld.so.1(1)

- Control is passed to the application.
- During the application's execution, the runtime linker can be called upon to perform any delayed function binding.
- If any shared objects are deleted from the process, finalization functions are called. By default, these functions are called in the order of the topologically sorted dependencies.
- The application can also call upon the services of the runtime linker to acquire additional shared objects by using `dlopen(3C)`. Symbols provided by these objects, can be bound to using `dlsym(3C)`

Further details on each of the previous topics can be found in the *Linker and Libraries Guide*.

The runtime linker uses a prescribed search path for locating the dynamic dependencies of an object. The default search paths are the runpath recorded in the object, followed by a series of defaults. For 32-bit objects, the defaults are `/lib` followed by `/usr/lib`. For 64-bit objects, the defaults are `/lib/64` followed by `/usr/lib/64`. These defaults component can be modified using a configuration file that is created with `crle(1)`. The runpath is specified when the dynamic object is constructed using the `-R` option to `ld(1)`. The environment variable `LD_LIBRARY_PATH` can be used to indicate directories to be searched before the default directories.

## ENVIRONMENT VARIABLES

Each environment variable can be specified with a `_32` or `_64` suffix. This makes the environment variable specific, respectively, to 32-bit or 64-bit processes. This environment variable overrides any non-suffixed version of the environment variable that may be in effect. Environment variables specified without a value, that have a `_32` or `_64` suffix, effectively cancel any associated generic environment variable setting.

`LD_AUDIT`, `LD_AUDIT_32`, and `LD_AUDIT_64`

A colon-separated list of objects that are loaded by the runtime linker. As each object is loaded, the object is examined for *Link-Auditing* interface routines. The routines that are present are called as specified in the *Link-Auditing* interface described in the *Linker and Libraries Guide*. Also, see the `-p` and `-P` options of `ld(1)`.

`LD_BIND_NOW`, `LD_BIND_NOW_32`, and `LD_BIND_NOW_64`

The runtime linker's default mode of performing lazy binding can be overridden by setting the environment variable `LD_BIND_NOW` to any non-null value. This setting causes the runtime linker to perform both *immediate* reference and *lazy* reference relocations during process initialization, before transferring control to the application. Also, see the `-z now` option of `ld(1)`.

`LD_CONFIG`, `LD_CONFIG_32`, and `LD_CONFIG_64`

Provides an alternative configuration file. Configuration files can be employed to alter default search paths, provide a directory cache, and provide alternate object dependencies. See `crle(1)`.

`LD_DEBUG`, `LD_DEBUG_32`, and `LD_DEBUG_64`

Provides a comma, or colon-separated list of tokens to cause the runtime linker to print debugging information to standard error. The special token `help` indicates

the full list of tokens available. The environment variable `LD_DEBUG_OUTPUT` can also be supplied to specify a file to which the debugging information is sent. The filename is suffixed with the process ID of the application generating the debugging information.

`LD_DEMANGLE`, `LD_DEMANGLE_32`, and `LD_DEMANGLE_64`

Any symbol name used as part of a diagnostic message is shown as defined within an ELF file. When `LD_DEMANGLE` is set to any non-null value, the runtime linker attempts to decode (demangle) any C++ symbol name.

`LD_FLAGS`, `LD_FLAGS_32`, and `LD_FLAGS_64`

Provides an alternative means of supplying environment variable information. Any of the `LD_XXX` environment variables can be specified as a `xxx` token. Multiple tokens can be supplied separated by commas. See `EXAMPLES`.

`LD_LIBRARY_PATH`, `LD_LIBRARY_PATH_32`, and `LD_LIBRARY_PATH_64`

The `LD_LIBRARY_PATH` environment variable, if set, is used to enhance the search path that the runtime linker uses to find dynamic dependencies.

`LD_LIBRARY_PATH` specifies a colon-separated list of directories that are searched before the default directories. Also notice that `LD_LIBRARY_PATH` adds additional semantics to `ld(1)`.

`LD_LOADFLTR`, `LD_LOADFLTR_32`, and `LD_LOADFLTR_64`

Filters are a form of shared object. Filters allow an alternative shared object to be selected at runtime that provide the implementation for any symbols that are defined within the filter. See the `-f` and `-F` options of `ld(1)`. By default, the alternative shared object processing is deferred until symbol resolution occurs against the filter. When `LD_LOADFLTR` is set to any non-null value, any filters are processed immediately when the filter is loaded. Also, see the `-z loadfltr` option of `ld(1)`.

`LD_NOAUDIT`, `LD_NOAUDIT_32`, and `LD_NOAUDIT_64`

Local auditing libraries can be defined within applications and shared objects. See the `-p` and `-P` options of `ld(1)`. When `LD_NOAUDIT` is set to any non-null value, the runtime linker ignores any local auditing libraries.

`LD_NOAUXFLTR`, `LD_NOAUXFLTR_32`, and `LD_NOAUXFLTR_64`

Auxiliary filters are a form of shared object. Auxiliary filters allow an alternative shared object to be selected at runtime which provides the implementation for any symbols that are defined within the filter. See the `-f` option of `ld(1)`. When `LD_NOAUXFLTR` is set to any non-null value, the runtime linker disables this alternative shared object lookup.

`LD_NOCONFIG`, `LD_NOCONFIG_32`, and `LD_NOCONFIG_64`

By default the runtime linker attempts to open and process a configuration file. When `LD_NOCONFIG` is set to any non-null value, the runtime linker disables this configuration file processing.

`LD_NODIRCONFIG`, `LD_NODIRCONFIG_32`, and `LD_NODIRCONFIG_64`

Provides a subset of `LD_NOCONFIG` in that any directory cache information provided in a configuration file is ignored.

ld.so.1(1)

`LD_NODIRECT`, `LD_NODIRECT_32`, and `LD_NODIRECT_64`

Direct binding information instructs the runtime linker to search directly for a symbol in an associated object. See the `-B direct` option of `ld(1)`. Without direct binding, the symbol search performed by the runtime linker follows the default model. When `LD_NODIRECT` is set to any non-null value, the runtime linker ignores any direct binding information.

`LD_NOENVCONFIG`, `LD_NOENVCONFIG_32`, and `LD_NOENVCONFIG_64`

Provides a subset of `LD_NOCONFIG` in that any environment variables provided in a configuration file are ignored.

`LD_NOLAZYLOAD`, `LD_NOLAZYLOAD_32`, and `LD_NOLAZYLOAD_64`

Dependencies that are labeled for lazy loading are not loaded into memory until explicit reference to the dependency has been made. See the `-z lazyload` option of `ld(1)`. When `LD_NOLAZYLOAD` is set to any non-null value, the runtime linker ignores a dependencies lazy loading label and loads the dependency immediately.

`LD_NOOBJALTER`, `LD_NOOBJALTER_32`, and `LD_NOOBJALTER_64`

Provides a subset of `LD_NOCONFIG` in that any alternative object dependencies provided in a configuration file are ignored.

`LD_NOVERSION`, `LD_NOVERSION_32`, and `LD_NOVERSION_64`

By default, the runtime linker verifies version dependencies for the primary executable and all of its dependencies. When `LD_NOVERSION` is set to any non-null value, the runtime linker disables this version checking.

`LD_ORIGIN`, `LD_ORIGIN_32`, and `LD_ORIGIN_64`

The immediate processing of `$ORIGIN` can be triggered by setting the environment variable `LD_ORIGIN` to any non-null value. Before Solaris 9, this option was useful for applications that invoked `chdir(2)` prior to locating dependencies that employed the `$ORIGIN` string token. The establishment of the current working directory by the runtime linker is now default thus making this option redundant.

`LD_PRELOAD`, `LD_PRELOAD_32`, and `LD_PRELOAD_64`

Provides a list of shared objects, separated by spaces. These objects are loaded after the program being executed but before any other shared objects that the program references. Symbol definitions provided by the preloaded objects interpose on references made by the shared objects that the program references. Symbol definitions provided by the preloaded objects do not interpose on the symbol definitions provided by the program.

`LD_PROFILE`, `LD_PROFILE_32`, and `LD_PROFILE_64`

Defines a shared object to be profiled by the runtime linker. When profiling is enabled, a profiling buffer file is created and mapped. The name of the buffer file is the name of the shared object being profiled with a `.profile` extension. By default, this buffer is placed under `/var/tmp`. The environment variable `LD_PROFILE_OUTPUT` can also be supplied to indicate an alternative directory in which to place the profiling buffer.

The profiling buffer contains `profil(2)` and call count information. This information is similar to the `gmon.out` information generated by programs that have been linked with the `-xpg` option of `cc`. Any applications that use the named shared object and run while this environment variable is set, accumulate data in the profile buffer. See also NOTES. The profile buffer information can be examined using `gprof(1)`.

The `LD_PROFILE` profiling technique is an alternative to other techniques that might be provided by the compilation system. The shared object being profiled does not have to be instrumented in any way, and `LD_PROFILE` should not be combined with a profile-instrumented application. See the *Linker and Libraries Guide* for more information on profiling shared objects.

`LD_SIGNAL`, `LD_SIGNAL_32`, and `LD_SIGNAL_64`

Provides a *numeric* signal number that the runtime linker uses to kill the process in the event of a fatal runtime error. See `thr_kill(3C)`. By default, `SIGKILL` is used. For example, providing the alternative signal number `6` (`SIGABRT`), can provide for the creation of a core file to aid debugging. See also the `RTLD_DI_SETSIGNAL` request to `dlinfo(3C)`.

Notice that environment variable names beginning with the characters `'LD_'` are reserved for possible future enhancements to `ld(1)` and `ld.so.1`.

## SECURITY

Secure processes have some restrictions applied to the evaluation of their dependencies and runpaths to prevent malicious dependency substitution or symbol interposition.

The runtime linker categorizes a process as secure if the `issetugid(2)` system call returns true for the process.

For 32-bit objects, the default trusted directories that are known to the runtime linker are `/lib/secure` and `/usr/lib/secure`. For 64-bit objects, the default trusted directories are `/lib/secure/64` and `/usr/lib/secure/64`. The utility `crle(1)` can be used to specify additional trusted directories that are applicable for secure applications. Administrators who use this technique should ensure that the target directories are suitably protected from malicious intrusion.

If an `LD_LIBRARY_PATH` family environment variable is in effect for a secure process, only the *trusted* directories specified by this variable are used to augment the runtime linker's search rules.

In a secure process, runpath components that are provided by the application or any of its dependencies are used, provided the component is a full pathname, that is, the pathname starts with a `'/'`.

In a secure process, the expansion of the `$ORIGIN` string is allowed only if the string expands to a *trusted* directory.

In a secure process, `LD_CONFIG` is ignored. A secure process uses the default configuration file, if a configuration file exists. See `crle(1)`.

ld.so.1(1)

In a secure process, LD\_SIGNAL is ignored.

Additional objects can be loaded with a secure process using the LD\_PRELOAD, or LD\_AUDIT environment variables. These objects must be specified as *full* pathnames or *simple* file names. Full pathnames are restricted to known *trusted* directories. Simple file names, in which no '/' appears in the name, are located subject to the search path restrictions previously described. Simple file names resolve only to known *trusted* directories.

In a secure process, any dependencies that consist of simple filenames are processed using the pathname restrictions previously described. Dependencies expressed as full pathnames or relative pathnames are used as is. Therefore, the developer of a secure process should ensure that the target directory referenced as a full pathname or relative pathname dependency is suitably protected from malicious intrusion.

When creating a secure process, relative pathnames should *not* be used to express dependencies, or to construct dlopen(3C) pathnames. This restriction should be applied to the application and to *all* dependencies.

#### EXAMPLES

**EXAMPLE 1** Using LD\_FLAGS to group environment variable information

The following use of LD\_FLAGS is equivalent to setting the individual environment variables LD\_BIND\_NOW and LD\_LIBRARY\_PATH for 32-bit applications:

```
example% LD_FLAGS_32=bind_now,library_path=/lib/one:/lib/two
```

The following use of LD\_FLAGS is equivalent to setting the individual environment variables LD\_LIBRARY\_PATH and LD\_PRELOAD for 64-bit applications:

```
example% LD_FLAGS_64=library_path=/lib/one/64,preload=foo.so
```

#### FILES

/lib/ld.so.1

Default runtime linker.

/lib/libc.so.1

Alternate interpreter for SVID ABI compatibility.

/usr/lib/ld.so

AOUT (BCP) runtime linker.

/usr/lib/0@0.so.1

A compatibility library to support null character pointers. See NOTES.

/lib/secure and /usr/lib/secure

LD\_PRELOAD location for secure applications.

/lib/secure/64 and /usr/lib/secure/64

LD\_PRELOAD location for secure 64-bit applications.

/lib/64/ld.so.1

Default runtime linker for 64-bit applications.

/usr/lib/64/0@0.so.1

A 64-bit compatibility library to support null character pointers. See NOTES.

`/var/ld/ld.config`

Default configuration file for 32-bit applications.

`/var/ld/64/ld.config`

Default configuration file for 64-bit applications.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO** `crle(1)`, `gprof(1)`, `ld(1)`, `ldd(1)`, `exec(2)`, `issetugid(2)`, `mmap(2)`, `profil(2)`, `dldaddr(3C)`, `dldclose(3C)`, `dldump(3C)`, `dlderror(3C)`, `dldinfo(3C)`, `dlopen(3C)`, `dlsym(3C)`, `thr_kill(3C)`, `proc(4)`, `attributes(5)`

*Linker and Libraries Guide*

**NOTES** Care should be exercised when using `LD_PROFILE` in combination with other process monitoring techniques, such as users of `proc(4)`. Multiple process monitoring techniques can result in deadlock conditions that leave the profile buffer locked. A locked buffer blocks any processes that try to record profiling information. To reduce this likelihood, the runtime linker's profile implementation determines if the process is being monitored at startup. If so, profiling of the process is silently disabled. However, this mechanism can not catch monitoring processes that attach to the process during its execution.

The user compatibility library `/usr/lib/0@0.so.1` provides a mechanism that establishes a value of 0 at location 0. Some applications exist that erroneously assume a null character pointer should be treated the same as a pointer to a null string. A segmentation violation occurs in these applications when a null character pointer is accessed. If this library is added to such an application at runtime using `LD_PRELOAD`, the library provides an environment that is sympathetic to this errant behavior. However, the user compatibility library is intended neither to enable the generation of such applications, nor to endorse this particular programming practice.

let(1)

**NAME** | let – shell built-in function to evaluate one or more arithmetic expressions

**SYNOPSIS**

**ksh** | `let arg...`

**DESCRIPTION**

**ksh** | Each *arg* is a separate "arithmetic expression" to be evaluated.

**EXIT STATUS** | The following exit values are returned:

0 | The value of the last expression is non-zero.

1 | The value of the last expression is zero.

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

<b>NAME</b>	lex – generate programs for lexical tasks
<b>SYNOPSIS</b>	<b>lex</b> [-cntv] [-e   -w] [ -V -Q [y   n]] [ <i>file...</i> ]
<b>DESCRIPTION</b>	The <code>lex</code> utility generates C programs to be used in lexical processing of character input, and that can be used as an interface to <code>yacc</code> . The C programs are generated from <code>lex</code> source code and conform to the ISO C standard. Usually, the <code>lex</code> utility writes the program it generates to the file <code>lex.yy.c</code> . The state of this file is unspecified if <code>lex</code> exits with a non-zero exit status. See <b>EXTENDED DESCRIPTION</b> for a complete description of the <code>lex</code> input language.
<b>OPTIONS</b>	The following options are supported: <ul style="list-style-type: none"> <li>-c                    Indicates C-language action (default option).</li> <li>-e                    Generates a program that can handle EUC characters (cannot be used with the -w option). <code>yytext [ ]</code> is of type <code>unsigned char [ ]</code>.</li> <li>-n                    Suppresses the summary of statistics usually written with the -v option. If no table sizes are specified in the <code>lex</code> source code and the -v option is not specified, then -n is implied.</li> <li>-t                    Writes the resulting program to standard output instead of <code>lex.yy.c</code>.</li> <li>-v                    Writes a summary of <code>lex</code> statistics to the standard error. (See the discussion of <code>lex</code> table sizes under the heading <i>Definitions</i> in <code>lex</code>.) If table sizes are specified in the <code>lex</code> source code, and if the -n option is not specified, the -v option may be enabled.</li> <li>-w                    Generates a program that can handle EUC characters (cannot be used with the -e option). Unlike the -e option, <code>yytext [ ]</code> is of type <code>wchar_t [ ]</code>.</li> <li>-V                    Prints out version information on standard error.</li> <li>-Q[y n]              Prints out version information to output file <code>lex.yy.c</code> by using -Qy. The -Qn option does not print out version information and is the default.</li> </ul>
<b>OPERANDS</b>	The following operand is supported: <ul style="list-style-type: none"> <li><i>file</i>                A pathname of an input file. If more than one such <i>file</i> is specified, all files will be concatenated to produce a single <code>lex</code> program. If no <i>file</i> operands are specified, or if a <i>file</i> operand is -, the standard input will be used.</li> </ul>
<b>OUTPUT</b>	The <code>lex</code> output files are described below.
<b>Stdout</b>	If the -t option is specified, the text file of C source code output of <code>lex</code> will be written to standard output.

lex(1)

	<p><b>Stderr</b>   If the <code>-t</code> option is specified informational, error and warning messages concerning the contents of <code>lex</code> source code input will be written to the standard error.</p> <p>If the <code>-t</code> option is not specified:</p> <ol style="list-style-type: none"><li>1. Informational error and warning messages concerning the contents of <code>lex</code> source code input will be written to either the standard output or standard error.</li><li>2. If the <code>-v</code> option is specified and the <code>-n</code> option is not specified, <code>lex</code> statistics will also be written to standard error. These statistics may also be generated if table sizes are specified with a <code>%</code> operator in the <code>Definitions in lex</code> section (see <code>EXTENDED DESCRIPTION</code>), as long as the <code>-n</code> option is not specified.</li></ol>
<p><b>Output Files</b></p>	<p>A text file containing C source code will be written to <code>lex.yy.c</code>, or to the standard output if the <code>-t</code> option is present.</p>
<p><b>EXTENDED DESCRIPTION</b></p>	<p>Each input file contains <code>lex</code> source code, which is a table of regular expressions with corresponding actions in the form of C program fragments.</p> <p>When <code>lex.yy.c</code> is compiled and linked with the <code>lex</code> library (using the <code>-l lex</code> operand with <code>c89</code> or <code>cc</code>), the resulting program reads character input from the standard input and partitions it into strings that match the given expressions.</p> <p>When an expression is matched, these actions will occur:</p> <ul style="list-style-type: none"><li>■ The input string that was matched is left in <code>ytext</code> as a null-terminated string; <code>ytext</code> is either an external character array or a pointer to a character string. As explained in <code>Definitions in lex</code>, the type can be explicitly selected using the <code>%array</code> or <code>%pointer</code> declarations, but the default is <code>%array</code>.</li><li>■ The external <code>int yyleng</code> is set to the length of the matching string.</li><li>■ The expression's corresponding program fragment, or action, is executed.</li></ul> <p>During pattern matching, <code>lex</code> searches the set of patterns for the single longest possible match. Among rules that match the same number of characters, the rule given first will be chosen.</p> <p>The general format of <code>lex</code> source is:</p> <pre>Definitions %% Rules %% User Subroutines</pre> <p>The first <code>%%</code> is required to mark the beginning of the rules (regular expressions and actions); the second <code>%%</code> is required only if user subroutines follow.</p>

Any line in the `Definitions in lex` section beginning with a blank character will be assumed to be a C program fragment and will be copied to the external definition area of the `lex.yy.c` file. Similarly, anything in the `Definitions in lex` section included between delimiter lines containing only `%{` and `%}` will also be copied unchanged to the external definition area of the `lex.yy.c` file.

Any such input (beginning with a blank character or within `%{` and `%}` delimiter lines) appearing at the beginning of the `Rules` section before any rules are specified will be written to `lex.yy.c` after the declarations of variables for the `yylex` function and before the first line of code in `yylex`. Thus, user variables local to `yylex` can be declared here, as well as application code to execute upon entry to `yylex`.

The action taken by `lex` when encountering any input beginning with a blank character or within `%{` and `%}` delimiter lines appearing in the `Rules` section but coming after one or more rules is undefined. The presence of such input may result in an erroneous definition of the `yylex` function.

## Definitions in lex

`Definitions in lex` appear before the first `%%` delimiter. Any line in this section not contained between `%{` and `%}` lines and not beginning with a blank character is assumed to define a `lex` substitution string. The format of these lines is:

```
name substitute
```

If a *name* does not meet the requirements for identifiers in the ISO C standard, the result is undefined. The string *substitute* will replace the string `{ name }` when it is used in a rule. The *name* string is recognized in this context only when the braces are provided and when it does not appear within a bracket expression or within double-quotes.

In the `Definitions in lex` section, any line beginning with a `%` (percent sign) character and followed by an alphanumeric word beginning with either `s` or `S` defines a set of start conditions. Any line beginning with a `%` followed by a word beginning with either `x` or `X` defines a set of exclusive start conditions. When the generated scanner is in a `%s` state, patterns with no state specified will be also active; in a `%x` state, such patterns will not be active. The rest of the line, after the first word, is considered to be one or more blank-character-separated names of start conditions. Start condition names are constructed in the same way as definition names. Start conditions can be used to restrict the matching of regular expressions to one or more states as described in `Regular expressions in lex`.

Implementations accept either of the following two mutually exclusive declarations in the `Definitions in lex` section:

```
%array          Declare the type of ytext to be a null-terminated character array.
%pointer        Declare the type of ytext to be a pointer to a null-terminated
                character string.
```

*Note:* When using the `%pointer` option, you may not also use the `yyles` function to alter *ytext*.

lex(1)

`%array` is the default. If `%array` is specified (or neither `%array` nor `%pointer` is specified), then the correct way to make an external reference to `yytext` is with a declaration of the form:

```
extern char yytext [ ]
```

If `%pointer` is specified, then the correct external reference is of the form:

```
extern char *yytext;
```

lex will accept declarations in the `Definitions in lex` section for setting certain internal table sizes. The declarations are shown in the following table.

Table Size Declaration in lex

Declaration	Description	Default
<code>%pn</code>	Number of positions	2500
<code>%nn</code>	Number of states	500
<code>%an</code>	Number of transitions	2000
<code>%en</code>	Number of parse tree nodes	1000
<code>%kn</code>	Number of packed character classes	10000
<code>%on</code>	Size of the output array	3000

Programs generated by lex need either the `-e` or `-w` option to handle input that contains EUC characters from supplementary codesets. If neither of these options is specified, `yytext` is of the type `char [ ]`, and the generated program can handle only ASCII characters.

When the `-e` option is used, `yytext` is of the type `unsigned char [ ]` and `yylen` gives the total number of *bytes* in the matched string. With this option, the macros `input ( )`, `unput (c)`, and `output (c)` should do a byte-based I/O in the same way as with the regular ASCII lex. Two more variables are available with the `-e` option, `yywtext` and `yywlen`, which behave the same as `yytext` and `yylen` would under the `-w` option.

When the `-w` option is used, `yytext` is of the type `wchar_t [ ]` and `yylen` gives the total number of *characters* in the matched string. If you supply your own `input ( )`, `unput (c)`, or `output (c)` macros with this option, they must return or accept EUC characters in the form of wide character (`wchar_t`). This allows a different interface between your program and the lex internals, to expedite some programs.

<b>Rules in lex</b>	<p>The Rules in lex source files are a table in which the left column contains regular expressions and the right column contains actions (C program fragments) to be executed when the expressions are recognized.</p> <pre>ERE action ERE action ...</pre> <p>The extended regular expression (ERE) portion of a row will be separated from <i>action</i> by one or more blank characters. A regular expression containing blank characters is recognized under one of the following conditions:</p> <ul style="list-style-type: none"> <li>■ The entire expression appears within double-quotes.</li> <li>■ The blank characters appear within double-quotes or square brackets.</li> <li>■ Each blank character is preceded by a backslash character.</li> </ul>
<b>User Subroutines in lex</b>	<p>Anything in the user subroutines section will be copied to <code>lex.yy.c</code> following <code>yylex</code>.</p>
<b>Regular Expressions in lex</b>	<p>The lex utility supports the set of Extended Regular Expressions (EREs) described on <code>regex(5)</code> with the following additions and exceptions to the syntax:</p> <pre>. . . .</pre> <p>Any string enclosed in double-quotes will represent the characters within the double-quotes as themselves, except that backslash escapes (which appear in the following table) are recognized. Any backslash-escape sequence is terminated by the closing quote. For example, "<code>\ 01</code>" represents a single string: the octal value 1 followed by the character 1.</p> <pre>&lt;state&gt;r &lt;state1, state2, ...&gt;r</pre> <p>The regular expression <i>r</i> will be matched only when the program is in one of the start conditions indicated by <i>state</i>, <i>state1</i>, and so forth. For more information, see <i>Actions in lex</i>. As an exception to the typographical conventions of the rest of this document, in this case <code>&lt;state&gt;</code> does not represent a metavariable, but the literal angle-bracket characters surrounding a symbol. The start condition is recognized as such only at the beginning of a regular expression.</p> <pre>r/x</pre> <p>The regular expression <i>r</i> will be matched only if it is followed by an occurrence of regular expression <i>x</i>. The token returned in <i>yytext</i> will only match <i>r</i>. If the trailing portion of <i>r</i> matches the beginning of <i>x</i>, the result is unspecified. The <i>r</i> expression cannot include further trailing context or the <code>\$</code> (match-end-of-line) operator; <i>x</i> cannot include the <code>^</code> (match-beginning-of-line) operator, nor trailing context, nor the <code>\$</code> operator. That is, only one occurrence of trailing context is allowed in a lex regular expression, and the <code>^</code> operator only can be used at the beginning of such an expression. A further restriction is that the trailing-context operator <code>/</code> (slash) cannot be grouped within parentheses.</p> <pre>{name}</pre> <p>When <i>name</i> is one of the substitution symbols from the <i>Definitions</i> section, the string, including the enclosing braces, will be replaced by the <i>substitute</i> value. The</p>

lex(1)

*substitute* value will be treated in the extended regular expression as if it were enclosed in parentheses. No substitution will occur if *{name}* occurs within a bracket expression or within double-quotes.

Within an ERE, a backslash character ( `\\`, `\ a`, `\ b`, `\ f`, `\ n`, `\ r`, `\ t`, `\ v` ) is considered to begin an escape sequence. In addition, the escape sequences in the following table will be recognized.

A literal newline character cannot occur within an ERE; the escape sequence `\ n` can be used to represent a newline character. A newline character cannot be matched by a period operator.

#### Escape Sequences in lex

Escape Sequences in lex		
Escape Sequence	Description	Meaning
<code>\digits</code>	A backslash character followed by the longest sequence of one, two or three octal-digit characters (01234567). If all of the digits are 0, (that is, representation of the NUL character), the behavior is undefined.	The character whose encoding is represented by the one-, two- or three-digit octal integer. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading <code>\</code> for each byte.
<code>\xdigits</code>	A backslash character followed by the longest sequence of hexadecimal-digit characters (01234567abcdefABCDEF). If all of the digits are 0, (that is, representation of the NUL character), the behavior is undefined.	The character whose encoding is represented by the hexadecimal integer.
<code>\c</code>	A backslash character followed by any character not described in this table. ( <code>\\</code> , <code>\a</code> , <code>\b</code> , <code>\f</code> , <code>\n</code> , <code>\r</code> , <code>\t</code> , <code>\v</code> ).	The character <i>c</i> , unchanged.

The order of precedence given to extended regular expressions for `lex` is as shown in the following table, from high to low.

*Note:* The escaped characters entry is not meant to imply that these are operators, but they are included in the table to show their relationships to the true operators. The start condition, trailing context and anchoring notations have been omitted from the table because of the placement restrictions described in this section; they can only appear at the beginning or ending of an ERE.

ERE Precedence in lex	
<i>collation-related bracket symbols</i>	[ = = ] [ : : ] [ . . ]
<i>escaped characters</i>	\<special character>
<i>bracket expression</i>	[ ]
<i>quoting</i>	". . . ."
<i>grouping</i>	( )
<i>definition</i>	{ name }
<i>single-character RE duplication</i>	* + ?
<i>concatenation</i>	
<i>interval expression</i>	{ m,n }
<i>alternation</i>	

The ERE anchoring operators ( `^` and `$` ) do not appear in the table. With `lex` regular expressions, these operators are restricted in their use: the `^` operator can only be used at the beginning of an entire regular expression, and the `$` operator only at the end. The operators apply to the entire regular expression. Thus, for example, the pattern `(^abc) | (def$)` is undefined; it can instead be written as two separate rules, one with the regular expression `^abc` and one with `def$`, which share a common action via the special `|` action (see below). If the pattern were written `^abc|def$`, it would match either of `abc` or `def` on a line by itself.

Unlike the general ERE rules, embedded anchoring is not allowed by most historical `lex` implementations. An example of embedded anchoring would be for patterns such as `(^)foo($)` to match `foo` when it exists as a complete word. This functionality can be obtained using existing `lex` features:

```
^foo/[ \ n] |
" foo"/[ \ n] /* found foo as a separate word */
```

Notice also that `$` is a form of trailing context (it is equivalent to `/\ n` and as such cannot be used with regular expressions containing another instance of the operator (see the preceding discussion of trailing context).

The additional regular expressions trailing-context operator `/` (slash) can be used as an ordinary character if presented within double-quotes, `" / "`; preceded by a backslash, `\ /`; or within a bracket expression, `[ / ]`. The start-condition `<` and `>` operators are special only in a start condition at the beginning of a regular expression; elsewhere in the regular expression they are treated as ordinary characters.

The following examples clarify the differences between `lex` regular expressions and regular expressions appearing elsewhere in this document. For regular expressions of the form `r/x`, the string matching `r` is always returned; confusion may arise when the beginning of `x` matches the trailing portion of `r`. For example, given the regular

lex(1)

expression `a*b/cc` and the input `aaabcc`, `ytext` would contain the string `aaab` on this match. But given the regular expression `x*/xy` and the input `xxxxy`, the token `xxx`, not `xx`, is returned by some implementations because `xxx` matches `x*`.

In the rule `ab*/bc`, the `b*` at the end of `r` will extend `r`'s match into the beginning of the trailing context, so the result is unspecified. If this rule were `ab/bc`, however, the rule matches the text `ab` when it is followed by the text `bc`. In this latter case, the matching of `r` cannot extend into the beginning of `x`, so the result is specified.

#### Actions in lex

The action to be taken when an ERE is matched can be a C program fragment or the special actions described below; the program fragment can contain one or more C statements, and can also include special actions. The empty C statement `;` is a valid action; any string in the `lex.yy.c` input that matches the pattern portion of such a rule is effectively ignored or skipped. However, the absence of an action is not valid, and the action `lex` takes in such a condition is undefined.

The specification for an action, including C statements and special actions, can extend across several lines if enclosed in braces:

```
ERE <one or more blanks> { program statement
program statement }
```

The default action when a string in the input to a `lex.yy.c` program is not matched by any expression is to copy the string to the output. Because the default behavior of a program generated by `lex` is to read the input and copy it to the output, a minimal `lex` source program that has just `%%` generates a C program that simply copies the input to the output unchanged.

Four special actions are available:

| ECHO; REJECT; BEGIN

| The action `|` means that the action for the next rule is the action for this rule. Unlike the other three actions, `|` cannot be enclosed in braces or be semicolon-terminated. It must be specified alone, with no other actions.

ECHO; Writes the contents of the string `ytext` on the output.

REJECT; Usually only a single expression is matched by a given string in the input. REJECT means "continue to the next expression that matches the current input," and causes whatever rule was the second choice after the current rule to be executed for the same input. Thus, multiple rules can be matched and executed for one input string or overlapping input strings. For example, given the regular expressions `xyz` and `xy` and the input `xyz`, usually only the regular expression `xyz` would match. The next attempted match would start after `z`. If the last action in the `xyz` rule is REJECT, both this rule and the `xy` rule would be executed. The REJECT action may be implemented in such a fashion that flow of control does not continue after it, as if it were equivalent to a `goto`

to another part of `yylex`. The use of `REJECT` may result in somewhat larger and slower scanners.

`BEGIN`

The action:

```
BEGIN newstate ;
```

switches the state (start condition) to *newstate*. If the string *newstate* has not been declared previously as a start condition in the `Definitions` in `lex` section, the results are unspecified. The initial state is indicated by the digit 0 or the token `INITIAL`.

The functions or macros described below are accessible to user code included in the `lex` input. It is unspecified whether they appear in the C code output of `lex`, or are accessible only through the `-l l` operand to `c89` or `cc` (the `lex` library).

<code>int yylex(void)</code>	Performs lexical analysis on the input; this is the primary function generated by the <code>lex</code> utility. The function returns zero when the end of input is reached; otherwise it returns non-zero values (tokens) determined by the actions that are selected.
<code>int yymore(void)</code>	When called, indicates that when the next input string is recognized, it is to be appended to the current value of <i>yytext</i> rather than replacing it; the value in <i>yylen</i> is adjusted accordingly.
<code>int yyless(int n)</code>	Retains <i>n</i> initial characters in <i>yytext</i> , NUL-terminated, and treats the remaining characters as if they had not been read; the value in <i>yylen</i> is adjusted accordingly.
<code>int input(void)</code>	Returns the next character from the input, or zero on end-of-file. It obtains input from the stream pointer <i>yyin</i> , although possibly via an intermediate buffer. Thus, once scanning has begun, the effect of altering the value of <i>yyin</i> is undefined. The character read is removed from the input stream of the scanner without any processing by the scanner.
<code>int unput(int c)</code>	Returns the character <i>c</i> to the input; <i>yytext</i> and <i>yylen</i> are undefined until the next expression is matched. The result of using <i>unput</i> for more characters than have been input is unspecified.

The following functions appear only in the `lex` library accessible through the `-l l` operand; they can therefore be redefined by a portable application:

lex(1)

```
int yywrap(void)
```

Called by `yylex` at end-of-file; the default `yywrap` always will return 1. If the application requires `yylex` to continue processing with another source of input, then the application can include a function `yywrap`, which associates another file with the external variable `FILE *yyin` and will return a value of zero.

```
int main(int argc, char *argv[ ])
```

Calls `yylex` to perform lexical analysis, then exits. The user code can contain `main` to perform application-specific operations, calling `yylex` as applicable.

The reason for breaking these functions into two lists is that only those functions in `libl.a` can be reliably redefined by a portable application.

Except for `input`, `unput` and `main`, all external and static names generated by `lex` begin with the prefix `yy` or `YY`.

**USAGE** Portable applications are warned that in the `Rules in lex` section, an ERE without an action is not acceptable, but need not be detected as erroneous by `lex`. This may result in compilation or run-time errors.

The purpose of `input` is to take characters off the input stream and discard them as far as the lexical analysis is concerned. A common use is to discard the body of a comment once the beginning of a comment is recognized.

The `lex` utility is not fully internationalized in its treatment of regular expressions in the `lex` source code or generated lexical analyzer. It would seem desirable to have the lexical analyzer interpret the regular expressions given in the `lex` source according to the environment specified when the lexical analyzer is executed, but this is not possible with the current `lex` technology. Furthermore, the very nature of the lexical analyzers produced by `lex` must be closely tied to the lexical requirements of the input language being described, which will frequently be locale-specific anyway. (For example, writing an analyzer that is used for French text will not automatically be useful for processing other languages.)

**EXAMPLES** **EXAMPLE 1** Using `lex`

The following is an example of a `lex` program that implements a rudimentary scanner for a Pascal-like syntax:

```
%{
/* need this for the call to atof() below */
#include <math.h>
/* need this for printf(), fopen() and stdin below */
#include <stdio.h>
}%

DIGIT    [0-9]
ID       [a-z][a-z0-9]*
%%

{DIGIT}+ {
                                printf("An integer: %s (%d)\n", yytext,
                                atoi(yytext));
```

**EXAMPLE 1** Using lex *(Continued)*

```

    }
{DIGIT}+ "." {DIGIT}*
    {
    printf("A float: %s (%g)\n", yytext,
    atof(yytext));
    }
if|then|begin|end|procedure|function
    {
    printf("A keyword: %s\n", yytext);
    }
{ID}
    printf("An identifier: %s\n", yytext);
"+"|"-"|"*"|"\/"
    printf("An operator: %s\n", yytext);
"{"[^]\n}*"
    /* eat up one-line comments */
[ \t\n]+
    /* eat up white space */
.
    printf("Unrecognized character: %s\n", yytext);
%%

int main(int argc, char *argv[ ])
{
    ++argv, --argc; /* skip over program name */
    if (argc > 0)
        yyin = fopen(argv[0], "r");
    else
        yyin = stdin;

    yylex();
}

```

**ENVIRONMENT VARIABLES**

See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of lex: LANG, LC\_ALL, LC\_COLLATE, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**EXIT STATUS**

The following exit values are returned:

0           Successful completion.  
>0          An error occurred.

**ATTRIBUTES**

See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbtool
Interface Stability	Standard

**SEE ALSO** [yacc\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [regex\(5\)](#), [standards\(5\)](#)

lex(1)

**NOTES** | If routines such as `yyback()`, `yywrap()`, and `yylock()` in `.l` (ell) files are to be external C functions, the command line to compile a C++ program must define the `__EXTERN_C__` macro. For example:

```
example% CC -D__EXTERN_C__ ... file
```

<b>NAME</b>	limit, ulimit, unlimited – set or get limitations on the system resources available to the current shell and its descendants
<b>SYNOPSIS</b>	<b>/usr/bin/ulimit</b> [-f] [ <i>blocks</i> ]
<b>sh</b>	<b>ulimit</b> [ - [HS] [ a   cdfnstv]] <b>ulimit</b> [ - [HS] [ c   d   f   n   s   t   v]] <i>limit</i>
<b>cs</b>	<b>limit</b> [-h] [ <i>resource</i> [ <i>limit</i> ]] <b>unlimit</b> [-h] [ <i>resource</i> ]
<b>ksh</b>	<b>ulimit</b> [-HSacdfnstv] [ <i>limit</i> ]
<b>DESCRIPTION</b>	
<b>/usr/bin/ulimit</b>	The <b>ulimit</b> utility sets or reports the file-size writing limit imposed on files written by the shell and its child processes (files of any size may be read). Only a process with appropriate privileges can increase the limit.
<b>sh</b>	The Bourne shell built-in function, <b>ulimit</b> , prints or sets hard or soft resource limits. These limits are described in <b>getrlimit(2)</b> .  If <i>limit</i> is not present, <b>ulimit</b> prints the specified limits. Any number of limits may be printed at one time. The <b>-a</b> option prints all limits.  If <i>limit</i> is present, <b>ulimit</b> sets the specified limit to <i>limit</i> . The string <b>unlimited</b> requests the largest valid limit. Limits may be set for only one resource at a time. Any user may set a soft limit to any value below the hard limit. Any user may lower a hard limit. Only a super-user may raise a hard limit. See <b>su(1M)</b> .  The <b>-H</b> option specifies a hard limit. The <b>-S</b> option specifies a soft limit. If neither option is specified, <b>ulimit</b> will set both limits and print the soft limit.  The following options specify the resource whose limits are to be printed or set. If no option is specified, the file size limit is printed or set.  -c        maximum core file size (in 512-byte blocks) -d        maximum size of data segment or heap (in kbytes) -f        maximum file size (in 512-byte blocks) -n        maximum file descriptor plus 1 -s        maximum size of stack segment (in kbytes) -t        maximum CPU time (in seconds) -v        maximum size of virtual memory (in kbytes)

## limit(1)

- cs**h | The C-shell built-in function, `limit`, limits the consumption by the current process or any process it spawns, each not to exceed *limit* on the specified *resource*. If *limit* is omitted, print the current limit; if *resource* is omitted, display all limits. (Run the `sysdef(1M)` command to obtain the maximum possible limits for your system. The values reported are in hexadecimal, but can be translated into decimal numbers using the `bc(1)` command).
- h            Use hard limits instead of the current limits. Hard limits impose a ceiling on the values of the current limits. Only the privileged user may raise the hard limits.
- resource* is one of:
- |                           |  |
|---------------------------|--|
| <code>cputime</code>      | Maximum CPU seconds per process.   |
| <code>filesize</code>     | Largest single file allowed. Limited to the size of the filesystem (see <code>df(1M)</code> ). |
| <code>datasize</code>     | The maximum size of a process's heap in kilobytes.   |
| <code>stacksize</code>    | Maximum stack size for the process. The default stack size is $2^{64}$ .                       |
| <code>coredumpsize</code> | Maximum size of a core dump (file). This is limited to the size of the filesystem.             |
| <code>descriptors</code>  | Maximum number of file descriptors (run <code>sysdef()</code> ).                               |
| <code>memorysize</code>   | Maximum size of virtual memory.  |
- limit* is a number, with an optional scaling factor, as follows:
- |                    |  |
|--------------------|--|
| <code>nh</code>    | Hours (for <code>cputime</code> ).   |
| <code>nk</code>    | <i>n</i> kilobytes. This is the default for all but <code>cputime</code> . |
| <code>nm</code>    | <i>n</i> megabytes or minutes (for <code>cputime</code> ).                 |
| <code>mm:ss</code> | Minutes and seconds (for <code>cputime</code> ).                           |
- `unlimit` removes a limitation on *resource*. If no *resource* is specified, then all resource limitations are removed. See the description of the `limit` command for the list of resource names.
- h            Remove corresponding hard limits. Only the privileged user may do this.
- ks**h | The Korn shell built-in function, `ulimit`, sets or displays a resource limit. The available resources limits are listed below. Many systems do not contain one or more of these limits. The limit for a specified resource is set when *limit* is specified. The value of *limit* can be a number in the unit specified below with each resource, or the value `unlimited`. The `-H` and `-S` flags specify whether the hard limit or the soft limit for the given resource is set. A hard limit cannot be increased once it is set. A soft limit

can be increased up to the value of the hard limit. If neither the `-H` or `-S` options is specified, the limit applies to both. The current resource limit is printed when *limit* is omitted. In this case, the soft limit is printed unless `-H` is specified. When more than one resource is specified, then the limit name and unit is printed before the value.

- a        Lists all of the current resource limits.
- c        The number of 512-byte blocks on the size of core dumps.
- d        The number of K-bytes on the size of the data area.
- f        The number of 512-byte blocks on files written by child processes (files of any size may be read).
- n        The number of file descriptors plus 1.
- s        The number of K-bytes on the size of the stack area.
- t        The number of seconds (CPU time) to be used by each process.
- v        The number of K-bytes for virtual memory.

If no option is given, `-f` is assumed.

#### Per-Shell Memory Parameters

The `heapsize`, `datasize`, and `stacksize` parameters are not system tunables. The only controls for these are hard limits, set in a shell startup file, or system-wide soft limits, which, for the current version of the Solaris OS, is 2<sup>64</sup>bytes.

#### OPTIONS

The following option is supported by `ulimit`:

- f        Sets (or reports, if no *blocks* operand is present), the file size limit in blocks. The `-f` option is also the default case.

#### OPERANDS

The following operand is supported by `ulimit`:

- blocks*    The number of 512-byte blocks to use as the new file size limit.

#### EXAMPLES

##### `/usr/bin/ulimit`

**EXAMPLE 1** Limiting the stack size

To limit the stack size to 512 kilobytes:

```
example% ulimit -s 512
example% ulimit -a
time(seconds)          unlimited
file(blocks)           100
data(kbytes)           523256
stack(kbytes)          512
coredump(blocks)       200
nofiles(descriptors)   64
memory(kbytes)         unlimited
```

## limit(1)

### sh/ksh **EXAMPLE 2** Limiting the number of file descriptors

To limit the number of file descriptors to 12:

```
example$ ulimit -n 12
example$ ulimit -a
time(seconds)          unlimited
file(blocks)           41943
data(kbytes)           523256
stack(kbytes)          8192
coredump(blocks)       200
nofiles(descriptors)   12
vmemory(kbytes)        unlimited
```

### csh **EXAMPLE 3** Limiting the core dump file size

To limit the size of a core dump file size to 0 kilobytes:

```
example% limit coredumpsize 0
example% limit
cputime                unlimited
filesize               unlimited
datasize               523256 kbytes
stacksize              8192 kbytes
coredumpsize           0 kbytes
descriptors            64
memorysize             unlimited
```

### **EXAMPLE 4** Removing the limitation for core file size

To remove the above limitation for the core file size:

```
example% unlimit coredumpsize
example% limit
cputime                unlimited
filesize               unlimited
datasize               523256 kbytes
stacksize              8192 kbytes
coredumpsize           unlimited
descriptors            64
memorysize             unlimited
```

### ENVIRONMENT VARIABLES

See environ(5) for descriptions of the following environment variables that affect the execution of ulimit: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

### EXIT STATUS

The following exit values are returned by ulimit:

0	Successful completion.
>0	A request for a higher limit was rejected or an error occurred.

limit(1)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

line(1)

**NAME** | line – read one line

**SYNOPSIS** | **line**

**DESCRIPTION** | The `line` utility copies one line (up to and including a new-line) from the standard input and writes it on the standard output. It returns an exit status of 1 on EOF and always prints at least a new-line. It is often used within shell files to read from the user's terminal.

**EXIT STATUS** | Exit status is:

0            Successful completion

>0          End-of-file on input.

<b>NAME</b>	lint – C program verifier
<b>SYNOPSIS</b>	<code>/usr/ucb/lint</code> [ <i>options</i> ]
<b>DESCRIPTION</b>	<code>/usr/ucb/lint</code> is the interface to the BSD Compatibility Package C program verifier. It is a script that looks for the link <code>/usr/ccs/bin/ucblint</code> to the C program verifier. <code>/usr/ccs/bin/ucblint</code> is available only with the SPROcc package, whose default location is <code>/opt/SUNWspro</code> . <code>/usr/ucb/lint</code> is identical to <code>/usr/ccs/bin/ucblint</code> , except that BSD headers are used and BSD libraries are linked <i>before</i> base libraries. The <code>/opt/SUNWspro/man/man1/lint.1</code> man page is available only with the SPROcc package.
<b>OPTIONS</b>	<p><code>/usr/ucb/lint</code> accepts the same options as <code>/usr/ccs/bin/ucblint</code>, with the following exceptions:</p> <ul style="list-style-type: none"> <li>-I <i>dir</i>            Search <i>dir</i> for included files whose names do not begin with a slash ( / ) prior to searching the usual directories. The directories for multiple -I options are searched in the order specified. The preprocessor first searches for #include files in the directory containing <i>sourcefile</i>, and then in directories named with -I options (if any), then <code>/usr/ucbinclude</code>, and finally, in <code>/usr/include</code>.</li> <li>-L <i>dir</i>            Add <i>dir</i> to the list of directories searched for libraries by <code>/usr/ccs/bin/ucblint</code>. This option is passed to <code>/usr/ccs/bin/ld</code>. Directories specified with this option are searched before <code>/usr/ucb/lib</code> and <code>/usr/lib</code>.</li> <li>-Y <i>P, dir</i>        Change the default directory used for finding libraries.</li> </ul>
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <ul style="list-style-type: none"> <li>0                    Successful completion.</li> <li>&gt;0                  An error occurred.</li> </ul>
<b>FILES</b>	<ul style="list-style-type: none"> <li><code>/usr/lint/bin/ld</code>        link editor</li> <li><code>/usr/lib/libc</code>         C library</li> <li><code>/usr/ucbinclude</code>      BSD Compatibility directory for header files</li> <li><code>/usr/ucb/lib</code>         BSD Compatibility directory for libraries</li> <li><code>/usr/ucb/lib/libucb</code>    BSD Compatibility C library</li> <li><code>/usr/lib/libsocket</code>    library containing socket routines</li> <li><code>/usr/lib/libnsl</code>        library containing network functions</li> <li><code>/usr/lib/libelf</code>        library containing routines to process ELF object files</li> <li><code>/usr/lib/libaio</code>        library containing asynchronous I/O routines</li> </ul>

<b>NAME</b>	list_devices – list allocatable devices
<b>SYNOPSIS</b>	<pre>list_devices [-s] [ -U uid] -l [device] list_devices [-s] [ -U uid] -n [device] list_devices [-s] [ -U uid] -u [device]</pre>
<b>DESCRIPTION</b>	<p>The <code>list_devices</code> utility lists the allocatable devices in the system according to specified qualifications.</p> <p>The <i>device</i> and all device special files associated with the device are listed. The device argument is optional and, if it is not present, all relevant devices are listed.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-l [<i>device</i>]        Lists the pathname(s) of the device special files associated with the device that are allocatable to the current process. If <i>device</i> is given, lists only the files associated with the specified device.</li> <li>-n [<i>device</i>]        Lists the pathname(s) of device special files associated with the device that are allocatable to the current process but are not currently allocated. If <i>device</i> is given, lists only the files associated with that device.</li> <li>-s                    Silent. Suppresses any diagnostic output.</li> <li>-u [<i>device</i>]        Lists the pathname(s) of device special files, associated with the device that are allocated to the owner of the current process. If <i>device</i> is given, list only the files associated with that device.</li> <li>-U <i>uid</i>             Uses the user ID <i>uid</i> instead of the real user ID of the current process when performing the <code>list_devices</code> operation. Only a user with the <code>solaris.devices.revoke</code> authorization can use this option.</li> </ul>
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <ul style="list-style-type: none"> <li>non—zero        An error occurred.</li> </ul>
<b>FILES</b>	<pre>/etc/security/device_allocate /etc/security/device_maps /etc/security/dev/* /usr/security/lib/*</pre>
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:

list\_devices(1)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO** [allocate\(1\)](#), [deallocate\(1\)](#), [bsmconv\(1M\)](#), [dminfo\(1M\)](#), [mkdevalloc\(1M\)](#), [mkdevmaps\(1M\)](#), [device\\_allocate\(4\)](#), [device\\_maps\(4\)](#), [attributes\(5\)](#)

**NOTES** The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See [bsmconv\(1M\)](#) for more information.

`/etc/security/dev`, [mkdevalloc\(1M\)](#), and [mkdevmaps\(1M\)](#) might not be supported in a future release of the Solaris Operating Environment.

<b>NAME</b>	listusers – list user login information				
<b>SYNOPSIS</b>	<b>listusers</b> [-g <i>groups</i> ] [-l <i>logins</i> ]				
<b>DESCRIPTION</b>	Executed without any options, this command lists all user logins sorted by login. The output shows the login ID and the account field value from the system's password database as specified by <code>/etc/nsswitch.conf</code> .				
<b>OPTIONS</b>	The following options are supported: <ul style="list-style-type: none"> <li>-g <i>groups</i>            Lists all user logins belonging to <i>group</i>, sorted by login. Multiple groups can be specified as a comma-separated list.</li> <li>-l <i>logins</i>            Lists the user login or logins specified by <i>logins</i>, sorted by login. Multiple logins can be specified as a comma-separated list.</li> </ul>				
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1" data-bbox="461 821 1430 909" style="margin-left: 20px;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
<b>SEE ALSO</b>	<code>nsswitch.conf(4)</code> , <code>attributes(5)</code>				
<b>NOTES</b>	A user login is one that has a UID of 100 or greater.  The -l and -g options can be combined. User logins will only be listed once, even if they belong to more than one of the selected groups.				

## llc2\_autoconfig(1)

- NAME** llc2\_autoconfig – generate LLC2 configuration files
- SYNOPSIS** /usr/lib/llc2/llc2\_autoconfig [-f]
- DESCRIPTION** The llc2\_autoconfig utility is used to generate LLC2 configuration files (/etc/llc2/default/llc2.\*). If there is no configuration file in /etc/llc2\_default/, it detects all the available interfaces in the system and generates corresponding default configuration files.
- If there are existing configuration files in /etc/llc2\_default/, it will check if those interfaces defined in the files still exist. If they do not exist in the system, it will set llc2\_on in those files to 0. After this, it will detect if there are new interfaces in the system. If there are, it will generate configuration files for them.
- OPTIONS** The following option is supported:
- f Erases all configuration files in /etc/llc2/default/. Then detects all the available interfaces in the system and generates corresponding default configuration files. Use this option with caution.
- FILES** /etc/llc2/default/llc2.\* LLC2 configuration files
- ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWllc

**SEE ALSO** llc2\_config(1), llc2(4), attributes(5), llc2(7D)

<b>NAME</b>	llc2_config – configure LLC2 interface parameters																
<b>SYNOPSIS</b>	<code>/usr/lib/llc2/llc2_config [-P   -U   -d   -q   -i <i>ppa</i>   -r <i>ppa</i>]</code>																
<b>DESCRIPTION</b>	The <code>llc2_config</code> utility is used to start/stop the LLC2 subsystem and to configure LLC2 interface parameters.																
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-d</code> Turns on debug mode. Extra debugging information will be printed out.</li> <li><code>-i <i>ppa</i></code> Initializes the corresponding interface using the file <code>/etc/llc2/default/llc2.<i>ppa</i></code>.</li> <li><code>-P</code> Reads in all <code>/etc/llc2/default/llc2.*</code> configuration files, opens those devices defined in the files, and sets up the streams needed for LLC2 to use those devices. Before doing this, <code>llc2_config -q</code> will not show anything.</li> <li><code>-q</code> Queries the LLC2 subsystem. Information similar to the following example will be printed out for all PPAs (Physical Point of Attachment) available under the LLC2 module:</li> </ul> <table style="margin-left: 40px;"> <thead> <tr> <th>PPA</th> <th>State</th> <th>ID</th> <th>MACAddr</th> <th>Type</th> <th>MaxSDU</th> <th>MinSDU</th> <th>Mode</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>up</td> <td>0000</td> <td>0800208a217e</td> <td>ethernet</td> <td>1500</td> <td>0</td> <td>3</td> </tr> </tbody> </table> <p>The fields displayed are described below:</p> <ul style="list-style-type: none"> <li>PPA The relative logical position of the interface.</li> <li>State The state of the interface: <ul style="list-style-type: none"> <li><i>up</i> The interface is initialized and operational.</li> <li><i>down</i> The interface was "discovered" by the LLC2 driver, has passed its bootup diagnostics, and is awaiting initialization.</li> <li><i>bad</i> The interface is known to the LLC2 driver, but failed one or more of the integrity checks performed at boot time. This might include detecting Interrupt Request and shared memory conflicts or failures detected during the execution of the level 0 diagnostics.</li> </ul> </li> <li>ID The interface ID.</li> <li>MACAddr The MAC address currently in effect for the interface.</li> <li>Type The MAC type. Current types supported include:</li> </ul>	PPA	State	ID	MACAddr	Type	MaxSDU	MinSDU	Mode	0	up	0000	0800208a217e	ethernet	1500	0	3
PPA	State	ID	MACAddr	Type	MaxSDU	MinSDU	Mode										
0	up	0000	0800208a217e	ethernet	1500	0	3										

## llc2\_config(1)

csma/cd 10 Megabit Ethernet  
ethernet Ethernet type device  
tkn-ring 4/16 Megabit Token Ring  
fddi 100 Megabit Fiber Distributed Data Interface

MaxSDU The Maximum Service Data Unit size transmitted on this interface.

Mode The Service Modes supported by this interface. This field consists of the bitwise logical-ORing of the supported modes, also defined in `/usr/include/sys/dlpi.h`.

`-r ppa` Uninitializes the corresponding interface. By using this option, and then using the `-i` option, the parameters associated with an interface can be changed.

`-U` Destroys all streams used by the LLC2 subsystem. This is the reverse of the `-P` option. After this is executed, `llc2_config -q` will not show anything.

**FILES** `/etc/llc2/default/llc2.*` LLC2 configuration files

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWllc

**SEE ALSO** `llc2_autoconfig(1)`, `llc2(4)`, `attributes(5)`, `llc2(7D)`

<b>NAME</b>	llc2_stats – LLC2 Station, SAP, and Connection Statistics
<b>SYNOPSIS</b>	<b>llc2_stats</b> <i>ppa</i> [-r] [-s <i>sap</i> ] [-c <i>connection</i> ]
<b>DESCRIPTION</b>	The llc2_stats command is used to retrieve statistical information from the Host-based Logical Link Control Class 2 component of the LLC2 Driver. Statistics are kept for the station, SAP (Service Access Point), and connection components.
<b>OPTIONS</b>	<p>The following options are supported:</p> <p>-c <i>connection</i>                      Specifies the connection of interest. Its value is entered in hexadecimal notation with no leading 0x.</p> <p>-r                                        Resets the specified counters to zero after reading them. This option is only valid if the <i>root</i> user is executing the command.</p> <p>-s <i>sap</i>                                 Specifies the SAP for this request. It is a single-byte value, expressed in hexadecimal notation with no leading 0x. For example, the NetBIOS sap, 240 (0xf0) would be entered as: -s f0.</p>
<b>OPERANDS</b>	<p>The following operand is supported:</p> <p><i>ppa</i>                                      The logical number used to address the adapter. The PPA (Physical Point of Attachment) must be the first argument.</p>
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Station Statistics</p> <p>The following command will display the station statistics for PPA 4. After the example, a brief description of each field is presented.</p> <pre>example% /usr/lib/llc2/llc2_stats 4</pre> <pre>Station values received: ppa                = 0x00000004  clearFlag = 0x00 # of saps (hex)    = 0x0002 saps (hex)        = 02 aa state             = 0x01 nullSapXidCmdRcvd = 0x00000000 nullSapXidRspSent = 0x00000000 nullSapTestCmdRcvd = 0x00000000 nullSapTestRspSent = 0x00000000 outOfState        = 0x00000000 allocFail         = 0x00000000 protocolError     = 0x00000000</pre> <p>The fields are described as follows:</p> <p><i>ppa</i>                                      The logical number used to address the adapter.</p> <p><i>clearFlag</i>                              This flag indicates if the statistics will be reset to zero after reading (set to a 1) or if the statistics are read only (set to 0).</p>

## llc2\_stats(1)

### EXAMPLE 1 Station Statistics (Continued)

# of saps	The number of SAPs currently bound on this station.
saps	The array of the station's Service Access Point (SAP) logical interface values between the LLC and its adjacent layers.
state	A number indicating the current state of the station component (0 = down, 1 = up).
nullSapXidCmdRcvd	The number of XID command Protocol Data Units (PDUs) received for the NULL SAP address (sap = 0x00).
nullSapXidRspSent	The number of XID response PDUs sent in response to XID command PDUs received for the null SAP address.
nullSapTestCmdRcvd	The number of TEST command PDUs received for the null SAP address.
nullSapTestRspSent	The number of TEST response PDUs sent in response to TEST command PDUs received for the null SAP address.
outOfState	The number of events received in an invalid state.
allocFail	The number of buffer allocation failures.
protocolError	The number of LLC protocol errors, that is, the receipt of malformed PDUs or the receipt of frame X when frame Y was expected.

### EXAMPLE 2 SAP Statistics

In the above display, there are two active SAPs, 0x02 and 0xaa. The following is an example of a command for retrieving the statistics for SAP 02 and a brief explanation of each field presented.

```
example% /usr/lib/llc2/llc2_stats 4 -s 02
```

```
Sap values received:
ppa                = 0x00000004  clearFlag = 0x00
sap                = 0x02
state              = 0x01
# of cons (hex)    = 0x0000000a
connections (hex)  = 0000 0001 0002 0003 0004 0005 0006 0007 0008 0009
xidCmdSent         = 0x00000000
xidCmdRcvd         = 0x00000000
xidRspSent         = 0x00000000
xidRspRcvd         = 0x00000000
testCmdSent        = 0x00000000
testCmdRcvd        = 0x00000000
testRspSent        = 0x00000000
```

**EXAMPLE 2** SAP Statistics (Continued)

```

testRspRcvd      = 0x00000000
uiSent           = 0x00000000
uiRcvd           = 0x00000000
outOfState       = 0x00000000
allocFail        = 0x00000000
protocolError    = 0x00000000

```

The fields are described as follows:

ppa	The logical number used to address the adapter.
clearFlag	This flag indicates if the statistics will be reset to zero after reading (set to a 1) or if the statistics are read only (set to 0).
sap	The specified Service Access Point (SAP) logical interface value for the station.
state	A number indicating the current state of the SAP component (0 = inactive, 1 = active).
# of cons	The number of active connections on this SAP.
connections	The array of active connection indexes.
xidCmdSent	The number of XID command PDUs sent (Source SAP = this sap).
xidCmdRcvd	The number of XID command PDUs received (Destination SAP = this sap).
xidRspSent	The number of XID response PDUs sent (Source SAP = this sap).
xidRspRcvd	The number of XID response PDUs received (Source SAP = this sap).
testCmdSent	The number of TEST command PDUs sent (Source SAP = this sap).
testCmdRcvd	The number of TEST command PDUs received (Destination SAP = this sap).
testRspSent	The number of TEST response PDUs sent (Source SAP = this sap).
testRspRcvd	The number of TEST response PDUs received (Source SAP = this sap).
uiSent	The number of Unnumbered Information Frames sent.
uiRcvd	The number of Unnumbered Information Frames received.

## llc2\_stats(1)

### EXAMPLE 2 SAP Statistics (Continued)

outOfState	The number of events received in an invalid state.
allocFail	The number of buffer allocation failures.
protocolError	The number of LLC protocol errors, that is, the receipt of malformed PDUs or the receipt of frame X when frame Y was expected.

### EXAMPLE 3 Connection Statistics

Ten established connections are associated with this SAP. To retrieve the statistics for connection 1, enter the following command:

```
example% /usr/lib/llc2/llc2_stats 4 -s 2 -c 1
Connection values received:
ppa          = 0x0004  clearFlag    = 0x00
sap          = 0x02    con          = 0x0001  sid          = 0x0201
stateOldest = 0x00    stateOlder  = 0x00    stateOld    = 0x01
state       = 0x08
dl_nodeaddr = 0x0080d84008c2          dl_sap      = 0x04
flag        = 0x50    dataFlag    = 0x00    timerOn     = 0x18
vs          = 0x29    vr          = 0x1e          nrRcvd     = 0x29  k          = 0x14
retryCount  = 0x0000  numToBeAcked = 0x0000  numToResend = 0x0000
macOutSave  = 0x0000  macOutDump  = 0x0000
iSent       = 0x0ba9  iRcvd       = 0x001e
frmrSent    = 0x0000  frmrRcvd    = 0x0000
rrSent      = 0x016a  rrRcvd      = 0x00c1
rnrSent     = 0x0000  rnrRcvd     = 0x06fb
rejSent     = 0x0000  rejRcvd     = 0x0000
sabmeSent   = 0x0000  sabmeRcvd   = 0x0001
uaSent      = 0x0001  uaRcvd      = 0x0000  discSent    = 0x0000
outOfState  = 0x0000  allocFail   = 0x0000  protocolError = 0x0000
localBusy   = 0x0000  remoteBusy  = 0x00b5  maxRetryFail = 0x0000
ackTimerExp = 0x0000  pollTimerExp = 0x0000  rejTimerExp  = 0x0000
remBusyTimerExp = 0x0000
inactTimerExp = 0x0000
sendAckTimerExp = 0x0000
```

ppa	The logical number used to address the adapter.
clearFlag	This flag indicates if the statistics will be reset to zero after reading (set to a 1) or if the statistics are read only (set to 0).
sap	The specified Service Access Point (SAP) logical interface value for the station.
con	The specified connection index value for the SAP.
stateOldest	A number representing the state of the connection component prior to stateOlder.

**EXAMPLE 3** Connection Statistics (Continued)

stateOlder	A number representing the state of the connection component prior to stateOld.
stateOld	A number representing the state of the connection component prior to state.
state	A number representing the most current state of the connection component. See Table 1.
sid	The Station Identifier composed of the SAP (upper byte) and connection index (lower byte).
dl_nodeaddr	The Data Link Node Address. This is the destination node's MAC address.
dl_sap	The destination node's SAP.
flag	The connection component processing flag. See Table 3.
dataFlag	A number representing the status of the data units from received I-frame PDUs (0 = not discarded, 1 = discarded, 2 = busy state entered with REJ PDU outstanding).
timerOn	A number representing the timer activity flag, with each bit representing an active timer for this connection. See Table 2 for timer definitions.
vs	The sequence number of the next I-frame PDU to send.
vr	The expected sequence number of the next I-frame PDU to be received.
nrRcvd	The sequence number plus 1 of the last sent I-frame PDU acknowledged by the remote node.
k	The transmit window size.
retryCount	The retryCount is incremented whenever a timer expiration occurs. These timers protect outbound frames.
numToBeAcked	The number of outbound I-frames awaiting acknowledgement.
numToResend	The number of outbound I-frames to be retransmitted.
macOutSave	No longer used.
macOutDump	No longer used.
iSent	The number of I-frames sent.

## llc2\_stats(1)

**EXAMPLE 3** Connection Statistics *(Continued)*

iRcvd	The number of I-frames received.
frmrSent	The number of Frame Reject PDUs (FRMR) sent.
frmrRcvd	The number of Frame Reject PDUs (FRMR) received.
rrSent	The number of Receiver Ready PDUs (RR) sent.
rrRcvd	The number of Receiver Ready PDUs (RR) received.
rnrSent	The number of Receiver Not Ready PDUs (RNR) sent.
rnrRcvd	The number of Receiver Not Ready PDUs (RNR) received.
rejSent	The number of Reject PDUs (REJ) sent.
rejRcvd	The number of Reject PDUs (REJ) received.
sabmeSent	The number of Set Asynchronous Balanced Mode Extended PDUs (SABME) sent.
sabmeRcvd	The number of Set Asynchronous Balanced Mode Extended PDUs (SABME) received.
uaSent	The number of Unnumbered Acknowledgment PDUs (UA) sent.
uaRcvd	The number of Unnumbered Acknowledgment PDUs (UA) received.
discSent	The number of Disconnect PDUs (DISC) sent.
outOfState	The number of events received in an invalid state.
allocFail	The number of buffer allocation failures.
protocolError	The number of LLC protocol errors, that is, the receipt of malformed PDUs or the receipt of frame X when frame Y was expected.
localBusy	The number of times this component was in local busy state and could not accept I-frames.
remoteBusy	The number of times the remote connection component was busy and could not accept I-frames.
maxRetryFail	The number of failures that occurred because maxRetry was reached.
ackTimerExp	The number of expirations of the Acknowledgement timer.
pollTimerExp	The number of expirations of the Poll timer.

**EXAMPLE 3** Connection Statistics (Continued)

rejTimerExp	The number of expirations of the Reject timer.
remBusyTimerExp	The number of expirations of the Remote Busy timer.
inactTimerExp	The number of expirations of the Inactivity timer.
sendAckTimerExp	The number of expirations of the Send Acknowledgement timer.

<b>NAME</b>	ln – make hard or symbolic links to files
<b>SYNOPSIS</b>	<pre> /usr/bin/ln [-fns] source_file [target] /usr/bin/ln [-fns] source_file... target /usr/xpg4/bin/ln [-fs] source_file [target] /usr/xpg4/bin/ln [-fs] source_file... target </pre>
<b>DESCRIPTION</b>	<p>In the first synopsis form, the <code>ln</code> utility creates a new directory entry (link) for the file specified by <i>source_file</i>, at the destination path specified by <i>target</i>. If <i>target</i> is not specified, the link is made in the current directory. This first synopsis form is assumed when the final operand does not name an existing directory; if more than two operands are specified and the final is not an existing directory, an error will result.</p> <p>In the second synopsis form, the <code>ln</code> utility creates a new directory entry for each file specified by a <i>source_file</i> operand, at a destination path in the existing directory named by <i>target</i>.</p> <p>The <code>ln</code> utility may be used to create both hard links and symbolic links. A hard link is a pointer to a file and is indistinguishable from the original directory entry. Any changes to a file are effective independent of the name used to reference the file. Hard links may not span file systems and may not refer to directories.</p> <p><code>ln</code> by default creates hard links. <i>source_file</i> is linked to <i>target</i>. If <i>target</i> is a directory, another file named <i>source_file</i> is created in <i>target</i> and linked to the original <i>source_file</i>.</p> <p>If <i>target</i> is an existing file and the <code>-f</code> option is not specified, <code>ln</code> will write a diagnostic message to standard error, do nothing more with the current <i>source_file</i>, and go on to any remaining <i>source_files</i>.</p> <p>A symbolic link is an indirect pointer to a file; its directory entry contains the name of the file to which it is linked. Symbolic links may span file systems and may refer to directories.</p> <p>File permissions for <i>target</i> may be different from those displayed with an <code>-l</code> listing of the <code>ls(1)</code> command. To display the permissions of <i>target</i>, use <code>ls -lL</code>. See <code>stat(2)</code> for more information.</p>
<b>/usr/bin/ln</b>	If <code>/usr/bin/ln</code> determines that the mode of <i>target</i> forbids writing, it prints the mode (see <code>chmod(1)</code> ), asks for a response, and reads the standard input for one line. If the response is affirmative, the link occurs, if permissible. Otherwise, the command exits.
<b>/usr/xpg4/bin/ln</b>	When creating a hard link, and the source file is itself a symbolic link, the target will be a hard link to the file referenced by the symbolic link, not to the symbolic link object itself ( <i>source_file</i> ).
<b>OPTIONS</b>	The following options are supported for both <code>/usr/bin/ln</code> and <code>/usr/xpg4/bin/ln</code> :

ln(1)

	<p>-f Links files without questioning the user, even if the mode of <i>target</i> forbids writing. This is the default if the standard input is not a terminal.</p> <p>-s Creates a symbolic link.</p> <p>If the -s option is used with two arguments, <i>target</i> may be an existing directory or a non-existent file. If <i>target</i> already exists and is not a directory, an error is returned. <i>source_file</i> may be any path name and need not exist. If it exists, it may be a file or directory and may reside on a different file system from <i>target</i>. If <i>target</i> is an existing directory, a file is created in directory <i>target</i> whose name is <i>source_file</i> or the last component of <i>source_file</i>. This file is a symbolic link that references <i>source_file</i>. If <i>target</i> does not exist, a file with name <i>target</i> is created and it is a symbolic link that references <i>source_file</i>.</p> <p>If the -s option is used with more than two arguments, <i>target</i> must be an existing directory or an error will be returned. For each <i>source_file</i>, a link is created in <i>target</i> whose name is the last component of <i>source_file</i>. Each new <i>source_file</i> is a symbolic link to the original <i>source_file</i>. The files and <i>target</i> may reside on different file systems.</p>
<b>/usr/bin/ln</b>	<p>The following option is supported for /usr/bin/ln only:</p> <p>-n If <i>target</i> is an existing file, writes a diagnostic message to stderr and goes on to any remaining <i>source_files</i>. The -f option overrides this option. This is the default behavior for /usr/bin/ln and /usr/xpg4/bin/ln, and is silently ignored.</p>
<b>OPERANDS</b>	<p>The following operands are supported:</p> <p><i>source_file</i> A path name of a file to be linked. This can be either a regular or special file. If the -s option is specified, <i>source_file</i> can also be a directory.</p> <p><i>target</i> The path name of the new directory entry to be created, or of an existing directory in which the new directory entries are to be created.</p>
<b>USAGE</b>	<p>See <code>largefile(5)</code> for the description of the behavior of <code>ln</code> when encountering files greater than or equal to 2 Gbyte ( <math>2^{31}</math> bytes).</p>
<b>ENVIRONMENT VARIABLES</b>	<p>See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>ln</code>: <code>LANG</code>, <code>LC_ALL</code>, <code>LC_CTYPE</code>, <code>LC_MESSAGES</code>, and <code>NLSPATH</code>.</p>
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <p>0 All the specified files were linked successfully</p> <p>&gt;0 An error occurred.</p>

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

**/usr/bin/ln**

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled

**/usr/xpg4/bin/ln**

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
CSI	Enabled
Interface Stability	Standard

**SEE ALSO** `chmod(1)`, `ls(1)`, `stat(2)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `standards(5)`

**NOTES** A symbolic link to a directory behaves differently than you might expect in certain cases. While an `ls(1)` command on such a link displays the files in the pointed-to directory, entering `ls -l` displays information about the link itself:

```
example% ln -s dir link
example% ls link
file1 file2 file3 file4
example% ls -l link
lrwxrwxrwx 1 user          7 Jan 11 23:27 link -> dir
```

When you change to a directory (see `cd(1)`) through a symbolic link, using `/usr/bin/sh` or `/usr/bin/csh`, you wind up in the pointed-to location within the file system. This means that the parent of the new working directory is not the parent of the symbolic link, but rather, the parent of the pointed-to directory. This will also happen when using `cd` with the `-P` option from `/usr/bin/ksh` or `/usr/xpg4/bin/sh`. For instance, in the following case, the final working directory is `/usr` and not `/home/user/linktest`.

```
example% pwd
/home/user/linktest
example% ln -s /usr/tmp symlink
example% cd symlink
example% cd . .
example% pwd
/usr
```

C shell users can avoid any resulting navigation problems by using the `pushd` and `popd` built-in commands instead of `cd`.

ln(1B)

<b>NAME</b>	ln – make hard or symbolic links to files
<b>SYNOPSIS</b>	<pre>/usr/ucb/ln [-fs] filename [linkname] /usr/ucb/ln [-fs] pathname... directory</pre>
<b>DESCRIPTION</b>	<p>The <code>/usr/ucb/ln</code> utility creates an additional directory entry, called a link, to a file or directory. Any number of links can be assigned to a file. The number of links does not affect other file attributes such as size, protections, data, etc.</p> <p><i>filename</i> is the name of the original file or directory. <i>linkname</i> is the new name to associate with the file or filename. If <i>linkname</i> is omitted, the last component of <i>filename</i> is used as the name of the link.</p> <p>If the last argument is the name of a directory, symbolic links are made in that directory for each <i>pathname</i> argument; <code>/usr/ucb/ln</code> uses the last component of each <i>pathname</i> as the name of each link in the named <i>directory</i>.</p> <p>A hard link (the default) is a standard directory entry just like the one made when the file was created. Hard links can only be made to existing files. Hard links cannot be made across file systems (disk partitions, mounted file systems). To remove a file, all hard links to it must be removed, including the name by which it was first created; removing the last hard link releases the inode associated with the file.</p> <p>A symbolic link, made with the <code>-s</code> option, is a special directory entry that points to another named file. Symbolic links can span file systems and point to directories. In fact, you can create a symbolic link that points to a file that is currently absent from the file system; removing the file that it points to does not affect or alter the symbolic link itself.</p> <p>A symbolic link to a directory behaves differently than you might expect in certain cases. While an <code>ls(1)</code> on such a link displays the files in the pointed-to directory, an <code>'ls -l'</code> displays information about the link itself:</p> <pre>example% /usr/ucb/ln -s dir link example% ls link file1 file2 file3 file4 example% ls -l link lrwxrwxrwx 1 user          7 Jan 11 23:27 link -&gt; dir</pre> <p>When you use <code>cd(1)</code> to change to a directory through a symbolic link, you wind up in the pointed-to location within the file system. This means that the parent of the new working directory is not the parent of the symbolic link, but rather, the parent of the pointed-to directory. For instance, in the following case the final working directory is <code>/usr</code> and not <code>/home/user/linktest</code>.</p> <pre>example% pwd /home/user/linktest example% /usr/ucb/ln -s /var/tmp symlink example% cd symlink example% cd . . example% pwd /usr</pre>

C shell users can avoid any resulting navigation problems by using the `pushd` and `popd` built-in commands instead of `cd`.

**OPTIONS**

- `-f` Force a hard link to a directory. This option is only available to the super-user, and should be used with extreme caution.
- `-s` Create a symbolic link or links.

**USAGE** See `largefile(5)` for the description of the behavior of `ln` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**EXAMPLES** **EXAMPLE 1** The `/usr/ucb/ln` command

The commands below illustrate the effects of the different forms of the `/usr/ucb/ln` command:

```
example% /usr/ucb/ln file link
example% ls -F file link
file  link
example% /usr/ucb/ln -s file symlink
example% ls -F file symlink
file  symlink@
example% ls -li file link symlink
 10606 -rw-r--r--  2 user          0 Jan 12 00:06 file
 10606 -rw-r--r--  2 user          0 Jan 12 00:06 link
 10607 lrwxrwxrwx  1 user          4 Jan 12 00:06 symlink -> file
example% /usr/ucb/ln -s nonesuch devoid
example% ls -F devoid
devoid@
example% cat devoid
devoid: No such file or directory
example% /usr/ucb/ln -s /proto/bin/* /tmp/bin
example% ls -F /proto/bin /tmp/bin
/proto/bin:
x*      y*      z*

/tmp/bin:
x@      y@      z@
```

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

**SEE ALSO** `cp(1)`, `ls(1)`, `mv(1)`, `rm(1)`, `link(2)`, `readlink(2)`, `stat(2)`, `symlink(2)`, `attributes(5)`, `largefile(5)`

**NOTES** When the last argument is a directory, simple basenames should not be used for *pathname* arguments. If a basename is used, the resulting symbolic link points to itself:

```
example% /usr/ucb/ln -s file /tmp
example% ls -l /tmp/file
lrwxrwxrwx  1 user          4 Jan 12 00:16 /tmp/file -> file
example% cat /tmp/file
```

ln(1B)

```
/tmp/file: Too many levels of symbolic links
```

To avoid this problem, use full pathnames, or prepend a reference to the PWD variable to files in the working directory:

```
example% rm /tmp/file
example% /usr/ucb/ln -s $PWD/file /tmp
lrwxrwxrwx  1 user 4      Jan 12 00:16 /tmp/file ->
/home/user/subdir/file
```

<b>NAME</b>	loadkeys, dumpkeys – load and dump keyboard translation tables						
<b>SYNOPSIS</b>	<b>loadkeys</b> [ <i>filename</i> ] <b>dumpkeys</b>						
<b>DESCRIPTION</b>	<p>loadkeys reads the file specified by <i>filename</i>, and modifies the keyboard streams module's translation tables. If no file is specified, loadkeys loads the file: <code>/usr/share/lib/keytables/type_</code><i>tt</i><code>/layout_</code><i>dd</i>, where <i>tt</i> is the value returned by the <code>KIOCTYPE ioctl</code>, and <i>dd</i> is the value returned by the <code>KIOCLAYOUT ioctl</code> (see <code>kb(7M)</code>). These keytable files specify only the entries that change between the specified layout and the default layout for the particular keyboard type. On self-identifying keyboards, the value returned by the <code>KIOCLAYOUT ioctl</code> is set from the DIP switches.</p> <p>dumpkeys writes the current contents of the keyboard streams module's translation tables, in the format specified by <code>keytables(4)</code>, to the standard output.</p>						
<b>FILES</b>	<code>/usr/share/lib/keytables/layout_</code> <i>dd</i> default keytable files						
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:						
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> <tr> <td>Interface Stability</td> <td>Evolving</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu	Interface Stability	Evolving
ATTRIBUTE TYPE	ATTRIBUTE VALUE						
Availability	SUNWcsu

<b>SEE ALSO</b>	<code>kbd(1)</code> , <code>keytables(4)</code> , <code>attributes(5)</code> , <code>kb(7M)</code> , <code>usbkbm(7M)</code>						

## locale(1)

<b>NAME</b>	locale – get locale-specific information
<b>SYNOPSIS</b>	<b>locale</b> [-a   -m] <b>locale</b> [-ck] <i>name...</i>
<b>DESCRIPTION</b>	<p>The <code>locale</code> utility writes information about the current locale environment, or all public locales, to the standard output. For the purposes of this section, a <i>public locale</i> is one provided by the implementation that is accessible to the application.</p> <p>When <code>locale</code> is invoked without any arguments, it summarizes the current locale environment for each locale category as determined by the settings of the environment variables.</p> <p>When invoked with operands, it writes values that have been assigned to the keywords in the locale categories, as follows:</p> <ul style="list-style-type: none"><li>■ Specifying a keyword name selects the named keyword and the category containing that keyword.</li><li>■ Specifying a category name selects the named category and all keywords in that category.</li></ul>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"><li>-a       Writes information about all available public locales. The available locales include <code>POSIX</code>, representing the <code>POSIX</code> locale.</li><li>-c       Writes the names of selected locale categories. The <code>-c</code> option increases readability when more than one category is selected (for example, via more than one keyword name or via a category name). It is valid both with and without the <code>-k</code> option.</li><li>-k       Writes the names and values of selected keywords. The implementation may omit values for some keywords; see <code>OPERANDS</code>.</li><li>-m       Writes names of available charmaps; see <code>localedef(1)</code>.</li></ul>
<b>OPERANDS</b>	<p>The following operand is supported:</p> <p><i>name</i>     The name of a locale category, the name of a keyword in a locale category, or the reserved name <code>charmap</code>. The named category or keyword will be selected for output. If a single <i>name</i> represents both a locale category name and a keyword name in the current locale, the results are unspecified; otherwise, both category and keyword names can be specified as <i>name</i> operands, in any sequence.</p>
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Examples of the locale utility</p> <p>In the following examples, the assumption is that locale environment variables are set as follows:</p> <pre>LANG=locale_x LC_COLLATE=locale_y</pre>

**EXAMPLE 1** Examples of the locale utility (Continued)

The command `locale` would result in the following output:

```
LANG=locale_x
LC_CTYPE="locale_x"
LC_NUMERIC="locale_x"
LC_TIME="locale_x"
LC_COLLATE=locale_y
LC_MONETARY="locale_x"
LC_MESSAGES="locale_x"
LC_ALL=
```

The command

```
LC_ALL=POSIX locale -ck decimal_point
```

would produce:

```
LC_NUMERIC
decimal_point="."
```

The following command shows an application of `locale` to determine whether a user-supplied response is affirmative:

```
if printf "%s\n" "$response" | /usr/xpg4/bin/grep -Eq\
    "$(locale yesexpr)"
then
    affirmative processing goes here
else
    non-affirmative processing goes here
fi
```

**ENVIRONMENT VARIABLES**

See `environ(5)` for the descriptions of `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

The `LANG`, `LC_*`, and `NLSPATH` environment variables must specify the current locale environment to be written out. These environment variables will be used if the `-a` option is not specified.

**EXIT STATUS**

The following exit values are returned:

- 0 All the requested information was found and output successfully.
- >0 An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWloc
CSI	Enabled

locale(1)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Standard

**SEE ALSO** [localedef\(1\)](#), [attributes\(5\)](#), [charmap\(5\)](#), [environ\(5\)](#), [locale\(5\)](#), [standards\(5\)](#)

**NOTES** If LC\_CTYPE or keywords in the category LC\_CTYPE are specified, only the values in the range 0x00-0x7f are written out.

If LC\_COLLATE or keywords in the category LC\_COLLATE are specified, no actual values are written out.

<b>NAME</b>	localedef – define locale environment												
<b>SYNOPSIS</b>	<b>localedef</b> [-c] [-C <i>compiler_options</i> ] [-f <i>charmap</i> ] [-i <i>sourcefile</i> ] [-L <i>linker_options</i> ] [-m <i>model</i> ] [-u <i>code_set_name</i> ] [-W <i>cc, arg</i> ] [-x <i>extensions_file</i> ] <i>localename</i>												
<b>DESCRIPTION</b>	<p>The <code>localedef</code> utility converts source definitions for locale categories into a format usable by the functions and utilities whose operational behavior is determined by the setting of the locale environment variables; see <code>environ(5)</code>.</p> <p>The utility reads source definitions for one or more locale categories belonging to the same locale from the file named in the <code>-i</code> option (if specified) or from standard input.</p> <p>Each category source definition is identified by the corresponding environment variable name and terminated by an <code>END category-name</code> statement. The following categories are supported.</p> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;">LC_CTYPE</td> <td>Defines character classification and case conversion.</td> </tr> <tr> <td>LC_COLLATE</td> <td>Defines collation rules.</td> </tr> <tr> <td>LC_MONETARY</td> <td>Defines the format and symbols used in formatting of monetary information.</td> </tr> <tr> <td>LC_NUMERIC</td> <td>Defines the decimal delimiter, grouping and grouping symbol for non-monetary numeric editing.</td> </tr> <tr> <td>LC_TIME</td> <td>Defines the format and content of date and time information.</td> </tr> <tr> <td>LC_MESSAGES</td> <td>Defines the format and values of affirmative and negative responses.</td> </tr> </table>	LC_CTYPE	Defines character classification and case conversion.	LC_COLLATE	Defines collation rules.	LC_MONETARY	Defines the format and symbols used in formatting of monetary information.	LC_NUMERIC	Defines the decimal delimiter, grouping and grouping symbol for non-monetary numeric editing.	LC_TIME	Defines the format and content of date and time information.	LC_MESSAGES	Defines the format and values of affirmative and negative responses.
LC_CTYPE	Defines character classification and case conversion.												
LC_COLLATE	Defines collation rules.												
LC_MONETARY	Defines the format and symbols used in formatting of monetary information.												
LC_NUMERIC	Defines the decimal delimiter, grouping and grouping symbol for non-monetary numeric editing.												
LC_TIME	Defines the format and content of date and time information.												
LC_MESSAGES	Defines the format and values of affirmative and negative responses.												
<b>OPTIONS</b>	<p>The following options are supported:</p> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;">-c</td> <td>Creates permanent output even if warning messages have been issued.</td> </tr> <tr> <td style="padding-right: 20px;">-C <i>compiler_options</i></td> <td>Passes the <i>compiler_options</i> to the C compiler (<code>cc</code>). If more than one option is specified, then the options must be enclosed in quotes (" ").</td> </tr> <tr> <td style="padding-right: 20px;">-f <i>charmap</i></td> <td>This is an old option. Use the <code>-W cc,arg</code> option instead.                  Specifies the pathname of a file containing a mapping of character symbols and collating element symbols to actual character encodings. This option must be specified if symbolic names (other than collating symbols defined in a <code>collating-symbol</code> keyword) are used. If the <code>-f</code> option is not present, the default character mapping will be used.</td> </tr> </table>	-c	Creates permanent output even if warning messages have been issued.	-C <i>compiler_options</i>	Passes the <i>compiler_options</i> to the C compiler ( <code>cc</code> ). If more than one option is specified, then the options must be enclosed in quotes (" ").	-f <i>charmap</i>	This is an old option. Use the <code>-W cc,arg</code> option instead. Specifies the pathname of a file containing a mapping of character symbols and collating element symbols to actual character encodings. This option must be specified if symbolic names (other than collating symbols defined in a <code>collating-symbol</code> keyword) are used. If the <code>-f</code> option is not present, the default character mapping will be used.						
-c	Creates permanent output even if warning messages have been issued.												
-C <i>compiler_options</i>	Passes the <i>compiler_options</i> to the C compiler ( <code>cc</code> ). If more than one option is specified, then the options must be enclosed in quotes (" ").												
-f <i>charmap</i>	This is an old option. Use the <code>-W cc,arg</code> option instead. Specifies the pathname of a file containing a mapping of character symbols and collating element symbols to actual character encodings. This option must be specified if symbolic names (other than collating symbols defined in a <code>collating-symbol</code> keyword) are used. If the <code>-f</code> option is not present, the default character mapping will be used.												

## localedef(1)

<code>-i sourcefile</code>	The path name of a file containing the source definitions. If this option is not present, source definitions will be read from standard input.
<code>-L linker_options</code>	Passes the <i>linker_options</i> to the C compiler (cc) that follows the C source filename. If more than one option is specified, then the options must be enclosed in quotes (" ").
<code>-m model</code>	This is an old option. Use the <code>-W cc,arg</code> option instead. Specifies whether <code>localedef</code> will generate a 64-bit or a 32-bit locale object.  Specify <i>model</i> as <code>ilp32</code> to generate a 32-bit locale object. Specify <code>lp64</code> to generate a 64-bit locale object. If the <code>-m</code> option is not specified, <code>localedef</code> generates a 32-bit locale object. And if no other options than <code>-c</code> , <code>-f</code> , and <code>-i</code> options are specified and if the system running <code>localedef</code> supports the 64-bit environment, <code>localedef</code> additionally generates a 64-bit locale object.
<code>-u code_set_name</code>	Specifies the name of a codeset used as the target mapping of character symbols and collating element symbols whose encoding values are defined in terms of the ISO/IEC 10646-1: 2000 standard position constant values. See NOTES.
<code>-W cc,arg</code>	Passes <i>arg</i> options to the C compiler. Each argument must be separated from the preceding by only a comma. A comma can be part of an argument by escaping it withan immediately preceding backslash character; the backslash is removed from the resulting argument.  Use this option instead of the <code>-C</code> and <code>-L</code> options.
<code>-x extensions_file</code>	Specifies the name of an extension file where various <code>localedef</code> options are listed. See <code>locale(5)</code> .

### OPERANDS

The following operand is supported:

<i>localename</i>	Identifies the locale. If the name contains one or more slash characters, <i>localename</i> will be interpreted as a path name where the created locale definitions will be stored. This capability may be restricted to users with appropriate privileges. (As a consequence of specifying one <i>localename</i> , although several categories can be processed in one execution, only categories belonging to the same locale can be processed.)
-------------------	--

**OUTPUT** localedef creates a temporary C source file that represents the locale's data. localedef then calls the C compiler to compile this C source file into a shared object.

If the `-m ilp32` option is specified, localedef calls the C compiler for generating 32-bit objects and generates a 32-bit locale object. If the `-m lp64` option is specified, localedef calls the C compiler for generating 64-bit objects and generates a 64-bit locale object.

If the `-m` option is not specified, localedef calls the C compiler for generating 32-bit objects and generates a 32-bit locale object. If no other options than `-c`, `-f`, and `-i` options are specified and if the system running localedef supports the 64-bit environment, localedef additionally calls the C compiler for generating 64-bit objects and generates a 64-bit locale object.

If no option to the C compiler is explicitly specified using the `-W`, `-C`, or `-L` options, localedef calls the C compiler with appropriate C compiler options to generate a locale object or objects.

If the `-m ilp32` option is specified, localedef generates a 32-bit locale object named:

*localename.so.version\_number*

If the `-m lp64` option is specified, localedef generates a 64-bit locale object named:

*localename.so.version\_number*

If the `-m` option is not specified, localedef generates a 32-bit locale object named:

*localename.so.version\_number*

and, if appropriate, generates a 64-bit locale object named:

*64-bit\_architecture\_name/localename.so.version\_number*

The shared object for the 32-bit environment must be moved to:

*/usr/lib/locale/localename/localename.so.version\_number*

The shared object for the 64-bit environment on SPARC must be moved to:

*/usr/lib/locale/localename/sparcv9/localename.so.version\_number*

The shared object for the 64-bit environment on AMD64 must be moved to:

*/usr/lib/locale/<localename>/amd64/<localename>.so.<version\_number>*

localedef also generates a text file named *localename* that is used for information only.

## localedef(1)

**ENVIRONMENT VARIABLES** See [environ\(5\)](#) for definitions of the following environment variables that affect the execution of `localedef`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS** The following exit values are returned:

0	No errors occurred and the locales were successfully created.
1	Warnings occurred and the locales were successfully created.
2	The locale specification exceeded implementation limits or the coded character set or sets used were not supported by the implementation, and no locale was created.
3	The capability to create new locales is not supported by the implementation.
>3	Warnings or errors occurred and no output was created.

If an error is detected, no permanent output will be created.

**FILES**

- `/usr/lib/localedef/extensions/generic_eucbc.x`  
Describes what a generic EUC locale uses in the system. This file is used by default.
- `/usr/lib/localedef/extensions/single_byte.x`  
Describes a generic single-byte file used in the system.
- `/usr/lib/locale/localename/localename.so.version_number`  
The shared object for the 32-bit environment.
- `/usr/lib/locale/localename/sparcv9/localename.so.version_number`  
The shared object for the 64-bit environment on SPARC.
- `/usr/lib/locale/<localename>/amd64/<localename>.so.<version_number>`  
The shared object for the 64-bit environment on AMD64.

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Standard

**SEE ALSO** [locale\(1\)](#), [iconv\\_open\(3C\)](#), [nl\\_langinfo\(3C\)](#), [strftime\(3C\)](#), [attributes\(5\)](#), [charmap\(5\)](#), [environ\(5\)](#), [extensions\(5\)](#), [locale\(5\)](#), [standards\(5\)](#)

**WARNINGS** If warnings occur, permanent output will be created if the `-c` option was specified. The following conditions will cause warning messages to be issued:

- If a symbolic name not found in the `charmap` file is used for the descriptions of the `LC_CTYPE` or `LC_COLLATE` categories (for other categories, this will be an error conditions).

- If optional keywords not supported by the implementation are present in the source.

**NOTES** When the `-u` option is used, the `code_set_name` option-argument is interpreted as a name of a codeset to which the ISO/IEC 10646-1: 2000 standard position constant values are converted. Both the ISO/IEC 10646-1: 2000 standard position constant values and other formats (decimal, hexadecimal, or octal) are valid as encoding values within the charmap file. The codeset can be any codeset that is supported by the `iconv_open(3C)` function on the system.

When conflicts occur between the charmap specification of `code_set_name`, `mb_cur_max`, or `mb_cur_min` and the corresponding value for the codeset represented by the `-u` option-argument `code_set_name`, the `localedef` utility fails as an error.

When conflicts occur between the charmap encoding values specified for symbolic names of characters of the portable character set and the character encoding values defined by the US-ASCII, the result is unspecified.

If a non-printable character in the charmap has a width specified that is not `-1`, `localedef` generates a warning.

## logger(1)

<b>NAME</b>	logger – add entries to the system log
<b>SYNOPSIS</b>	<b>logger</b> [-i] [-f <i>file</i> ] [-p <i>priority</i> ] [-t <i>tag</i> ] [ <i>message</i> ] ...
<b>DESCRIPTION</b>	The <b>logger</b> command provides a method for adding one-line entries to the system log file from the command line. One or more <i>message</i> arguments can be given on the command line, in which case each is logged immediately. If this is unspecified, either the file indicated with -f or the standard input is added to the log. Otherwise, a <i>file</i> can be specified, in which case each line in the file is logged. If neither is specified, <b>logger</b> reads and logs messages on a line-by-line basis from the standard input.
<b>OPTIONS</b>	The following options are supported:  -f <i>file</i> Uses the contents of <i>file</i> as the message to log. -i                      Logs the process ID of the <b>logger</b> process with each line. -p <i>priority</i> Enters the message with the specified <i>priority</i> . The message priority can be specified numerically, or as a <i>facility.level</i> pair. For example, '-p local3.info' assigns the message priority to the info level in the local3 facility. The default priority is user.notice. -t <i>tag</i> Marks each line added to the log with the specified <i>tag</i> .
<b>OPERANDS</b>	The following operand is supported:  <i>message</i> One of the string arguments whose contents are concatenated together, in the order specified, separated by single space characters.
<b>EXAMPLES</b>	<b>EXAMPLE 1</b> Examples of the <b>logger</b> command  The following example:  example% <b>logger</b> System rebooted  logs the message 'System rebooted' to the default priority level notice to be treated by <b>syslogd</b> as are other messages to the facility user.  The next example:  example% <b>logger</b> -p local0.notice -t HOSTIDM -f /dev/idmc  reads from the file /dev/idmc and logs each line in that file as a message with the tag 'HOSTIDM' at priority level notice to be treated by <b>syslogd</b> as are other messages to the facility local0.
<b>ENVIRONMENT VARIABLES</b>	See <b>environ(5)</b> for descriptions of the following environment variables that affect the execution of <b>logger</b> : LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.
<b>EXIT STATUS</b>	The following exit values are returned:  0                      Successful completion.

logger(1)

>0 An error occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Standard

**SEE ALSO** `mailx(1)`, `write(1)`, `syslogd(1M)`, `syslog(3C)`, `attributes(5)`, `environ(5)`, `standards(5)`

logger(1B)

**NAME** logger – add entries to the system log

**SYNOPSIS** /usr/ucb/logger [-f *filename*] [-i] [-p *priority*] [-t *tag*] mm [*message*]...

**DESCRIPTION** The logger utility provides a method for adding one-line entries to the system log file from the command line. One or more *message* arguments can be given on the command line, in which case each is logged immediately. If *message* is unspecified, either the file indicated with -f or the standard input is added to the log. Otherwise, a *filename* can be specified, in which case each line in the file is logged. If neither is specified, logger reads and logs messages on a line-by-line basis from the standard input.

**OPTIONS** The following options are supported:

- i Log the process ID of the logger process with each line.
- f *filename* Use the contents of *filename* as the message to log.
- p *priority* Enter the message with the specified *priority*. The message priority can be specified numerically, or as a *facility.level* pair. For example, '-p local3.info' assigns the message priority to the info level in the local3 facility. The default priority is user.notice.
- t *tag* Mark each line added to the log with the specified *tag*.

**EXAMPLES**

**EXAMPLE 1** Logging a message

The command:

```
example% logger System rebooted
```

will log the message 'System rebooted' to the facility at priority notice to be treated by syslogd as other messages to the facility notice are.

**EXAMPLE 2** Logging messages from a file

The command:

```
example% logger -p local0.notice -t HOSTIDM -f /dev/idmc
```

will read from the file /dev/idmc and will log each line in that file as a message with the tag 'HOSTIDM' at priority notice to be treated by syslogd as other messages to the facility local0 are.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

**SEE ALSO** syslogd(1M), syslog(3C), attributes(5)

<b>NAME</b>	login – sign on to the system
<b>SYNOPSIS</b>	<b>login</b> [-p] [-d <i>device</i> ] [-R <i>repository</i> ] [-s <i>service</i> ] [-t <i>terminal</i> ] [-u <i>identity</i> ] [-U <i>ruser</i> ] [-h <i>hostname</i> [ <i>terminal</i> ]-r <i>hostname</i> ] [ <i>name</i> [ <i>environ</i> ] ...]
<b>DESCRIPTION</b>	<p>The <code>login</code> command is used at the beginning of each terminal session to identify oneself to the system. <code>login</code> is invoked by the system when a connection is first established, after the previous user has terminated the login shell by issuing the <code>exit</code> command.</p> <p>If <code>login</code> is invoked as a command, it must replace the initial command interpreter. To invoke <code>login</code> in this fashion, type:</p> <pre>exec login</pre> <p>from the initial shell. The C shell and Korn shell have their own builtins of <code>login</code>. See <a href="#">ksh(1)</a> and <a href="#">csh(1)</a> for descriptions of login builtins and usage.</p> <p><code>login</code> asks for your user name, if it is not supplied as an argument, and your password, if appropriate. Where possible, echoing is turned off while you type your password, so it will not appear on the written record of the session.</p> <p>If you make any mistake in the login procedure, the message:</p> <pre>Login incorrect</pre> <p>is printed and a new login prompt will appear. If you make five incorrect login attempts, all five may be logged in <code>/var/adm/loginlog</code>, if it exists. The TTY line will be dropped.</p> <p>If password aging is turned on and the password has "aged" (see <a href="#">passwd(1)</a> for more information), the user is forced to change the password. In this case the <code>/etc/nsswitch.conf</code> file is consulted to determine password repositories (see <a href="#">nsswitch.conf(4)</a>). The password update configurations supported are limited to the following five cases.</p> <ul style="list-style-type: none"> <li>■ <code>passwd: files</code></li> <li>■ <code>passwd: files nis</code></li> <li>■ <code>passwd: files nisplus</code></li> <li>■ <code>passwd: compat (==&gt; files nis)</code></li> <li>■ <code>passwd: compat (==&gt; files nisplus)</code></li> </ul> <pre>passwd_compat: nisplus</pre> <p>Failure to comply with the configurations will prevent the user from logging onto the system because <a href="#">passwd(1)</a> will fail. If you do not complete the login successfully within a certain period of time, it is likely that you will be silently disconnected.</p> <p>After a successful login, accounting files are updated. Device owner, group, and permissions are set according to the contents of the <code>/etc/logindevperm</code> file, and the time you last logged in is printed (see <a href="#">logindevperm(4)</a>).</p>

## login(1)

The user-ID, group-ID, supplementary group list, and working directory are initialized, and the command interpreter (usually ksh) is started.

The basic *environment* is initialized to:

```
HOME=your-login-directory
LOGNAME=your-login-name
PATH=/usr/bin:
SHELL=last-field-of-passwd-entry
MAIL=/var/mail/
TZ=timezone-specification
```

For Bourne shell and Korn shell logins, the shell executes `/etc/profile` and `$HOME/.profile`, if it exists. For C shell logins, the shell executes `/etc/.login`, `$HOME/.cshrc`, and `$HOME/.login`. The default `/etc/profile` and `/etc/.login` files check quotas (see `quota(1M)`), print `/etc/motd`, and check for mail. None of the messages are printed if the file `$HOME/.hushlogin` exists. The name of the command interpreter is set to `-` (dash), followed by the last component of the interpreter's path name, for example, `-sh`.

If the *login-shell* field in the password file (see `passwd(4)`) is empty, then the default command interpreter, `/usr/bin/sh`, is used. If this field is `*` (asterisk), then the named directory becomes the root directory. At that point, `login` is re-executed at the new level, which must have its own root structure.

The environment may be expanded or modified by supplying additional arguments to `login`, either at execution time or when `login` requests your login name. The arguments may take either the form `xxx` or `xxx=yyy`. Arguments without an `=` (equal sign) are placed in the environment as:

```
Ln=xxx
```

where *n* is a number starting at 0 and is incremented each time a new variable name is required. Variables containing an `=` (equal sign) are placed in the environment without modification. If they already appear in the environment, then they replace the older values.

There are two exceptions: The variables `PATH` and `SHELL` cannot be changed. This prevents people logged into restricted shell environments from spawning secondary shells that are not restricted. `login` understands simple single-character quoting conventions. Typing a `\` (backslash) in front of a character quotes it and allows the inclusion of such characters as spaces and tabs.

Alternatively, you can pass the current environment by supplying the `-p` flag to `login`. This flag indicates that all currently defined environment variables should be passed, if possible, to the new environment. This option does not bypass any environment variable restrictions mentioned above. Environment variables specified on the login line take precedence, if a variable is passed by both methods.

To enable remote logins by root, edit the `/etc/default/login` file by inserting a `#` (pound sign) before the `CONSOLE=/dev/console` entry. See `FILES`.

**SECURITY** For accounts in name services which support automatic account locking, the account may be configured to be automatically locked (see `user_attr(4)` and `policy.conf(4)`) if successive failed login attempts equals or exceeds `RETRIES`. Currently, only the "files" repository (see `passwd(4)` and `shadow(4)`) supports automatic account locking. See also `pam_unix_auth(5)`.

The `login` command uses `pam(3PAM)` for authentication, account management, session management, and password management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the modules to be used for `login`. Here is a partial `pam.conf` file with entries for the `login` command using the UNIX authentication, account management, and session management modules:

```
login auth      required pam_authtok_get.so.1
login auth      required pam_dhkeys.so.1
login auth      required pam_unix_auth.so.1
login auth      required pam_dial_auth.so.1

login account   requisite pam_roles.so.1
login account   required pam_projects.so.1
login account   required pam_unix_account.so.1

login session   required pam_unix_session.so.1
```

The Password Management stack looks like the following:

```
other password  required pam_dhkeys.so.1
other password  requisite pam_authtok_get.so.1
other password  requisite pam_authtok_check.so.1
other password  required pam_authtok_store.so.1
```

If there are no entries for the service, then the entries for the "other" service will be used. If multiple authentication modules are listed, then the user may be prompted for multiple passwords.

When `login` is invoked through `rlogind` or `telnetd`, the service name used by PAM is `rlogin` or `telnet`, respectively.

**OPTIONS** The following options are supported:

`-d device`

`login` accepts a device option, *device*. *device* is taken to be the path name of the TTY port `login` is to operate on. The use of the device option can be expected to improve `login` performance, since `login` will not need to call `ttyname(3C)`. The `-d` option is available only to users whose UID and effective UID are root. Any other attempt to use `-d` will cause `login` to quietly exit.

`-h hostname [ terminal ]`

Used by `in.telnetd(1M)` to pass information about the remote host and terminal type.

Terminal type as a second argument to the `-h` option should not start with a hyphen (-).

`-p`

Used to pass environment variables to the `login` shell.

## login(1)

- r *hostname*  
Used by `in.rlogind(1M)` to pass information about the remote host.
- R *repository*  
Used to specify the PAM repository that should be used to tell PAM about the “identity” (see option -u below). If no “identity” information is passed, the repository is not used.
- s *service*  
Indicates the PAM service name that should be used. Normally, this argument is not necessary and is used only for specifying alternative PAM service names. For example: “`ktelnet`” for the Kerberized telnet process.
- u *identity*  
Specifies the “identity” string associated with the user who is being authenticated. This will usually *not* be the same as that user’s Unix login name. For Kerberized login sessions, this will be the Kerberos principal name associated with the user.
- U *ruser*  
Indicates the name of the person attempting to login on the remote side of the `rlogin` connection. When `in.rlogind(1M)` is operating in Kerberized mode, that daemon will process the terminal and remote user name information prior to invoking `login`, so the “`ruser`” data is indicated using this command line parameter. Normally (non-Kerberos authenticated `rlogin`), the `login` daemon will read the remote user information from the client.

**EXIT STATUS** The following exit values are returned:

- 0 Successful operation.
- non-zero Error.

FILES		
	<code>\$HOME/.cshrc</code>	initial commands for each <code>cs</code> h
	<code>\$HOME/.hushlogin</code>	suppresses login messages
	<code>\$HOME/.login</code>	user’s login commands for <code>cs</code> h
	<code>\$HOME/.profile</code>	user’s login commands for <code>sh</code> and <code>ksh</code>
	<code>\$HOME/.rhosts</code>	private list of trusted hostname/username combinations
	<code>/etc/.login</code>	system-wide <code>cs</code> h login commands
	<code>/etc/issue</code>	issue or project identification
	<code>/etc/logindevperm</code>	login-based device permissions
	<code>/etc/motd</code>	message-of-the-day
	<code>/etc/nologin</code>	message displayed to users attempting to login during machine shutdown
	<code>/etc/passwd</code>	password file

<code>/etc/profile</code>	system-wide sh and ksh login commands
<code>/etc/shadow</code>	list of users' encrypted passwords
<code>/usr/bin/sh</code>	user's default command interpreter
<code>/var/adm/lastlog</code>	time of last login
<code>/var/adm/loginlog</code>	record of failed login attempts
<code>/var/adm/utmpx</code>	accounting
<code>/var/adm/wtmpx</code>	accounting
<code>/var/mail/<i>your-name</i></code>	mailbox for user <i>your-name</i>
<code>/etc/default/login</code>	Default value can be set for the following flags in <code>/etc/default/login</code> . For example: <code>TIMEZONE=EST5EDT</code> <b>TIMEZONE</b> Sets the TZ environment variable of the shell (see <code>environ(5)</code> ). <b>HZ</b> Sets the HZ environment variable of the shell. <b>ULIMIT</b> Sets the file size limit for the login. Units are disk blocks. Default is zero (no limit). <b>CONSOLE</b> If set, root can login on that device only. This will not prevent execution of remote commands with <code>rsh(1)</code> . Comment out this line to allow login by root. <b>PASSREQ</b> Determines if login requires a non-null password. <b>ALTSHELL</b> Determines if login should set the SHELL environment variable. <b>PATH</b> Sets the initial shell PATH variable. <b>SUPATH</b> Sets the initial shell PATH variable for root. <b>TIMEOUT</b> Sets the number of seconds (between 0 and 900) to wait before abandoning a login session. <b>UMASK</b> Sets the initial shell file creation mode mask. See <code>umask(1)</code> .

## login(1)

### SYSLOG

Determines whether the `syslog(3C)` `LOG_AUTH` facility should be used to log all root logins at level `LOG_NOTICE` and multiple failed login attempts at `LOG_CRIT`.

### DISABLETIME

If present, and greater than zero, the number of seconds that `login` will wait after `RETRIES` failed attempts or the PAM framework returns `PAM_ABORT`. Default is 20 seconds. Minimum is 0 seconds. No maximum is imposed.

### SLEEPTIME

If present, sets the number of seconds to wait before the login failure message is printed to the screen. This is for any login failure other than `PAM_ABORT`. Another login attempt is allowed, providing `RETRIES` has not been reached or the PAM framework is returned `PAM_MAXTRIES`. Default is 4 seconds. Minimum is 0 seconds. Maximum is 5 seconds.

Both `su(1M)` and `sulogin(1M)` are affected by the value of `SLEEPTIME`.

### RETRIES

Sets the number of retries for logging in (see `pam(3PAM)`). The default is 5. The maximum number of retries is 15. For accounts configured with automatic locking (see `SECURITY` above), the account is locked and `login` exits. If automatic locking has not been configured, `login` exits without locking the account.

### SYSLOG\_FAILED\_LOGINS

Used to determine how many failed login attempts will be allowed by the system before a failed login message is logged, using the `syslog(3C)` `LOG_NOTICE` facility. For example, if the variable is set to 0, `login` will log *all* failed login attempts.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Evolving

**SEE ALSO** [csh\(1\)](#), [exit\(1\)](#), [ksh\(1\)](#), [mail\(1\)](#), [mailx\(1\)](#), [newgrp\(1\)](#), [passwd\(1\)](#), [rlogin\(1\)](#), [rsh\(1\)](#), [sh\(1\)](#), [shell\\_builtins\(1\)](#), [telnet\(1\)](#), [umask\(1\)](#), [in.rlogind\(1M\)](#), [in.telnetd\(1M\)](#), [logins\(1M\)](#), [quota\(1M\)](#), [su\(1M\)](#), [sulogin\(1M\)](#), [syslogd\(1M\)](#), [useradd\(1M\)](#), [userdel\(1M\)](#), [pam\(3PAM\)](#), [rcmd\(3SOCKET\)](#), [syslog\(3C\)](#), [ttyname\(3C\)](#), [auth\\_attr\(4\)](#), [exec\\_attr\(4\)](#), [hosts.equiv\(4\)](#), [issue\(4\)](#), [logindevperm\(4\)](#), [loginlog\(4\)](#), [nologin\(4\)](#), [nsswitch.conf\(4\)](#), [pam.conf\(4\)](#), [passwd\(4\)](#), [policy.conf\(4\)](#), [profile\(4\)](#), [shadow\(4\)](#), [user\\_attr\(4\)](#), [utmpx\(4\)](#), [wtmpx\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [pam\\_unix\\_account\(5\)](#), [pam\\_unix\\_auth\(5\)](#), [pam\\_unix\\_session\(5\)](#), [pam\\_authtok\\_check\(5\)](#), [pam\\_authtok\\_get\(5\)](#), [pam\\_authtok\\_store\(5\)](#), [pam\\_dhkeys\(5\)](#), [pam\\_passwd\\_auth\(5\)](#), [termio\(7I\)](#)

**DIAGNOSTICS**

Login incorrect  
The user name or the password cannot be matched.

Not on system console  
Root login denied. Check the `CONSOLE` setting in `/etc/default/login`.

No directory! Logging in with `home=/`  
The user's home directory named in the `passwd(4)` database cannot be found or has the wrong permissions. Contact your system administrator.

No shell  
Cannot execute the shell named in the `passwd(4)` database. Contact your system administrator.

NO LOGINS: System going down in *N* minutes  
The machine is in the process of being shut down and logins have been disabled.

**WARNINGS**

Users with a UID greater than 76695844 are not subject to password aging, and the system does not record their last login time.

If you use the `CONSOLE` setting to disable root logins, you should arrange that remote command execution by root is also disabled. See [rsh\(1\)](#), [rcmd\(3SOCKET\)](#), and [hosts.equiv\(4\)](#) for further details.

**NOTES**

The `pam_unix(5)` module is no longer supported. Similar functionality is provided by `pam_unix_account(5)`, `pam_unix_auth(5)`, `pam_unix_session(5)`, `pam_authtok_check(5)`, `pam_authtok_get(5)`, `pam_authtok_store(5)`, `pam_dhkeys(5)`, and `pam_passwd_auth(5)`.

## logname(1)

<b>NAME</b>	logname – return user’s login name
<b>SYNOPSIS</b>	<b>logname</b>
<b>DESCRIPTION</b>	The logname utility will write the user’s login name to standard output. The login name is the string that would be returned by the <code>getlogin(3C)</code> function. Under the conditions where <code>getlogin()</code> would fail, logname will write a diagnostic message to standard error and exit with a non-zero exit status.
<b>ENVIRONMENT VARIABLES</b>	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of logname: <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .
<b>EXIT STATUS</b>	The following error values are returned:  0                               Successful completion.  >0                               An error occurred.
<b>FILES</b>	<code>/etc/profile</code> environment for user at login time <code>/var/adm/utmpx</code> user and accounting information
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
Interface Stability	Standard

**SEE ALSO** `env(1)`, `login(1)`, `getlogin(3C)`, `utmpx(4)`, `attributes(5)`, `environ(5)`, `standards(5)`

**NAME** | logout – shell built-in function to exit from a login session

**SYNOPSIS**

**cs**h | **l**ogout

**DESCRIPTION**

**cs**h | Terminate a login shell.

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO** | `cs(1)`, `login(1)`, `attributes(5)`

look(1)

**NAME** look – find words in the system dictionary or lines in a sorted list

**SYNOPSIS** /usr/bin/look [-d] [-f] [-tc] *string* [*filename*]

**DESCRIPTION** The look command consults a sorted *filename* and prints all lines that begin with *string*.

If no *filename* is specified, look uses /usr/share/lib/dict/words with collating sequence -df.

look limits the length of a word to search for to 256 characters.

**OPTIONS**

- d Dictionary order. Only letters, digits, TAB and SPACE characters are used in comparisons.
- f Fold case. Upper case letters are not distinguished from lower case in comparisons.
- tc Set termination character. All characters to the right of *c* in *string* are ignored.

**FILES** /usr/share/lib/dict/words spelling list

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

Availability	SUNWesu

**SEE ALSO** grep(1), sort(1), attributes(5)

<b>NAME</b>	lookbib – find references in a bibliographic database				
<b>SYNOPSIS</b>	<b>lookbib</b> <i>database</i>				
<b>DESCRIPTION</b>	<p>A bibliographic reference is a set of lines, constituting fields of bibliographic information. Each field starts on a line beginning with a ‘%’, followed by a key-letter, then a blank, and finally the contents of the field, which may continue until the next line starting with ‘%’.</p> <p>The <code>lookbib</code> utility uses an inverted index made by <code>indxbib</code> to find sets of bibliographic references. It reads keywords typed after the ‘&gt;’ prompt on the terminal, and retrieves records containing all these keywords. If nothing matches, nothing is returned except another ‘&gt;’ prompt.</p> <p>It is possible to search multiple databases, as long as they have a common index made by <code>indxbib(1)</code>. In that case, only the first argument given to <code>indxbib</code> is specified to <code>lookbib</code>.</p> <p>If <code>lookbib</code> does not find the index files (the <code>.i[abc]</code> files), it looks for a reference file with the same name as the argument, without the suffixes. It creates a file with a <code>.ig</code> suffix, suitable for use with <code>fgrep</code> (see <code>grep(1)</code>). <code>lookbib</code> then uses this <code>fgrep</code> file to find references. This method is simpler to use, but the <code>.ig</code> file is slower to use than the <code>.i[abc]</code> files, and does not allow the use of multiple reference files.</p>				
<b>FILES</b>	<p><code>x.ia</code></p> <p><code>x.ib</code></p> <p><code>x.ic</code>      index files</p> <p><code>x.ig</code>      reference file</p>				
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWdoc</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWdoc

<b>BUGS</b>	Probably all dates should be indexed, since many disciplines refer to literature written in the 1800s or earlier.				

## lorder(1)

<b>NAME</b>	<code>lorder</code> – find ordering relation for an object or library archive						
<b>SYNOPSIS</b>	<code>lorder filename...</code>						
<b>DESCRIPTION</b>	<p>The input is one or more object or library archive <i>filenames</i> (see <a href="#">ar(1)</a>). The standard output is a list of pairs of object file or archive member names; the first file of the pair refers to external identifiers defined in the second. The output may be processed by <a href="#">tsort(1)</a> to find an ordering of a library suitable for one-pass access by <code>ld</code>. Note that the link editor <code>ld</code> is capable of multiple passes over an archive in the portable archive format (see <code>ar.h(3HEAD)</code>) and does not require that <code>lorder</code> be used when building an archive. The usage of the <code>lorder</code> command may, however, allow for a more efficient access of the archive during the link edit process.</p> <p>The following example builds a new library from existing <code>.o</code> files.</p> <pre>ar -cr library `lorder *.o   tsort `</pre>						
<b>FILES</b>	<table><tr><td><code>TMPDIR/*symref</code></td><td>temporary files</td></tr><tr><td><code>TMPDIR/*symdef</code></td><td>temporary files</td></tr><tr><td><code>TMPDIR</code></td><td>usually <code>/var/tmp</code> but can be redefined by setting the environment variable <code>TMPDIR</code> (see <a href="#">tmpnam(3C)</a>)</td></tr></table>	<code>TMPDIR/*symref</code>	temporary files	<code>TMPDIR/*symdef</code>	temporary files	<code>TMPDIR</code>	usually <code>/var/tmp</code> but can be redefined by setting the environment variable <code>TMPDIR</code> (see <a href="#">tmpnam(3C)</a> )
<code>TMPDIR/*symref</code>	temporary files						
<code>TMPDIR/*symdef</code>	temporary files						
<code>TMPDIR</code>	usually <code>/var/tmp</code> but can be redefined by setting the environment variable <code>TMPDIR</code> (see <a href="#">tmpnam(3C)</a> )						
<b>ATTRIBUTES</b>	See <a href="#">attributes(5)</a> for descriptions of the following attributes:						
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWbtool</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWbtool		
ATTRIBUTE TYPE	ATTRIBUTE VALUE						
Availability	SUNWbtool						
<b>SEE ALSO</b>	<a href="#">ar(1)</a> , <a href="#">ld(1)</a> , <a href="#">tsort(1)</a> , <a href="#">tmpnam(3C)</a> , <a href="#">ar.h(3HEAD)</a> , <a href="#">attributes(5)</a>						
<b>NOTES</b>	<p><code>lorder</code> will accept as input any object or archive file, regardless of its suffix, provided there is more than one input file. If there is but a single input file, its suffix must be <code>.o</code>.</p> <p>The length of the filename for <code>TMPDIR</code> is limited to whatever <code>sed</code> allows.</p>						

<b>NAME</b>	lp – submit print request
<b>SYNOPSIS</b>	<pre>lp [-c] [-m] [-p] [-s] [-w] [-d destination] [-f form-name]     [-H special-handling] [-n number] [-o option] [-P page-list]     [-q priority-level] [-S character-set   print-wheel] [-t title]     [ -T content-type [-r]] [-y mode-list] [file...]  lp -i request-ID... [-c] [-m] [-p] [-s] [-w] [-d destination] [-f form-name]     [-H special-handling] [-n number] [-o option] [-P page-list]     [-q priority-level] [-S character-set   print-wheel] [-t title]     [ -T content-type [-r]] [-y mode-list]</pre>
<b>DESCRIPTION</b>	<p>The lp utility submits print requests to a destination. There are two formats of the lp command.</p> <p>The first form of lp prints files (<i>file</i>) and associated information (collectively called a <i>print request</i>). If <i>file</i> is not specified, lp assumes the standard input. Use a hyphen (-) with <i>file</i> to specify the standard input. Files are printed in the order in which they appear on the command line.</p> <p>The second form of lp changes print request options. This form of lp can only be used on a Solaris 2.6 Operating Environment or compatible versions of the LP print server. The print request identified by <i>request-ID</i> is changed according to the printing options specified. The printing options available are the same as those with the first form of the lp. If the request has finished printing when the lp command is executed, the change is rejected. If the request is in the process of printing, it will be stopped and restarted from the beginning (unless the -P option has been given).</p> <p>The print client commands locate destination information using the “printers” database in the name service switch. See <code>nsswitch.conf(4)</code>, <code>printers(4)</code>, and <code>printers.conf(4)</code> for details.</p>
<b>OPTIONS</b>	<p>Printers that have a 4.x or BSD-based print server are not configured to handle BSD protocol extensions. lp handles print requests sent to such destinations differently (see NOTES).</p> <p>The following options are supported:</p> <p>-c                                       Copies <i>file</i> before printing.</p> <p>  Unless -c is specified, users should not remove any <i>file</i> before the print request has completely printed. Changes made to <i>file</i> after the print request is made but before it is printed will be reflected in the printed output. <i>file</i> will be linked (as opposed to copied).</p> <p>-d <i>destination</i>                       Prints <i>file</i> on a specific destination. The -d option is used to set the destination only when the job is first created. (<i>Note:</i> To move existing jobs to a different destination, see <code>lpmove(1M)</code>.) <i>destination</i> can be either a printer or a class of printers (see <code>lpadmin(1M)</code>).</p>

## lp(1)

	Specify <i>destination</i> using atomic or POSIX-style ( <i>server:destination</i> ) names. See <code>standards(5)</code> for information regarding POSIX.
-f <i>form-name</i>	Prints <i>file</i> on <i>form-name</i> . The LP print service ensures that the form is mounted on the printer. The print request is rejected if the printer does not support <i>form-name</i> , if <i>form-name</i> is not defined for the system, or if the user is not allowed to use <i>form-name</i> (see <code>lpforms(1M)</code> ).
-H <i>special-handling</i>	Prints the print request according to the value of <i>special-handling</i> . The following <i>special-handling</i> values are acceptable:  hold Do not print the print request until notified. If printing has already begun, stop it. Other print requests will go ahead of a request that has been put on hold ( <i>held print request</i> ) until the print request is resumed.  resume Resume a held print request. If the print request had begun to print when held, it will be the next print request printed, unless it is superseded by an <i>immediate</i> print request.  immediate Print the print request next. If more than one print request is assigned, the most recent print request is printed next. If a print request is currently printing on the desired printer, a <code>hold</code> request must be issued to allow the immediate request to print. The <code>immediate</code> request is only available to LP administrators.
-i <i>request-ID</i>	Changes options for the print request identified by <i>request-ID</i> . There must be a space between <code>-i</code> and <i>request-ID</i> . This option applies only to jobs that are in a local queue on a print server.
-m	Sends mail after <i>file</i> has printed (see <code>mail(1)</code> ). By default, no mail is sent upon normal completion of a print request.
-n <i>number</i>	Prints a specific number of copies of <i>file</i> . Specify <i>number</i> as a digit. The default for <i>number</i> is 1.
-o <i>option</i>	Specifies printer-dependent <i>options</i> . Specify several options by specifying <code>-o option</code> multiple times ( <code>-o option -o option -o option</code> ). Printer-dependent options

may also be specified using the `-o` keyletter once, followed by a list of options enclosed in double quotes (`-o "option option option"`). The following options are valid:

`nobanner`

Does not print a banner page with the request. This option can be disallowed by the LP administrator.

`nofilebreak`

Prints multiple files without inserting a form feed between them.

`length=numberi | numberc | number`

Prints the print request with pages of a specific length in inches, centimeters, or number of lines. Append the letter `i` for inches or `c` for centimeters to `number`. Indicate the number of lines by specifying `number` alone. `length=66` indicates a page length of 66 lines. `length=11i` indicates a page length of 11 inches. `length=27.94c` indicates a page length of 27.94 centimeters.

This option may not be used with the `-f` option.

`width=numberi | numberc | number`

Prints the print request with pages of a specific width in inches, centimeters, or number of columns. Append the letter `i` for inches or `c` for centimeters to `number`. Indicate the number of columns by specifying `number` alone. `width=65` indicates a page width of 65 columns. `width=6.5i` indicates a page width of 6.5 inches. `width=10c` indicates a page width of 10 centimeters.

This option may not be used with the `-f` option.

`lpi=number`

Prints the print request with the line pitch set to `number` lines in an inch. Use `number` to specify the number of lines in an inch.

This option may not be used with the `-f` option.

`cpi=n | pica | elite | compressed`

Prints the print request with the character pitch set to `number` characters in an inch. Use `number` to specify the number of characters in an inch. Use `pica` to set character pitch to pica (10 characters per inch), or `elite` to set character pitch to elite (12 characters per inch) Use `compressed` to set

## lp(1)

	<p>character pitch to as many characters as the printer can handle. There is no standard number of characters per inch for all printers; see the <code>terminfo</code> database (see <code>terminfo(4)</code>) for the default character pitch for your printer. This option may not be used with the <code>-f</code> option.</p>
	<p><code>stty=stty-option-list</code> Prints the request using a list of options valid for the <code>stty</code> command (see <code>stty(1)</code>). Enclose the list in single quotes ( <code>' '</code> ) if it contains blanks.</p>
<code>-P page-list</code>	<p>Prints the pages specified in <i>page-list</i> in ascending order. Specify <i>page-list</i> as a of range of numbers, single page number, or a combination of both.</p> <p>The <code>-P</code> option can only be used if there is a filter available to handle it; otherwise, the print request will be rejected.</p>
<code>-p</code>	<p>Enables notification on completion of the print request. Delivery of the notification is dependent on additional software.</p>
<code>-q priority-level</code>	<p>Assigns the print request a priority in the print queue. Specify <i>priority-level</i> as an integer between from 0 and 39. Use 0 to indicate the highest priority; 39 to indicate the lowest priority. If no priority is specified, the default priority for a print service is assigned by the LP administrator. The LP administrator may also assign a default priority to individual users.</p>
<code>-s</code>	<p>Suppresses the display of messages sent from <code>lp</code>.</p>
<code>-S character-set  </code> <code>-S print-wheel</code>	<p>Prints the request using the <i>character-set</i> or <i>print-wheel</i>. If a form was requested and requires a character set or print wheel other than the one specified with the <code>-S</code> option, the request is rejected. Printers using mountable print wheels or font cartridges use the print wheel or font cartridge mounted at the time of the print request, unless the <code>-S</code> option is specified.</p> <p>Printers Using Print Wheels: If <i>print wheel</i> is not one listed by the LP administrator as acceptable for the printer the request is rejected unless the print wheel is already mounted on the printer.</p> <p>Printers Using Selectable or Programmable Character Sets: If the <code>-S</code> option is not specified, <code>lp</code> uses the standard character set. If <i>character-set</i> is not defined in</p>

	the <code>terminfo</code> database for the printer (see <code>terminfo(4)</code> ), or is not an alias defined by the LP administrator, the request is rejected.
<code>-t title</code>	Prints a title on the banner page of the output. Enclose <i>title</i> in quotes if it contains blanks. If <i>title</i> is not specified, the name of the file is printed on the banner page.
<code>-T content-type [-r]</code>	Prints the request on a printer that can support the specified <i>content-type</i> . If no printer accepts this type directly, a filter will be used to convert the content into an acceptable type. If the <code>-r</code> option is specified, a filter will not be used. If <code>-r</code> is specified, and no printer accepts the <i>content-type</i> directly, the request is rejected. If the <i>content-type</i> is not acceptable to any printer, either directly or with a filter, the request is rejected.
<code>-w</code>	Writes a message on the user's terminal after the <i>files</i> have been printed. If the user is not logged in, then mail will be sent instead.
<code>-y mode-list</code>	Prints the request according to the printing modes listed in <i>mode-list</i> . The allowed values for <i>mode-list</i> are locally defined.
	This option may be used only if there is a filter available to handle it; otherwise, the print request will be rejected.
<b>OPERANDS</b>	The following operand is supported:
	<i>file</i> The name of the file to be printed. Specify <i>file</i> as a pathname or as a hyphen (-) to indicate the standard input. If <i>file</i> is not specified, <code>lp</code> uses the standard input.
<b>USAGE</b>	See <code>largefile(5)</code> for the description of the behavior of <code>lp</code> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).
<b>ENVIRONMENT VARIABLES</b>	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>lp</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , <code>NLSPATH</code> , and <code>PATH</code> .
	<code>LC_TIME</code> Determine the format and contents of date and time strings displayed in the <code>lp</code> banner page, if any.
	<code>LPDEST</code> Determine the destination. If the <code>LPDEST</code> environment variable is not set, the <code>PRINTER</code> environment variable shall be used. The <code>-d dest</code> option takes precedence over <code>LPDEST</code> . Results are undefined when <code>-d</code> is not specified and <code>LPDEST</code> contains a value that is not a valid destination name.

lp(1)

**PRINTER** Determine the output device or destination. If the `LPDEST` and `PRINTER` environment variables are not set, an unspecified output device is used. The `-d dest` option and the `LPDEST` environment variable shall take precedence over `PRINTER`. Results are undefined when `-d` is not specified, `LPDEST` is unset, and `PRINTER` contains a value that is not a valid device or destination name.

**TZ** Determine the timezone used to calculate date and time strings displayed in the `lp` banner page, if any. If `TZ` is unset or null, an unspecified default timezone shall be used.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.  
 non-zero An error occurred.

**FILES**

<code>/var/spool/lp/*</code>	LP print queue.
<code>\$HOME/.printers</code>	User-configurable printer database.
<code>/etc/printers.conf</code>	System printer configuration database.
<code>printers.conf.byname</code>	NIS version of <code>/etc/printers.conf</code> .
<code>printers.org_dir</code>	NIS+ version of <code>/etc/printers.conf</code> .

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpcu
CSI	Enabled (see NOTES)
Interface Stability	Standard

**SEE ALSO** `cancel(1)`, `enable(1)`, `lpq(1B)`, `lpr(1B)`, `lprm(1B)`, `lpstat(1)`, `mail(1)`, `postprint(1)`, `pr(1)`, `stty(1)`, `accept(1M)`, `lpadmin(1M)`, `lpfilter(1M)`, `lpforms(1M)`, `lpmove(1M)`, `lpsched(1M)`, `lpshut(1M)`, `lpssystem(1M)`, `lpusers(1M)`, `nsswitch.conf(4)`, `printers(4)`, `printers.conf(4)`, `terminfo(4)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `standards(5)`

**NOTES** CSI-capability assumes that printer names are composed of ASCII characters.

Print jobs are assumed to contain one type of data. That type of data is either specified on the command line or autodetected (simple, PostScript) based on the contents of the first file in the job.

Printers that have a 4.x or BSD-based print server. are not configured to handle BSD protocol extensions. `lp` handles print requests sent to such printers in the following ways:

1. Print requests with more than 52 filenames will be truncated to 52 files. `lp` displays a warning message.
2. The `-f`, `-H`, `-o`, `-P`, `-p`, `-q`, `-S`, `-T`, and `-y` options may require a protocol extension to pass to a print server. If `lp` cannot handle the print request, it displays a warning message.

LP administrators enable protocol extensions by setting a printer's `bsdaddr` entry in `/etc/printers.conf`. Changing the `bsdaddr` entry in `/etc/printers.conf` to:

```
destination:bsdaddr=server,destination,Solaris
```

generates a set of BSD print protocol extensions that can be processed by a Solaris print server. `lp` supports only `Solaris` protocol extensions at this time.

## lpc(1B)

<b>NAME</b>	<code>lpc</code> – line printer control program
<b>SYNOPSIS</b>	<code>/usr/ucb/lpc</code> [ <i>command</i> [ <i>parameter...</i> ] ]
<b>DESCRIPTION</b>	<p>The <code>lpc</code> utility controls the operation of local printers.</p> <p>Use <code>lpc</code> to perform the following functions:</p> <ul style="list-style-type: none"><li>■ start or stop a printer,</li><li>■ disable or enable a printer's spooling queue,</li><li>■ rearrange the order of jobs in a print queue, or</li><li>■ display the status of a printer print queue and printer daemon.</li></ul> <p><code>lpc</code> can be run from the command line or interactively. Specifying <code>lpc</code> with the optional <i>command</i> and <i>parameter</i> arguments causes <code>lpc</code> to interpret the first argument as an <code>lpc</code> command, and all other arguments as parameters to that command. Specifying <code>lpc</code> without arguments causes it to run interactively, prompting the user for <code>lpc</code> commands with <code>lpc&gt;</code>. By redirecting the standard input, <code>lpc</code> can read commands from a file.</p>
<b>USAGE</b>	<p><code>lpc</code> commands may be typed in their entirety or abbreviated to an unambiguous substring. Some <code>lpc</code> commands are available to all users; others are available only to super-users.</p> <p>All users may execute the following <code>lpc</code> commands:</p> <p>? [<i>command ...</i>]   help [<i>command ...</i>] Displays a short description of <i>command</i>. <i>command</i> is an <code>lpc</code> command. If <i>command</i> is not specified, displays a list of <code>lpc</code> commands.</p> <p>exit   quit Exits from <code>lpc</code>.</p> <p>status [all   <i>printer ...</i>] Displays the status of print daemons and print queues. <i>all</i> specifies that this command is performed on all locally attached printers. <i>printer</i> indicates this command is performed on specific printers. Specify <i>printer</i> as an atomic name. See <code>printers.conf(4)</code> for information regarding naming conventions for atomic names.</p> <p>Only a super-user may execute the following <code>lpc</code> commands:</p> <p>abort [all   <i>printer ...</i>] Terminates an active spooling daemon. Disables printing (by preventing new daemons from being started by <code>lpr(1B)</code>) for <i>printer</i>. <i>all</i> specifies this command is performed on all locally attached printers. <i>printer</i> indicates this command is performed on specific printers. Specify <i>printer</i> as an atomic name. See <code>printers.conf(4)</code> for information regarding naming conventions for atomic names.</p> <p>clean [all   <i>printer ...</i>] Removes files created in the print spool directory by the print daemon from <i>printer</i>'s print queue. <i>all</i> specifies that this command is performed on all locally attached</p>

`printers.printer` indicates this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`disable [all | printer ...]`

Turns off the print queue for *printer*. Prevents new printer jobs from being entered into the print queue for *printer* by `lpr(1B)`. `all` specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`down [all | printer ...] [message]`

Turns the queue for *printer* off and disables printing on *printer*. Inserts *message* in the printer status file. *message* does not need to be quoted; multiple arguments to *message* are treated as arguments are to `echo(1)`. Use `down` to take a printer down and inform users. `all` specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`enable [all | printer ...]`

Enables `lpr(1B)` to add new jobs in the spool queue. `all` specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`restart [all | printer ...]`

Attempts to start a new printer daemon. `restart` is useful when a print daemon dies unexpectedly and leaves jobs in the print queue. `all` specifies that this command is performed on all locally attached printers. *printer* indicates that this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`start [all | printer ...]`

Enables printing. Starts a spooling daemon for the *printer*. `all` specifies that this command is performed on all locally attached printers. *printer* indicates the command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`stop [all | printer ...]`

Stops a spooling daemon after the current job is complete. Disables printing at that time. `all` specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

## lpc(1B)

`topq printer [request-ID ...] [user ...]`

Moves *request-ID* or print jobs belonging to *user* on *printer* to the beginning of the print queue. Specify *user* as a user's login name. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

`up [all | printer ...]`

Turns the queue for *printer* on and enables printing on *printer*. Deletes the message in the printer status file (inserted by `down`). Use `up` to undo the effects of `down`. `all` specifies that this command is performed on all locally attached printers. *printer* indicates this command is performed on specific printers. Specify *printer* as an atomic name. See `printers.conf(4)` for information regarding naming conventions for atomic names.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

**FILES** `/var/spool/lp/*` LP print queue.

`/var/spool/lp/system/pstatus` Printer status information file.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscplp

**SEE ALSO** `echo(1)`, `lpq(1B)`, `lpr(1B)`, `lprm(1B)`, `lpstat(1)`, `lpsched(1M)`, `lpshut(1M)`, `svcadm(1M)`, `printers.conf(4)`, `attributes(5)`

**DIAGNOSTICS** Use the `svcs(1)` utility to check if `svc:/application/print/server` is running. If it is not running, use `svcadm enable svc:/application/print/server` to start `lpsched`. See `svcadm(1M)`.

Ambiguous command

Indicates that the `lpc` command or abbreviation matches more than one command.

?Invalid command

Indicates that the `lpc` command or abbreviation is not recognized.

?Privileged command

Indicates that the `lpc` command or abbreviation can be executed only by a super-user.

`lpc: printer` : unknown printer to the print service

Indicates that *printer* does not exist in the LP database. Check that *printer* was correctly specified. Use `lpstat -p` or the `status` command (see `lpstat(1)` or `USAGE`) to check the status of printers.

lpc: error on opening queue to spooler

Indicates that the connection to lpsched failed. Usually means that the printer server has died or is hung. Use /usr/lib/lp/lpsched to check if the printer spooler daemon is running.

lpc: Can't send message to LP print service

lpc: Can't receive message from LP print service

Indicates that the LP print service stopped. Contact the LP administrator.

lpc: Received unexpected message from LP print service

Indicates a problem with the software. Contact the LP administrator.

## lpq(1B)

<b>NAME</b>	lpq – display the content of a print queue
<b>SYNOPSIS</b>	<code>/usr/ucb/lpq [-P <i>destination</i>] [-l] [+ [<i>interval</i>]] [<i>request-ID</i>...] [<i>user</i>...]</code>
<b>DESCRIPTION</b>	<p>The <code>lpq</code> utility displays the information about the contents of a print queue. A print queue is comprised of print requests that are waiting in the process of being printed.</p> <p><code>lpq</code> displays the following information to the standard output:</p> <ul style="list-style-type: none"><li>■ the username of the person associated with a print request,</li><li>■ the position of a print request in the print queue,</li><li>■ the name of file or files comprising a print request,</li><li>■ the job number of a print request, and</li><li>■ the size of the file requested by a print request. File size is reported in bytes.</li></ul> <p>Normally, only as much information as will fit on one line is displayed. If the name of the input file associated with a print request is not available, the input file field indicates the standard input.</p> <p>The print client commands locate destination information using the <code>printers</code> database in the name service switch. See <code>nsswitch.conf(4)</code>, <code>printers(4)</code>, and <code>printers.conf(4)</code> for details.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"><li>-P <i>destination</i>      Displays information about printer or class of printers (see <code>lpadmin(1M)</code>). Specify <i>destination</i> using atomic or POSIX-style (<code>server:destination</code>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic names and <code>standards(5)</code> for information regarding POSIX.</li><li>-l                      Displays information in long format. Long format includes the name of the host from which a print request originated in the display.</li><li>+ [<i>interval</i>]        Displays information at specific time intervals. Stops displaying information when the print queue is empty. Clears the screen before reporting displaying the print queue. Specify <i>interval</i> as the number of seconds between displays. If <i>interval</i> is not specified only executes once.</li></ul>
<b>OPERANDS</b>	<p>The following operands are supported:</p> <ul style="list-style-type: none"><li><i>request-ID</i>            The job number associated with a print request.</li><li><i>user</i>                    The name of the user about whose jobs <code>lpq</code> reports information. Specify <i>user</i> as a valid username.</li></ul>
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <ul style="list-style-type: none"><li>0                        Successful completion.</li></ul>

non-zero           An error occurred.

<b>FILES</b>	/var/spool/print/[cd]f*	Spooling directory and request files for jobs awaiting transfer.

## lpr(1B)

<b>NAME</b>	<code>lpr</code> – submit print requests
<b>SYNOPSIS</b>	<code>/usr/ucb/lpr</code> [-P <i>destination</i> ] [-# <i>number</i> ] [-C <i>class</i> ] [-J <i>job</i> ] [-T <i>title</i> ] [-i [ <i>indent</i> ]] [-1   -2   -3   -4 <i>font</i> ] [-w <i>cols</i> ] [-m] [-h] [-s] [-filter_option] [ <i>file...</i> ]
<b>DESCRIPTION</b>	<p>The <code>lpr</code> utility submits print requests to a destination. <code>lpr</code> prints files (<i>file</i>) and associated information, collectively called a <i>print request</i>. If <i>file</i> is not specified, <code>lpr</code> assumes the standard input.</p> <p>The print client commands locate destination information using the “printers” database in the name service switch. See <code>nsswitch.conf(4)</code>, <code>printers(4)</code>, and <code>printers.conf(4)</code> for details.</p> <p>Print requests with more than 52 <i>files</i> specified will be truncated to 52 files. <code>lpr</code> displays a warning message.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"><li>-P <i>destination</i> Prints <i>file</i> on a specific printer or class of printers (see <code>lpadmin(1M)</code>). Specify <i>destination</i> using atomic or POSIX-style (<i>server:destination</i>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic names and <code>standards(5)</code> for information regarding POSIX.</li><li>-# <i>number</i> Prints a specific number of copies. Specify <i>number</i> as a positive integer. The default for <i>number</i> is 1.</li><li>-C <i>class</i> Prints <i>class</i> as the job classification on the banner page of the output. Enclose <i>class</i> in double quotes if it contains blanks. If <i>class</i> is not specified, the name of the system (as returned by <code>hostname</code>) is printed as the job classification. See <code>hostname(1)</code>.</li><li>-J <i>job</i> Prints <i>job</i> as the <i>job name</i> on the banner page of the output. Enclose <i>job</i> in double quotes if it contains blanks. If <i>job</i> is not specified, <i>file</i> (or in the case of multiple files, the first <i>file</i> specified on the command line) is printed as the job name on the banner page of the output.</li><li>-T <i>title</i> Prints a title on the page header of the output. Enclose <i>title</i> in double quotes if it contains blanks. The -T option is ignored unless it is specified with the -p filter option.</li><li>-i <i>indent</i> Indents the output a specific number of SPACE characters. Use <i>indent</i> to indicate the number of SPACE characters to be indented. Specify <i>indent</i> as a positive</li></ul>

	integer. If the optional argument to indent is not specified, then eight <code>SPACE</code> characters is the default. The <code>-i</code> option is ignored unless it is specified with the <code>-p</code> filter option.						
<code>-1   -2   -3   -4 font</code>	Mounts the specified font in the font position 1, 2, 3, or 4. Specify <i>font</i> as a valid font name.						
<code>-w cols</code>	Prints <i>file</i> with pages of a specific width. <i>cols</i> indicates the number of columns wide. The <code>-w</code> option is ignored unless it is specified with the <code>-p</code> filter option.						
<code>-m</code>	Sends mail after <i>file</i> has printed. See <code>mail(1)</code> . By default, no mail is sent upon normal completion of a print request.						
<code>-h</code>	Suppresses printing of the banner page of the output.						
<code>-s</code>	Uses full pathnames (as opposed to symbolic links) to <i>file</i> rather than trying to copy them. This means <i>file</i> should not be modified or removed until it has completed printing. Option <code>-s</code> only prevents copies of local files from being made on the local machine. Option <code>-s</code> only works with specified <i>files</i> . If the <code>lpr</code> command is at the end of a pipeline, <i>file</i> is copied to the spool.						
<code>- filter_option</code>	<p>Notifies the print spooler that <i>file</i> is not a standard text file. Enables the spooling daemon to use the appropriate filters to print <i>file</i>.</p> <p><i>filter_options</i> offer a standard user interface. All filter options may not be available for, or applicable to, all printers.</p> <p>Specify <i>filter_option</i> as a single character.</p> <p>If <i>filter_option</i> is not specified and the printer can interpret PostScript®, inserting ‘%!’ as the first two characters of <i>file</i> causes <i>file</i> to be interpreted as PostScript.</p> <p>The following filter options are supported:</p> <table border="0"> <tr> <td><code>p</code></td> <td>Use <code>pr</code> to format the files. See <code>pr(1)</code>.</td> </tr> <tr> <td><code>l</code></td> <td>Print control characters and suppress page breaks.</td> </tr> <tr> <td><code>t</code></td> <td><i>file</i> contains <code>troff</code> (cat phototypesetter) binary data.</td> </tr> </table>	<code>p</code>	Use <code>pr</code> to format the files. See <code>pr(1)</code> .	<code>l</code>	Print control characters and suppress page breaks.	<code>t</code>	<i>file</i> contains <code>troff</code> (cat phototypesetter) binary data.
<code>p</code>	Use <code>pr</code> to format the files. See <code>pr(1)</code> .						
<code>l</code>	Print control characters and suppress page breaks.						
<code>t</code>	<i>file</i> contains <code>troff</code> (cat phototypesetter) binary data.						

## lpr(1B)

- n *file* contains `ditroff` data from device independent troff.
- d *file* contains `tex` data in DVI format from Stanford.
- g *file* contains standard plot data produced by `plot(1B)` routines.
- v *file* contains a raster image. *printer* must support an appropriate imaging model such as PostScript in order to print the image.
- c *file* contains data produced by `cifplot`.
- f Interprets the first character of each line as a standard FORTRAN carriage control character.

**OPERANDS** The following operand is supported:

*file* The name of the file to be printed. Specify *file* as a pathname. If *file* is not specified, `lpr` uses the standard input.

**USAGE** See `largefile(5)` for the description of the behavior of `lpr` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**EXIT STATUS** The following exit values are returned:

0 Successful completion.  
 non-zero An error occurred.

**FILES**

<code>/var/spool/print/.seq</code>	File containing the sequence numbers for job ID assignment
<code>/var/spool/print/[cd]f*</code>	Spooling directories and files
<code>/var/spool/lp/*</code>	LP print queue
<code>\$HOME/.printers</code>	User-configurable printer database
<code>/etc/printers.conf</code>	System printer configuration database
<code>printers.conf.byname</code>	NIS version of <code>/etc/printers.conf</code>
<code>printers.org_dir</code>	NIS+ version of <code>/etc/printers.conf</code>

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscplp
CSI	Enabled (see NOTES)

**SEE ALSO** hostname(1), lp(1), lpc(1B), lpq(1B), lprm(1B), lpstat(1), mail(1), plot(1B), pr(1), troff(1), lpadmin(1M), nsswitch.conf(4), printers(4), printers.conf(4), attributes(5), largefile(5), standards(5)

**DIAGNOSTICS** lpr: *destination* | : unknown destination  
*destination* was not found in the LP configuration database. Usually this is a typing mistake; however, it may indicate that the *destination* does not exist on the system. Use lpstat -p to display information about the status of the print service.

**NOTES** lpr is CSI-enabled except for the *printer* name.

Print jobs are assumed to contain one type of data. That type of data is either specified on the command line or autodetected (simple, PostScript) based on the contents of the first file in the job.

## lprm(1B)

<b>NAME</b>	<code>lprm</code> – remove print requests from the print queue				
<b>SYNOPSIS</b>	<code>/usr/ucb/lprm [-P <i>destination</i>] [-] [ <i>request-ID...</i>] [ <i>user...</i>]</code>				
<b>DESCRIPTION</b>	<p>The <code>lprm</code> utility removes print requests (<i>request-ID</i>) from the print queue.</p> <p>Without arguments, <code>lprm</code> deletes the current print request. <code>lprm</code> reports the name of the file associated with print requests that it removes. <code>lprm</code> is silent if there are no applicable print requests to remove.</p> <p>Users can only remove print requests associated with their user name. See <b>NOTES</b>. If a superuser executes <code>lprm</code> and specifies the <i>user</i> operand, <code>lprm</code> removes all print requests belonging to the specified user.</p> <p>The print client commands locate destination information using the “printers” database in the name service switch. See <code>nsswitch.conf(4)</code>, <code>printers(4)</code>, and <code>printers.conf(4)</code> for details.</p>				
<b>OPTIONS</b>	<p>The following options are supported:</p> <table><tr><td><code>-P <i>destination</i></code></td><td>The name of the printer or class of printers (see <code>lpadmin(1M)</code>) from which to remove print requests. Specify destination using atomic or POSIX-style (<i>server:destination</i>) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic names and <code>standards(5)</code> for information regarding POSIX.</td></tr><tr><td><code>-</code></td><td>If a user specifies this option, removes all print requests owned by that user. If a superuser specifies this option, removes all requests in the print queue. Job ownership is determined by the user’s login name and host name on the machine from which <code>lpr</code> was executed. See <b>NOTES</b>.</td></tr></table>	<code>-P <i>destination</i></code>	The name of the printer or class of printers (see <code>lpadmin(1M)</code> ) from which to remove print requests. Specify destination using atomic or POSIX-style ( <i>server:destination</i> ) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic names and <code>standards(5)</code> for information regarding POSIX.	<code>-</code>	If a user specifies this option, removes all print requests owned by that user. If a superuser specifies this option, removes all requests in the print queue. Job ownership is determined by the user’s login name and host name on the machine from which <code>lpr</code> was executed. See <b>NOTES</b> .
<code>-P <i>destination</i></code>	The name of the printer or class of printers (see <code>lpadmin(1M)</code> ) from which to remove print requests. Specify destination using atomic or POSIX-style ( <i>server:destination</i> ) names. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic names and <code>standards(5)</code> for information regarding POSIX.				
<code>-</code>	If a user specifies this option, removes all print requests owned by that user. If a superuser specifies this option, removes all requests in the print queue. Job ownership is determined by the user’s login name and host name on the machine from which <code>lpr</code> was executed. See <b>NOTES</b> .				
<b>OPERANDS</b>	<p>The following operands are supported.</p> <table><tr><td><i>user</i></td><td>Removes print requests associated with a specific user. Specify <i>user</i> as a valid user name. This option can only be used by a superuser.</td></tr><tr><td><i>request-ID</i></td><td>Removes a specific print request. Specify <i>request-ID</i> as the job number (Job) associated with a print request and reported by <code>lpq</code>. See <code>lpq(1B)</code>.</td></tr></table>	<i>user</i>	Removes print requests associated with a specific user. Specify <i>user</i> as a valid user name. This option can only be used by a superuser.	<i>request-ID</i>	Removes a specific print request. Specify <i>request-ID</i> as the job number (Job) associated with a print request and reported by <code>lpq</code> . See <code>lpq(1B)</code> .
<i>user</i>	Removes print requests associated with a specific user. Specify <i>user</i> as a valid user name. This option can only be used by a superuser.				
<i>request-ID</i>	Removes a specific print request. Specify <i>request-ID</i> as the job number (Job) associated with a print request and reported by <code>lpq</code> . See <code>lpq(1B)</code> .				
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Removing a print request</p> <p>The following example removes request-ID 385 from destination <code>killtree</code>:</p> <pre>example% lprm -P killtree 385</pre>				
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <table><tr><td>0</td><td>Successful completion.</td></tr><tr><td>non-zero</td><td>An error occurred.</td></tr></table>	0	Successful completion.	non-zero	An error occurred.
0	Successful completion.				
non-zero	An error occurred.				

<b>FILES</b>	/var/spool/print/[cd]f*	Spooling directories and files.
	/var/spool/lp/*	LP print queue
	\$HOME/.printers	User-configurable printer database
	/etc/printers.conf	System printer configuration database
	printers.conf.byname	NIS version of /etc/printers.conf
	printers.org_dir	NIS+ version of /etc/printers.conf

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscplp

**SEE ALSO** lp(1), lpc(1B), lpq(1B), lpr(1B), lpstat(1), lpadmin(1M), nsswitch.conf(4), printers(4), printers.conf(4), attributes(5), standards(5)

**NOTES** Users can only remove print requests associated with their user name. By default, users can only remove print requests on the host from which the print request was submitted. If a superuser has set `user-equivalence=true` in `/etc/printers.conf` on the print server, users can remove print requests associated with their user name on any host. Superusers can remove print requests on the host from which the print request was submitted. Superusers can also remove print requests from the print server.

## lpstat(1)

<b>NAME</b>	lpstat – print information about the status of the print service								
<b>SYNOPSIS</b>	<pre>lpstat [-d] [-r] [-R] [-s] [-t] [ -a <i>list</i>] [ -c <i>list</i>] [ -f <i>list</i> [-l]] [ -o <i>list</i>] [ -p <i>list</i>] [-D] [-l]] [ -S <i>list</i>] [-l]] [ -u [ <i>login-ID -list</i>] ] [ -v <i>list</i>]</pre>								
<b>DESCRIPTION</b>	<p>The <code>lpstat</code> utility displays information about the current status of the LP print service to standard output.</p> <p>If no options are given, <code>lpstat</code> prints the status of all the user's print requests made by <code>lp</code>. See <a href="#">lp(1)</a>. Any arguments that are not <i>options</i> are assumed to be <i>request-IDs</i> as returned by <code>lp</code>. The <code>lpstat</code> command prints the status of such requests. <i>options</i> may appear in any order and may be repeated and intermixed with other arguments. Some key letters may be followed by an optional <i>list</i> that can be in one of two forms: a list of items separated from one another by a comma, or a list of items separated from one another by spaces enclosed in quotes. For example:</p> <pre>example% lpstat -u "user1 user2 user3"</pre> <p>Specifying <code>all</code> after any key letter that takes <i>list</i> as an argument causes all information relevant to the key letter to be printed. For example, the command:</p> <pre>example% lpstat -o all</pre> <p>prints the status of all output requests.</p> <p>The omission of a <i>list</i> following such key letters causes all information relevant to the key letter to be printed. For example, the command:</p> <pre>example% lpstat -o</pre> <p>prints the status of all output requests.</p> <p>The print client commands locate destination information using the “printers” database in the name service switch. See <a href="#">nsswitch.conf(4)</a>, <a href="#">printers(4)</a>, and <a href="#">printers.conf(4)</a> for details.</p>								
<b>OPTIONS</b>	<p>The following options are supported on all platforms.</p> <table><tr><td>-d</td><td>Prints the default destination for output requests.</td></tr><tr><td>-o <i>list</i></td><td>Prints the status of output requests. <i>list</i> is a list of intermixed printer names, class names, and request-IDs. The key letter <code>-o</code> may be omitted. Specify printer and class names using atomic or POSIX-style (<i>server:destination</i>) names. See <a href="#">standards(5)</a> for information regarding POSIX.</td></tr><tr><td>-r</td><td>Prints the status of the LP request scheduler.</td></tr><tr><td>-R</td><td>Prints a number showing the position of each request in the print queue.</td></tr></table>	-d	Prints the default destination for output requests.	-o <i>list</i>	Prints the status of output requests. <i>list</i> is a list of intermixed printer names, class names, and request-IDs. The key letter <code>-o</code> may be omitted. Specify printer and class names using atomic or POSIX-style ( <i>server:destination</i> ) names. See <a href="#">standards(5)</a> for information regarding POSIX.	-r	Prints the status of the LP request scheduler.	-R	Prints a number showing the position of each request in the print queue.
-d	Prints the default destination for output requests.								
-o <i>list</i>	Prints the status of output requests. <i>list</i> is a list of intermixed printer names, class names, and request-IDs. The key letter <code>-o</code> may be omitted. Specify printer and class names using atomic or POSIX-style ( <i>server:destination</i> ) names. See <a href="#">standards(5)</a> for information regarding POSIX.								
-r	Prints the status of the LP request scheduler.								
-R	Prints a number showing the position of each request in the print queue.								

- s** Prints a status summary, including the status of the LP scheduler, the default destination, a list of printers and their associated devices, a list of the machines sharing print services, a list of all forms currently mounted, and a list of all recognized character sets and print wheels.
- t** Prints all status information. This includes all the information obtained with the **-s** option, plus the acceptance and idle/busy status of all printers.
- u** [*login-ID-list*] Prints the status of output requests for users. The *login-ID-list* argument may include any or all of the following constructs:
- login-ID*  
a user on any system
  - system\_name*!*login-ID*  
a user on system *system\_name*
  - system\_name*!all  
all users on system *system\_name*
  - all!*login-ID*  
a user on all systems
  - all  
all users on all systems
- v** [*list*] Prints the names of printers and the path names of the devices associated with them or remote system names for network printers. *list* is a list of printer names.
- The following options return accurate results only if they are issued from a Solaris 2.6 Operating Environment or compatible version of the LP print server.
- a** [*list*] Reports whether print destinations are accepting requests. *list* is a list of intermixed printer names and class names.
- c** [*list*] Prints name of all classes and their members. *list* is a list of class names.
- f** [*list*] [-1] Prints a verification that the forms in *list* are recognized by the LP print service. *list* is a list of forms; the default is all. The -1 option will list the form descriptions.
- p** [*list*] [-D] [-1] Prints the status of printers. *list* is a list of printer names. If the -D option is given, a brief description is printed for each printer in *list*. If the -1 option is given and the printer is on the local machine, a full

## lpstat(1)

	description of each printer's configuration is returned, including the form mounted, the acceptable content and printer types, a printer description, and the interface used.
-s [ <i>list</i> ] [-l]	Prints a verification that the character sets or the print wheels specified in <i>list</i> are recognized by the LP print service. Items in <i>list</i> can be character sets or print wheels; the default for the list is <code>all</code> . If the <code>-l</code> option is given, each line is appended by a list of printers that can handle the print wheel or character set. The list also shows whether the print wheel or character set is mounted, or specifies the built-in character set into which it maps.
-d	Prints the default destination for output requests.
-o [ <i>list</i> ]	Prints the status of output requests. <i>list</i> is a list of intermixed printer names, class names, and <i>request-IDs</i> . The key letter <code>-o</code> may be omitted.
-r	Prints the status of the LP request scheduler.
-R	Prints a number showing the position of each request in the print queue.
-s	Prints a status summary, including the status of the LP scheduler, the default destination, a list of printers and their associated devices, a list of the machines sharing print services, a list of all forms currently mounted, and a list of all recognized character sets and print wheels.
-t	Prints all status information. This includes all the information obtained with the <code>-s</code> option, plus the acceptance and idle/busy status of all printers.
-u [ <i>login-ID-list</i> ]	Prints the status of output requests for users. The <i>login-ID-list</i> argument may include any or all of the following constructs:  <i>login-ID</i> a user on any system  <i>system_name</i> ! <i>login-ID</i> a user on system <i>system_name</i>  <i>system_name</i> ! <code>all</code> all users on system <i>system_name</i>  <code>all</code> ! <i>login-ID</i> a user on all systems  <code>all</code> all users on all systems

`-v [list]` Prints the names of printers and the path names of the devices associated with them or remote system names for network printers. *list* is a list of printer names.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.  
non-zero An error occurred.

**FILES**

<code>/var/spool/print/*</code>	LP print queue.
<code>\$HOME/.printers</code>	User-configurable printer database.
<code>/etc/printers.conf</code>	System configuration database.
<code>printers.conf.byname</code>	NIS version of <code>/etc/printers.conf</code> .
<code>printers.org_dir</code>	NIS+ version of <code>/etc/printers.conf</code> .

## lptest(1B)

<b>NAME</b>	lptest – generate line printer ripple pattern
<b>SYNOPSIS</b>	<code>/usr/ucb/lptest [ length [count]]</code>
<b>DESCRIPTION</b>	<p>The <code>lptest</code> utility writes the traditional <i>ripple test</i> pattern to the standard output. In 96 lines, the ripple test pattern prints all 96 printable ASCII characters in each position. The ripple test pattern was originally created to test printers. It is also useful for testing terminals, driving terminal ports, debugging, and performing tasks that require a quick supply of random data.</p> <p>This command is obsolete.</p>
<b>OPTIONS</b>	<p><i>length</i> Specifies the length of the output line in characters. 79 characters is the default.</p> <p><i>count</i> Specifies the number of output lines. 200 lines is the default. If <i>count</i> is specified, <i>length</i> must also be specified.</p>
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>non-zero An error occurred.</p>
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscplp

**SEE ALSO** `attributes(5)`

<b>NAME</b>	ls – list contents of directory																		
<b>SYNOPSIS</b>	<pre> /usr/bin/ls [-aAbcCdeEfFghHilLmnopqrRstux1@] [file...] /usr/xpg4/bin/ls [-aAbcCdeEfFghHilLmnopqrRstux1@] [file...] /usr/xpg6/bin/ls [-aAbcCdeEfFghHilLmnopqrRstux1@] [file...] </pre>																		
<b>DESCRIPTION</b>	<p>For each <i>file</i> that is a directory, <code>ls</code> lists the contents of the directory. For each <i>file</i> that is an ordinary file, <code>ls</code> repeats its name and any other information requested. The output is sorted alphabetically by default. When no argument is given, the current directory is listed. When several arguments are given, the arguments are first sorted appropriately, but file arguments appear before directories and their contents.</p> <p>There are three major listing formats. The default format for output directed to a terminal is multi-column with entries sorted down the columns. The <code>-1</code> option allows single column output and <code>-m</code> enables stream output format. In order to determine output formats for the <code>-C</code>, <code>-x</code>, and <code>-m</code> options, <code>ls</code> uses an environment variable, <code>COLUMNS</code>, to determine the number of character positions available on one output line. If this variable is not set, the <code>terminfo(4)</code> database is used to determine the number of columns, based on the environment variable, <code>TERM</code>. If this information cannot be obtained, 80 columns are assumed.</p> <p>The mode printed under the <code>-l</code> option consists of ten characters. The first character can be one of the following:</p> <table border="0" style="margin-left: 20px;"> <tr><td>d</td><td>The entry is a directory.</td></tr> <tr><td>D</td><td>The entry is a door.</td></tr> <tr><td>l</td><td>The entry is a symbolic link.</td></tr> <tr><td>b</td><td>The entry is a block special file.</td></tr> <tr><td>c</td><td>The entry is a character special file.</td></tr> <tr><td>p</td><td>The entry is a FIFO (or “named pipe”) special file.</td></tr> <tr><td>P</td><td>The entry is an event port.</td></tr> <tr><td>s</td><td>The entry is an AF_UNIX address family socket.</td></tr> <tr><td>–</td><td>The entry is an ordinary file.</td></tr> </table> <p>The next 9 characters are interpreted as three sets of three bits each. The first set refers to the owner’s permissions; the next to permissions of others in the user-group of the file; and the last to all others. Within each set, the three characters indicate permission to read, to write, and to execute the file as a program, respectively. For a directory, “execute” permission is interpreted to mean permission to search the directory for a specified file. The character after permissions is ACL indication. A plus sign is displayed if there is an ACL associated with the file. Nothing is displayed if there are just permissions.</p> <p><code>ls -l</code> (the long list) prints its output as follows for the POSIX locale:</p>	d	The entry is a directory.	D	The entry is a door.	l	The entry is a symbolic link.	b	The entry is a block special file.	c	The entry is a character special file.	p	The entry is a FIFO (or “named pipe”) special file.	P	The entry is an event port.	s	The entry is an AF_UNIX address family socket.	–	The entry is an ordinary file.
d	The entry is a directory.																		
D	The entry is a door.																		
l	The entry is a symbolic link.																		
b	The entry is a block special file.																		
c	The entry is a character special file.																		
p	The entry is a FIFO (or “named pipe”) special file.																		
P	The entry is an event port.																		
s	The entry is an AF_UNIX address family socket.																		
–	The entry is an ordinary file.																		

ls(1)

```
-rwxrwxrwx+ 1 smith dev 10876 May 16 9:42 part2
```

Reading from right to left, you see that the current directory holds one file, named `part2`. Next, the last time that file's contents were modified was 9:42 A.M. on May 16. The file contains 10,876 characters, or bytes. The owner of the file, or the user, belongs to the group `dev` (perhaps indicating "development"), and his or her login name is `smith`. The number, in this case 1, indicates the number of links to file `part2` (see `cp(1)`). The plus sign indicates that there is an ACL associated with the file. *Note:* If the `-@` option has been specified, the presence of extended attributes supersede the presence of an ACL and the plus sign is replaced with an 'at' sign (`@`). Finally, the dash and letters tell you that user, group, and others have permissions to read, write, and execute `part2`.

The execute (`x`) symbol here occupies the third position of the three-character sequence. A `-` in the third position would have indicated a denial of execution permissions.

The permissions are indicated as follows:

<code>r</code>	The file is readable.
<code>w</code>	The file is writable.
<code>x</code>	The file is executable.
<code>-</code>	The indicated permission is <i>not</i> granted.
<code>s</code>	The set-user-ID or set-group-ID bit is on, and the corresponding user or group execution bit is also on.
<code>S</code>	Undefined bit-state (the set-user-ID or set-group-id bit is on and the user or group execution bit is off). For group permissions, this applies only to non-regular files.
<code>t</code>	The 1000 (octal) bit, or sticky bit, is on (see <code>chmod(1)</code> ), and execution is on.
<code>T</code>	The 1000 bit is turned on, and execution is off (undefined bit-state).
<code>/usr/bin/ls</code>	<code>l</code> Mandatory locking occurs during access (on a regular file, the set-group-ID bit is on and the group execution bit is off).
<code>/usr/xpg4/bin/ls</code> and <code>/usr/xpg6/bin/ls</code>	<code>L</code> Mandatory locking occurs during access (on a regular file, the set-group-ID bit is on and the group execution bit is off).

For user and group permissions, the third position is sometimes occupied by a character other than `x` or `-`. `s` or `S` also can occupy this position, referring to the state of the set-ID bit, whether it be the user's or the group's. The ability to assume the same ID as the user during execution is, for example, used during login when you begin as root but need to assume the identity of the user you login as.

In the case of the sequence of group permissions, `l` can occupy the third position. `l` refers to mandatory file and record locking. This permission describes a file's ability to allow other files to lock its reading or writing permissions during access.

For others permissions, the third position can be occupied by `t` or `T`. These refer to the state of the sticky bit and execution permissions.

## OPTIONS

`/usr/bin/ls`,  
`/usr/xpg4/bin/ls`,  
and  
`/usr/xpg6/bin/ls`

The following options are supported:

The following options are supported for all three versions:

- a Lists all entries, including those that begin with a dot (`.`), which are normally not listed.
- A Lists all entries, including those that begin with a dot (`.`), with the exception of the working directory (`.`) and the parent directory (`..`).
- b Forces printing of non-printable characters to be in the octal `\ddd` notation.
- c Uses time of last modification of the i-node (file created, mode changed, and so forth) for sorting (`-t`) or printing (`-l` or `-n`).
- C Multi-column output with entries sorted down the columns. This is the default output format.
- d If an argument is a directory, lists only its name (not its contents). Often used with `-l` to get the status of a directory.
- e The same as `-l`, except displays time to the second, and with one format for all files regardless of age: `mmm dd hhh:mm:ss yyyy`.
- E The same as `-l`, except displays time to the nanosecond and with one format for all files regardless of age: `yyyy-mm-dd hh:mm:ss.nnnnnnnnnn` (ISO 8601 format).
- f Forces each argument to be interpreted as a directory and list the name found in each slot. This option turns off `-l`, `-t`, `-s`, and `-r`, and turns on `-a`. The order is the order in which entries appear in the directory.
- g The same as `-l`, except that the owner is not printed.
- h All sizes are scaled to a human readable format, for example, `14K`, `234M`, `2.7G`, or `3.0T`. Scaling is done by repetitively dividing by `1024`.
- H If a symbolic link referencing a file of type directory is specified on the command line, this option lists the directory that the link references rather than the link itself.
- i For each file, prints the i-node number in the first column of the report.
- l Lists in long format, giving mode, ACL indication, number of links, owner, group, size in bytes, and time of last modification for each file (see above). If the file is a special file, the size field instead contains the major and minor device numbers. If the time of last modification is greater than six months ago, it is shown in the format 'month date year' for the POSIX locale. When the `LC_TIME` locale category is not set to the POSIX locale, a

ls(1)

	different format of the time field can be used. Files modified within six months show 'month date time'. If the file is a symbolic link, the filename is printed followed by "→" and the path name of the referenced file.
-L	If an argument is a symbolic link, this option evaluates the file information and file type of the file or directory that the link references, rather than those of the link itself. However, the name of the link is displayed, rather than the referenced file or directory.
-m	Streams output format. Files are listed across the page, separated by commas.
-n	The same as -l, except that the owner's UID and group's GID numbers are printed, rather than the associated character strings.
-o	The same as -l, except that the group is not printed.
-p	Puts a slash (/) after each filename if the file is a directory.
-q	Forces printing of non-printable characters in file names as the character question mark (?).
-r	Reverses the order of sort to get reverse alphabetic or oldest first as appropriate.
-R	Recursively lists subdirectories encountered.
-s	Gives size in blocks, including indirect blocks, for each entry.
-t	Sorts by time stamp (latest first) instead of by name. The default is the last modification time. (See -u and -c.)
-u	Uses time of last access instead of last modification for sorting (with the -t option) or printing (with the -l option).
-@	The same as -l, except that extended attribute information supersedes ACL information. An @ is displayed after the file permission bits for files that have extended attributes.
-x	Multi-column output with entries sorted across rather than down the page.
-1	Prints one entry per line of output.
<b>/usr/bin/ls</b>	-F Marks directories with a trailing slash (/), doors with a trailing greater-than sign (>), executable files with a trailing asterisk (*), FIFOs with a trailing vertical bar ( ), symbolic links with a trailing "at" sign (@), and AF_UNIX address family sockets with a trailing equals sign (=). Follows symlinks named as operands.

Specifying more than one of the options in the following mutually exclusive pairs is not considered an error: -C and -l (ell), -m and -l (ell), -x and -l (ell), -@ and -l (ell). The -l (ell) option overrides the other option specified in each pair.

Specifying more than one of the options in the following mutually exclusive pairs is not considered an error: `-C` and `-l` (one), `-H` and `-L`, `-c` and `-u`, and `-e` and `-E`. The last option specified in each of these pairs determines the output format.

**/usr/xpg4/bin/ls**    `-F`        Marks directories with a trailing slash (/), doors with a trailing greater-than sign (>), executable files with a trailing asterisk (\*), FIFOs with a trailing vertical bar (|), symbolic links with a trailing "at" sign (@), and AF\_UNIX address family sockets with a trailing equals sign (=). Follows symlinks named as operands.

Specifying more than one of the options in the following mutually exclusive pairs is not considered an error: `-C` and `-l` (ell), `-m` and `-l` (ell), `-x` and `-l` (ell), `-@` and `-l` (ell), `-C` and `-l` (one), `-H` and `-L`, `-c` and `-u`, and `-e` and `-E`. The last option specified in each pair determines the output format.

**/usr/xpg6/bin/ls**    `-F`        Marks directories with a trailing slash (/), doors with a trailing greater-than sign (>), executable files with a trailing asterisk (\*), FIFOs with a trailing vertical bar (|), symbolic links with a trailing "at" sign (@), and AF\_UNIX address family sockets with a trailing equals sign (=). Does not follow symlinks named as operands unless the `-H` or `-L` option is specified.

Specifying more than one of the options in the following mutually exclusive pairs is not considered an error: `-C` and `-l` (ell), `-m` and `-l` (ell), `-x` and `-l` (ell), `-@` and `-l` (ell), `-C` and `-l` (one), `-H` and `-L`, `-c` and `-u`, and `-e` and `-E`. The last option specified in each pair determines the output format.

**OPERANDS**        The following operand is supported:

*file*            A path name of a file to be written. If the file specified is not found, a diagnostic message is output on standard error.

**USAGE**            See `largefile(5)` for the description of the behavior of `ls` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**EXAMPLES**        **EXAMPLE 1** Viewing File Permissions

An example of a file's permissions is:

```
-rwxr--r--
```

This describes a file that is readable, writable, and executable by the user and readable by the group and others.

Another example of a file's permissions is:

```
-rwsr-xr-x
```

This describes a file that is readable, writable, and executable by the user, readable and executable by the group and others, and allows its user-ID to be assumed, during execution, by the user presently executing it.

ls(1)

**EXAMPLE 1** Viewing File Permissions (Continued)

Another example of a file's permissions is:

```
-rw-rw1---
```

This describes a file that is readable and writable only by the user and the group and can be locked during access.

**EXAMPLE 2** Printing the Names of All Files

This command prints the names of all files in the current directory, including those that begin with a dot (.), which normally do not print:

```
example% ls -a
```

**EXAMPLE 3** Providing File Information

Another example of a command line is:

```
example% ls -aisn
```

This command provides information on all files, including those that begin with a dot (a), the i-number—the memory address of the i-node associated with the file—printed in the left-hand column (i); the size (in blocks) of the files, printed in the column to the right of the i-numbers (s); finally, the report is displayed in the numeric version of the long list, printing the UID (instead of user name) and GID (instead of group name) numbers associated with the files.

When the sizes of the files in a directory are listed, a total count of blocks, including indirect blocks, is printed.

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `ls`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_TIME`, `LC_MESSAGES`, `NLSPATH`, and `TZ`.

**COLUMNS** Determines the user's preferred column position width for writing multiple text-column output. If this variable contains a string representing a decimal integer, the `ls` utility calculates how many path name text columns to write (see `-C`) based on the width provided. If `COLUMNS` is not set or is invalid, 80 is used. The column width chosen to write the names of files in any given directory is constant. File names are not be truncated to fit into the multiple text-column output.

**EXIT STATUS**

0 All information was written successfully.  
>0 An error occurred.

**FILES**

`/etc/group` group IDs for `ls -l` and `ls -g`

/etc/passwd user IDs for `ls -l` and `ls -o`  
 /usr/share/lib/terminfo/?/\* terminal information database

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

**/usr/bin/ls**

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled
Interface Stability	Stable

**/usr/xpg4/bin/ls**

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
CSI	Enabled
Interface Stability	Standard

**/usr/xpg6/bin/ls**

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu6
CSI	Enabled
Interface Stability	Standard

**SEE ALSO** `chmod(1)`, `cp(1)`, `setfacl(1)`, `terminfo(4)`, `attributes(5)`, `environ(5)`, `fsattr(5)`, `largefile(5)`, `standards(5)`

**NOTES** Unprintable characters in file names can confuse the columnar output options.

The total block count is incorrect if there are hard links among the files.

The sort order of `ls` output is affected by the locale and can be overridden by the `LC_COLLATE` environment variable. For example, if `LC_COLLATE` equals `C`, dot files appear first, followed by names beginning with upper-case letters, then followed by names beginning with lower-case letters. But if `LC_COLLATE` equals `en_US.ISO8859-1`, then leading dots as well as case are ignored in determining the sort order.

## ls(1B)

<b>NAME</b>	ls – list the contents of a directory
<b>SYNOPSIS</b>	<code>/usr/ucb/ls [-aAcCdFgILqrRstu1] file...</code>
<b>DESCRIPTION</b>	<p>For each <i>filename</i> that is a directory, <code>ls</code> lists the contents of the directory; for each <i>filename</i> that is a file, <code>ls</code> repeats its name and any other information requested. By default, the output is sorted alphabetically. When no argument is given, the current directory is listed. When several arguments are given, the arguments are first sorted appropriately, but file arguments are processed before directories and their contents.</p>
<b>Permissions Field</b>	<p>The mode printed under the <code>-l</code> option contains 10 characters interpreted as follows. If the first character is:</p> <ul style="list-style-type: none"><li>d Entry is a directory.</li><li>D Entry is a door.</li><li>b Entry is a block-type special file.</li><li>c Entry is a character-type special file.</li><li>l Entry is a symbolic link.</li><li>p Entry is a FIFO (also known as “named pipe”) special file.</li><li>s Entry is an AF_UNIX address family socket.</li><li>– Entry is a plain file.</li></ul> <p>The next 9 characters are interpreted as three sets of three bits each. The first set refers to owner permissions; the next refers to permissions to others in the same user-group; and the last refers to all others. Within each set, the three characters indicate permission respectively to read, to write, or to execute the file as a program. For a directory, “execute” permission is interpreted to mean permission to search the directory. The permissions are indicated as follows:</p> <ul style="list-style-type: none"><li>r The file is readable.</li><li>w The file is writable.</li><li>x The file is executable.</li><li>– The indicated permission is not granted.</li></ul> <p>The group-execute permission character is given as <code>s</code> if the file has the set-group-id bit set; likewise the owner-execute permission character is given as <code>S</code> if the file has the set-user-id bit set.</p> <p>The last character of the mode (normally <code>x</code> or <code>'–'</code>) is <code>true</code> if the 1000 bit of the mode is on. See <code>chmod(1)</code> for the meaning of this mode. The indications of set-ID and 1000 bits of the mode are capitalized (<code>S</code> and <code>T</code>, respectively) if the corresponding execute permission is <i>not</i> set.</p> <p>A plus sign (+) appended to the list of permissions indicates that an ACL is associated with the file.</p>

When the sizes of the files in a directory are listed, a total count of blocks, including indirect blocks, is printed.

**OPTIONS**

The following options are supported:

- a Lists all entries; in the absence of this option, entries whose names begin with a `'.'` are *not* listed (except for the privileged user, for whom `ls` normally prints even files that begin with a `'.'`).
- A Same as `-a`, except that `'.'` and `'..'` are not listed.
- c Uses time of last edit (or last mode change) for sorting or printing.
- C Forces multi-column output, with entries sorted down the columns; for `ls`, this is the default when output is to a terminal.
- d If argument is a directory, lists only its name (not its contents); often used with `-l` to get the status of a directory.
- f Forces each argument to be interpreted as a directory and lists the name found in each slot. This option turns off `-l`, `-t`, `-s`, and `-r`, and turns on `-a`; the order is the order in which entries appear in the directory.
- F Marks directories with a trailing slash (`/`), doors with a trailing greater-than sign (`>`), executable files with a trailing asterisk (`*`), FIFOs with a trailing vertical bar (`|`), symbolic links with a trailing at-sign (`@`), and AF\_UNIX address family sockets with a trailing equals sign (`=`).
- g For `ls`, shows the group ownership of the file in a long output.
- i For each file, prints the i-node number in the first column of the report.
- l Lists in long format, giving mode, ACL indication, number of links, owner, size in bytes, and time of last modification for each file. If the file is a special file the size field will instead contain the major and minor device numbers. If the time of last modification is greater than six months ago, it is shown in the format `'month date year'`; files modified within six months show `'month date time'`. If the file is a symbolic link, the pathname of the linked-to file is printed preceded by `'->'`.
- L If argument is a symbolic link, lists the file or directory the link references rather than the link itself.
- q Displays non-graphic characters in filenames as the character `?`; for `ls`, this is the default when output is to a terminal.
- r Reverses the order of sort to get reverse alphabetic or oldest first as appropriate.
- R Recursively lists subdirectories encountered.
- s Gives size of each file, including any indirect blocks used to map the file, in kilobytes.
- t Sorts by time modified (latest first) instead of by name.

## ls(1B)

- u Uses time of last access instead of last modification for sorting (with the `-t` option) and/or printing (with the `-l` option).
- l Forces one entry per line output format; this is the default when output is not to a terminal.

**OPERANDS** The following operand is supported:

*file* A path name of a file to be listed. If the file specified is not found, a diagnostic message will be output on standard error.

**USAGE** See `largefile(5)` for the description of the behavior of `ls` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**FILES** `/etc/group` to get group ID for '`ls -g`'  
`/etc/passwd` to get user IDs for '`ls -l`' and '`ls -o`'

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

**SEE ALSO** `ls(1)`, `attributes(5)`, `largefile(5)`

**NOTES** NEWLINE and TAB are considered printing characters in filenames.

The output device is assumed to be 80 columns wide.

The option setting based on whether the output is a teletype is undesirable as '`ls -s`' is much different than '`ls -s | lpr`'. On the other hand, not doing this setting would make old shell scripts which used `ls` almost certain losers.

Unprintable characters in file names may confuse the columnar output options.

<b>NAME</b>	m4 – macro processor
<b>SYNOPSIS</b>	<pre> /usr/ccs/bin/m4 [-e] [-s] [-B int] [-H int] [-S int] [-T int] [ -Dname   [=val]] ... [-U name] ... [file...]  /usr/xpg4/bin/m4 [-e] [-s] [-B int] [-H int] [-S int] [-T int] [ -Dname   [ ...=val]] [-U name] ... [file...] </pre>
<b>DESCRIPTION</b>	<p>The m4 utility is a macro processor intended as a front end for C, assembler, and other languages. Each of the argument files is processed in order. If there are no files, or if a file is -, the standard input is read. The processed text is written on the standard output. <i>Note:</i> m4 cannot include more than nine nested files and will write a diagnostic message if that number is exceeded.</p>
<b>Macro Syntax</b>	<p>Macro calls have the form:</p> <pre>name (arg1, arg2, . . . , argn)</pre> <p>The open parenthesis character, (, must immediately follow the name of the macro. If the name of a defined macro is not followed by a (, it is deemed to be a call of that macro with no arguments. Potential macro names consist of alphanumeric characters and underscore (_), where the first character is not a digit.</p> <p>Leading unquoted blanks, TABs, and NEWLINES are ignored while collecting arguments. Left and right single quotes are used to quote strings. The value of a quoted string is the string stripped of the quotes.</p>
<b>Macro Processing</b>	<p>When a macro name is recognized, its arguments are collected by searching for a matching right parenthesis. If fewer arguments are supplied than are in the macro definition, the trailing arguments are taken to be NULL. Macro evaluation proceeds normally during the collection of the arguments, and any commas or right parentheses that happen to turn up within the value of a nested call are as effective as those in the original input text. After argument collection, the value of the macro is pushed back onto the input stream and rescanned.</p>
<b>OPTIONS</b>	<p>The options and their effects are as follows:</p> <ul style="list-style-type: none"> <li>-Bint      Changes the size of the push-back and argument collection buffers from the default of 4,096.</li> <li>-e          Operates interactively. Interrupts are ignored and the output is unbuffered.</li> <li>-Hint      Changes the size of the symbol table hash array from the default of 199. The size should be prime.</li> <li>-s          Enables line sync output for the C preprocessor (#line . . .)</li> <li>-Sint      Changes the size of the call stack from the default of 100slots. Macros take three slots, and non-macro arguments take one.</li> <li>-Tint      Changes the size of the token buffer from the default of 512bytes.</li> </ul> <p>To be effective, the above flags must appear before any file names and before any -D or -U flags:</p>

## m4(1)

	<code>-D name[=val]</code>	Defines <i>name</i> to <i>val</i> or to NULL in <i>val</i> 's absence.
	<code>-Uname</code>	Undefines <i>name</i> .
<b>OPERANDS</b>	The following operand is supported:	
	<i>file</i>	A path name of a text file to be processed. If no <i>file</i> is given, or if it is <code>-</code> , the standard input is read.
<b>USAGE</b>	The m4 utility makes available the following built-in macros. These macros may be redefined, but once this is done the original meaning is lost. Their values are NULL unless otherwise stated.	
	<code>changequote</code>	Change quote symbols to the first and second arguments. The symbols may be up to five characters long. <code>changequote</code> without arguments restores the original values (that is, <code>' '</code> ).
	<code>changecom</code>	Change left and right comment markers from the default <code>#</code> and <code>NEWLINE</code> . With no arguments, the comment mechanism is effectively disabled. With one argument, the left marker becomes the argument and the right marker becomes <code>NEWLINE</code> . With two arguments, both markers are affected. Comment markers may be up to five characters long.
	<code>decr</code>	Returns the value of its argument decremented by 1.
	<code>define</code>	The second argument is installed as the value of the macro whose name is the first argument. Each occurrence of <code>\$n</code> in the replacement text, where <i>n</i> is a digit, is replaced by the <i>n</i> -th argument. Argument 0 is the name of the macro; missing arguments are replaced by the null string; <code> \$#</code> is replaced by the number of arguments; <code> \$*</code> is replaced by a list of all the arguments separated by commas; <code> \$@</code> is like <code> \$*</code> , but each argument is quoted (with the current quotes).
	<code>defn</code>	Returns the quoted definition of its argument(s). It is useful for renaming macros, especially built-ins.
	<code>divert</code>	m4 maintains 10 output streams, numbered 0-9. The final output is the concatenation of the streams in numerical order. Initially stream 0 is the current stream. The <code>divert</code> macro changes the current output stream to its (digit-string) argument. Output diverted to a stream other than 0 through 9 is discarded.
	<code>divnum</code>	Returns the value of the current output stream.
	<code>dn1</code>	Reads and discards characters up to and including the next <code>NEWLINE</code> .
	<code>dumpdef</code>	Prints current names and definitions, for the named items, or for all if no arguments are given.
	<code>errprint</code>	Prints its argument on the diagnostic output file.

<code>/usr/ccs/bin/m4</code>	eval	Evaluates its argument as an arithmetic expression, using 32-bit signed-integer arithmetic. The following operators are supported: parentheses, unary <code>-</code> , unary <code>+</code> , <code>!</code> , <code>~</code> , <code>*</code> , <code>/</code> , <code>%</code> , <code>+</code> , <code>-</code> , relationals, bitwise <code>&amp;</code> , <code> </code> , <code>&amp;&amp;</code> , and <code>  </code> . Octal and hex numbers may be specified as in C. The second argument specifies the radix for the result; the default is 10. The third argument may be used to specify the minimum number of digits in the result.
<code>/usr/xpg4/bin/m4</code>	eval	Evaluates its argument as an arithmetic expression, using 32-bit signed-integer arithmetic. The following operators are supported: parentheses, unary <code>-</code> , unary <code>+</code> , <code>!</code> , <code>~</code> , <code>*</code> , <code>/</code> , <code>%</code> , <code>+</code> , <code>-</code> , <code>&lt;&lt;</code> , <code>&gt;&gt;</code> , relationals, bitwise <code>&amp;</code> , <code> </code> , <code>&amp;&amp;</code> , and <code>  </code> . Precedence and associativity are as in C. Octal and hex numbers may also be specified as in C. The second argument specifies the radix for the result; the default is 10. The third argument may be used to specify the minimum number of digits in the result.
	ifdef	If the first argument is defined, the value is the second argument, otherwise the third. If there is no third argument, the value is <code>NULL</code> . The word <code>unix</code> is predefined.
	ifelse	This macro has three or more arguments. If the first argument is the same string as the second, then the value is the third argument. If not, and if there are more than four arguments, the process is repeated with arguments 4, 5, 6 and 7. Otherwise, the value is either the fourth string, or, if it is not present, <code>NULL</code> .
	include	Returns the contents of the file named in the argument.
	incr	Returns the value of its argument incremented by 1. The value of the argument is calculated by interpreting an initial digit-string as a decimal number.
	index	Returns the position in its first argument where the second argument begins (zero origin), or <code>-1</code> if the second argument does not occur.
	len	Returns the number of characters in its argument.
	m4exit	This macro causes immediate exit from <code>m4</code> . Argument 1, if given, is the exit code; the default is 0.
	m4wrap	Argument 1 will be pushed back at final EOF. Example: <code>m4wrap('cleanup( )')</code>
	maketemp	Fills in a string of <code>"X"</code> characters in its argument with the current process ID.
	popdef	Removes current definition of its argument(s), exposing the previous one, if any.
	pushdef	Like <code>define</code> , but saves any previous definition.

m4(1)

<code>shift</code>	Returns all but its first argument. The other arguments are quoted and pushed back with commas in between. The quoting nullifies the effect of the extra scan that will subsequently be performed.
<code>sinclude</code>	This macro is identical to <code>include</code> , except that it says nothing if the file is inaccessible.
<code>substr</code>	Returns a substring of its first argument. The second argument is a zero origin number selecting the first character; the third argument indicates the length of the substring. A missing third argument is taken to be large enough to extend to the end of the first string.
<code>syscmd</code>	This macro executes the command given in the first argument. No value is returned.
<code>sysval</code>	This macro is the return code from the last call to <code>syscmd</code> .
<code>translit</code>	Transliterates the characters in its first argument from the set given by the second argument to the set given by the third. No abbreviations are permitted.
<code>traceon</code>	This macro with no arguments, turns on tracing for all macros (including built-ins). Otherwise, turns on tracing for named macros.
<code>traceoff</code>	Turns off trace globally and for any macros specified.
<code>undefine</code>	Removes the definition of the macro named in its argument.
<code>undivert</code>	This macro causes immediate output of text from diversions named as arguments, or all diversions if no argument. Text may be undiverted into another diversion. Undiverting discards the diverted text.

## EXAMPLES

### EXAMPLE 1 Examples of m4 files

If the file `m4src` contains the lines:

```
The value of `VER' is "VER".
ifdef(`VER', ``VER'' is defined to be VER., VER is not defined.)
ifndef(VER, 1, ``VER'' is `VER'.)
ifndef(VER, 2, ``VER'' is `VER'., ``VER'' is not 2.)
end
```

then the command:

```
m4 m4src
```

or the command:

```
m4 -U VER m4src
```

produces the output:

**EXAMPLE 1** Examples of m4 files (Continued)

```

The value of VER is "VER".
VER is not defined.

VER is not 2.
end

```

The command:

```
m4 -D VER m4src
```

produces the output:

```

The value of VER is "".
VER is defined to be .

VER is not 2.
end

```

The command:

```
m4 -D VER=1 m4src
```

produces the output:

```

The value of VER is "1".
VER is defined to be 1.
VER is 1.
VER is not 2.
end

```

The command:

```
m4 -D VER=2 m4src
```

produces the output:

```

The value of VER is "2".
VER is defined to be 2.

VER is 2.
end

```

**ENVIRONMENT  
VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of m4: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

```

0          Successful completion.
>0        An error occurred

```

If the `m4exit` macro is used, the exit value can be specified by the input file.

m4(1)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

`/usr/ccs/bin/m4`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

`/usr/xpg4/bin/m4`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
Interface Stability	Standard

**SEE ALSO** `as(1)`, `attributes(5)`, `environ(5)`, `standards(5)`

<b>NAME</b>	mac – calculate message authentication codes of the input
<b>SYNOPSIS</b>	<code>/usr/bin/mac -l   [-v] -a algorithm [-k keyfile] [file...]</code>
<b>DESCRIPTION</b>	<p>The <code>mac</code> utility calculates the message authentication code (MAC) of the given file or files or stdin using the algorithm specified.</p> <p>If more than one file is given, each line of output is the MAC of a single file.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <p><code>-a algorithm</code> Specifies the name of the algorithm to use during the encryption or decryption process. See <i>USAGE</i>, <i>Algorithms</i> for details. <i>Note:</i> Algorithms for producing general length MACs are not supported.</p> <p><code>-k keyfile</code> Specifies the file containing the key value for the encryption algorithm. Each algorithm has specific key material requirements, as stated in the PKCS#11 specification. If <code>-k</code> is not specified, <code>mac</code> prompts for key material using <code>getpassphrase(3C)</code>.</p> <p>For information on generating a key file, see <code>dd(1M)</code> or <i>System Administration Guide: Security Services</i>.</p> <p><code>-l</code> Displays the list of algorithms available on the system. This list can change depending on the configuration of the cryptographic framework. The key sizes are displayed in bits.</p> <p><code>-v</code> Provides verbose information.</p>
<b>USAGE</b>	
<b>Algorithms</b>	<p>The supported algorithms are displayed with the <code>-l</code> option. These algorithms are provided by the cryptographic framework. Each supported algorithm is an alias to the most commonly used and least restricted version of a particular algorithm type. For example, <code>md5_hmac</code> is an alias to <code>CKM_MD5_HMAC</code>.</p> <p>These aliases are used with the <code>-a</code> option and are case-sensitive.</p>
<b>Passphrase</b>	<p>When the <code>-k</code> option is not used during encryption and decryption tasks, the user is prompted for a passphrase. The passphrase is manipulated into a more secure key using the PBKDF2 algorithm specified in PKCS #5.</p>
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Listing available algorithms</p> <pre>example\$ mac -l Algorithm      Keysize:  Min   Max ----- des_mac                64    64 sha1_hmac              8   512 md5_hmac               8   512</pre>

mac(1)

**EXAMPLE 2** Getting the message authentication code for a file

```
example$ mac -v -k mykey -a sha1_hmac /export/foo
sha1_hmac (/export/foo) = 913ced311df10f1708d9848641ca8992f4718057
```

**EXIT STATUS** The following exit values are returned:

0           Successful completion.  
>0          An error occurred.

RSA PKCS#5 v2.0 <http://www.rsasecurity.com/rsalabs/pkcs/pkcs-5>

mach(1)

**NAME** mach – display the processor type of the current host

**SYNOPSIS** mach

**DESCRIPTION** The mach command displays the processor-type of the current host.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO** `arch(1)`, `uname(1)`, `attributes(5)`

**NOTES** mach and `uname -p` return equivalent values; therefore, Independent Software Vendors (ISV) and others who need to ascertain processor type are encouraged to use `uname` with the `-p` option instead of the mach command. The mach command is provided for compatibility with previous releases, but generally its use is discouraged.

## machid(1)

<b>NAME</b>	machid, sun, iAPX286, i286, i386, i486, i860, pdp11, sparc, u3b, u3b2, u3b5, u3b15, vax, u370 – get processor type truth value																						
<b>SYNOPSIS</b>	<b>sun</b> <b>iAPX286</b> <b>i386</b> <b>pdp11</b> <b>sparc</b> <b>u3b</b> <b>u3b2</b> <b>u3b5</b> <b>u3b15</b> <b>vax</b> <b>u370</b>																						
<b>DESCRIPTION</b>	<p>The following commands will return a true value (exit code of 0) if you are using an instruction set that the command name indicates.</p> <table><tr><td>sun</td><td>True if you are on a Sun system.</td></tr><tr><td>iAPX286</td><td>True if you are on a computer using an iAPX286 processor.</td></tr><tr><td>i386</td><td>True if you are on a computer using an iAPX386 processor.</td></tr><tr><td>pdp11</td><td>True if you are on a PDP-11/45™ or PDP-11/70™.</td></tr><tr><td>sparc</td><td>True if you are on a computer using a SPARC-family processor.</td></tr><tr><td>u3b</td><td>True if you are on a 3B20 computer.</td></tr><tr><td>u3b2</td><td>True if you are on a 3B2 computer.</td></tr><tr><td>u3b5</td><td>True if you are on a 3B5 computer.</td></tr><tr><td>u3b15</td><td>True if you are on a 3B15 computer.</td></tr><tr><td>vax</td><td>True if you are on a VAX-11/750™ or VAX-11/780™.</td></tr><tr><td>u370</td><td>True if you are on an IBM® System/370™ computer.</td></tr></table> <p>The commands that do not apply will return a false (non-zero) value. u3b2	True if you are on a 3B2 computer.																						
u3b5	True if you are on a 3B5 computer.																						
u3b15	True if you are on a 3B15 computer.																						
vax	True if you are on a VAX-11/750™ or VAX-11/780™.																						
u370	True if you are on an IBM® System/370™ computer.																						
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:																						

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO** `make(1S)`, `sh(1)`, `test(1)`, `true(1)`, `uname(1)`, `attributes(5)`

**NOTES** The machid family of commands is obsolete. Use `uname -p` and `uname -m` instead.

## madv.so.1(1)

<b>NAME</b>	madv.so.1 – madv library
<b>SYNOPSIS</b>	<code>/usr/lib/madv.so.1</code>
<b>DESCRIPTION</b>	<p>The <code>madv.so.1</code> shared object provides a means by which the VM advice can be selectively configured for a launched process (or processes) and its descendants. To enable <code>madv.so.1</code>, the following string needs to be present in the environment (see <a href="#">ld.so.1(1)</a>) along with one or more MADV environment variables:</p> <pre>LD_PRELOAD=\$LD_PRELOAD:madv.so.1</pre>
<b>ENVIRONMENT VARIABLES</b>	<p>If the <code>madv.so.1</code> shared object is specified in the <code>LD_PRELOAD</code> list, the following environment variables are read by the <code>madv</code> shared object to determine to which created process(es) to apply the specified advice.</p> <p><code>MADV=advice</code> MADV specifies the VM advice to use for all heap, shared memory, and mmap regions in the process address space. This advice is applied to all created processes.</p> <p>Values for <i>advice</i> correspond to values in <code>&lt;sys/mman.h&gt;</code> used in <code>madvise(3C)</code> to specify memory access patterns:</p> <ul style="list-style-type: none"><li>normal</li><li>random</li><li>sequential</li><li>access_lwp</li><li>access_many</li><li>access_default</li></ul> <p><code>MADVCFGFILE=config-file</code> <i>config-file</i> is a text file which contains one or more <code>madv</code> configuration entries of the form:</p> <pre>exec-name exec-args:advice-opts</pre> <p>Advice specified in <i>config-file</i> takes precedence over that specified by the MADV environment variable. When <code>MADVCFGFILE</code> is not set, advice is taken from file <code>/etc/madv.conf</code> if it exists.</p> <p><i>exec-name</i> specifies the name of an application or executable. The corresponding advice is set for newly created processes (see <code>getexecname(3C)</code>) that match the first <i>exec-name</i> found in the file.</p> <p><i>exec-name</i> can be a full pathname, a base name, or a pattern string. See <a href="#">File Name Generation</a> in <a href="#">sh(1)</a> for a discussion of pattern matching.</p> <p><i>exec-args</i> is an optionally specified pattern string to match against arguments. Advice is set only if <i>exec-args</i> is not specified or occurs within the arguments to <i>exec-name</i>.</p> <p><i>advice-opts</i> is a comma-separated list specifying the advice for various memory region(s):</p>

<code>madv=advice</code>	Applies to all heap, shared memory, and mmap regions in the process address space.
<code>heap=advice</code>	The heap is defined to be the brk area (see <code>brk(2)</code> ). Applies to the existing heap and for any additional heap memory allocated in the future.
<code>shm=advice</code> <code>ism=advice</code> <code>dism=advice</code>	Shared memory segments (see <code>shmat(2)</code> ) attached using any flags, flag <code>SHM_SHARE_MMU</code> , or flag <code>SHM_PAGEABLE</code> respectively. Options <code>ism</code> and <code>dism</code> take precedence over option <code>shm</code> .
<code>map=advice</code> <code>mapshared=advice</code> <code>mappprivate=advice</code> <code>mapanon=advice</code>	Mappings established through <code>mmap(2)</code> using any flags, flag <code>MAP_SHARED</code> , flag <code>MAP_PRIVATE</code> , or flag <code>MAP_ANON</code> , respectively. Options <code>mapshared</code> , <code>mappprivate</code> , and <code>mapanon</code> take precedence over option <code>map</code> . Option <code>mapanon</code> takes precedence over <code>mapshared</code> and <code>mappprivate</code> .
<code>MADVERRFILE=pathname</code>	By default, error messages are logged via <code>syslog(3C)</code> using level <code>LOG_ERR</code> and facility <code>LOG_USER</code> . If <code>MADVERRFILE</code> contains a valid <i>pathname</i> (such as <code>/dev/stderr</code> ), error messages will be logged there instead.

**EXAMPLES** **EXAMPLE 1** Applying advice to all ISM segments

The following configuration applies advice to all ISM segments for application `/usr/bin/foo`:

```
example$ LD_PRELOAD=$LD_PRELOAD:madv.so.1
example$ MADVCFGFILE=madvcfg
example$ export LD_PRELOAD MADVCFGFILE
example$ cat $MADVCFGFILE
/usr/bin/foo:ism=access_lwp
```

**EXAMPLE 2** Setting advice for all applications with exception

The following configuration sets advice for all applications with the exception of `ls`.

```
example$ LD_PRELOAD=$LD_PRELOAD:madv.so.1
example$ MADV=access_many
example$ MADVCFGFILE=madvcfg
example$ export LD_PRELOAD MADV MADVCFGFILE
example$ cat $MADVCFGFILE
ls:
```

madv.so.1(1)

**EXAMPLE 3** Precedence rules (continuation from Example 2)

Because MADVCFGFILE takes precedence over MADV, specifying '\*' (pattern match all) for the *exec-name* of the last madv configuration entry would be equivalent to setting MADV. The following is equivalent to example 2:

```
example$ LD_PRELOAD=$LD_PRELOAD:madv.so.1
example$ MADVCFGFILE=madvcfg
example$ export LD_PRELOAD MADVCFGFILE
example$ cat $MADVCFGFILE
ls:
*:madv=access_many
```

**EXAMPLE 4** Applying advice for different regions

The following configuration applies one type of advice for mmap regions and different advice for heap and shared memory regions for a select set of applications with exec names that begin with foo:

```
example$ LD_PRELOAD=$LD_PRELOAD:madv.so.1
example$ MADVCFGFILE=madvcfg
example$ export LD_PRELOAD MADVCFGFILE
example$ cat $MADVCFGFILE
foo*:madv=access_many,heap=sequential,shm=access_lwp
```

**EXAMPLE 5** Applying advice selectively

The following configuration applies advice for the heap of applications beginning with ora that have ora1 as an argument:

```
example$ LD_PRELOAD=$LD_PRELOAD:madv.so.1
example$ MADVCFGFILE=madvcfg
example$ export LD_PRELOAD MADVCFGFILE
example$ cat $MADVCFGFILE
ora* ora1:heap=access_many
```

**FILES** /etc/madv.conf Configuration file

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu (32-bit)
	SUNWesxu (64-bit)
Interface Stability	Unstable

**SEE ALSO** [cat\(1\)](#), [ld.so.1\(1\)](#), [proc\(1\)](#), [sh\(1\)](#), [brk\(2\)](#), [exec\(2\)](#), [fork\(2\)](#), [mmap\(2\)](#), [memcntl\(2\)](#), [shmat\(2\)](#), [getexecname\(3C\)](#), [madvise\(3C\)](#), [syslog\(3C\)](#), [proc\(4\)](#), [attributes\(5\)](#)

**NOTES** The advice is inherited. A child process has the same advice as its parent. On `exec()` (see [exec\(2\)](#)), the advice is set back to the default system advice unless different advice has been configured via the madv shared object.

Advice is only applied to `mmap` regions explicitly created by the user program. Those regions established by the run-time linker or by system libraries making direct system calls (for example, `libthread` allocations for thread stacks) are not affected.

## mail(1)

<b>NAME</b>	mail, rmail – read mail or send mail to users
<b>SYNOPSIS</b>	
<b>Sending Mail</b>	<b>mail</b> [-tw] [-m <i>message_type</i> ] <i>recipient</i> ... <b>rmail</b> [-tw] [-m <i>message_type</i> ] <i>recipient</i> ...
<b>Reading Mail</b>	<b>mail</b> [-ehpPqr] [-f <i>file</i> ]
<b>Debugging</b>	<b>mail</b> [-x <i>debug_level</i> ] [ <i>other_mail_options</i> ] <i>recipient</i> ...
<b>DESCRIPTION</b>	<p>A <i>recipient</i> is usually a domain style address (“<i>user@machine</i>”) or a user name recognized by <a href="#">login(1)</a>. When <i>recipients</i> are named, <b>mail</b> assumes a message is being sent. It reads from the standard input up to an end-of-file (Control-d) or, if reading from a terminal device, until it reads a line consisting of just a period. When either of those indicators is received, <b>mail</b> adds the <i>letter</i> to the <i>mailfile</i> for each <i>recipient</i>.</p> <p>A <i>letter</i> is composed of some <i>header lines</i> followed by a blank line followed by the <i>message content</i>. The <i>header lines</i> section of the letter consists of one or more UNIX postmarks:</p> <pre>From <i>sender date_and_time</i> [<i>remote from remote_system_name</i>]</pre> <p>followed by one or more standardized message header lines of the form:</p> <pre><i>keyword-name</i>: [<i>printable text</i>]</pre> <p>where <i>keyword-name</i> is comprised of any printable, non-whitespace characters other than colon (:). A <code>MIME-version:</code> header line indicates that the message is formatted as described in RFC 2045. A <code>Content-Length:</code> header line, indicating the number of bytes in the <i>message content</i>, is always present unless the letter consists of only header lines with no message content. A <code>Content-Type:</code> header line that describes the type of the <i>message content</i> (such as <code>text/plain</code>, <code>application/octet-stream</code>, and so on) is also present, unless the letter consists of only header lines with no message content. Header lines may be continued on the following line if that line starts with white space.</p>
<b>OPTIONS</b>	
<b>Sending Mail</b>	The following command-line arguments affect sending mail:
-m <i>message_type</i>	A <code>Message-Type:</code> line is added to the message header with the value of <i>message_type</i> .
-t	A <code>To:</code> line is added to the message header for each of the intended <i>recipients</i> .
-w	A letter is sent to a remote recipient without waiting for the completion of the remote transfer program.
	If a letter is found to be undeliverable, it is returned to the sender with diagnostics that indicate the location and nature of the failure. If <b>mail</b> is interrupted during input, the message is saved in the file <code>dead.letter</code> to allow editing and resending.

`dead.letter` is always appended to, thus preserving any previous contents. The initial attempt to append to (or create) `dead.letter` is in the current directory. If this fails, `dead.letter` is appended to (or created in) the user's login directory. If the second attempt also fails, no `dead.letter` processing is done.

`rmail` only permits the sending of mail; `uucp(1C)` uses `rmail` as a security precaution. Any application programs that generate mail messages should be sure to invoke `rmail` rather than `mail` for message transport and/or delivery.

If the local system has the Basic Networking Utilities installed, mail can be sent to a recipient on a remote system. There are numerous ways to address mail to recipients on remote systems depending on the transport mechanisms available to the local system. The two most prevalent addressing schemes are Domain-style and UUCP-style.

#### Domain-style addressing

Remote recipients are specified by appending an '@' and domain (and possibly sub-domain) information to the recipient name (such as `user@sf.att.com`). (The local system administrator should be consulted for details on which addressing conventions are available on the local system.)

#### UUCP-style addressing

Remote recipients are specified by prefixing the recipient name with the remote system name and an exclamation point, such as `sysa!user`. If `cs(1)` is the default shell, `sysa!user` should be used. A series of system names separated by exclamation points can be used to direct a letter through an extended network (such as `sysa!sysb!sysc!user` or `sysa!\sysb!\sysc!user`).

### Reading Mail

The following command-line arguments affect reading mail:

- e                    Test for the presence of mail. `mail` prints nothing.  
  
An exit status of 0 is returned if the user has mail. Otherwise, an exit status of 1 is returned.
- E                    Similar to -e, but tests only for the presence of *new* mail.  
  
An exit status of 0 is returned if the user has new mail to read, an exit status of 1 is returned if the user has no mail, or an exit status of 2 is returned if the user has mail which has already been read.
- h                    A window of headers are initially displayed rather than the latest message. The display is followed by the ? prompt.
- p                    All messages are printed without prompting for disposition.
- P                    All messages are printed with *all* header lines displayed, rather than the default selective header line display.
- q                    `mail` terminates after interrupts. Normally an interrupt causes only the termination of the message being printed.
- r                    Messages are printed in first-in, first-out order.

## mail(1)

`-f file` mail uses *file* (such as *mbox*) instead of the default *mailfile*.

mail, unless otherwise influenced by command-line arguments, prints a user's mail messages in last-in, first-out order. The default mode for printing messages is to display only those header lines of immediate interest. These include, but are not limited to, the UNIX From and >From postmarks, From:, Date:, Subject:, and Content-Length: header lines, and any recipient header lines such as To:, Cc:, Bcc:, and so forth. After the header lines have been displayed, mail displays the contents (body) of the message only if it contains no unprintable characters. Otherwise, mail issues a warning statement about the message having binary content and not display the content. This can be overridden by means of the p command.

For each message, the user is prompted with a ? and a line is read from the standard input. The following commands are available to determine the disposition of the message:

#	Print the number of the current message.
-	Print previous message.
<new-line>,+, or n	Print the next message.
! <i>command</i>	Escape to the shell to do <i>command</i> .
a	Print message that arrived during the mail session.
d, or dp	Delete the current message and print the next message.
d <i>n</i>	Delete message number <i>n</i> . Do not go on to next message.
dq	Delete message and quit mail.
h	Display a window of headers around current message.
h <i>n</i>	Display a window of headers around message number <i>n</i> .
h a	Display headers of all messages in the user's <i>mailfile</i> .
h d	Display headers of messages scheduled for deletion.
m [ <i>persons</i> ]	Mail (and delete) the current message to the named <i>persons</i> .
<i>n</i>	Print message number <i>n</i> .
p	Print current message again, overriding any indications of binary (that is, unprintable) content.
P	Override default brief mode and print current message again, displaying all header lines.
q, or Control-d	Put undeleted mail back in the <i>mailfile</i> and quit mail.

r [ <i>users</i> ]	Reply to the sender, and other <i>users</i> , then delete the message.
s [ <i>files</i> ]	Save message in the named <i>files</i> (mbox is default) and delete the message.
u [ <i>n</i> ]	Undelete message number <i>n</i> (default is last read).
w [ <i>files</i> ]	Save message contents, without any header lines, in the named <i>files</i> (mbox is default) and delete the message.
x	Put all mail back in the <i>mailfile</i> unchanged and exit mail.
y [ <i>files</i> ]	Same as -w option.
?	Print a command summary.

When a user logs in, the presence of mail, if any, is usually indicated. Also, notification is made if new mail arrives while using mail.

The permissions of *mailfile* can be manipulated using `chmod(1)` in two ways to alter the function of mail. The other permissions of the file can be read-write (0666), read-only (0664), or neither read nor write (0660) to allow different levels of privacy. If changed to other than the default (mode 0660), the file is preserved even when empty to perpetuate the desired permissions. (The administrator can override this file preservation using the DEL\_EMPTY\_MAILFILE option of mailcnfg.)

The group ID of the mailfile must be mail to allow new messages to be delivered, and the mailfile must be writable by group mail.

### Debugging

The following command-line arguments cause mail to provide debugging information:

-x *debug\_level*                      mail creates a trace file containing debugging information.

The -x option causes mail to create a file named `/tmp/MLDBGprocess_id` that contains debugging information relating to how mail processed the current message. The absolute value of *debug\_level* controls the verbosity of the debug information. 0 implies no debugging. If *debug\_level* is greater than 0, the debug file is retained *only* if mail encountered some problem while processing the message. If *debug\_level* is less than 0, the debug file is always be retained. The *debug\_level* specified via -x overrides any specification of DEBUG in `/etc/mail/mailcnfg`. The information provided by the -x option is esoteric and is probably only useful to system administrators.

### Delivery Notification

Several forms of notification are available for mail by including one of the following lines in the message header.

Transport-Options: [ /options ]

Default-Options: [ /options ]

## mail(1)

>To: *recipient* [ */options* ]

Where the “*/options*” can be one or more of the following:

<i>/delivery</i>	Inform the sender that the message was successfully delivered to the <i>recipient</i> 's mailbox.
<i>/nodelivery</i>	Do not inform the sender of successful deliveries.
<i>/ignore</i>	Do not inform the sender of failed deliveries.
<i>/return</i>	Inform the sender if mail delivery fails. Return the failed message to the sender.
<i>/report</i>	Same as <i>/return</i> except that the original message is not returned.

The default is */nodelivery/return*. If contradictory options are used, the first is recognized and later, conflicting, terms are ignored.

**OPERANDS** The following operand is supported for sending mail:

*recipient* A domain style address (“*user@machine*”) or user login name recognized by [login\(1\)](#).

**USAGE** See [largefile\(5\)](#) for the description of the behavior of `mail` and `rmail` when encountering files greater than or equal to 2 Gbyte (2<sup>31</sup> bytes).

**ENVIRONMENT VARIABLES** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `mail`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

`TZ` Determine the timezone used with date and time strings.

**EXIT STATUS** The following exit values are returned:

0	Successful completion when the user had mail.
1	The user had no mail or an initialization error occurred.
>1	An error occurred after initialization.

**FILES**

<code>dead.letter</code>	unmailable text
<code>/etc/passwd</code>	to identify sender and locate <i>recipients</i>
<code>\$HOME/mbox</code>	saved mail
<code>\$MAIL</code>	variable containing path name of <i>mailfile</i>
<code>/tmp/ma*</code>	temporary file
<code>/tmp/MLDBG*</code>	debug trace file
<code>/var/mail/*.lock</code>	lock for mail directory
<code>/var/mail/:saved</code>	directory for holding temp files to prevent loss of data in the event of a system crash

`/var/mail/user` incoming mail for *user*; that is, the *mailfile*

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO** `chmod(1)`, `csch(1)`, `login(1)`, `mailx(1)`, `uucp(1C)`, `uuencode(1C)`, `vacation(1)`, `write(1)`, `attributes(5)`, `environ(5)`, `largefile(5)`

*Solaris Advanced User's Guide*

**NOTES** The interpretation and resulting action taken because of the header lines described in the Delivery Notifications section only occur if this version of `mail` is installed on the system where the delivery (or failure) happens. Earlier versions of `mail` might not support any types of delivery notification.

Conditions sometimes result in a failure to remove a lock file.

After an interrupt, the next message might not be printed. Printing can be forced by typing a `p`.

mail(1B)

**NAME** mail, Mail – interactive message processing system

**SYNOPSIS** /usr/ucb/mail ...  
/usr/ucb/Mail ...

**DESCRIPTION** /usr/ucb/mail and /usr/ucb/Mail are provided as links to /usr/bin/mailx.  
See mailx(1) for more information on the usage of these commands.

**SEE ALSO** mailx(1),attributes(5)

<b>NAME</b>	mailcompat – provide SunOS compatibility for Solaris mailbox format				
<b>DESCRIPTION</b>	<p>mailcompat is a program to provide SunOS 4.x compatability for the Solaris mailbox format. You would typically run mailcompat to be able to read mail on a workstation running SunOS 4.x when your mail server is running Solaris.</p> <p>Enabling mailcompat creates an entry in your .forward file, if it exists. If this file does not exist, mailcompat will create it. Disabling mailcompat will remove the entry from the .forward file, and if this was the only entry, will remove the entire file.</p> <p>To execute mailcompat, log onto the Solaris mail server and enter mailcompat on the command line. Answer the queries provided by the program.</p>				
<b>USAGE</b>	See largefile(5) for the description of the behavior of mailcompat when encountering files greater than or equal to 2 Gbyte ( 2 <sup>31</sup> bytes).				
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Examples of the mailcompat feature.</p> <p>The following example enables the mailcompat feature for the user "john".</p> <pre>example% mailcompat This program can be used to store your mail in a format that you can read with SunOS 4.X based mail readers To enable the mailcompat feature a ".forward" file is created. Would you like to enable the mailcompat feature? Y Mailcompat feature ENABLED.Run mailcompat with no arguments to remove it example%</pre> <p>The following example disables the mailcompat feature for the user "john".</p> <pre>example% mailcompat This program can be used to store your mail in a format that you can read with SunOS 4.X based mail readers You have a .forward file in your home directory containing:   " /usr/bin/mailcompat johns" Would you like to remove it and disable the mailcompat feature? y Back to normal reception of mail. example%</pre>				
<b>FILES</b>	~/ .forward      list of recipients for forwarding messages				
<b>ATTRIBUTES</b>	See attributes(5) for descriptions of the following attributes:

## mailp(1)

<b>NAME</b>	mailp, digestp, filep, newsp, filofaxp, franklinp, timemanp, timesysp – frontends to the mp Text to PDL (Printer Description Language) pretty print filter																
<b>SYNOPSIS</b>	<b>mailp</b> [ <i>options</i> ] <i>filename</i> ... <b>newsp</b> [ <i>options</i> ] <i>filename</i> ... <b>digestp</b> [ <i>options</i> ] <i>filename</i> ... <b>filep</b> [ <i>options</i> ] <i>filename</i> ... <b>filofaxp</b> [ <i>options</i> ] <i>filename</i> ... <b>franklinp</b> [ <i>options</i> ] <i>filename</i> ... <b>timemanp</b> [ <i>options</i> ] <i>filename</i> ... <b>timesysp</b> [ <i>options</i> ] <i>filename</i> ...																
<b>DESCRIPTION</b>	<p>The mailp utility is a frontend to the mp(1) program. It uses different names to provide various mp options:</p> <table><tr><td>mailp</td><td>Prints out mail messages.</td></tr><tr><td>newsp</td><td>Prints out USENET news articles.</td></tr><tr><td>digestp</td><td>Prints out USENET digest files.</td></tr><tr><td>filep</td><td>Prints out ordinary ASCII files.</td></tr><tr><td>filofaxp</td><td>Prints out in Filofax personal organiser format.</td></tr><tr><td>franklinp</td><td>Prints out in Franklin Planner personal organiser format.</td></tr><tr><td>timemanp</td><td>Prints out in Time Manager personal organiser format.</td></tr><tr><td>timesysp</td><td>Prints out in Time/System International personal organiser format.</td></tr></table> <p>mailp and the associated programs read each <i>filename</i> in sequence and generate a prettified version of the contents. If no filename arguments are provided, mailp reads the standard input.</p> <p>mailp works in two ways. With the -D option, it will work as an X print server client to produce the PDL of the target printer and spool it. With the -d or -P option, it will generate and spool PostScript™ output.</p>	mailp	Prints out mail messages.	newsp	Prints out USENET news articles.	digestp	Prints out USENET digest files.	filep	Prints out ordinary ASCII files.	filofaxp	Prints out in Filofax personal organiser format.	franklinp	Prints out in Franklin Planner personal organiser format.	timemanp	Prints out in Time Manager personal organiser format.	timesysp	Prints out in Time/System International personal organiser format.
mailp	Prints out mail messages.																
newsp	Prints out USENET news articles.																
digestp	Prints out USENET digest files.																
filep	Prints out ordinary ASCII files.																
filofaxp	Prints out in Filofax personal organiser format.																
franklinp	Prints out in Franklin Planner personal organiser format.																
timemanp	Prints out in Time Manager personal organiser format.																
timesysp	Prints out in Time/System International personal organiser format.																
<b>OPTIONS</b>	<p>The following options are supported:</p> <table><tr><td>-d <i>printer</i></td><td>Sends output to the named printer. Otherwise, sends output to the printer named in the PRINTER environment variable.</td></tr><tr><td>-D</td><td>Generates the PDL for the target printer and spools it to the printer.</td></tr><tr><td>-F</td><td>Instead of printing who the mail article is <i>for</i>, the top header will contain who the mail article is <i>from</i>. This is a useful option for people with their own personal printer.</td></tr></table>	-d <i>printer</i>	Sends output to the named printer. Otherwise, sends output to the printer named in the PRINTER environment variable.	-D	Generates the PDL for the target printer and spools it to the printer.	-F	Instead of printing who the mail article is <i>for</i> , the top header will contain who the mail article is <i>from</i> . This is a useful option for people with their own personal printer.										
-d <i>printer</i>	Sends output to the named printer. Otherwise, sends output to the printer named in the PRINTER environment variable.																
-D	Generates the PDL for the target printer and spools it to the printer.																
-F	Instead of printing who the mail article is <i>for</i> , the top header will contain who the mail article is <i>from</i> . This is a useful option for people with their own personal printer.																

- h           Banner printing is disabled. Most of the information that typically appears on the banner sheet is output in the mp banners.
- l           Formats output in landscape mode. Two pages of text will be printed per sheet of paper.
- P *printer*   Same as -d option.
- s *subject*   Uses *subject* as the new subject for the printout. If you are printing ordinary ASCII files which have been specified on the command line, the subject will default to the name of each of these files.

**OPERANDS**   The following operand is supported:

*filename*       The name of the file to be read.

**ENVIRONMENT VARIABLES**   If none of the -d, -D, or -P options is used, mailp uses the PRINTER environment variable to determine the printer to which the output from the mp(1) program is sent. If the PRINTER variable is not found, the default destination is the PostScript™ printer.

**EXIT STATUS**   The following exit values are returned:

- 0           Successful completion.
- 1           An error occurred.

**ATTRIBUTES**   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmp

**SEE ALSO**   mp(1), attributes(5)

**NOTES**   The -P option, which spools the PDL directly to the target printer in mp(1), produces PostScript™ when used in mailp so as to be backward compatible.

## mailq(1)

<b>NAME</b>	mailq – print the mail queue
<b>SYNOPSIS</b>	<code>/usr/bin/mailq [-Ac] [-q <i>subarg</i>] [-v]</code>
<b>DESCRIPTION</b>	<p>The mailq utility displays a summary of the mail messages queued for future delivery.</p> <p>The first line displayed for each mail message shows the internal identifier used on this host for the message, the size of the message in bytes, the date and time the message was accepted into the queue, and the envelope sender of the message. The second line of the display shows the error message that caused this message to be retained in the queue. This line will not be displayed if the message is being processed for the first time.</p> <p>The mailq utility used to be identical to sendmail -bp. Now it checks for the authorization attribute, solaris.mail.mailq. If the check for the invoking user succeeds, sendmail -bp is executed with the remaining argument vector. Otherwise, an error message is printed. This authorization attribute is by default enabled for all users. It can be disabled by modifying the Basic Solaris User entry in prof_attr(4).</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"><li>-Ac            Like sendmail(IM), this flag tells mailq to use submit.cf rather than sendmail.cf even if the operation mode does not indicate an initial mail submission. This will result in the client queue /var/spool/clientmqueue being displayed rather than the default server queue /var/spool/mqueue.</li><li>-qp[<i>time</i>]    Similar to -qtime, except that instead of periodically forking a child to process the queue, sendmail forks a single persistent child for each queue that alternates between processing the queue and sleeping. The sleep time is given as the argument. The sleep time default is 1 second. The process will always sleep at least 5 seconds if the queue was empty in the previous queue run.</li><li>-qf            Processes saved messages in the queue once and does not fork(), but runs in the foreground.</li><li>-qG <i>name</i>     Processes jobs in the queue group called <i>name</i> only.</li><li>-q[!]I <i>substr</i>   Limits processed jobs to those containing <i>substr</i> as a substring of the queue id, or not when ! is specified.</li><li>-q[!]R <i>substr</i>   Limits processed jobs to those containing <i>substr</i> as a substring of one of the recipients, or not when ! is specified.</li><li>-q[!]S <i>substr</i>   Limits processed jobs to those containing <i>substr</i> as a substring of the sender, or not when ! is specified.</li><li>-v            Prints verbose information. This adds the priority of the message and a single character indicator (+ or blank) indicating whether a warning message has been sent on the first line of the message. Additionally, extra lines may be intermixed with the recipients that</li></ul>

indicate the "controlling user" information. This shows who will own any programs that are executed on behalf of this message and the name of the alias this command is expanded from, if any.

**EXIT STATUS** 0 Successful completion.

>0 An error occurred.

**FILES** /etc/security/prof\_attr local source for execution profile attributes

/var/spool/mqueue default server queue

/var/spool/clientmqueue client queue

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsndmu

**SEE ALSO** `sendmail(1M)`, `prof_attr(4)`, `attributes(5)`

## mailstats(1)

<b>NAME</b>	mailstats – print statistics collected by sendmail																		
<b>SYNOPSIS</b>	<b>mailstats</b> [-o] [-c ] [-C <i>configfile</i> ] [-f <i>statisticsfile</i> ] [-p] [-P]																		
<b>DESCRIPTION</b>	<p>The mailstats utility prints out the statistics collected by the sendmail(1M) program on mailer usage. These statistics are collected if the file indicated by the StatusFile configuration option of sendmail (defined in /etc/mail/sendmail.cf) exists. The default statistics file is /etc/mail/statistics.</p> <p>To enable mailstats, you must, as root, touch /etc/mail/statistics. See the StatusFile processing option in sendmail(1M).</p> <p>mailstats first prints the time that the statistics file was created and the last time it was modified. Then, the statistics for each mailer are displayed on a single line, each with the following whitespace-separated fields:</p> <table><tr><td>M</td><td>The mailer number.</td></tr><tr><td>msgsf</td><td>Number of messages from the mailer.</td></tr><tr><td>bytes_from</td><td>Kbytes from the mailer.</td></tr><tr><td>msgsto</td><td>Number of messages to the mailer.</td></tr><tr><td>bytes_to</td><td>Kbytes to the mailer.</td></tr><tr><td>msgsrj</td><td>Number of messages rejected by the mailer.</td></tr><tr><td>msgsd</td><td>Number of messages discarded by the mailer.</td></tr><tr><td>msgsq</td><td>Number of messages quarantined by the mailer.</td></tr><tr><td>Mailer</td><td>The name of the mailer.</td></tr></table> <p>The display of statistics described above is followed by a separation line containing only equal sign (=) characters. After the separation line, a line preceded with a “T” and totaling the values for all of the mailers is displayed. This is followed by another line preceded with a “C” that lists the number of TCP connections.</p> <p>To reinitialize the statistics file once a night, add an entry to root’s crontab(1):</p> <pre>mailstats -p &gt; /dev/null</pre>	M	The mailer number.	msgsf	Number of messages from the mailer.	bytes_from	Kbytes from the mailer.	msgsto	Number of messages to the mailer.	bytes_to	Kbytes to the mailer.	msgsrj	Number of messages rejected by the mailer.	msgsd	Number of messages discarded by the mailer.	msgsq	Number of messages quarantined by the mailer.	Mailer	The name of the mailer.
M	The mailer number.																		
msgsf	Number of messages from the mailer.																		
bytes_from	Kbytes from the mailer.																		
msgsto	Number of messages to the mailer.																		
bytes_to	Kbytes to the mailer.																		
msgsrj	Number of messages rejected by the mailer.																		
msgsd	Number of messages discarded by the mailer.																		
msgsq	Number of messages quarantined by the mailer.																		
Mailer	The name of the mailer.																		
<b>OPTIONS</b>	<p>The following options are supported:</p> <table><tr><td>-c</td><td>Try to use submit.cf instead of the default sendmail configuration file.</td></tr><tr><td>-C <i>configfile</i></td><td>Specify a sendmail configuration file.</td></tr><tr><td>-f <i>statisticsfile</i></td><td>Specify a sendmail statistics file.</td></tr><tr><td>-o</td><td>Do not display the name of the mailer in the output.</td></tr></table>	-c	Try to use submit.cf instead of the default sendmail configuration file.	-C <i>configfile</i>	Specify a sendmail configuration file.	-f <i>statisticsfile</i>	Specify a sendmail statistics file.	-o	Do not display the name of the mailer in the output.										
-c	Try to use submit.cf instead of the default sendmail configuration file.																		
-C <i>configfile</i>	Specify a sendmail configuration file.																		
-f <i>statisticsfile</i>	Specify a sendmail statistics file.																		
-o	Do not display the name of the mailer in the output.																		

- p Output information in program-readable mode and clear statistics.
- P Output information in program-readable mode without clearing statistics.

**USAGE** See [largefile\(5\)](#) for the description of the behavior of `mailstats` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**FILES**

<code>/dev/null</code>	Zero-lined file
<code>/etc/mail/statistics</code>	Default <code>sendmail</code> statistics file
<code>/etc/mail/sendmail.cf</code>	Default <code>sendmail</code> configuration file

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsndmu
Output Stability	Unstable

**SEE ALSO** [crontab\(1\)](#), [cron\(1M\)](#), [sendmail\(1M\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

## mailx(1)

<b>NAME</b>	mailx – interactive message processing system
<b>SYNOPSIS</b>	<b>mailx</b> [-BdeHiInNURvV~] [ -f <i>file</i>   + <i>folder</i> ] [-T <i>file</i> ] [-u <i>user</i> ] <b>mailx</b> [-BdFintUv~] [-b <i>bcc</i> ] [-c <i>cc</i> ] [-h <i>number</i> ] [-r <i>address</i> ] [-s <i>subject</i> ] <i>recipient...</i> <b>/usr/ucb/mail</b> ... <b>/usr/ucb/Mail</b> ...
<b>DESCRIPTION</b>	<p>The mail utilities listed above provide a comfortable, flexible environment for sending and receiving mail messages electronically.</p> <p>When reading mail, the mail utilities provide commands to facilitate saving, deleting, and responding to messages. When sending mail, the mail utilities allow editing, reviewing and other modification of the message as it is entered.</p> <p>Incoming mail is stored in a standard file for each user, called the <code>mailbox</code> for that user. When the mail utilities are called to read messages, the <code>mailbox</code> is the default place to find them. As messages are read, they are marked to be moved to a secondary file for storage, unless specific action is taken, so that the messages need not be seen again. This secondary file is called the <code>mbox</code> and is normally located in the user's <code>HOME</code> directory (see <code>MBOX</code> in <code>ENVIRONMENT VARIABLES</code> for a description of this file). Messages can be saved in other secondary files named by the user. Messages remain in a secondary file until forcibly removed.</p> <p>The user can access a secondary file by using the <code>-f</code> option. Messages in the secondary file can then be read or otherwise processed using the same Commands as in the primary <code>mailbox</code>. This gives rise within these pages to the notion of a current <code>mailbox</code>.</p>
<b>OPTIONS</b>	<p>On the command line options start with a dash (-). Any other arguments are taken to be destinations (recipients). If no recipients are specified, <code>mailx</code> attempts to read messages from the <code>mailbox</code>.</p> <p><b>-B</b> Do not buffer standard input or standard output.</p> <p><b>-b <i>bcc</i></b> Set the blind carbon copy list to <i>bcc</i>. <i>bcc</i> should be enclosed in quotes if it contains more than one name.</p> <p><b>-c <i>cc</i></b> Set the carbon copy list to <i>cc</i>. <i>cc</i> should be enclosed in quotes if it contains more than one name.</p> <p><b>-d</b> Turn on debugging output. (Neither particularly interesting nor recommended.)</p> <p><b>-e</b> Test for the presence of mail. <code>mailx</code> prints nothing and exits with a successful return code if there is mail to read.</p> <p><b>-F</b> Record the message in a file named after the first recipient. Overrides the <code>record</code> variable, if set (see <code>Internal Variables</code>).</p>

-f <i>[file]</i>	Read messages from <i>file</i> instead of mailbox. If no <i>file</i> is specified, the mbox is used.
-f [ + <i>folder</i> ]	Use the file <i>folder</i> in the folder directory (same as the <code>folder</code> command). The name of this directory is listed in the <code>folder</code> variable.
-H	Print header summary only.
-h <i>number</i>	The number of network “hops” made so far. This is provided for network software to avoid infinite delivery loops. This option and its argument are passed to the delivery program.
-I	Include the newsgroup and article-id header lines when printing mail messages. This option requires the <code>-f</code> option to be specified.
-i	Ignore interrupts. See also <code>ignore</code> in Internal Variables.
-N	Do not print initial header summary.
-n	Do not initialize from the system default <code>mailx.rc</code> or <code>Mail.rc</code> file. See USAGE.
-r <i>address</i>	Use <i>address</i> as the return address when invoking the delivery program. All tilde commands are disabled. This option and its argument is passed to the delivery program.
-s <i>subject</i>	Set the Subject header field to <i>subject</i> . <i>subject</i> should be enclosed in quotes if it contains embedded white space.
-T <i>file</i>	Message-id and article-id header lines are recorded in <i>file</i> after the message is read. This option also sets the <code>-I</code> option.
-t	Scan the input for <code>To:</code> , <code>Cc:</code> , and <code>Bcc:</code> fields. Any recipients on the command line will be ignored.
-U	Convert UUCP-style addresses to internet standards. Overrides the <code>conv</code> environment variable.
-u <i>user</i>	Read <i>user</i> ’s mailbox. This is only effective if <i>user</i> ’s mailbox is not read protected.
-V	Print the mailx version number and exit.
-v	Pass the <code>-v</code> flag to <code>sendmail(1M)</code> .
-~	Interpret tilde escapes in the input even if not reading from a tty.

**OPERANDS** The following operands are supported:

*recipient* Addressee of message.

## USAGE

mailx(1)

### Starting Mail

At startup time, mailx executes the system startup file `/etc/mail/mailx.rc`. If invoked as `mail` or `Mail`, the system startup file `/etc/mail/Mail.rc` is used instead.

The system startup file sets up initial display options and alias lists and assigns values to some internal variables. These variables are flags and valued parameters which are set and cleared using the `set` and `unset` commands. See *Internal Variables*.

With the following exceptions, regular commands are legal inside startup files: `!`, `Copy`, `edit`, `followup`, `Followup`, `hold`, `mail`, `preserve`, `reply`, `Reply`, `shell`, and `visual`. An error in the startup file causes the remaining lines in the file to be ignored.

After executing the system startup file, the mail utilities execute the optional personal startup file `$HOME/.mailrc`, wherein the user can override the values of the internal variables as set by the system startup file.

If the `-n` option is specified, however, the mail utilities do not execute the system startup file.

Many system administrators include the commands

```
set appenddeadletter
unset replyall
unset pipeignore
```

in the system startup files (to be compatible with past Solaris behavior), but this does not meet standards requirements for mailx. To get standard behavior for mailx, users should use the `-n` option or include the following commands in a personal startup file:

```
unset appenddeadletter
set replyall
set pipeignore
```

When reading mail, the mail utilities are in *command mode*. A header summary of the first several messages is displayed, followed by a prompt indicating the mail utilities can accept regular commands (see *Commands* below). When sending mail, the mail utilities are in *input mode*. If no subject is specified on the command line, and the `asksub` variable is set, a prompt for the subject is printed.

As the message is typed, the mail utilities read the message and store it in a temporary file. Commands may be entered by beginning a line with the tilde (`~`) escape character followed by a single command letter and optional arguments. See *Tilde Escapes* for a summary of these commands.

### Reading Mail

Each message is assigned a sequential number, and there is at any time the notion of a current message, marked by a right angle bracket (`>`) in the header summary. Many commands take an optional list of messages (*message-list*) to operate on. In most cases, the current message is set to the highest-numbered message in the list after the command is finished executing.

The default for *message-list* is the current message. A *message-list* is a list of message identifiers separated by spaces, which may include:

<i>n</i>	Message number <i>n</i> .										
.	The current message.										
^	The first undeleted message.										
\$	The last message.										
*	All messages.										
+	The next undeleted message.										
-	The previous undeleted message.										
<i>n-m</i>	An inclusive range of message numbers.										
<i>user</i>	All messages from <i>user</i> .										
<i>/string</i>	All messages with <i>string</i> in the Subject line (case ignored).										
<i>:c</i>	All messages of type <i>c</i> , where <i>c</i> is one of: <table> <tr> <td>d</td> <td>deleted messages</td> </tr> <tr> <td>n</td> <td>new messages</td> </tr> <tr> <td>o</td> <td>old messages</td> </tr> <tr> <td>r</td> <td>read messages</td> </tr> <tr> <td>u</td> <td>unread messages</td> </tr> </table>	d	deleted messages	n	new messages	o	old messages	r	read messages	u	unread messages
d	deleted messages										
n	new messages										
o	old messages										
r	read messages										
u	unread messages										

Notice that the context of the command determines whether this type of message specification makes sense.

Other arguments are usually arbitrary strings whose usage depends on the command involved. Filenames, where expected, are expanded using the normal shell conventions (see [sh\(1\)](#)). Special characters are recognized by certain commands and are documented with the commands below.

## Sending Mail

Recipients listed on the command line may be of three types: login names, shell commands, or alias groups. Login names may be any network address, including mixed network addressing. If mail is found to be undeliverable, an attempt is made to return it to the sender's mailbox. If the recipient name begins with a pipe symbol ( | ), the rest of the name is taken to be a shell command to pipe the message through. This provides an automatic interface with any program that reads the standard input, such as [lp\(1\)](#) for recording outgoing mail on paper. Alias groups are set by the alias command (see [Commands](#) below) or in a system startup file (for example, \$HOME/.mailrc). Aliases are lists of recipients of any type.

mailx(1)

### Forwarding Mail

To forward a specific message, include it in a message to the desired recipients with the `~f` or `~m` tilde escapes. See `Tilde Escapes` below. To forward mail automatically, add a comma-separated list of addresses for additional recipients to the `.forward` file in your home directory. This is different from the format of the `alias` command, which takes a space-separated list instead. *Note:* Forwarding addresses must be valid, or the messages will “bounce.” You cannot, for instance, reroute your mail to a new host by forwarding it to your new address if it is not yet listed in the NIS aliases domain.

### Commands

Regular commands are of the form

```
[ command ] [ message-list ] [ arguments ]
```

In *input mode*, commands are recognized by the escape character, `tilde (~)`, and lines not treated as commands are taken as input for the message. If no command is specified in *command mode*, next is assumed. The following is a complete list of `mailx` commands:

`!shell-command`

Escape to the shell. See `SHELL` in `ENVIRONMENT VARIABLES`.

`# comment`

NULL command (comment). Useful in `mailrc` files.

`=`

Print the current message number.

`?`

Prints a summary of commands.

`alias alias name . . .`

`group alias name . . .`

Declare an alias for the given names. The names are substituted when `alias` is used as a recipient. Useful in the `mailrc` file. With no arguments, the command displays the list of defined aliases.

`alternates name . . .`

Declare a list of alternate names for your login. When responding to a message, these names are removed from the list of recipients for the response. With no arguments, print the current list of alternate names. See also `allnet` in `Internal Variables`.

`cd [directory]`

`chdir [directory]`

Change directory. If `directory` is not specified, `$HOME` is used.

`copy [file]`

`copy [message-list] file`

Copy messages to the file without marking the messages as saved. Otherwise equivalent to the `save` command.

Copy [*message-list*]

Save the specified messages in a file whose name is derived from the author of the message to be saved, without marking the messages as saved. Otherwise equivalent to the Save command.

delete [*message-list*]

Delete messages from the mailbox. If autoprint is set, the next message after the last one deleted is printed (see Internal Variables).

discard [*header-field*. . .]

ignore [*header-field*. . .]

Suppress printing of the specified header fields when displaying messages on the screen. Examples of header fields to ignore are Status and Received. The fields are included when the message is saved, unless the `alwaysignore` variable is set. The More, Page, Print, and Type commands override this command. If no header is specified, the current list of header fields being ignored is printed. See also the `undiscard` and `unignore` commands.

dp [*message-list*]

dt [*message-list*]

Delete the specified messages from the mailbox and print the next message after the last one deleted. Roughly equivalent to a delete command followed by a print command.

echo *string* . . .

Echo the given strings (like `echo(1)`).

edit [*message-list*]

Edit the given messages. Each message is placed in a temporary file and the program named by the `EDITOR` variable is invoked to edit it (see ENVIRONMENT VARIABLES). Default editor is `ed(1)`.

exit

xit

Exit from mailx, without changing the mailbox. No messages are saved in the mbox (see also quit).

field [*message-list*] *header-file*

Display the value of the header field in the specified message.

file [*file*]

folder [*file*]

Quit from the current file of messages and read in the specified file. Several special characters are recognized when used as file names:

% the current mailbox.

%*user* the mailbox for *user*.

# the previous mail file.

& the current mbox.

+*file* The named file in the *folder* directory (listed in the `folder` variable).

## mailx(1)

With no arguments, print the name of the current mail file, and the number of messages and characters it contains.

### folders

Print the names of the files in the directory set by the `folder` variable (see `Internal Variables`).

### Followup [*message*]

Respond to a message, recording the response in a file whose name is derived from the author of the message. Overrides the `record` variable, if set. If the `replyall` variable is set, the actions of `Followup` and `followup` are reversed. See also the `followup`, `Save`, and `Copy` commands and `outfolder` in `Internal Variables`, and the `Starting Mail` section in `USAGE` above.

### followup [*message-list*]

Respond to the first message in the *message-list*, sending the message to the author of each message in the *message-list*. The subject line is taken from the first message and the response is recorded in a file whose name is derived from the author of the first message. If the `replyall` variable is set, the actions of `followup` and `Followup` are reversed. See also the `Followup`, `Save`, and `Copy` commands and `outfolder` in `Internal Variables`, and the `Starting Mail` section in `USAGE` above.

### from [*message-list*]

Print the header summary for the specified messages. If no messages are specified, print the header summary for the current message.

### group *alias name* . . .

### alias *alias name* . . .

Declare an alias for the given names. The names are substituted when `alias` is used as a recipient. Useful in the `mailrc` file.

### headers [*message*]

Print the page of headers which includes the message specified. The `screen` variable sets the number of headers per page (see `Internal Variables`). See also the `z` command.

### help

Print a summary of commands.

### hold [*message-list*]

### preserve [*message-list*]

Hold the specified messages in the mailbox.

### if *s* | *r* | *t*

### *mail-commands*

### else

### *mail-commands*

### endif

Conditional execution, where *s* executes following *mail-commands*, up to an `else` or `endif`, if the program is in *send* mode, *r* causes the *mail-commands* to be executed only in *receive* mode, and *t* causes the *mail-commands* to be executed only if `mailx` is being run from a terminal. Useful in the `mailrc` file.

**inc**

Incorporate messages that arrive while you are reading the system mailbox. The new messages are added to the message list in the current mail session. This command does not commit changes made during the session, and prior messages are not renumbered.

**ignore** [*header-field* ...]

**discard** [*header-field* ...]

Suppress printing of the specified header fields when displaying messages on the screen. Examples of header fields to ignore are `Status` and `Cc`. All fields are included when the message is saved. The `More`, `Page`, `Print` and `Type` commands override this command. If no header is specified, the current list of header fields being ignored is printed. See also the `undiscard` and `unignore` commands.

**list**

Print all commands available. No explanation is given.

**load**

**[message] file** The specified message is replaced by the message in the named file. `file` should contain a single mail message including mail headers (as saved by the `save` command).

**mail recipient** ...

Mail a message to the specified recipients.

**Mail recipient**

Mail a message to the specified recipients, and record it in a file whose name is derived from the author of the message. Overrides the `record` variable, if set. See also the `Save` and `Copy` commands and `outfolder` in `Internal Variables`.

**mbox** [*message-list*]

Arrange for the given messages to end up in the standard mbox save file when mailx terminates normally. See `MBOX` in `ENVIRONMENT VARIABLES` for a description of this file. See also the `exit` and `quit` commands.

**more** [*message-list*]

**page** [*message-list*]

Print the specified messages. If `crt` is set, the messages longer than the number of lines specified by the `crt` variable are paged through the command specified by the `PAGER` variable. The default command is `pg(1)` or if the `bsdcompat` variable is set, the default is `more(1)`. See `ENVIRONMENT VARIABLES`. Same as the `print` and `type` commands.

**More** [*message-list*]

**Page** [*message-list*]

Print the specified messages on the screen, including all header fields. Overrides suppression of fields by the `ignore` command. Same as the `Print` and `Type` commands.

**new** [*message-list*]

**New** [*message-list*]

**unread** [*message-list*]

## mailx(1)

### Unread

[*message-list*] Take a message list and mark each message as *not* having been read.

### next [*message*]

Go to the next message matching *message*. If *message* is not supplied, this command finds the next message that was not deleted or saved. A *message-list* may be specified, but in this case the first valid message in the list is the only one used. This is useful for jumping to the next message from a specific user, since the name would be taken as a command in the absence of a real command. See the discussion of *message-list* above for a description of possible message specifications.

### pipe [*message-list*] [*shell-command*]

| [*message-list*] [*shell-command*]

Pipe the message through the given *shell-command*. The message is treated as if it were read. If no arguments are given, the current message is piped through the command specified by the value of the `cmd` variable. If the `page` variable is set, a form feed character is inserted after each message (see `Internal Variables`).

### preserve [*message-list*]

hold [*message-list*]

Preserve the specified messages in the mailbox.

### print [*message-list*]

type [*message-list*]

Print the specified messages. If `crt` is set, the messages longer than the number of lines specified by the `crt` variable are paged through the command specified by the `PAGER` variable. The default command is `pg(1)` or if the `bsdcompat` variable is set, the default is `more(1)`. See `ENVIRONMENT VARIABLES`. Same as the `more` and `page` commands.

### Print [*message-list*]

Type [*message-list*]

Print the specified messages on the screen, including all header fields. Overrides suppression of fields by the `ignore` command. Same as the `More` and `Page` commands.

### put [*file*]

put [*message-list*] *file*

Save the specified message in the given file. Use the same conventions as the `print` command for which header fields are ignored.

### Put [*file*]

Put [*message-list*] *file*

Save the specified message in the given file. Overrides suppression of fields by the `ignore` command.

### quit

Exit from `mailx`, storing messages that were read in `mbox` and unread messages in the mailbox. Messages that have been explicitly saved in a file are deleted unless the `keepsave` variable is set.

reply [*message-list*]

respond [*message-list*]

replysender [*message-list*]

Send a response to the author of each message in the *message-list*. The subject line is taken from the first message. If `record` is set to a file, a copy of the reply is added to that file. If the `replyall` variable is set, the actions of Reply/Respond and reply/respond are reversed. The `replysender` command is not affected by the `replyall` variable, but sends each reply only to the sender of each message. See the Starting Mail section in USAGE above.

Reply [*message*]

Respond [*message*]

replyall [*message*]

Reply to the specified message, including all other recipients of that message. If the variable `record` is set to a file, a copy of the reply added to that file. If the `replyall` variable is set, the actions of Reply/Respond and reply/respond are reversed. The `replyall` command is not affected by the `replyall` variable, but always sends the reply to all recipients of the message. See the Starting Mail section in USAGE above.

retain

Add the list of header fields named to the *retained list*. Only the header fields in the retain list are shown on your terminal when you print a message. All other header fields are suppressed. The set of retained fields specified by the `retain` command overrides any list of ignored fields specified by the `ignore` command. The `Type` and `Print` commands can be used to print a message in its entirety. If `retain` is executed with no arguments, it lists the current set of retained fields.

Save [*message-list*]

Save the specified messages in a file whose name is derived from the author of the first message. The name of the file is taken to be the author's name with all network addressing stripped off. See also the `Copy`, `followup`, and `Followup` commands and `outfolder` in Internal Variables.

save [*file*]

save [*message-list*] *file*

Save the specified messages in the given file. The file is created if it does not exist. The file defaults to `mbox`. The message is deleted from the mailbox when `mailx` terminates unless `keepsave` is set (see also Internal Variables and the `exit` and `quit` commands).

set

set *variable*

set *variable=string*

set *variable=number*

Define a *variable*. To assign a *value* to *variable*, separate the variable name from the value by an '=' (there must be no space before or after the '='). A variable may be given a null, string, or numeric *value*. To embed SPACE characters within a *value*, enclose it in quotes.

With no arguments, `set` displays all defined variables and any values they might have. See Internal Variables for a description of all predefined mail variables.

## mailx(1)

**shell**  
Invoke an interactive shell. See also `SHELL` in ENVIRONMENT VARIABLES.

**size** [*message-list*]  
Print the size in characters of the specified messages.

**source** *file*  
Read commands from the given file and return to command mode.

**top** [*message-list*]  
Print the top few lines of the specified messages. If the `toplines` variable is set, it is taken as the number of lines to print (see Internal Variables). The default is 5.

**touch** [*message-list*]  
Touch the specified messages. If any message in *message-list* is not specifically saved in a file, it is placed in the `mbox`, or the file specified in the `MBOX` environment variable, upon normal termination. See `exit` and `quit`.

**Type** [*message-list*]  
**Print** [*message-list*]  
Print the specified messages on the screen, including all header fields. Overrides suppression of fields by the `ignore` command.

**type** [*message-list*]  
**print** [*message-list*]  
Print the specified messages. If `crt` is set, the messages longer than the number of lines specified by the `crt` variable are paged through the command specified by the `PAGER` variable. The default command is `pg(1)`. See ENVIRONMENT VARIABLES.

**unalias** [*alias*] ...  
**ungroup** [*alias*] ...  
Remove the definitions of the specified aliases.

**undelete** [*message-list*]  
Restore the specified deleted messages. Will only restore messages deleted in the current mail session. If `autoprint` is set, the last message of those restored is printed (see Internal Variables).

**undiscard** [*header-field* ...]  
**unignore** [*header-field* ...]  
Remove the specified header fields from the list being ignored. If no header fields are specified, all header fields are removed from the list being ignored.

**unretain** [*header-field* ...]  
Remove the specified header fields from the list being retained. If no header fields are specified, all header fields are removed from the list being retained.

**unread** [*message-list*]  
**Unread** [*message-list*] Same as the `new` command.

**unset** *variable* ...  
Erase the specified variables. If the variable was imported from the environment (that is, an environment variable or exported shell variable), it cannot be unset from within `mailx`.

version

Print the current version and release date of the mailx utility.

visual [*message-list*]

Edit the given messages with a screen editor. Each messages is placed in a temporary file and the program named by the VISUAL variable is invoked to edit it (see ENVIRONMENT VARIABLES). Notice that the default visual editor is vi.

write [*message-list*] file

Write the given messages on the specified file, minus the header and trailing blank line. Otherwise equivalent to the save command.

xit

exit

Exit from mailx, without changing the mailbox. No messages are saved in the mbox (see also quit).

z[+ | -]

Scroll the header display forward or backward one screen-full. The number of headers displayed is set by the screen variable (see Internal Variables).

## Tilde Escapes

The following tilde escape commands can be used when composing mail to send. These may be entered only from *input mode*, by beginning a line with the tilde escape character (~). See *escape* in Internal Variables for changing this special character. The escape character can be entered as text by typing it twice.

~ ! <i>shell-command</i>	Escape to the shell. If present, run <i>shell-command</i> .
~ .	Simulate end of file (terminate message input).
~ : <i>mail-command</i>	
~ _ <i>mail-command</i>	Perform the command-level request. Valid only when sending a message while reading mail.
~ ?	Print a summary of tilde escapes.
~ A	Insert the autograph string Sign into the message (see Internal Variables).
~ a	Insert the autograph string sign into the message (see Internal Variables).
~ b <i>name</i> ...	Add the <i>names</i> to the blind carbon copy (Bcc) list. This is like the carbon copy (Cc) list, except that the names in the Bcc list are not shown in the header of the mail message.
~ c <i>name</i> ...	Add the <i>names</i> to the carbon copy (Cc) list.
~ d	Read in the dead-letter file. See DEAD in ENVIRONMENT VARIABLES for a description of this file.
~ e	Invoke the editor on the partial message. See also EDITOR in ENVIRONMENT VARIABLES.

## mailx(1)

<code>~f [message-list]</code>	Forward the specified message, or the current message being read. Valid only when sending a message while reading mail. The messages are inserted into the message without alteration (as opposed to the <code>~m</code> escape).
<code>~F [message-list]</code>	Forward the specified message, or the current message being read, including all header fields. Overrides the suppression of fields by the <code>ignore</code> command.
<code>~h</code>	Prompt for Subject line and To, Cc, and Bcc lists. If the field is displayed with an initial value, it may be edited as if you had just typed it.
<code>~i variable</code>	Insert the value of the named variable into the text of the message. For example, <code>~A</code> is equivalent to <code>'~i sign.'</code> Environment variables set and exported in the shell are also accessible by <code>~i</code> .
<code>~m [message-list]</code>	Insert the listed messages, or the current message being read into the letter. Valid only when sending a message while reading mail. The text of the message is shifted to the right, and the string contained in the <code>indentprefix</code> variable is inserted as the leftmost characters of each line. If <code>indentprefix</code> is not set, a TAB character is inserted into each line.
<code>~M [message-list]</code>	Insert the listed messages, or the current message being read, including the header fields, into the letter. Valid only when sending a message while reading mail. The text of the message is shifted to the right, and the string contained in the <code>indentprefix</code> variable is inserted as the leftmost characters of each line. If <code>indentprefix</code> is not set, a TAB character is inserted into each line. Overrides the suppression of fields by the <code>ignore</code> command.
<code>~p</code>	Print the message being entered.
<code>~q</code>	Quit from input mode by simulating an interrupt. If the body of the message is not null, the partial message is saved in <code>dead-letter</code> . See <code>DEAD</code> in ENVIRONMENT VARIABLES for a description of this file.
<code>~R</code>	Mark message for return receipt.

<code>~r file</code>	
<code>~&lt; file</code>	
<code>~&lt; ! shell-command</code>	Read in the specified file. If the argument begins with an exclamation point (!), the rest of the string is taken as an arbitrary shell command and is executed, with the standard output inserted into the message.
<code>~s string ...</code>	Set the subject line to <i>string</i> .
<code>~t name ...</code>	Add the given <i>names</i> to the To list.
<code>~v</code>	Invoke a preferred screen editor on the partial message. The default visual editor is <code>vi(1)</code> . See also <code>VISUAL</code> in ENVIRONMENT VARIABLES.
<code>~w file</code>	Write the message into the given file, without the header.
<code>~x</code>	Exit as with <code>~q</code> except the message is not saved in <code>dead-letter</code> .
<code>~   shell-command</code>	Pipe the body of the message through the given <i>shell-command</i> . If the <i>shell-command</i> returns a successful exit status, the output of the command replaces the message.

**Internal Variables**

The following variables are internal variables. They may be imported from the execution environment or set using the `set` command at any time. The `unset` command may be used to erase variables.

<code>allnet</code>	All network names whose last component (login name) match are treated as identical. This causes the <i>message-list</i> message specifications to behave similarly. Disabled by default. See also the <code>alternates</code> command and the <code>metoo</code> and <code>fuzzymatch</code> variables.
<code>alwaysignore</code>	Ignore header fields with <code>ignore</code> everywhere, not just during <code>print</code> or <code>type</code> . Affects the <code>save</code> , <code>Save</code> , <code>copy</code> , <code>Copy</code> , <code>top</code> , <code>pipe</code> , and <code>write</code> commands, and the <code>~m</code> and <code>~f</code> tilde escapes. Enabled by default.
<code>append</code>	Upon termination, append messages to the end of the <code>mbox</code> file instead of prepending them. Although disabled by default, <code>append</code> is set in the system startup file (which can be suppressed with the <code>-n</code> command line option).
<code>appenddeadletter</code>	Append to the <code>deadletter</code> file rather than overwrite it. Although disabled by default, <code>appenddeadletter</code> is frequently set in the system startup file. See <code>Starting Mail</code> in <code>USAGE</code> above.

## mailx(1)

askbcc	Prompt for the Bcc list after the Subject is entered if it is not specified on the command line with the -b option. Disabled by default.
askcc	Prompt for the Cc list after the Subject is entered if it is not specified on the command line with the -c option. Disabled by default.
asksub	Prompt for subject if it is not specified on the command line with the -s option. Enabled by default.
autoinc	Automatically incorporate new messages into the current session as they arrive. This has an affect similar to issuing the inc command every time the command prompt is displayed. Disabled by default, but autoinc is set in the default system startup file for mailx; it is not set for /usr/ucb/mail or /usr/ucb/Mail.
autoprint	Enable automatic printing of messages after delete and undelete commands. Disabled by default.
bang	Enable the special-casing of exclamation points (!) in shell escape command lines as in vi(1). Disabled by default.
bsdcompat	Set automatically if mailx is invoked as mail or Mail. Causes mailx to use /etc/mail/Mail.rc as the system startup file. Changes the default pager to more(1).
cmd= <i>shell-command</i>	Set the default command for the pipe command. No default value.
conv= <i>conversion</i>	Convert uucp addresses to the specified address style, which can be either:  internet            This requires a mail delivery program conforming to the RFC822 standard for electronic mail addressing.  optimize            Remove loops in uucp(1C) address paths (typically generated by the reply command). No rerouting is performed; mail has no knowledge of UUCP routes or connections.  Conversion is disabled by default. See also sendmail(1M) and the -U command-line option.

crt[= <i>number</i> ]	Pipe messages having more than <i>number</i> lines through the command specified by the value of the <code>PAGER</code> variable ( <code>pg(1)</code> or <code>more(1)</code> by default). If <i>number</i> is not specified, the current window size is used. Disabled by default.
debug	Enable verbose diagnostics for debugging. Messages are not delivered. Disabled by default.
dot	Take a period on a line by itself, or EOF during input from a terminal as end-of-file. Disabled by default, but <code>dot</code> is set in the system startup file (which can be suppressed with the <code>-n</code> command line option).
fcc	By default, <code>mailx</code> will treat any address containing a slash ("/") character as a local "send to file" address. By unsetting this option, this behavior is disabled. Enabled by default.
flipr	Reverse the effect of the <code>followup/Followup</code> and <code>reply/Reply</code> command pairs. If both <code>flipr</code> and <code>replyall</code> are set, the effect is as if neither was set.
from	Extract the author listed in the header summary from the <code>From:</code> header instead of the UNIX <code>From</code> line. Enabled by default.
fuzzymatch	The <code>from</code> command searches for messages from the indicated sender. By default, the full sender address must be specified. By setting this option, only a sub-string of the sender address need be specified. Disabled by default.
escape= <i>c</i>	Substitute <i>c</i> for the <code>~</code> escape character. Takes effect with next message sent.
folder= <i>directory</i>	The directory for saving standard mail files. User-specified file names beginning with a plus (+) are expanded by preceding the file name with this directory name to obtain the real file name. If <i>directory</i> does not start with a slash (/), <code>\$HOME</code> is prepended to it. There is no default for the <code>folder</code> variable. See also <code>outfolder</code> below.
header	Enable printing of the header summary when entering <code>mailx</code> . Enabled by default.
hold	Preserve all messages that are read in the mailbox instead of putting them in the standard <code>mbox</code> save file. Disabled by default.

## mailx(1)

<code>ignore</code>	Ignore interrupts while entering messages. Handy for noisy dial-up lines. Disabled by default.
<code>ignoreeof</code>	Ignore end-of-file during message input. Input must be terminated by a period (.) on a line by itself or by the <code>~.</code> command. See also <code>dot</code> above. Disabled by default.
<code>indentprefix=string</code>	When <code>indentprefix</code> is set, <i>string</i> is used to mark indented lines from messages included with <code>~m</code> . The default is a TAB character.
<code>keep</code>	When the mailbox is empty, truncate it to zero length instead of removing it. Disabled by default.
<code>iprompt=string</code>	The specified prompt string is displayed before each line on input is requested when sending a message.
<code>keepsave</code>	Keep messages that have been saved in other files in the mailbox instead of deleting them. Disabled by default.
<code>makeremote</code>	When replying to all recipients of a message, if an address does not include a machine name, it is assumed to be relative to the sender of the message. Normally not needed when dealing with hosts that support RFC822.
<code>metoo</code>	If your login appears as a recipient, do not delete it from the list. Disabled by default.
<code>mustbang</code>	Force all mail addresses to be in bang format.
<code>onehop</code>	When responding to a message that was originally sent to several recipients, the other recipient addresses are normally forced to be relative to the originating author's machine for the response. This flag disables alteration of the recipients' addresses, improving efficiency in a network where all machines can send directly to all other machines (that is, one hop away). Disabled by default.
<code>outfolder</code>	Locate the files used to record outgoing messages in the directory specified by the <code>folder</code> variable unless the path name is absolute. Disabled by default. See <code>folder</code> above and the <code>Save</code> , <code>Copy</code> , <code>followup</code> , and <code>Followup</code> commands.
<code>page</code>	Used with the <code>pipe</code> command to insert a form feed after each message sent through the pipe. Disabled by default.

pipeignore	Omit ignored header when outputting to the <code>pipe</code> command. Although disabled by default, <code>pipeignore</code> is frequently set in the system startup file. See <code>Starting Mail</code> in <code>USAGE</code> above.
postmark	Your "real name" to be included in the <code>From</code> line of messages you send. By default this is derived from the <code>comment</code> field in your <code>passwd(4)</code> file entry.
prompt= <i>string</i>	Set the <i>command mode</i> prompt to <i>string</i> . Default is "? ", unless the <code>bsdcompat</code> variable is set, then the default is "&".
quiet	Refrain from printing the opening message and version when entering <code>mailx</code> . Disabled by default.
record= <i>file</i>	Record all outgoing mail in <i>file</i> . Disabled by default. See also <code>outfolder</code> above.
replyall	Reverse the effect of the <code>reply</code> and <code>Reply and followup</code> and <code>Followup</code> commands. Although set by default, <code>replyall</code> is frequently unset in the system startup file. See <code>flipr</code> and <code>Starting Mail</code> in <code>USAGE</code> above.
returnaddr= <i>string</i>	The default sender address is that of the current user. This variable can be used to set the sender address to any arbitrary value. Set with caution.
save	Enable saving of messages in <code>dead-letter</code> on interrupt or delivery error. See <code>DEAD</code> for a description of this file. Enabled by default.
screen= <i>number</i>	Sets the number of lines in a screen-full of headers for the <code>headers</code> command. <i>number</i> must be a positive number.  The default is set according to baud rate or window size. With a baud rate less than 1200, <i>number</i> defaults to 5, if baud rate is exactly 1200, it defaults to 10. If you are in a window, <i>number</i> defaults to the default window size minus 4. Otherwise, the default is 20.
sendmail= <i>shell-command</i>	Alternate command for delivering messages. <i>Note:</i> In addition to the expected list of recipients, <code>mail</code> also passes the <code>-i</code> and <code>-m</code> flags to the command. Since these flags are not appropriate to other commands, you may have to use a shell script that strips them from the arguments list before invoking the desired command. Default is <code>/usr/bin/rmail</code> .
sendwait	Wait for background mailer to finish before returning. Disabled by default.

## mailx(1)

showname	Causes the message header display to show the sender's real name (if known) rather than their mail address. Disabled by default, but <code>showname</code> is set in the <code>/etc/mail/mailx.rc</code> system startup file for <code>mailx</code> .
showto	When displaying the header summary and the message is from you, print the recipient's name instead of the author's name.
sign= <i>string</i>	The variable inserted into the text of a message when the <code>~a</code> (autograph) command is given. No default (see also <code>~i</code> in Tilde Escapes).
Sign= <i>string</i>	The variable inserted into the text of a message when the <code>~A</code> command is given. No default (see also <code>~i</code> in Tilde Escapes).
toplines= <i>number</i>	The number of lines of header to print with the <code>top</code> command. Default is 5.
verbose	Invoke <code>sendmail(1M)</code> with the <code>-v</code> flag.
translate	<p>The name of a program to translate mail addresses. The program receives mail addresses as arguments. The program produces, on the standard output, lines containing the following data, in this order:</p> <ul style="list-style-type: none"><li>■ the postmark for the sender (see the <code>postmark</code> variable)</li><li>■ translated mail addresses, one per line, corresponding to the program's arguments. Each translated address will replace the corresponding address in the mail message being sent.</li><li>■ a line containing only "y" or "n". if the line contains "y" the user will be asked to confirm that the message should be sent.</li></ul> <p>The <code>translate</code> program will be invoked for each mail message to be sent. If the program exits with a non-zero exit status, or fails to produce enough output, the message is not sent.</p>

### Large File Behavior

See `largefile(5)` for the description of the behavior of `mailx` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

### ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `mailx`: `HOME`, `LANG`, `LC_CTYPE`, `LC_TIME`, `LC_MESSAGES`, `NLSPATH`, and `TERM`.

DEAD	The name of the file in which to save partial letters in case of untimely interrupt. Default is <code>\$HOME/dead.letter</code> .
EDITOR	The command to run when the <code>edit</code> or <code>~e</code> command is used. Default is <code>ed(1)</code> .
LISTER	The command (and options) to use when listing the contents of the folder directory. The default is <code>ls(1)</code> .
MAIL	The name of the initial mailbox file to read (in lieu of the standard system mailbox). The default is <code>/var/mail/username</code> .
MAILRC	The name of the startup file. Default is <code>\$HOME/.mailrc</code> .
MAILX_HEAD	The specified string is included at the beginning of the body of each message that is sent.
MAILX_TAIL	The specified string is included at the end of the body of each message that is sent.
MBOX	The name of the file to save messages which have been read. The <code>exit</code> command overrides this function, as does saving the message explicitly in another file. Default is <code>\$HOME/mbox</code> .
PAGER	The command to use as a filter for paginating output. This can also be used to specify the options to be used. Default is <code>pg(1)</code> , or if the <code>bsdcompat</code> variable is set, the default is <code>more(1)</code> . See Internal Variables.
SHELL	The name of a preferred command interpreter. Default is <code>sh(1)</code> .
VISUAL	The name of a preferred screen editor. Default is <code>vi(1)</code> .

**EXIT STATUS** When the `-e` option is specified, the following exit values are returned:

0	Mail was found.
>0	Mail was not found or an error occurred.

Otherwise, the following exit values are returned:

0	Successful completion. Notice that this status implies that all messages were <i>sent</i> , but it gives no assurances that any of them were actually <i>delivered</i> .
>0	An error occurred

<b>FILES</b>	<code>\$HOME/.mailrc</code>	personal startup file
	<code>\$HOME/mbox</code>	secondary storage file
	<code>\$HOME/.Maillock</code>	lock file to prevent multiple writers of system mailbox
	<code>/etc/mail/mailx.rc</code>	optional system startup file for mailx only

## mailx(1)

/etc/mail/Mail.rc	BSD compatibility system-wide startup file for /usr/ucb/mail and /usr/ucb/Mail
/tmp/R[emqsx] *	temporary files
/usr/share/lib/mailx/mailx.help*	help message files
/var/mail/*	post office directory

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Standard

**SEE ALSO** biff(1B), echo(1), ed(1), ex(1), fmt(1), lp(1), ls(1), mail(1), mail(1B), mailcompat(1), more(1), pg(1), sh(1), uucp(1C), vacation(1), vi(1), newaliases(1M), sendmail(1M), aliases(4), passwd(4), attributes(5), environ(5), largefile(5), standards(5)

**NOTES** Where *shell-command* is shown as valid, arguments are not always allowed. Experimentation is recommended.

Internal variables imported from the execution environment cannot be unset.

The full internet addressing is not fully supported by mailx. The new standards need some time to settle down.

Replies do not always generate correct return addresses. Try resending the errant reply with onehop set.

mailx does not lock your record file. So, if you use a record file and send two or more messages simultaneously, lines from the messages may be interleaved in the record file.

The format for the alias command is a space-separated list of recipients, while the format for an alias in either the .forward or /etc/aliases is a comma-separated list.

To read mail on a workstation running Solaris 1.x when your mail server is running Solaris 2.x, first execute the mailcompat(1) program.

<b>NAME</b>	make – maintain, update, and regenerate related programs and files
<b>SYNOPSIS</b>	<pre> /usr/ccs/bin/make [-d] [-dd] [-D] [-DD] [-e] [-i] [-k] [-n] [-p]   [-P] [-q] [-r] [-s] [-S] [-t] [-V] [-f <i>makefile</i>]... [-K <i>statefile</i>]...   [<i>target</i>...] [ <i>macro</i> = <i>value</i>...]  /usr/xpg4/bin/make [-d] [-dd] [-D] [-DD] [-e] [-i] [-k] [-n] [-p]   [-P] [-q] [-r] [-s] [-S] [-t] [-V] [-f <i>makefile</i>]... [<i>target</i>...] [ <i>macro</i>   = <i>value</i>...] </pre>
<b>DESCRIPTION</b>	<p>The make utility executes a list of shell commands associated with each <i>target</i>, typically to create or update a file of the same name. <i>makefile</i> contains entries that describe how to bring a target up to date with respect to those on which it depends, which are called <i>dependencies</i>. Since each dependency is a target, it may have dependencies of its own. Targets, dependencies, and sub-dependencies comprise a tree structure that make traces when deciding whether or not to rebuild a <i>target</i>.</p> <p>The make utility recursively checks each <i>target</i> against its dependencies, beginning with the first target entry in <i>makefile</i> if no <i>target</i> argument is supplied on the command line. If, after processing all of its dependencies, a target file is found either to be missing, or to be older than any of its dependencies, make rebuilds it. Optionally with this version of make, a target can be treated as out-of-date when the commands used to generate it have changed since the last time the target was built.</p> <p>To build a given target, make executes the list of commands, called a <i>rule</i>. This rule may be listed explicitly in the target's makefile entry, or it may be supplied implicitly by make.</p> <p>If no <i>target</i> is specified on the command line, make uses the first target defined in <i>makefile</i>.</p> <p>If a <i>target</i> has no makefile entry, or if its entry has no rule, make attempts to derive a rule by each of the following methods, in turn, until a suitable rule is found. Each method is described under <a href="#">USAGE</a> below.</p> <ul style="list-style-type: none"> <li>■ Pattern matching rules.</li> <li>■ Implicit rules, read in from a user-supplied makefile.</li> <li>■ Standard implicit rules (also known as suffix rules), typically read in from the file <code>/usr/share/lib/make/make.rules</code>.</li> <li>■ SCCS retrieval. make retrieves the most recent version from the SCCS history file (if any). See the description of the <code>.SCCS_GET</code>: special-function target for details.</li> <li>■ The rule from the <code>.DEFAULT</code>: target entry, if there is such an entry in the makefile.</li> </ul> <p>If there is no makefile entry for a <i>target</i>, if no rule can be derived for building it, and if no file by that name is present, make issues an error message and halts.</p>
<b>OPTIONS</b>	The following options are supported:

## make(1S)

-d	Displays the reasons why make chooses to rebuild a target. make displays any and all dependencies that are newer. In addition, make displays options read in from the MAKEFLAGS environment variable.
-dd	Displays the dependency check and processing in vast detail.
-D	Displays the text of the makefiles read in.
-DD	Displays the text of the makefiles, make .rules file, the state file, and all hidden-dependency reports.
-e	Environment variables override assignments within makefiles.
-f <i>makefile</i>	<p>Uses the description file <i>makefile</i>. A '-' as the <i>makefile</i> argument denotes the standard input. The contents of <i>makefile</i>, when present, override the standard set of implicit rules and predefined macros. When more than one '-f <i>makefile</i>' argument pair appears, make uses the concatenation of those files, in order of appearance.</p> <p>When no <i>makefile</i> is specified, /usr/ccs/bin/make tries the following in sequence, except when in POSIX mode (see the . POSIX <a href="#">Special-Function Targets</a> in the <a href="#">USAGE</a> section below):</p> <ul style="list-style-type: none"><li>■ If there is a file named <i>makefile</i> in the working directory, make uses that file. If, however, there is an SCCS history file (SCCS/s.<i>makefile</i>) which is newer, make attempts to retrieve and use the most recent version.</li><li>■ In the absence of the above file(s), if a file named <i>Makefile</i> is present in the working directory, make attempts to use it. If there is an SCCS history file (SCCS/s.<i>Makefile</i>) that is newer, make attempts to retrieve and use the most recent version.</li></ul> <p>When no <i>makefile</i> is specified, /usr/ccs/bin/make in POSIX mode and /usr/xpg4/bin/make try the following files in sequence:</p> <ul style="list-style-type: none"><li>■ ./makefile, ./Makefile</li><li>■ s.makefile, SCCS/s.makefile</li><li>■ s.Makefile, SCCS/s.Makefile</li></ul>
-i	Ignores error codes returned by commands. Equivalent to the special-function target '. IGNORE:'.
-k	When a nonzero error status is returned by a rule, or when make cannot find a rule, abandons work on the current target, but continues with other dependency branches that do not depend on it.

<code>-k <i>statefile</i></code>	Uses the state file <i>statefile</i> . A '-' as the <i>statefile</i> argument denotes the standard input. The contents of <i>statefile</i> , when present, override the standard set of implicit rules and predefined macros. When more than one '-k <i>statefile</i> ' argument pair appears, make uses the concatenation of those files, in order of appearance. (See also <code>.KEEP_STATE</code> and <code>.KEEP_STATE_FILE</code> in the <a href="#">Special-Function Targets</a> section).
<code>-n</code>	No execution mode. Prints commands, but does not execute them. Even lines beginning with an @ are printed. However, if a command line contains a reference to the \$(MAKE) macro, that line is always executed (see the discussion of MAKEFLAGS in <a href="#">Reading Makefiles and the Environment</a> ). When in POSIX mode, lines beginning with a "+" are executed.
<code>-p</code>	Prints out the complete set of macro definitions and target descriptions.
<code>-P</code>	Merely reports dependencies, rather than building them.
<code>-q</code>	Question mode. make returns a zero or nonzero status code depending on whether or not the target file is up to date. When in POSIX mode, lines beginning with a "+" are executed.
<code>-r</code>	Does not read in the default makefile <code>/usr/share/lib/make/make.rules</code> .
<code>-s</code>	Silent mode. Does not print command lines before executing them. Equivalent to the special-function target <code>.SILENT:</code> .
<code>-S</code>	Undoes the effect of the -k option. Stops processing when a non-zero exit status is returned by a command.
<code>-t</code>	Touches the target files (bringing them up to date) rather than performing their rules. <i>Warning:</i> This can be <i>dangerous</i> when files are maintained by more than one person. When the <code>.KEEP_STATE:</code> target appears in the makefile, this option updates the state file just as if the rules had been performed. When in POSIX mode, lines beginning with a "+" are executed.
<code>-V</code>	Puts make into SysV mode. Refer to <a href="#">sysv-make(1)</a> for respective details.

**OPERANDS** The following operands are supported:

<i>target</i>	Target names, as defined in <a href="#">USAGE</a> .
<i>macro=value</i>	Macro definition. This definition overrides any regular definition for the specified macro within the makefile itself, or in the environment. However, this definition can still be overridden by conditional macro assignments.

**USAGE** The usage of make is described below:

make(1S)

### Reading Makefiles and the Environment

When `make` first starts, it reads the `MAKEFLAGS` environment variable to obtain any of the following options specified present in its value: `-d`, `-D`, `-e`, `-i`, `-k`, `-n`, `-p`, `-q`, `-r`, `-s`, `-S`, or `-t`. Due to the implementation of POSIX.2 (see `POSIX.2(5)`), the `MAKEFLAGS` values will contain a leading `'-` character. The `make` utility then reads the command line for additional options, which also take effect.

Next, `make` reads in a default makefile that typically contains predefined macro definitions, target entries for implicit rules, and additional rules, such as the rule for retrieving SCCS files. If present, `make` uses the file `make.rules` in the current directory; otherwise it reads the file `/usr/share/lib/make/make.rules`, which contains the standard definitions and rules. Use the directive:

```
include /usr/share/lib/make/make.rules
```

in your local `make.rules` file to include them.

Next, `make` imports variables from the environment (unless the `-e` option is in effect), and treats them as defined macros. Because `make` uses the most recent definition it encounters, a macro definition in the makefile normally overrides an environment variable of the same name. When `-e` is in effect, however, environment variables are read in *after* all makefiles have been read. In that case, the environment variables take precedence over definitions in the makefile.

Next, `make` reads any makefiles you specify with `-f`, or one of `makefile` or `Makefile` as described above and then the state file, in the local directory if it exists. If the makefile contains a `.KEEP_STATE_FILE` target, then it reads the state file that follows the target. Refer to special target `.KEEP_STATE_FILE` for details.

Next (after reading the environment if `-e` is in effect), `make` reads in any macro definitions supplied as command line arguments. These override macro definitions in the makefile and the environment both, but only for the `make` command itself.

`make` exports environment variables, using the most recently defined value. Macro definitions supplied on the command line are not normally exported, unless the macro is also an environment variable.

`make` does not export macros defined in the makefile. If an environment variable is set, and a macro with the same name is defined on the command line, `make` exports its value as defined on the command line. Unless `-e` is in effect, macro definitions within the makefile take precedence over those imported from the environment.

The macros `MAKEFLAGS`, `MAKE`, `SHELL`, `HOST_ARCH`, `HOST_MACH`, and `TARGET_MACH` are special cases. See [Special-Purpose Macros](#) below for details.

### Makefile Target Entries

A target entry has the following format:

```
target [[::]] [dependency] ... [; command] ...  
      [command]  
      ...
```

The first line contains the name of a target, or a space-separated list of target names, terminated with a colon or double colon. If a list of targets is given, this is equivalent to having a separate entry of the same form for each target. The colon(s) may be followed by a *dependency*, or a dependency list. `make` checks this list before building the target. The dependency list may be terminated with a semicolon (;), which in turn can be followed by a single Bourne shell command. Subsequent lines in the target entry begin with a TAB and contain Bourne shell commands. These commands comprise the rule for building the target.

Shell commands may be continued across input lines by escaping the NEWLINE with a backslash (\). The continuing line must also start with a TAB.

To rebuild a target, `make` expands macros, strips off initial TAB characters and either executes the command directly (if it contains no shell metacharacters), or passes each command line to a Bourne shell for execution.

The first *non-empty* line that does not begin with a TAB or '#' begins another target or macro definition.

### Special Characters

Special characters are defined below.

<i>Global</i>	#	Start a comment. The comment ends at the next NEWLINE. If the '#' follows the TAB in a command line, that line is passed to the shell (which also treats '#' as the start of a comment).
	include <i>filename</i>	If the word <code>include</code> appears as the first seven letters of a line and is followed by a SPACE or TAB, the string that follows is taken as a filename to interpolate at that line. <code>include</code> files can be nested to a depth of no more than about 16. If <i>filename</i> is a macro reference, it is expanded.
<i>Targets and Dependencies</i>	:	Target list terminator. Words following the colon are added to the dependency list for the target or targets. If a target is named in more than one colon-terminated target entry, the dependencies for all its entries are added to form that target's complete dependency list.
	::	Target terminator for alternate dependencies. When used in place of a ':' the double-colon allows a target to be checked and updated with respect to alternate dependency lists. When the target is out-of-date with respect to dependencies listed in the first alternate, it is built according to the rule for that entry. When out-of-date with respect to dependencies in another alternate, it is built according the rule in that other

## make(1S)

		entry. Implicit rules do not apply to double-colon targets; you must supply a rule for each entry. If no dependencies are specified, the rule is always performed.
	<i>target</i> [+ <i>target</i> . . . ] :	Target group. The rule in the target entry builds all the indicated targets as a group. It is normally performed only once per make run, but is checked for command dependencies every time a target in the group is encountered in the dependency scan.
	%	Pattern matching wild card metacharacter. Like the '*' shell wild card, '%' matches any string of zero or more characters in a target name or dependency, in the target portion of a conditional macro definition, or within a pattern replacement macro reference. Notice that only one '%' can appear in a target, dependency-name, or pattern-replacement macro reference.
	./ <i>pathname</i>	make ignores the leading './' characters from targets with names given as pathnames relative to "dot," the working directory.
Macros	=	Macro definition. The word to the left of this character is the macro name; words to the right comprise its value. Leading and trailing white space characters are stripped from the value. A word break following the = is implied.
	\$	Macro reference. The following character, or the parenthesized or bracketed string, is interpreted as a macro reference: make expands the reference (including the \$) by replacing it with the macro's value.
	( ) { }	Macro-reference name delimiters. A parenthesized or bracketed word appended to a \$ is taken as the name of the macro being referred to. Without the delimiters, make recognizes only the first character as the macro name.
	\$\$	A reference to the dollar-sign macro, the value of which is the character '\$'. Used to pass variable expressions beginning with \$ to the shell, to refer to environment variables which are expanded by the shell, or to delay processing of dynamic macros within the dependency list of a target, until that target is actually processed.
	\\$	Escaped dollar-sign character. Interpreted as a literal dollar sign within a rule.
	+=	When used in place of '=', appends a string to a macro definition (must be surrounded by white space, unlike '=').

<i>Rules</i>	<p><b>:=</b> Conditional macro assignment. When preceded by a list of targets with explicit target entries, the macro definition that follows takes effect when processing only those targets, and their dependencies.</p> <p><b>:sh =</b> Define the value of a macro to be the output of a command (see <a href="#">Command Substitutions</a> below).</p> <p><b>:sh</b> In a macro reference, execute the command stored in the macro, and replace the reference with the output of that command (see <a href="#">Command Substitutions</a> below).</p> <p><b>+</b> make will always execute the commands preceded by a "+", even when -n is specified.</p> <p><b>-</b> make ignores any nonzero error code returned by a command line for which the first non-TAB character is a '-'. This character is not passed to the shell as part of the command line. make normally terminates when a command returns nonzero status, unless the -i or -k options, or the .IGNORE: special-function target is in effect.</p> <p><b>@</b> If the first non-TAB character is a @, make does not print the command line before executing it. This character is not passed to the shell.</p> <p><b>?</b> Escape command-dependency checking. Command lines starting with this character are not subject to command dependency checking.</p> <p><b>!</b> Force command-dependency checking. Command-dependency checking is applied to command lines for which it would otherwise be suppressed. This checking is normally suppressed for lines that contain references to the '?' dynamic macro (for example, '\$?').</p> <p>When any combination of '+', '-', '@', '?', or '!' appear as the first characters after the TAB, all that are present apply. None are passed to the shell.</p>
<b>Special-Function Targets</b>	<p>When incorporated in a makefile, the following target names perform special-functions:</p> <p><b>.DEFAULT :</b> If it has an entry in the makefile, the rule for this target is used to process a target when there is no other entry for it, no rule for building it, and no SCCS history file from which to retrieve a current version. make ignores any dependencies for this target.</p> <p><b>.DONE :</b> If defined in the makefile, make processes this target and its dependencies after all other targets are built. This target is also performed when make halts with an error, unless the .FAILED target is defined.</p>

## make(1S)

<code>.FAILED:</code>	This target, along with its dependencies, is performed instead of <code>.DONE</code> when defined in the makefile and <code>make</code> halts with an error.
<code>.GET_POSIX:</code>	This target contains the rule for retrieving the current version of an SCCS file from its history file in the current working directory. <code>make</code> uses this rule when it is running in POSIX mode.
<code>.IGNORE:</code>	Ignore errors. When this target appears in the makefile, <code>make</code> ignores non-zero error codes returned from commands. When used in POSIX mode, <code>.IGNORE</code> could be followed by target names only, for which the errors will be ignored.
<code>.INIT:</code>	If defined in the makefile, this target and its dependencies are built before any other targets are processed.
<code>.KEEP_STATE:</code>	If this target is in effect, <code>make</code> updates the state file, <code>.make.state</code> , in the current directory. This target also activates command dependencies, and hidden dependency checks. If either the <code>.KEEP_STATE:</code> target appears in the makefile, or the environment variable <code>KEEP_STATE</code> is set (" <code>setenv KEEP_STATE</code> "), <code>make</code> will rebuild everything in order to collect dependency information, even if all the targets were up to date due to previous <code>make</code> runs. See also the <a href="#">ENVIRONMENT VARIABLES</a> section. This target has no effect if used in POSIX mode.
<code>.KEEP_STATE_FILE:</code>	This target has no effect if used in POSIX mode. This target implies <code>.KEEP_STATE</code> . If the target is followed by a filename, <code>make</code> uses it as the state file. If the target is followed by a directory name, <code>make</code> looks for a <code>.make.state</code> file in that directory. If the target is not followed by any name, <code>make</code> looks for <code>.make.state</code> file in the current working directory.
<code>.MAKE_VERSION:</code>	A target-entry of the form:  <code>.MAKE_VERSION: VERSION-number</code>  enables version checking. If the version of <code>make</code> differs from the version indicated by a string like " <code>VERSION-1.0</code> ", <code>make</code> issues a warning message.
<code>.NO_PARALLEL:</code>	Currently, this target has no effect, it is, however, reserved for future use.
<code>.PARALLEL:</code>	Currently of no effect, but reserved for future use.

<code>.POSIX:</code>	This target enables POSIX mode.
<code>.PRECIOUS:</code>	List of files not to delete. <code>make</code> does not remove any of the files listed as dependencies for this target when interrupted. <code>make</code> normally removes the current target when it receives an interrupt. When used in POSIX mode, if the target is not followed by a list of files, all the file are assumed precious.
<code>.SCCS_GET:</code>	This target contains the rule for retrieving the current version of an SCCS file from its history file. To suppress automatic retrieval, add an entry for this target with an empty rule to your makefile.
<code>.SCCS_GET_POSIX:</code>	This target contains the rule for retrieving the current version of an SCCS file from its history file. <code>make</code> uses this rule when it is running in POSIX mode.
<code>.SILENT:</code>	Run silently. When this target appears in the makefile, <code>make</code> does not echo commands before executing them. When used in POSIX mode, it could be followed by target names, and only those will be executed silently.
<code>.SUFFIXES:</code>	The suffixes list for selecting implicit rules (see <a href="#">The Suffixes List</a> ).
<code>.WAIT:</code>	Currently of no effect, but reserved for future use.

*Clearing Special Targets*

In this version of `make`, you can clear the definition of the following special targets by supplying entries for them with no dependencies and no rule:

```
.DEFAULT, .SCCS_GET, and .SUFFIXES
```

**Command Dependencies**

When the `.KEEP_STATE:` target is effective, `make` checks the command for building a target against the state file. If the command has changed since the last `make` run, `make` rebuilds the target.

**Hidden Dependencies**

When the `.KEEP_STATE:` target is effective, `make` reads reports from `cpp(1)` and other compilation processors for any “hidden” files, such as `#include` files. If the target is out of date with respect to any of these files, `make` rebuilds it.

**Macros**

Entries of the form

```
macro=value
```

define macros. *macro* is the name of the macro, and *value*, which consists of all characters up to a comment character or unescaped `NEWLINE`, is the value. `make` strips both leading and trailing white space in accepting the value.

Subsequent references to the macro, of the forms: `$(name)` or `${name}` are replaced by *value*. The parentheses or brackets can be omitted in a reference to a macro with a single-character name.

make(1S)

	Macro references can contain references to other macros, in which case nested references are expanded first.
<i>Suffix Replacement Macro References</i>	Substitutions within macros can be made as follows:  <pre>\$(name:string1=string2)</pre> where <i>string1</i> is either a suffix, or a word to be replaced in the macro definition, and <i>string2</i> is the replacement suffix or word. Words in a macro value are separated by SPACE, TAB, and escaped NEWLINE characters.
<i>Pattern Replacement Macro References</i>	Pattern matching replacements can also be applied to macros, with a reference of the form:  <pre>\$(name: op%os= np%ns)</pre> where <i>op</i> is the existing (old) prefix and <i>os</i> is the existing (old) suffix, <i>np</i> and <i>ns</i> are the new prefix and new suffix, respectively, and the pattern matched by % (a string of zero or more characters), is carried forward from the value being replaced. For example:  <pre>PROGRAM=fabricate DEBUG= \$(PROGRAM:%=tmp/%-g)</pre> sets the value of DEBUG to tmp/fabricate-g.  Notice that pattern replacement macro references cannot be used in the dependency list of a pattern matching rule; the % characters are not evaluated independently. Also, any number of % metacharacters can appear after the equal-sign.
<i>Appending to a Macro</i>	Words can be appended to macro values as follows:  <pre>macro += word...</pre>
<b>Special-Purpose Macros</b>	When the MAKEFLAGS variable is present in the environment, make takes options from it, in combination with options entered on the command line. make retains this combined value as the MAKEFLAGS macro, and exports it automatically to each command or shell it invokes.  Notice that flags passed by way of MAKEFLAGS are only displayed when the -d, or -dd options are in effect.  The MAKE macro is another special case. It has the value make by default, and temporarily overrides the -n option for any line in which it is referred to. This allows nested invocations of make written as:  <pre>\$(MAKE) . . .</pre> to run recursively, with the -n flag in effect for all commands but make. This lets you use 'make -n' to test an entire hierarchy of makefiles.  For compatibility with the 4.2 BSD make, the MFLAGS macro is set from the MAKEFLAGS variable by prepending a '-'. MFLAGS is not exported automatically.

The SHELL macro, when set to a single-word value such as `/usr/bin/csh`, indicates the name of an alternate shell to use. The default is `/bin/sh`. Notice that `make` executes commands that contain no shell metacharacters itself. Built-in commands, such as `dirs` in the C shell, are not recognized unless the command line includes a metacharacter (for instance, a semicolon). This macro is neither imported from, nor exported to the environment, regardless of `-e`. To be sure it is set properly, you must define this macro within every makefile that requires it.

The syntax of the VPATH macro is:

```
VPATH = [ pathname [ : pathname ] ... ]
```

VPATH specifies a list of directories to search for the files, which are targets or dependencies, when `make` is executed. VPATH is also used in order to search for the include files mentioned in the particular makefile.

When processing a target or a dependency or an include directive, `make` checks the existence of the file with the same name in the current directory. If the file is found to be missing, `make` will search for this file in the list of directories presented in VPATH (like the PATH variable in the shell). Unlike the PATH variable, VPATH is used in order to search for the files with relative pathnames. When `make` attempts to apply implicit rules to the target, it also searches for the dependency files using VPATH.

When the file is found using VPATH, internal macros `$$`, `@<`, `$$?`, `$$*`, and their alternative forms (with D or F appended) are set in accordance with the name derived from VPATH. For instance, if the target `subdir/foo.o` is found in the directory `/aaa/bbb` using VPATH, then the value of the internal macro `$$` for this target will be `/aaa/bbb/subdir/foo.o`.

If a target or a dependency file is found using VPATH, then any occurrences of the word that is the same as the target name in the subsequent rules will be replaced with the actual name of the target derived from VPATH.

For example:

```
VPATH=./subdir
file.o : file.c
    cc -c file.c -o file.o
```

If `file.c` is found in `./subdir`, then the command

```
cc -c ./subdir/file.c -o file.o
```

will be executed.

The following macros are provided for use with cross-compilation:

HOST_ARCH	The machine architecture of the host system. By default, this is the output of the <code>mach(1)</code> command, prepended with <code>'-'</code> . Under normal circumstances, this value should never be altered by the user.
-----------	--

## make(1S)

HOST_MACH	The machine architecture of the host system. By default, this is the output of the <code>arch(1)</code> command, prepended with '-'. Under normal circumstances, this value should never be altered by the user.
TARGET_ARCH	The machine architecture of the target system. By default, the output of <code>mach</code> , prepended with '-'.

### Dynamic Macros

There are several dynamically maintained macros that are useful as abbreviations within rules. They are shown here as references; if you were to define them, `make` would simply override the definition.

<code>\$*</code>	The basename of the current target, derived as if selected for use with an implicit rule.
<code>\$&lt;</code>	The name of a dependency file, derived as if selected for use with an implicit rule.
<code>\$@</code>	The name of the current target. This is the only dynamic macro whose value is strictly determined when used in a dependency list. (In which case it takes the form '\$\$@'.)
<code>\$?</code>	The list of dependencies that are newer than the target. Command-dependency checking is automatically suppressed for lines that contain this macro, just as if the command had been prefixed with a '?'. See the description of '?', under <i>Special Character Rules</i> above. You can force this check with the <code>!</code> command-line prefix.
<code>\$%</code>	The name of the library member being processed. (See <a href="#">Library Maintenance</a> below.)

To refer to the `$@` dynamic macro within a dependency list, precede the reference with an additional '\$' character (as in, '\$\$@'). Because `make` assigns `$<` and `$*` as it would for implicit rules (according to the suffixes list and the directory contents), they may be unreliable when used within explicit target entries.

These macros can be modified to apply either to the filename part, or the directory part of the strings they stand for, by adding an upper case F or D, respectively (and enclosing the resulting name in parentheses or braces). Thus, '\$ (@D)' refers to the directory part of the string '\$@'; if there is no directory part, '.' is assigned. '\$ (@F)' refers to the filename part.

### Conditional Macro Definitions

A macro definition of the form:

```
target-list := macro = value
```

make(1S)

indicates that when processing any of the targets listed *and their dependencies*, *macro* is to be set to the *value* supplied. Notice that if a conditional macro is referred to in a dependency list, the *\$* must be delayed (use *\$\$* instead). Also, *target-list* may contain a *%* pattern, in which case the macro will be conditionally defined for all targets encountered that match the pattern. A pattern replacement reference can be used within the *value*.

You can temporarily append to a macro's value with a conditional definition of the form:

*target-list := macro += value*

**Predefined Macros**

make supplies the macros shown in the table that follows for compilers and their options, host architectures, and other commands. Unless these macros are read in as environment variables, their values are not exported by make. If you run make with any of these set in the environment, it is a good idea to add commentary to the makefile to indicate what value each is expected to take. If *-r* is in effect, make does not read the default makefile (*./make.rules* or */usr/share/lib/make/make.rules*) in which these macro definitions are supplied.

**Implicit Rules**

When a target has no entry in the makefile, make attempts to determine its class (if any) and apply the rule for that class. An implicit rule describes how to build any target of a given class, from an associated dependency file. The class of a target can be determined either by a pattern, or by a suffix; the corresponding dependency file (with the same basename) from which such a target might be built. In addition to a predefined set of implicit rules, make allows you to define your own, either by pattern, or by suffix.

*Pattern Matching Rules*

A target entry of the form:

```
tp%ts: dp%ds
      rule
```

is a pattern matching rule, in which *tp* is a target prefix, *ts* is a target suffix, *dp* is a dependency prefix, and *ds* is a dependency suffix (any of which may be null). The '%' stands for a basename of zero or more characters that is matched in the target, and is used to construct the name of a dependency. When make encounters a match in its search for an implicit rule, it uses the rule in that target entry to build the target from the dependency file. Pattern-matching implicit rules typically make use of the \$@ and \$< dynamic macros as placeholders for the target and dependency names. Other, regular dependencies may occur in the dependency list; however, none of the regular dependencies may contain '%'. An entry of the form:

```
tp%ts: [dependency... ] dp%ds [dependency... ]
      rule
```

is a valid pattern matching rule.

*Suffix Rules*

When no pattern matching rule applies, make checks the target name to see if it ends with a suffix in the known suffixes list. If so, make checks for any suffix rules, as well as a dependency file with same root and another recognized suffix, from which to build it.

The target entry for a suffix rule takes the form:

```
DsTs: rule
```

where *Ts* is the suffix of the target, *Ds* is the suffix of the dependency file, and *rule* is the rule for building a target in the class. Both *Ds* and *Ts* must appear in the suffixes list. (A suffix need not begin with a '.' to be recognized.)

A suffix rule with only one suffix describes how to build a target having a null (or no) suffix from a dependency file with the indicated suffix. For instance, the `.c` rule could be used to build an executable program named `file` from a C source file named `'file.c'`. If a target with a null suffix has an explicit dependency, `make` omits the search for a suffix rule.

make reads in the standard set of implicit rules from the file `/usr/share/lib/make/make.rules`, unless `-r` is in effect, or there is a `make.rules` file in the local directory that does not include that file.

### The Suffixes List

The suffixes list is given as the list of dependencies for the `.SUFFIXES:` special-function target. The default list is contained in the `SUFFIXES` macro (See *Table of Predefined Macros* for the standard list of suffixes). You can define additional `.SUFFIXES:` targets; a `.SUFFIXES` target with no dependencies clears the list of suffixes. Order is significant within the list; make selects a rule that corresponds to the target's suffix and the first dependency-file suffix found in the list. To place suffixes at the head of the list, clear the list and replace it with the new suffixes, followed by the default list:

```
.SUFFIXES:
.SUFFIXES: suffixes $(SUFFIXES)
```

A tilde (~) indicates that if a dependency file with the indicated suffix (minus the ~) is under SCCS its most recent version should be retrieved, if necessary, before the target is processed.

### Library Maintenance

A target name of the form:

```
lib (member ...)
```

refers to a member, or a space-separated list of members, in an `ar(1)` library.

The dependency of the library member on the corresponding file must be given as an explicit entry in the makefile. This can be handled by a pattern matching rule of the form:

```
lib (%s) : %s
```

where `.s` is the suffix of the member; this suffix is typically `.o` for object libraries.

A target name of the form:

```
lib ( (symbol) )
```

refers to the member of a randomized object library that defines the entry point named *symbol*.

### Command Execution

Command lines are executed one at a time, *each by its own process or shell*. Shell commands, notably `cd`, are ineffectual across an unescaped `NEWLINE` in the makefile. A line is printed (after macro expansion) just before being executed. This is suppressed if it starts with a `'@'`, if there is a `.SILENT:` entry in the makefile, or if make is run

make(1S)

with the `-s` option. Although the `-n` option specifies printing without execution, lines containing the macro `$(MAKE)` are executed regardless, and lines containing the `@` special character are printed. The `-t` (touch) option updates the modification date of a file without executing any rules. This can be dangerous when sources are maintained by more than one person.

make invokes the shell with the `-e` (exit-on-errors) argument. Thus, with semicolon-separated command sequences, execution of the later commands depends on the success of the former. This behavior can be overridden by starting the command line with a `' -'`, or by writing a shell script that returns a non-zero status only as it finds appropriate.

### Bourne Shell Constructs

To use the Bourne shell `if` control structure for branching, use a command line of the form:

```
if expression ; \  
then command ; \  
    ... ; \  
else command ; \  
    ... ; \  
fi
```

Although composed of several input lines, the escaped `NEWLINE` characters insure that make treats them all as one (shell) command line.

To use the Bourne shell `for` control structure for loops, use a command line of the form:

```
for var in list ; \  
do command ; \  
    ... ; \  
done
```

To refer to a shell variable, use a double-dollar-sign (`$$`). This prevents expansion of the dollar-sign by make.

### Command Substitutions

To incorporate the standard output of a shell command in a macro, use a definition of the form:

```
MACRO :sh =command
```

The command is executed only once, standard error output is discarded, and `NEWLINE` characters are replaced with `SPACES`. If the command has a non-zero exit status, make halts with an error.

To capture the output of a shell command in a macro reference, use a reference of the form:

```
$(MACRO :sh)
```

where *MACRO* is the name of a macro containing a valid Bourne shell command line. In this case, the command is executed whenever the reference is evaluated. As with shell command substitutions, the reference is replaced with the standard output of the command. If the command has a non-zero exit status, make halts with an error.

In contrast to commands in rules, the command is not subject for macro substitution; therefore, a dollar sign (\$) need not be replaced with a double dollar sign (\$\$).

*Signals*

INT, SIGTERM, and QUIT signals received from the keyboard halt `make` and remove the target file being processed unless that target is in the dependency list for `.PRECIOUS`:

**EXAMPLES****EXAMPLE 1** Defining dependencies

This makefile says that `pgm` depends on two files `a.o` and `b.o`, and that they in turn depend on their corresponding source files (`a.c` and `b.c`) along with a common file `incl.h`:

```
pgm: a.o b.o
    $(LINK.c) -o $@a.o b.o
a.o: incl.h a.c
    cc -c a.c
b.o: incl.h b.c
    cc -c b.c
```

**EXAMPLE 2** Using implicit rules

The following makefile uses implicit rules to express the same dependencies:

```
pgm: a.o b.o
    cc a.o b.o -o pgm
a.o b.o: incl.h
```

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `make`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

`KEEP_STATE`

This environment variable has the same effect as the `.KEEP_STATE`: special-function target. It enables command dependencies, hidden dependencies and writing of the state file.

`USE_SVR4_MAKE`

This environment variable causes `make` to invoke the generic System V version of `make` (`/usr/ccs/lib/avr4.make`). See [sysv-make\(1\)](#).

`MAKEFLAGS`

This variable is interpreted as a character string representing a series of option characters to be used as the default options. The implementation will accept both of the following formats (but need not accept them when intermixed):

1. The characters are option letters without the leading hyphens or blank character separation used on a command line.
2. The characters are formatted in a manner similar to a portion of the `make` command line: options are preceded by hyphens and blank-character-separated. The `macro=name` macro

## make(1S)

definition operands can also be included. The difference between the contents of `MAKEFLAGS` and the command line is that the contents of the variable will not be subjected to the word expansions (see `wordexp(3C)`) associated with parsing the command line values.

When the command-line options `-f` or `-p` are used, they will take effect regardless of whether they also appear in `MAKEFLAGS`. If they otherwise appear in `MAKEFLAGS`, the result is undefined.

The `MAKEFLAGS` variable will be accessed from the environment before the makefile is read. At that time, all of the options (except `-f` and `-p`) and command-line macros not already included in `MAKEFLAGS` are added to the `MAKEFLAGS` macro. The `MAKEFLAGS` macro will be passed into the environment as an environment variable for all child processes. If the `MAKEFLAGS` macro is subsequently set by the makefile, it replaces the `MAKEFLAGS` variable currently found in the environment.

### PROJECTDIR

Provides a directory to be used to search for SCCS files not found in the current directory. In all of the following cases, the search for SCCS files is made in the directory `SCCS` in the identified directory. If the value of `PROJECTDIR` begins with a slash, it shall be considered an absolute pathname. Otherwise, the value of `PROJECTDIR` is treated as a user name and that user's initial working directory shall be examined for a subdirectory `src` or `source`. If such a directory is found, it shall be used. Otherwise, the value is used as a relative pathname.

If `PROJECTDIR` is not set or has a null value, the search for SCCS files shall be made in the directory `SCCS` in the current directory. The setting of `PROJECTDIR` affects all files listed in the remainder of this utility description for files with a component named `SCCS`.

### EXIT STATUS

When the `-q` option is specified, the make utility will exit with one of the following values:

- 0 Successful completion.
- 1 The target was not up-to-date.
- >1 An error occurred.

When the `-q` option is not specified, the `make` utility will exit with one of the following values:

0           Successful completion  
>0          An error occurred

**FILES**

makefile	current version(s) of make
Makefile	description file
s.makefile	
s.Makefile	SCCS history files for the above makefile(s) in the current directory
SCCS/s.makefile	
SCCS/s.Makefile	SCCS history files for the above makefile(s)
make.rules	default file for user-defined targets, macros, and implicit rules
/usr/share/lib/make/make.rules	makefile for standard implicit rules and macros (not read if <code>make.rules</code> is)
.make.state	state file in the local directory

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

*Solaris Advanced User's Guide*

**DIAGNOSTICS**

Don't know how to make target '`target`'

There is no makefile entry for `target`, and none of `make`'s implicit rules apply (there is no dependency file with a suffix in the suffixes list, or the target's suffix is not in the list).

## make(1S)

\*\*\* *target* removed.  
make was interrupted while building *target*. Rather than leaving a partially-completed version that is newer than its dependencies, make removes the file named *target*.

\*\*\* *target* not removed.  
make was interrupted while building *target* and *target* was not present in the directory.

\*\*\* *target* could not be removed, *reason*  
make was interrupted while building *target*, which was not removed for the indicated reason.

Read of include file `'file'` failed  
The makefile indicated in an include directive was not found, or was inaccessible.

Loop detected when expanding macro value `'macro'`  
A reference to the macro being defined was found in the definition.

Could not write state file `'file'`  
You used the `.KEEP_STATE: target`, but do not have write permission on the state file.

\*\*\* Error code *n*  
The previous shell command returned a nonzero error code.

\*\*\* *signal message*  
The previous shell command was aborted due to a signal. If `'- core dumped'` appears after the message, a core file was created.

Conditional macro conflict encountered  
Displayed only when `-d` is in effect, this message indicates that two or more parallel targets currently being processed depend on a target which is built differently for each by virtue of conditional macros. Since the target cannot simultaneously satisfy both dependency relationships, it is conflicted.

**BUGS** Some commands return nonzero status inappropriately; to overcome this difficulty, prefix the offending command line in the rule with a `'-'`.

Filenames with the characters `'='`, `':'`, or `'@'`, do not work.

You cannot build `file.o` from `lib(file.o)`.

Options supplied by `MAKEFLAGS` should be reported for nested make commands. Use the `-d` option to find out what options the nested command picks up from `MAKEFLAGS`.

This version of make is incompatible in certain respects with previous versions:

- The `-d` option output is much briefer in this version. `-dd` now produces the equivalent voluminous output.
- make attempts to derive values for the dynamic macros `'$*'`, `'$<'`, and `'$?'`, while processing explicit targets. It uses the same method as for implicit rules; in some cases this can lead either to unexpected values, or to an empty value being

assigned. (Actually, this was true for earlier versions as well, even though the documentation stated otherwise.)

- make no longer searches for SCCS history "(s)" files.
- Suffix replacement in macro references are now applied after the macro is expanded.

There is no guarantee that makefiles created for this version of make will work with earlier versions.

If there is no `make.rules` file in the current directory, and the file `/usr/share/lib/make/make.rules` is missing, make stops before processing any targets. To force make to run anyway, create an empty `make.rules` file in the current directory.

Once a dependency is made, make assumes the dependency file is present for the remainder of the run. If a rule subsequently removes that file and future targets depend on its existence, unexpected errors may result.

When hidden dependency checking is in effect, the `$?` macro's value includes the names of hidden dependencies. This can lead to improper filename arguments to commands when `$?` is used in a rule.

Pattern replacement macro references cannot be used in the dependency list of a pattern matching rule.

Unlike previous versions, this version of make strips a leading `./` from the value of the `$$@` dynamic macro.

With automatic SCCS retrieval, this version of make does not support tilde suffix rules.

The only dynamic macro whose value is strictly determined when used in a dependency list is `$$@` (takes the form `$$@`).

make invokes the shell with the `-e` argument. This cannot be inferred from the syntax of the rule alone.

## man(1)

<b>NAME</b>	man – find and display reference manual pages
<b>SYNOPSIS</b>	<b>man</b> [-] [-adFlrt] [-M <i>path</i> ] [-T <i>macro-package</i> ] [-s <i>section</i> ] <i>name</i> ... <b>man</b> [-M <i>path</i> ] -k <i>keyword</i> ... <b>man</b> [-M <i>path</i> ] -f <i>file</i> ...
<b>DESCRIPTION</b>	The man command displays information from the reference manuals. It displays complete manual pages that you select by <i>name</i> , or one-line summaries selected either by <i>keyword</i> (-k), or by the name of an associated file (-f). If no manual page is located, man prints an error message.
<b>Source Format</b>	Reference Manual pages are marked up with either nroff (see <a href="#">nroff(1)</a> ) or SGML (Standard Generalized Markup Language) tags (see <a href="#">sgml(5)</a> ). The man command recognizes the type of markup and processes the file accordingly. The various source files are kept in separate directories depending on the type of markup.
<b>Location of Manual Pages</b>	<p>The online Reference Manual page directories are conventionally located in /usr/share/man. The nroff sources are located in the /usr/share/man/man* directories. The SGML sources are located in the /usr/share/man/sman* directories. Each directory corresponds to a section of the manual. Since these directories are optionally installed, they might not reside on your host. You might have to mount /usr/share/man from a host on which they do reside.</p> <p>If there are preformatted, up-to-date versions in the corresponding cat* or fmt* directories, man simply displays or prints those versions. If the preformatted version of interest is out of date or missing, man reformats it prior to display and stores the preformatted version if cat* or fmt* is writable. The windex database is not updated. See <a href="#">catman(1M)</a>. If directories for the preformatted versions are not provided, man reformats a page whenever it is requested. man uses a temporary file to store the formatted text during display.</p> <p>If the standard output is not a terminal, or if the '-' flag is given, man pipes its output through <a href="#">cat(1)</a>. Otherwise, man pipes its output through <a href="#">more(1)</a> to handle paging and underlining on the screen.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"><li>-a Shows all manual pages matching <i>name</i> within the MANPATH search path. Manual pages are displayed in the order found.</li><li>-d Debugs. Displays what a section-specifier evaluates to, method used for searching, and paths searched by man.</li><li>-f <i>file</i> ... man attempts to locate manual pages related to any of the given <i>files</i>. It strips the leading path name components from each <i>file</i>, and then prints one-line summaries containing the resulting basename or names. This option also uses the windex database.</li><li>-F Forces man to search all directories specified by MANPATH or the man.cf file, rather than using the windex lookup database. This option is useful if the database is not up to date and it has been</li></ul>

made the default behavior of the man command. The option therefore does not have to be invoked and is documented here for reference only.

- k *keyword* ... Prints out one-line summaries from the `windex` database (table of contents) that contain any of the given *keywords*. The `windex` database is created using `catman(1M)`.
- l Lists all manual pages found matching *name* within the search path.
- M *path* Specifies an alternate search path for manual pages. *path* is a colon-separated list of directories that contain manual page directory subtrees. For example, if *path* is `/usr/share/man:/usr/local/man`, man searches for *name* in the standard location, and then `/usr/local/man`. When used with the `-k` or `-f` options, the `-M` option must appear first. Each directory in the *path* is assumed to contain subdirectories of the form `man*` or `sman*`, one for each section. This option overrides the `MANPATH` environment variable.
- r Reformats the manual page, but does not display it. This replaces the `man -t name` combination.
- s *section* ... Specifies sections of the manual for man to search. The directories searched for *name* are limited to those specified by *section*. *section* can be a numerical digit, perhaps followed by one or more letters to match the desired section of the manual, for example, `"3libcub"`. Also, *section* can be a word, for example, `local`, `new`, `old`, `public`. *section* can also be a letter. To specify multiple sections, separate each section with a comma. This option overrides the `MANPATH` environment variable and the `man.cf` file. See `Search Path` below for an explanation of how man conducts its search.
- t man arranges for the specified manual pages to be `t`roffed to a suitable raster output device (see `troff(1)`). If both the `-` and `-t` flags are given, man updates the `t`roffed versions of each named *name* (if necessary), but does not display them.
- T *macro-package* Formats manual pages using *macro-package* rather than the standard `-man` macros defined in `/usr/share/lib/tmac/an`. See `Search Path` under `USAGE` for a complete explanation of the default search path order.

**OPERANDS** The following operand is supported:

*name* A keyword or the name of a standard utility.

**USAGE** The usage of man is described below:

man(1)

**Manual Page Sections**

Entries in the reference manuals are organized into *sections*. A section name consists of a major section name, typically a single digit, optionally followed by a subsection name, typically one or more letters. An unadorned major section name, for example, "9", does not act as an abbreviation for the subsections of that name, such as "9e", "9f", or "9s". That is, each subsection must be searched separately by `man -s`. Each section contains descriptions apropos to a particular reference category, with subsections refining these distinctions. See the `intro` manual pages for an explanation of the classification used in this release.

**Search Path**

Before searching for a given *name*, `man` constructs a list of candidate directories and sections. `man` searches for *name* in the directories specified by the `MANPATH` environment variable. If this variable is not set, `/usr/share/man` is searched by default.

Within the manual page directories, `man` confines its search to the sections specified in the following order:

- *sections* specified on the command line with the `-s` option
- *sections* embedded in the `MANPATH` environment variable
- *sections* specified in the `man.cf` file for each directory specified in the `MANPATH` environment variable

If none of the above exist, `man` searches each directory in the manual page path, and displays the first matching manual page found.

The `man.cf` file has the following format:

```
MANSECTS=section [,section] . . .
```

Lines beginning with '#' and blank lines are considered comments, and are ignored. Each directory specified in `MANPATH` can contain a manual page configuration file, specifying the default search order for that directory.

**Formatting Manual Pages**

Manual pages are marked up in `nroff(1)` or `sgml(5)`. `Nroff` manual pages are processed by `nroff(1)` or `troff(1)` with the `-man` macro package. Please refer to `man(5)` for information on macro usage. SGML—tagged manual pages are processed by an SGML parser and passed to the formatter.

**Preprocessing Nroff Manual Pages**

When formatting an `nroff` manual page, `man` examines the first line to determine whether it requires special processing. If the first line is a string of the form:

```
'\ " X
```

where *X* is separated from the '"' by a single SPACE and consists of any combination of characters in the following list, `man` pipes its input to `troff(1)` or `nroff(1)` through the corresponding preprocessors.

```
e          eqn(1), or neqn for nroff
```

```
r          refer(1)
```

t [tbl\(1\)](#)

v [vgrind\(1\)](#)

If `eqn` or `neqn` is invoked, it automatically reads the file `/usr/pub/eqnchar` (see [eqnchar\(5\)](#)). If `nroff(1)` is invoked, [col\(1\)](#) is automatically used.

### Referring to Other nroff Manual Pages

If the first line of the `nroff` manual page is a reference to another manual page entry fitting the pattern:

```
.so man*/sourcefile
```

`man` processes the indicated file in place of the current one. The reference must be expressed as a path name relative to the root of the manual page directory subtree.

When the second or any subsequent line starts with `.so`, `man` ignores it; [troff\(1\)](#) or [nroff\(1\)](#) processes the request in the usual manner.

### Processing SGML Manual Pages

Manual pages are identified as being marked up in SGML by the presence of the string `<!DOCTYPE`. If the file also contains the string `SHADOW_PAGE`, the file refers to another manual page for the content. The reference is made with a file entity reference to the manual page that contains the text. This is similar to the `.so` mechanism used in the `nroff` formatted man pages.

### ENVIRONMENT VARIABLES

See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `man`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**MANPATH** A colon-separated list of directories; each directory can be followed by a comma-separated list of sections. If set, its value overrides `/usr/share/man` as the default directory search path, and the `man.cf` file as the default section search path. The `-M` and `-s` flags, in turn, override these values.)

**PAGER** A program to use for interactively delivering `man`'s output to the screen. If not set, `'more -s'` is used. See [more\(1\)](#).

**TCAT** The name of the program to use to display `troffed` manual pages.

**TROFF** The name of the formatter to use when the `-t` flag is given. If not set, [troff\(1\)](#) is used.

### EXAMPLES

**EXAMPLE 1** Creating a PostScript Version of a man page

The following example creates the `pipe(2)` man page in postscript:

```
% setenv 'TROFF troff -Tpost'
% setenv TCAT '/usr/lib/lp/postscript/dpost'
% man -t -s 2 pipe > /tmp/output.ps
```

This is an alternative to using `man -t`, which sends the man page to the default printer, if the user wants a postscript file version of the man page.

man(1)

**EXAMPLE 2** Creating a Text Version of a man page

The following example creates the `pipe(2)` man page in ascii text:

```
man pipe.2 | col -x -b > pipe.text
```

This is an alternative to using `man -t`, which sends the man page to the default printer, if the user wants a text file version of the man page.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.  
>0 An error occurred.

**FILES**

`/usr/share/man`  
Root of the standard manual page directory subtree

`/usr/share/man/man?/*`  
Unformatted nroff manual entries

`/usr/share/man/sman?/*`  
Unformatted SGML manual entries

`/usr/share/man/cat?/*`  
nroffed manual entries

`/usr/share/man/fmt?/*`  
troffed manual entries

`/usr/share/man/windex`  
Table of contents and keyword database

`/usr/share/lib/tmac/an`  
Standard `-man` macro package

`/usr/share/lib/sgml/locale/C/dtd/*`  
SGML document type definition files

`/usr/share/lib/sgml/locale/C/solbook/*`  
SGML style sheet and entity definitions directories

`/usr/share/lib/pub/eqnchar`  
Standard definitions for `eqn` and `neqn`

`man.cf`  
Default search order by section

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdoc

ATTRIBUTE TYPE	ATTRIBUTE VALUE
CSI	Enabled, see NOTES.
Interface Stability	Standard

**SEE ALSO** [apropos\(1\)](#), [cat\(1\)](#), [col\(1\)](#), [dpost\(1\)](#), [eqn\(1\)](#), [more\(1\)](#), [nroff\(1\)](#), [refer\(1\)](#), [tbl\(1\)](#), [troff\(1\)](#), [vgrind\(1\)](#), [whatis\(1\)](#), [catman\(1M\)](#), [attributes\(5\)](#), [environ\(5\)](#), [eqnchar\(5\)](#), [man\(5\)](#), [sgml\(5\)](#), [standards\(5\)](#)

**NOTES** The `-f` and `-k` options use the `windex` database, which is created by `catman(1M)`.

The `man` command is CSI-capable. However, some utilities invoked by the `man` command, namely, `troff`, `eqn`, `neqn`, `refer`, `tbl`, and `vgrind`, are not verified to be CSI-capable. Because of this, the `man` command with the `-t` option can not handle non-EUC data. Also, using the `man` command to display man pages that require special processing through `eqn`, `neqn`, `refer`, `tbl`, or `vgrind` can not be CSI-capable.

**BUGS** The manual is supposed to be reproducible either on a phototypesetter or on an ASCII terminal. However, on a terminal some information (indicated by font changes, for instance) is lost.

Some dumb terminals cannot process the vertical motions produced by the `e` (see [eqn\(1\)](#)) preprocessing flag. To prevent garbled output on these terminals, when you use `e`, also use `t`, to invoke [col\(1\)](#) implicitly. This workaround has the disadvantage of eliminating superscripts and subscripts, even on those terminals that can display them. Control-q clears a terminal that gets confused by [eqn\(1\)](#) output.

mconnect(1)

**NAME** mconnect – connect to SMTP mail server socket

**SYNOPSIS** **mconnect** [-p *port*] [-r] [*hostname*]

**DESCRIPTION** The `mconnect` utility opens a connection to the mail server on a given host, so that it can be tested independently of all other mail software. If no host is given, the connection is made to the local host. Servers expect to speak the Simple Mail Transfer Protocol (SMTP) on this connection. Exit by typing the `quit` command. Typing `EOF` sends an end of file to the server. An interrupt closes the connection immediately and exits.

**OPTIONS** The following options are supported:

- p *port* Specify the port number instead of the default SMTP port (number 25) as the next argument.
- r "Raw" mode: disable the default line buffering and input handling. This produces an effect similar to `telnet(1)` to port number 25.

**OPERANDS** The following operand is supported:

- hostname* The name of a given host.

**USAGE** The `mconnect` command is IPv6-enabled. See `ip6(7P)`.

**FILES** `/etc/mail/sendmail.hf` help file for SMTP commands

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO** `telnet(1)`, `sendmail(1M)`, `attributes(5)`, `ip6(7P)`

Postel, Jonathan B., *RFC 821, Simple Mail Transfer Protocol*, Information Sciences Institute, University of Southern California, August 1982.

<b>NAME</b>	mcs – manipulate the comment section of an object file
<b>SYNOPSIS</b>	<b>mcs</b> [-cdpVz] [-a <i>string</i> ] [-n <i>name</i> ] <i>file...</i>
<b>DESCRIPTION</b>	<p>The <b>mcs</b> command is used to manipulate a section, by default the <code>.comment</code> section, in an ELF object file. It is used to add to, delete, print, and compress the contents of a section in an ELF object file, and print only the contents of a section in a COFF object file. <b>mcs</b> cannot add, delete, or compress the contents of a section that is contained within a segment.</p> <p>If the input file is an archive (see <code>ar.h(3HEAD)</code>), the archive is treated as a set of individual files. For example, if the <code>-a</code> option is specified, the string is appended to the comment section of each ELF object file in the archive; if the archive member is not an ELF object file, then it is left unchanged.</p> <p><b>mcs</b> must be given one or more of the options described below. It applies, in order, each of the specified options to each file.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-a <i>string</i></code> Appends <i>string</i> to the comment section of the ELF object files. If <i>string</i> contains embedded blanks, it must be enclosed in quotation marks.</li> <li><code>-c</code> Compresses the contents of the comment section of the ELF object files. All duplicate entries are removed. The ordering of the remaining entries is not disturbed.</li> <li><code>-d</code> Deletes the contents of the comment section from the ELF object files. The section header for the comment section is also removed.</li> <li><code>-n <i>name</i></code> Specifies the name of the comment section to access if other than <code>.comment</code>. By default, <b>mcs</b> deals with the section named <code>.comment</code>. This option can be used to specify another section. <b>mcs</b> can take multiple <code>-n</code> options to allow for specification of multiple section comments.</li> <li><code>-p</code> Prints the contents of the comment section on the standard output. Each section printed is tagged by the name of the file from which it was extracted, using the format <code>file [member_name] :</code> for archive files and <code>file :</code> for other files.</li> <li><code>-V</code> Prints on standard error the version number of <b>mcs</b>.</li> <li><code>-z</code> Replaces any <code>SHT_PROGBITS</code> sections with zeros while retaining the original attributes of the sections.</li> </ul>
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Printing a file's comment section</p> <p>The following entry</p> <pre>example% mcs -p elf.file</pre>

mcs(1)

**EXAMPLE 1** Printing a file's comment section *(Continued)*

prints the comment section of the file `elf.file`.

**EXAMPLE 2** Appending a string to a comment section

The following entry

```
example% mcs -a xyz elf.file
```

appends string `xyz` to `elf.file`'s comment section.

**FILES** `/tmp/mcs*` temporary files

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbtool
Interface Stability	Stable

**SEE ALSO** `ar(1)`, `as(1)`, `ld(1)`, `ar.h(3HEAD)`, `elf(3ELF)`, `tmpnam(3C)`, `a.out(4)`, `attributes(5)`

**NOTES** When `mcs` deletes a section using the `-d` option, it tries to bind together sections of type `SHT_REL` and target sections pointed to by the `sh_info` section header field. If one is to be deleted, `mcs` attempts to delete the other of the pair.

By using the `-z` option, it is possible to make an object file by removing the contents of `SHT_PROGBITS` sections while retaining the object file's original structure as an ELF file. The need for use of the `-z` option is limited. However, the option can be used to deliver an object file when the contents of `SHT_PROGBITS` sections are not relevant.

<b>NAME</b>	<code>mdb</code> – modular debugger
<b>SYNOPSIS</b>	<code>mdb</code> [-fkmwyAFMS] [ $\pm$ o <i>option</i> ] [-p <i>pid</i> ] [-s <i>distance</i> ] [-I <i>path</i> ] [-L <i>path</i> ] [-P <i>prompt</i> ] [-R <i>root</i> ] [-V <i>dis-version</i> ] [object [core]   core   <i>suffix</i> ]
<b>DESCRIPTION</b>	
<b>Introduction</b>	<p>The <code>mdb</code> utility is an extensible utility for low-level debugging and editing of the live operating system, operating system crash dumps, user processes, user process core dumps, and object files. For a more detailed description of <code>mdb</code> features, refer to the manual, <i>Solaris Modular Debugger Guide</i>.</p> <p>Debugging is the process of analyzing the execution and state of a software program in order to remove defects. Traditional debugging tools provide facilities for execution control so that programmers can re-execute programs in a controlled environment and display the current state of program data or evaluate expressions in the source language used to develop the program.</p> <p>Unfortunately, these techniques are often inappropriate for debugging complex software systems such as an operating system, where bugs may not be reproducible and program state is massive and distributed, for programs that are highly optimized, have had their debug information removed, or are themselves low-level debugging tools, or for customer situations where the developer can only access post-mortem information.</p> <p><code>mdb</code> provides a completely customizable environment for debugging these programs and scenarios, including a dynamic module facility that programmers can use to implement their own debugging commands to perform program-specific analysis. Each <code>mdb</code> module can be used to examine the program in several different contexts, including live and post-mortem.</p>
<b>Definitions</b>	<p>The <i>target</i> is the program being inspected by the debugger. <code>mdb</code> currently provides support for the following types of targets: user processes, user process core files, the live operating system (via <code>/dev/kmem</code> and <code>/dev/ksyms</code>), operating system crash dumps, user process images recorded inside an operating system crash dump, ELF object files, and raw binary files. Each target exports a standard set of properties, including one or more address spaces, one or more symbol tables, a set of load objects, and a set of threads that can be examined using the debugger commands described below.</p> <p>A debugger command, or <i>dcmd</i> (pronounced dee-command) in <code>mdb</code> terminology, is a routine in the debugger that can access any of the properties of the current target. <code>mdb</code> parses commands from standard input, and then executes the corresponding <code>dcmds</code>. Each <code>dcmd</code> can also accept a list of string or numerical arguments, as shown in the syntax description below. <code>mdb</code> contains a set of built-in <code>dcmds</code>, described below, that are always available. You can also extend the capabilities of <code>mdb</code> itself by writing your own <code>dcmds</code>, as described in the <i>Solaris Modular Debugger Guide</i>.</p>

## mdb(1)

A *walker* is a set of routines that describe how to walk, or iterate, through the elements of a particular program data structure. A walker encapsulates the data structure's implementation from `dcmds` and from `mdb` itself. You can use walkers interactively, or use them as a primitive to build other `dcmds` or walkers. As with `dcmds`, you can extend `mdb` by implementing your own walkers as part of a debugger module.

A debugger module, or *dmod* (pronounced dee-mod), is a dynamically loaded library containing a set of `dcmds` and walkers. During initialization, `mdb` will attempt to load `dmods` corresponding to the load objects present in the target. You can subsequently load or unload `dmods` at any time while running `mdb`. `mdb` ships with a set of standard `dmods` for debugging the Solaris kernel. The *Solaris Modular Debugger Guide* contains more information on developing your own debugger modules.

A *macro file* is a text file containing a set of commands to execute. Macro files are typically used to automate the process of displaying a simple data structure. `mdb` provides complete backward compatibility for the execution of macro files written for [adb\(1\)](#), and the Solaris installation includes a set of macro files for debugging the Solaris kernel that may be used with either tool.

### Syntax

The debugger processes commands from standard input. If standard input is a terminal, `mdb` provides terminal editing capabilities. `mdb` can also process commands from macro files and from `dcmd` pipelines, described below. The language syntax is designed around the concept of computing the value of an expression (typically a memory address in the target), and then applying a `dcmd` to that address. The current address location is referred to as *dot*, and its value is referenced using `."`.

A *metacharacter* is one of the following characters:

```
[ ] | ! / \ ? = > $ : ;  
      NEWLINE SPACE TAB
```

A *blank* is a `TAB` or a `SPACE`. A *word* is a sequence of characters separated by one or more non-quoted metacharacters. Some of the metacharacters only function as delimiters in certain contexts, as described below. An *identifier* is a sequence of letters, digits, underscores, periods, or backquotes beginning with a letter, underscore, or period. Identifiers are used as the names of symbols, variables, `dcmds`, and walkers. Commands are delimited by a `NEWLINE` or semicolon ( ; ).

A `dcmd` is denoted by one of the following words or metacharacters:

```
/ \ ? = > $character :character ::identifier
```

`dcmds` named by metacharacters or prefixed by a single `$` or `:` are provided as built-in operators, and implement complete compatibility with the command set of the legacy [adb\(1\)](#) utility. Once a `dcmd` has been parsed, the `/`, `\`, `?`, `=`, `>`, `$`, and `:` characters are no longer recognized as metacharacters until the termination of the argument list.

A *simple-command* is a dcmd followed by a sequence of zero or more blank-separated words. The words are passed as arguments to the invoked dcmd, except as specified under *Quoting* and *Arithmetic Expansion* below. Each dcmd returns an exit status that indicates it was either successful, failed, or was invoked with invalid arguments.

A *pipeline* is a sequence of one or more simple commands separated by `|`. Unlike the shell, dcmds in mdb pipelines are not executed as separate processes. After the pipeline has been parsed, each dcmd is invoked in order from left to right. Each dcmd's output is processed and stored as described under *dcmd Pipelines* below. Once the left-hand dcmd is complete, its processed output is used as input for the next dcmd in the pipeline. If any dcmd does not return a successful exit status, the pipeline is aborted.

An *expression* is a sequence of words that is evaluated to compute a 64-bit unsigned integer value. The words are evaluated using the rules described under *Arithmetic Expansion* below.

**Commands** A *command* is one of the following:

*pipeline* [*!* *word* . . .] [*;*]

A simple-command or pipeline can be optionally suffixed with the `!` character, indicating that the debugger should open a `pipe(2)` and send the standard output of the last dcmd in the mdb pipeline to an external process created by executing `$SHELL -c` followed by the string formed by concatenating the words after the `!` character. For more details, refer to *Shell Escapes* below.

*expression pipeline* [*!* *word* . . .] [*;*]

A simple-command or pipeline can be prefixed with an expression. Before execution of the pipeline, the value of `dot` (the variable denoted by `."`) is set to the value of the expression.

*expression , expression pipeline* [*!* *word* . . .] [*;*]

A simple-command or pipeline can be prefixed with two expressions. The first is evaluated to determine the new value of `dot`, and the second is evaluated to determine a repeat count for the first dcmd in the pipeline. This dcmd will be executed *count* times before the next dcmd in the pipeline is executed. The repeat count only applies to the first dcmd in the pipeline.

*, expression pipeline* [*!* *word* . . .] [*;*]

If the initial expression is omitted, `dot` is not modified but the first dcmd in the pipeline will be repeated according to the value of the expression.

*expression* [*!* *word* . . .] [*;*]

A command can consist only of an arithmetic expression. The expression is evaluated and the `dot` variable is set to its value, and then the previous dcmd and arguments are executed using the new value of `dot`.

mdb(1)

	<p><i>expression</i>, <i>expression</i> [<i>!</i> <i>word</i> . . .] [ ; ]</p> <p>A command can consist only of a dot expression and repeat count expression. After dot is set to the value of the first expression, the previous dcmd and arguments are repeatedly executed the number of times specified by the value of the second expression.</p> <p>, <i>expression</i> [<i>!</i> <i>word</i> . . .] [ ; ]</p> <p>If the initial expression is omitted, dot is not modified but the previous dcmd and arguments are repeatedly executed the number of times specified by the value of the count expression.</p> <p>! <i>word</i> . . . [ ; ]</p> <p>If the command begins with the ! character, no dcmds are executed and the debugger simply executes \$SHELL -c followed by the string formed by concatenating the words after the ! character.</p>																		
<b>Comments</b>	<p>A word beginning with // causes that word and all the subsequent characters up to a NEWLINE to be ignored.</p>																		
<b>Arithmetic Expansion</b>	<p>Arithmetic expansion is performed when an mdb command is preceded by an optional expression representing a start address, or a start address and a repeat count. Arithmetic expansion can also be performed to compute a numerical argument for a dcmd. An arithmetic expression can appear in an argument list enclosed in square brackets preceded by a dollar sign (\$ [ <i>expression</i> ]), and will be replaced by the value of the expression.</p> <p>Expressions may contain any of the following special words:</p> <table><tr><td><i>integer</i></td><td>The specified integer value. Integer values may be prefixed with 0i or 0I to indicate binary values, 0o or 0O to indicate octal values, 0t or 0T to indicate decimal values, and 0x or 0X to indicate hexadecimal values (the default).</td></tr><tr><td>0[tT][0-9]+.[0-9]+</td><td>The specified decimal floating point value, converted to its IEEE double-precision floating point representation.</td></tr><tr><td>'ccccccc'</td><td>The integer value computed by converting each character to a byte equal to its ASCII value. Up to eight characters may be specified in a character constant. Characters are packed into the integer in reverse order (right-to-left) beginning at the least significant byte.</td></tr><tr><td>&lt;<i>identifier</i></td><td>The value of the variable named by <i>identifier</i>.</td></tr><tr><td><i>identifier</i></td><td>The value of the symbol named by <i>identifier</i>.</td></tr><tr><td>(<i>expression</i>)</td><td>The value of <i>expression</i>.</td></tr><tr><td>.</td><td>The value of dot.</td></tr><tr><td>&amp;</td><td>The most recent value of dot used to execute a dcmd.</td></tr><tr><td>+</td><td>The value of dot incremented by the current increment.</td></tr></table>	<i>integer</i>	The specified integer value. Integer values may be prefixed with 0i or 0I to indicate binary values, 0o or 0O to indicate octal values, 0t or 0T to indicate decimal values, and 0x or 0X to indicate hexadecimal values (the default).	0[tT][0-9]+.[0-9]+	The specified decimal floating point value, converted to its IEEE double-precision floating point representation.	'ccccccc'	The integer value computed by converting each character to a byte equal to its ASCII value. Up to eight characters may be specified in a character constant. Characters are packed into the integer in reverse order (right-to-left) beginning at the least significant byte.	< <i>identifier</i>	The value of the variable named by <i>identifier</i> .	<i>identifier</i>	The value of the symbol named by <i>identifier</i> .	( <i>expression</i> )	The value of <i>expression</i> .	.	The value of dot.	&	The most recent value of dot used to execute a dcmd.	+	The value of dot incremented by the current increment.
<i>integer</i>	The specified integer value. Integer values may be prefixed with 0i or 0I to indicate binary values, 0o or 0O to indicate octal values, 0t or 0T to indicate decimal values, and 0x or 0X to indicate hexadecimal values (the default).																		
0[tT][0-9]+.[0-9]+	The specified decimal floating point value, converted to its IEEE double-precision floating point representation.																		
'ccccccc'	The integer value computed by converting each character to a byte equal to its ASCII value. Up to eight characters may be specified in a character constant. Characters are packed into the integer in reverse order (right-to-left) beginning at the least significant byte.																		
< <i>identifier</i>	The value of the variable named by <i>identifier</i> .																		
<i>identifier</i>	The value of the symbol named by <i>identifier</i> .																		
( <i>expression</i> )	The value of <i>expression</i> .																		
.	The value of dot.																		
&	The most recent value of dot used to execute a dcmd.																		
+	The value of dot incremented by the current increment.																		

$\wedge$  The value of dot decremented by the current increment.

The increment is a global variable that stores the total bytes read by the last formatting dcmd. For more information on the increment, refer to the discussion of `Formatting dcmds` below.

Unary operators are right associative and have higher precedence than binary operators. The unary operators are:

<i>#expression</i>	Logical negation.
<i>~expression</i>	Bitwise complement.
<i>-expression</i>	Integer negation.
<i>%expression</i>	The value of a pointer-sized quantity at the object file location corresponding to virtual address <i>expression</i> in the target's virtual address space.
<i>%/[csil]/expression</i>	The value of a char, short, int, or long-sized quantity at the object file location corresponding to virtual address <i>expression</i> in the target's virtual address space.
<i>%/[1248]/expression</i>	The value of a one, two, four, or eight-byte quantity at the object file location corresponding to virtual address <i>expression</i> in the target's virtual address space.
<i>*expression</i>	The value of a pointer-sized quantity at virtual address <i>expression</i> in the target's virtual address space.
<i>*/[csil]/expression</i>	The value of a char, short, int, or long-sized quantity at virtual address <i>expression</i> in the target's virtual address space.
<i>*/[1248]/expression</i>	The value of a one, two, four, or eight-byte quantity at virtual address <i>expression</i> in the target's virtual address space.

Binary operators are left associative and have lower precedence than unary operators. The binary operators, in order of precedence from highest to lowest, are:

*	Integer multiplication.
%	Integer division.
#	Left-hand side rounded up to next multiple of right-hand side.
+	Integer addition.
-	Integer subtraction.
<<	Bitwise shift left.
>>	Bitwise shift right.

mdb(1)

	<p>== Logical equality.</p> <p>!= Logical inequality.</p> <p>&amp; Bitwise AND.</p> <p>^ Bitwise exclusive OR.</p> <p>  Bitwise inclusive OR.</p>																
<b>Quoting</b>	<p>Each metacharacter described above (see <i>Syntax</i>) terminates a word unless quoted. Characters can be quoted (forcing <code>mdb</code> to interpret each character as itself without any special significance) by enclosing them in a pair of single ( <code>' '</code> ) or double ( <code>" "</code> ) quote marks. A single quote cannot appear within single quotes. Inside double quotes, <code>mdb</code> recognizes the C programming language character escape sequences.</p>																
<b>Shell Escapes</b>	<p>The <code>!</code> character can be used to create a pipeline between an <code>mdb</code> command and the user's shell. If the <code>\$SHELL</code> environment variable is set, <code>mdb</code> will fork and exec this program for shell escapes; otherwise <code>/bin/sh</code> is used. The shell is invoked with the <code>-c</code> option followed by a string formed by concatenating the words after the <code>!</code> character. The <code>!</code> character takes precedence over all other metacharacters, except semicolon ( <code>;</code> ) and <code>NEWLINE</code>. Once a shell escape is detected, the remaining characters up to the next semicolon or <code>NEWLINE</code> are passed as is to the shell. The output of shell commands may not be piped to <code>mdb</code> dcmds. Commands executed by a shell escape have their output sent directly to the terminal, not to <code>mdb</code>.</p>																
<b>Variables</b>	<p>A <i>variable</i> is a variable name, a corresponding integer value, and a set of attributes. A variable name is a sequence of letters, digits, underscores, or periods. A variable can be assigned a value using the <code>&gt; dcmd</code> or <code>::typeset dcmd</code>, and its attributes can be manipulated using the <code>::typeset dcmd</code>. Each variable's value is represented as a 64-bit unsigned integer. A variable may have one or more of the following attributes: read-only (cannot be modified by the user), persistent (cannot be unset by the user), and tagged (user-defined indicator).</p> <p>The following variables are defined as persistent:</p> <table><tr><td>0</td><td>The most recent value printed using the <code>/, \, ?,</code> or <code>= dcmd</code>.</td></tr><tr><td>9</td><td>The most recent count used with the <code>\$&lt; dcmd</code>.</td></tr><tr><td>b</td><td>The virtual address of the base of the data section.</td></tr><tr><td>d</td><td>The size of the data section in bytes.</td></tr><tr><td>e</td><td>The virtual address of the entry point.</td></tr><tr><td>m</td><td>The initial bytes (magic number) of the target's primary object file, or zero if no object file has been read yet.</td></tr><tr><td>t</td><td>The size of the text section in bytes.</td></tr><tr><td>hits</td><td>The count of the number of times the matched software event specifier has been matched. See <i>Event Callbacks</i>, below.</td></tr></table>	0	The most recent value printed using the <code>/, \, ?,</code> or <code>= dcmd</code> .	9	The most recent count used with the <code>\$&lt; dcmd</code> .	b	The virtual address of the base of the data section.	d	The size of the data section in bytes.	e	The virtual address of the entry point.	m	The initial bytes (magic number) of the target's primary object file, or zero if no object file has been read yet.	t	The size of the text section in bytes.	hits	The count of the number of times the matched software event specifier has been matched. See <i>Event Callbacks</i> , below.
0	The most recent value printed using the <code>/, \, ?,</code> or <code>= dcmd</code> .																
9	The most recent count used with the <code>\$&lt; dcmd</code> .																
b	The virtual address of the base of the data section.																
d	The size of the data section in bytes.																
e	The virtual address of the entry point.																
m	The initial bytes (magic number) of the target's primary object file, or zero if no object file has been read yet.																
t	The size of the text section in bytes.																
hits	The count of the number of times the matched software event specifier has been matched. See <i>Event Callbacks</i> , below.																

`thread` The thread identifier of the current representative thread. The value of the identifier depends on the threading model used by the current target. See *Thread Support*, below.

In addition, the `mdb` kernel and process targets will export the current values of the representative thread's register set as named variables. The names of these variables will depend on the target's platform and instruction set architecture.

### Symbol Name Resolution

As explained in the *Syntax* description above, a symbol identifier present in an expression context evaluates to the value of this symbol. The value typically denotes the virtual address of the storage associated with the symbol in the target's virtual address space. A target may support multiple symbol tables including, but not limited to, a primary executable symbol table, a primary dynamic symbol table, a run-time link-editor symbol table, and standard and dynamic symbol tables for each of a number of load objects (such as shared libraries in a user process, or kernel modules in the Solaris kernel). The target typically searches the primary executable's symbol tables first, and then one or more of the other symbol tables. Notice that ELF symbol tables only contain entries for external, global, and static symbols; automatic symbols do not appear in the symbol tables processed by `mdb`.

Additionally, `mdb` provides a private user-defined symbol table that is searched prior to any of the target symbol tables. The private symbol table is initially empty, and can be manipulated using the `::nmadd` and `::nmdel` dcmds. The `::nm -P` option can be used to display the contents of the private symbol table. The private symbol table allows the user to create symbol definitions for program functions or data that were either missing from the original program or stripped out. These definitions are then used whenever `mdb` converts a symbolic name to an address, or an address to the nearest symbol.

As targets contain multiple symbol tables, and each symbol table may include symbols from multiple object files, different symbols with the same name may exist. `mdb` uses the backquote (``) character as a symbol name scoping operator to allow the programmer to obtain the value of the desired symbol in this situation. The programmer can specify the scope used to resolve a symbol name as either: *object`name*, or *file`name*, or *object`file`name*. The object identifier refers to the name of a load object. The file identifier refers to the basename of a source file that has a symbol of type `STT_FILE` in the specified object's symbol table. The object identifier's interpretation depends on the target type.

The `mdb` kernel target expects *object* to specify the basename of a loaded kernel module. For example, the symbol name

```
specfs`_init
```

evaluates to the value of the `_init` symbol in the `specfs` kernel module.

The `mdb` process target expects *object* to specify the name of the executable or of a loaded shared library. It may take any of the following forms:

mdb(1)

1. An exact match (that is, a full pathname): `/usr/lib/libc.so.1`
2. An exact basename match: `libc.so.1`
3. An initial basename match up to a `."` suffix: `libc.so` or `libc`
4. The literal string `a.out` is accepted as an alias for the executable.

The process target will also accept any of the four forms described above preceded by an optional link-map id (lmid). The lmid prefix is specified by an initial `"LM"` followed by the link-map id in hexadecimal followed by an additional backquote. For example, the symbol name

```
LM0`libc.so.1`_init
```

will evaluate to the value of the `_init` symbol in the `libc.so.1` library that is loaded on link-map 0 (`LM_ID_BASE`). The link-map specifier may be necessary to resolve symbol naming conflicts in the event that the same library is loaded on more than one link map. For more information on link maps, refer to the *Linker and Libraries Guide* and `dlopen(3C)`. Link-map identifiers will be displayed when symbols are printed according to the setting of the `showlmid` option, as described under `OPTIONS`.

In the case of a naming conflict between symbols and hexadecimal integer values, `mdb` will attempt to evaluate an ambiguous token as a symbol first, before evaluating it as an integer value. For example, the token `f` may either refer to the decimal integer value 15 specified in hexadecimal (the default base), or to a global variable named `f` in the target's symbol table. If a symbol with an ambiguous name is present, the integer value can be specified by using an explicit `0x` or `0X` prefix.

### dcmd and Walker Name Resolution

As described earlier, each `mdb` dmod provides a set of `dcmds` and `walkers`. `dcmds` and `walkers` are tracked in two distinct, global namespaces. `mdb` also keeps track of a `dcmd` and `walker` namespace associated with each dmod. Identically named `dcmds` or `walkers` within a given dmod are not allowed: a dmod with this type of naming conflict will fail to load. Name conflicts between `dcmds` or `walkers` from different dmods are allowed in the global namespace. In the case of a conflict, the first `dcmd` or `walker` with that particular name to be loaded is given precedence in the global namespace. Alternate definitions are kept in a list in load order. The backquote character (```) may be used in a `dcmd` or `walker` name as a scoping operator to select an alternate definition. For example, if dmods `m1` and `m2` each provide a `dcmd` `d`, and `m1` is loaded prior to `m2`, then:

```
::d           Executes m1's definition of d.  
::m1`d       Executes m1's definition of d.  
::m2`d       Executes m2's definition of d.
```

If module `m1` were now unloaded, the next `dcmd` on the global definition list (`m2`d`) would be promoted to global visibility. The current definition of a `dcmd` or `walker` can be determined using the `::which` `dcmd`, described below. The global definition list can be displayed using the `::which -v` option.

<b>dcmd Pipelines</b>	<p>dcmds can be composed into a pipeline using the <code> </code> operator. The purpose of a pipeline is to pass a list of values, typically virtual addresses, from one dcmd or walker to another. Pipeline stages might be used to map a pointer from one type of data structure to a pointer to a corresponding data structure, to sort a list of addresses, or to select the addresses of structures with certain properties.</p> <p>mdb executes each dcmd in the pipeline in order from left to right. The leftmost dcmd is executed using the current value of dot, or using the value specified by an explicit expression at the start of the command. When a <code> </code> operator is encountered, mdb creates a pipe (a shared buffer) between the output of the dcmd to its left and the mdb parser, and an empty list of values. As the dcmd executes, its standard output is placed in the pipe and then consumed and evaluated by the parser, as if mdb were reading this data from standard input. Each line must consist of an arithmetic expression terminated by a NEWLINE or semicolon (<code>;</code>). The value of the expression is appended to the list of values associated with the pipe. If a syntax error is detected, the pipeline is aborted.</p> <p>When the dcmd to the left of a <code> </code> operator completes, the list of values associated with the pipe is then used to invoke the dcmd to the right of the <code> </code> operator. For each value in the list, dot is set to this value and the right-hand dcmd is executed. Only the rightmost dcmd in the pipeline has its output printed to standard output. If any dcmd in the pipeline produces output to standard error, these messages are printed directly to standard error and are not processed as part of the pipeline.</p>
<b>Signal Handling</b>	<p>The debugger ignores the <code>PIPE</code> and <code>QUIT</code> signals. The <code>INT</code> signal aborts the command that is currently executing. The debugger intercepts and provides special handling for the <code>ILL</code>, <code>TRAP</code>, <code>EMT</code>, <code>FPE</code>, <code>BUS</code>, and <code>SEGV</code> signals. If any of these signals are generated asynchronously (that is, delivered from another process using <code>kill(2)</code>), mdb will restore the signal to its default disposition and dump core. However, if any of these signals are generated synchronously by the debugger process itself and a dcmd from an externally loaded dmod is currently executing, and standard input is a terminal, mdb will provide a menu of choices allowing the user to force a core dump, quit without producing a core dump, stop for attach by a debugger, or attempt to resume. The resume option will abort all active commands and unload the dmod whose dcmd was active at the time the fault occurred. It can then be subsequently re-loaded by the user. The resume option provides limited protection against buggy dcmds. Refer to <code>WARNINGS</code>, <code>Use of the Error Recovery Mechanism</code>, below for information about the risks associated with the resume option.</p>
<b>Command Re-entry</b>	<p>The text of the last <code>HISTSIZE</code> (default 128) commands entered from a terminal device are saved in memory. The in-line editing facility, described next, provides key mappings for searching and fetching elements from the history list.</p>
<b>In-line Editing</b>	<p>If standard input is a terminal device, mdb provides some simple emacs-style facilities for editing the command line. The <code>search</code>, <code>previous</code>, and <code>next</code> commands in edit mode provide access to the history list. Only strings, not patterns, are matched when searching. In the table below, the notation for control characters is caret (<code>^</code>) followed</p>

## mdb(1)

by a character shown in upper case. The notation for escape sequences is M- followed by a character. For example, M-f (pronounced meta-eff) is entered by depressing ESC followed by 'f', or by depressing Meta followed by 'f' on keyboards that support a Meta key. A command line is committed and executed using RETURN or NEWLINE. The edit commands are:

^F	Move cursor forward (right) one character.
M-f	Move cursor forward one word.
^B	Move cursor backward (left) one character.
M-b	Move cursor backward one word.
^A	Move cursor to start of line.
^E	Move cursor to end of line.
^D	Delete current character, if the current line is not empty. If the current line is empty, ^D denotes EOF and the debugger will exit.
M-^H	(Meta-backspace) Delete previous word.
^K	Delete from the cursor to the end of the line.
^L	Clear the screen and reprint the current line.
^T	Transpose current character with next character.
^N	Fetch the next command from the history. Each time ^N is entered, the next command forward in time is retrieved.
^P	Fetch the previous command from the history. Each time ^P is entered, the next command backward in time is retrieved.
^R[ <i>string</i> ]	Search backward in the history for a previous command line containing <i>string</i> . The string should be terminated by a RETURN or NEWLINE. If <i>string</i> is omitted, the previous history element containing the most recent string is retrieved.

The editing mode also interprets the following user-defined sequences as editing commands. User defined sequences can be read or modified using the [stty\(1\)](#) command.

erase	User defined erase character (usually ^H or ^?). Delete previous character.
intr	User defined interrupt character (usually ^C). Abort the current command and print a new prompt.
kill	User defined kill character (usually ^U). Kill the entire current command line.
quit	User defined quit character (usually ^\). Quit the debugger.

suspend	User defined suspend character (usually ^Z). Suspend the debugger.
werase	User defined word erase character (usually ^W). Erase the preceding word.

On keyboards that support an extended keypad with arrow keys, mdb will interpret these keystrokes as editing commands:

up-arrow	Fetch the previous command from the history (same as ^P).
down-arrow	Fetch the next command from the history (same as ^N).
left-arrow	Move cursor backward one character (same as ^B).
right-arrow	Move cursor forward one character (same as ^F).

### Output Pager

mdb provides a built-in output pager. The output pager is enabled if the debugger's standard output is a terminal device. Each time a command is executed, mdb will pause after one screenful of output is produced and will display a pager prompt:

```
>> More [<space>, <cr>, q, n, c, a] ?
```

The following key sequences are recognized by the pager:

SPACE	Display the next screenful of output.
a, A	Abort the current top-level command and return to the prompt.
c, C	Continue displaying output without pausing at each screenful until the current top-level command is complete.
n, N, NEWLINE, RETURN	Display the next line of output.
q, Q, ^C, ^\	Quit (abort) the current dcmd only.

### Formatting dcmds

The /, \, ?, and = metacharacters are used to denote the special output formatting dcmds. Each of these dcmds accepts an argument list consisting of one or more format characters, repeat counts, or quoted strings. A format character is one of the ASCII characters shown in the table below. Format characters are used to read and format data from the target. A repeat count is a positive integer preceding the format character that is always interpreted in base 10 (decimal). A repeat count may also be specified as an expression enclosed in square brackets preceded by a dollar sign (\$ [ ]). A string argument must be enclosed in double-quotes (" "). No blanks are necessary between format arguments.

The formatting dcmds are:

/	Display data from the target's virtual address space starting at the virtual address specified by dot.
---	--

## mdb(1)

\	Display data from the target's physical address space starting at the physical address specified by dot.
?	Display data from the target's primary object file starting at the object file location corresponding to the virtual address specified by dot.
=	Display the value of dot itself in each of the specified data formats. The = dcmd is therefore useful for converting between bases and performing arithmetic.

In addition to dot, mdb keeps track of another global value called the *increment*. The increment represents the distance between dot and the address following all the data read by the last formatting dcmd. For example, if a formatting dcmd is executed with dot equal to address A, and displays a 4-byte integer, then after this dcmd completes, dot is still A, but the increment is set to 4. The + character (described under *Arithmetic Expansion* above) would now evaluate to the value A + 4, and could be used to reset dot to the address of the next data object for a subsequent dcmd.

Most format characters increase the value of the increment by the number of bytes corresponding to the size of the data format, shown in the table. The table of format characters can be displayed from within mdb using the `::formats` dcmd. The format characters are:

+	increment dot by the count (variable size)
-	decrement dot by the count (variable size)
B	hexadecimal int (1 byte)
C	character using C character notation (1 byte)
D	decimal signed int (4 bytes)
E	decimal unsigned long long (8 bytes)
F	double (8 bytes)
G	octal unsigned long long (8 bytes)
H	swap bytes and shorts (4 bytes)
I	address and disassembled instruction (variable size)
J	hexadecimal long long (8 bytes)
K	hexadecimal uintptr_t (4 or 8 bytes)
N	newline
O	octal unsigned int (4 bytes)
P	symbol (4 or 8 bytes)
Q	octal signed int (4 bytes)

R	binary int (8 bytes)
S	string using C string notation (variable size)
T	horizontal tab
U	decimal unsigned int (4 bytes)
V	decimal unsigned int (1 byte)
W	default radix unsigned int (4 bytes)
X	hexadecimal int (4 bytes)
Y	decoded time32_t (4 bytes)
Z	hexadecimal long long (8 bytes)
^	decrement dot by increment * count (variable size)
a	dot as symbol+offset
b	octal unsigned int (1 byte)
c	character (1 byte)
d	decimal signed short (2 bytes)
e	decimal signed long long (8 bytes)
f	float (4 bytes)
g	octal signed long long (8 bytes)
h	swap bytes (2 bytes)
i	disassembled instruction (variable size)
n	newline
o	octal unsigned short (2 bytes)
p	symbol (4 or 8 bytes)
q	octal signed short (2 bytes)
r	whitespace
s	raw string (variable size)
t	horizontal tab
u	decimal unsigned short (2 bytes)
v	decimal signed int (1 byte)
w	default radix unsigned short (2 bytes)
x	hexadecimal short (2 bytes)

mdb(1)

y            decoded time64\_t (8 bytes)

The /, \, and ? formatting dcmts can also be used to write to the target's virtual address space, physical address space, or object file by specifying one of the following modifiers as the first format character, and then specifying a list of words that are either immediate values or expressions enclosed in square brackets preceded by a dollar sign (\$ [ ]).

The write modifiers are:

- v            Write the lowest byte of the value of each expression to the target beginning at the location specified by dot.
- w            Write the lowest two bytes of the value of each expression to the target beginning at the location specified by dot.
- W            Write the lowest 4 bytes of the value of each expression to the target beginning at the location specified by dot.
- Z            Write the complete 8 bytes of the value of each expression to the target beginning at the location specified by dot.

The /, \, and ? formatting dcmts can also be used to search for a particular integer value in the target's virtual address space, physical address space, and object file, respectively, by specifying one of the following modifiers as the first format character, and then specifying a value and optional mask. The value and mask are each specified as either immediate values or expressions enclosed in square brackets preceded by a dollar sign. If only a value is specified, mdb reads integers of the appropriate size and stops at the address containing the matching value. If a value V and mask M are specified, mdb reads integers of the appropriate size and stops at the address containing a value X where  $(X \& M) == V$ . At the completion of the dcmtd, dot is updated to the address containing the match. If no match is found, dot is left at the last address that was read.

The search modifiers are:

- l            Search for the specified 2-byte value.
- L            Search for the specified 4-byte value.
- M            Search for the specified 8-byte value.

Notice that for both user and kernel targets, an address space is typically composed of a set of discontinuous segments. It is not legal to read from an address that does not have a corresponding segment. If a search reaches a segment boundary without finding a match, it will abort when the read past the end of the segment boundary fails.

**Execution Control**

mdb provides facilities for controlling and tracing the execution of a live running program. Currently, only the user process target provides support for execution control. mdb provides a simple model of execution control: a target process can be started from within the debugger using `::run`, or mdb can attach to an existing process using `:A`, `::attach`, or the `-p` command-line option, as described below. A list of traced software events can be specified by the user. Each time a traced event occurs in the target process, all threads in the target stop, the thread that triggered the event is chosen as the representative thread, and control returns to the debugger. Once the target program is set running, control can be asynchronously returned to the debugger by typing the user-defined interrupt character (typically `^C`).

A *software event* is a state transition in the target program that is observed by the debugger. For example, the debugger may observe the transition of a program counter register to a value of interest (a breakpoint) or the delivery of a particular signal.

A *software event specifier* is a description of a class of software events that is used by the debugger to instrument the target program in order to observe these events. The `::events` dcmd is used to list the software event specifiers. A set of standard properties is associated with each event specifier, as described under `::events`, below.

The debugger can observe a variety of different software events, including breakpoints, watchpoints, signals, machine faults, and system calls. New specifiers can be created using `::bp`, `::fltbp`, `::sigbp`, `::sysbp`, or `::wp`. Each specifier has an associated callback (an mdb command string to execute as if it had been typed at the command prompt) and a set of properties, as described below. Any number of specifiers for the same event may be created, each with different callbacks and properties. The current list of traced events and the properties of the corresponding event specifiers can be displayed using the `::events` dcmd. The event specifier properties are defined as part of the description of the `::events` and `::evset` dcmds, below.

The execution control built-in dcmds, described below, are always available, but will issue an error message indicating they are not supported if applied to a target that does not support execution control. For more information about the interaction of `exec`, `attach`, `release`, and `job` control with debugger execution control, refer to NOTES, below.

**Event Callbacks**

The `::evset` dcmd and event tracing dcmds allow you to associate an event callback (using the `-c` option) with each event specifier. The event callbacks are strings that represent mdb commands to execute when the corresponding event occurs in the target. These commands are executed as if they had been typed at the command prompt. Before executing each callback, the `dot` variable is set to the value of the representative thread's program counter and the `"hits"` variable is set to the number of times this specifier has been matched, including the current match.

If the event callbacks themselves contain one or more commands to continue the target (for example, `::cont` or `::step`), these commands do not immediately continue the target and wait for it to stop again. Instead, inside of an event callback, the `continue`

mdb(1)

dcmds note that a continue operation is now pending, and then return immediately. Therefore, if multiple dcmds are included in an event callback, the step or continue dcmd should be the last command specified. Following the execution of *all* event callbacks, the target will immediately resume execution if *all* matching event callbacks requested a continue. If conflicting continue operations are requested, the operation with the highest precedence determines what type of continue will occur. The order of precedence from highest to lowest is: step, step-over (next), step-out, continue.

### Thread Support

mdb provides facilities to examine the stacks and registers of each thread associated with the target. The persistent “thread” variable contains the current representative thread identifier. The format of the thread identifier depends on the target. The `::regs` and `::fpregs` dcmds can be used to examine the register set of the representative thread, or of another thread if its register set is currently available. In addition, the register set of the representative thread is exported as a set of named variables. The user can modify the value of one or more registers by applying the `>` dcmd to the corresponding named variable.

The mdb kernel target exports the virtual address of the corresponding internal thread structure as the identifier for a given thread. The *Solaris Modular Debugger Guide* provides more information on debugging support for threads in the Solaris kernel. The mdb process target provides proper support for examination of multi-threaded user processes that use the native `lwp_*` interfaces, `/usr/lib/libthread.so` or `/usr/lib/lwp/libthread.so`. When debugging a live user process, mdb will detect if a single threaded process `dlopen`s or closes `libthread` and will automatically adjust its view of the threading model on-the-fly. The process target thread identifiers will correspond to either the `lwpid_t`, `thread_t`, or `pthread_t` of the representative, depending on the threading model used by the application.

If mdb is debugging a user process target and the target makes use of compiler-supported thread-local storage, mdb will automatically evaluate symbol names referring to thread-local storage to the address of the storage corresponding to the current representative thread. The `::tls` built-in dcmd can be used to display the value of the symbol for threads other than the representative thread.

### Built-in dcmds

mdb provides a set of built-in dcmds that are always defined. Some of these dcmds are only applicable to certain targets: if a dcmd is not applicable to the current target, it will fail and print a message indicating “command is not supported by current target”. In many cases, mdb provides a mnemonic equivalent (`::identifier`) for the legacy `adb(1)` dcmd names. For example, `::quit` is provided as the equivalent of `$q`. Programmers who are experienced with `adb(1)` or who appreciate brevity or arcana may prefer the `$` or `:` forms of the built-ins. Programmers who are new to mdb may prefer the more verbose `::` form. The built-ins are shown in alphabetical order. If a `$` or `:` form has a `::identifier` equivalent, it is shown underneath the `::identifier` form. The built-in dcmds are:

```
> variable-name
> /modifier/variable-name
```

Assign the value of dot to the specified named variable. Some variables are read-only and may not be modified. If the > is followed by a modifier character surrounded by / /, then the value is modified as part of the assignment. The modifier characters are:

c	unsigned char quantity (1-byte)
s	unsigned short quantity (2-byte)
i	unsigned int quantity (4-byte)
l	unsigned long quantity (4-byte in 32-bit, 8-byte in 64-bit)

Notice that these operators do not perform a cast. Instead, they fetch the specified number of low-order bytes (on little-endian architectures) or high-order bytes (big-endian architectures). Modifiers are provided for backwards compatibility; the `mdb */modifier/` and `%/modifier/` syntax should be used instead.

`$< macro-name`

Read and execute commands from the specified macro file. The filename may be given as an absolute or relative path. If the filename is a simple name (that is, if it does not contain a '/'), `mdb` will search for it in the macro file include path. If another macro file is currently being processed, this file is closed and replaced with the new file.

`$<< macro-name`

Read and execute commands from the specified macro file (as with `$<`), but do not close the current open macro file.

`$?`

Print the process-ID and current signal of the target if it is a user process or core file, and then print the general register set of the representative thread.

`[ address ] $C [ count ]`

Print a C stack backtrace, including stack frame pointer information. If the `dcmd` is preceded by an explicit `address`, a backtrace beginning at this virtual memory address is displayed. Otherwise the stack of the representative thread is displayed. If an optional count value is given as an argument, no more than `count` arguments are displayed for each stack frame in the output.

`[ base ] $d`

Get or set the default output radix. If the `dcmd` is preceded by an explicit expression, the default output radix is set to the given `base`; otherwise the current radix is printed in base 10 (decimal). The default radix is base 16 (hexadecimal).

`$e`

Print a list of all known external (global) symbols of type object or function, the value of the symbol, and the first 4 (32-bit `mdb`) or 8 (64-bit `mdb`) bytes stored at this location in the target's virtual address space. The `: :nm dcmd` provides more flexible options for displaying symbol tables.

`$P prompt-string`

Set the prompt to the specified `prompt-string`. The default prompt is '>'. The prompt can also be set using `: :set -P` or the `-P` command-line option.

## mdb(1)

### *distance* \$s

Get or set the symbol matching *distance* for address-to-symbol-name conversions. The symbol matching distance modes are discussed along with the `-s` command-line option under `OPTIONS`. The symbol matching distance may also be modified using the `::set -s` option. If no distance is specified, the current setting is displayed.

### \$v

Print a list of the named variables that have non-zero values. The `::vars dcmd` provides other options for listing variables.

### *width* \$w

Set the output page *width* to the specified value. Typically, this command is not necessary as `mdb` queries the terminal for its width and handles resize events.

### \$W

Re-open the target for writing, as if `mdb` had been executed with the `-w` option on the command line. Write mode can also be enabled with the `::set -w` option.

[ *pid* ] ::attach [ *core* | *pid* ]

[ *pid* ] :A [ *core* | *pid* ]

If the user process target is active, attach to and debug the specified process-ID or *core* file. The core file pathname should be specified as a string argument. The process-ID may be specified as the string argument, or as the value of the expression preceding the `dcmd`. Recall that the default base is hexadecimal, so decimal PIDs obtained using `pgrep(1)` or `ps(1)` should be preceded with "0t" when specified as expressions.

[*address*] ::bp [+/-dDesT] [-c *cmd*] [-n *count*] *sym* ...

*address* :b [*cmd* ...]

Set a breakpoint at the specified locations. The `::bp` `dcmd` sets a breakpoint at each address or symbol specified, including an optional address specified by an explicit expression preceding the `dcmd`, and each string or immediate value following the `dcmd`. The arguments may either be symbol names or immediate values denoting a particular virtual address of interest. If a symbol name is specified, it may refer to a symbol that cannot yet be evaluated in the target process. That is, it may consist of an object name and function name in a load object that has not yet been opened. In this case, the breakpoint is deferred and it will not be active in the target until an object matching the given name is loaded. The breakpoint will be automatically enabled when the load object is opened. Breakpoints on symbols defined in a shared library should always be set using a symbol name and not using an address expression, as the address may refer to the corresponding Procedure Linkage Table (PLT) entry instead of the actual symbol definition. Breakpoints set on PLT entries may be overwritten by the run-time link-editor when the PLT entry is subsequently resolved to the actual symbol definition. The `-d`, `-D`, `-e`, `-s`, `-t`, `-T`, `-c`, and `-n` options have the same meaning as they do for the `::evset` `dcmd`, as described below. If the `:b` form of the `dcmd` is used, a breakpoint is only set at the virtual address specified by the expression preceding the `dcmd`. The arguments following the `:b` `dcmd` are concatenated together to form the callback string. If this string contains meta-characters, it must be quoted.

`::cat filename ...`

Concatenate and display files. Each filename may be specified as a relative or absolute pathname. The file contents will be printed to standard output, but will not be passed to the output pager. This dcmd is intended to be used with the `|` operator; the programmer can initiate a pipeline using a list of addresses stored in an external file.

`::cont [ SIG ]`

`:c [ SIG ]`

Suspend the debugger, continue the target program, and wait for it to terminate or stop following a software event of interest. If the target is already running because the debugger was attached to a running program with the `-o nostop` option enabled, this dcmd simply waits for the target to terminate or stop after an event of interest. If an optional signal name or number (see `signal.h(3HEAD)`) is specified as an argument, the signal is immediately delivered to the target as part of resuming its execution. If the `SIGINT` signal is traced, control may be asynchronously returned to the debugger by typing the user-defined interrupt character (usually `^C`). This `SIGINT` signal will be automatically cleared and will not be observed by the target the next time it is continued. If no target program is currently running, `::cont` will start a new program running as if by `::run`.

`address ::context`

`address $p`

Context switch to the specified process. A context switch operation is only valid when using the kernel target. The process context is specified using the *address* of its `proc` structure in the kernel's virtual address space. The special context address "0" is used to denote the context of the kernel itself. `mdb` can only perform a context switch when examining a crash dump if the dump contains the physical memory pages of the specified user process (as opposed to just kernel pages). The kernel crash dump facility can be configured to dump all pages or the pages of the current user process using `dumpadm(1M)`. The `::status` dcmd can be used to display the contents of the current crash dump.

When the user requests a context switch from the kernel target, `mdb` constructs a new target representing the specified user process. Once the switch occurs, the new target interposes its dcmds at the global level: thus the `/` dcmd will now format and display data from the virtual address space of the user process, the `::mappings` dcmd will display the mappings in the address space of the user process, and so on. The kernel target can be restored by executing `0 ::context`.

`::dcmds`

List the available dcmds and print a brief description for each one.

`[ address ] ::delete [ id | all ]`

`[ address ] :d [ id | all ]`

Delete the event specifiers with the given *id* number. The *id* number argument is interpreted in decimal by default. If an optional *address* is specified preceding the dcmd, all event specifiers that are associated with the given virtual address are

deleted (for example, all breakpoints or watchpoints affecting that address). If the special argument "all" is given, all event specifiers are deleted, except those that are marked sticky (T flag). The `::events` dcmd displays the current list of event specifiers.

`[ address ] ::dis [ -fw ] [ -n count ] [ address ]`

Disassemble starting at or around the *address* specified by the final argument, or the current value of dot. If the address matches the start of a known function, the entire function is disassembled. Otherwise, a "window" of instructions before and after the specified address is printed in order to provide context. By default, instructions are read from the target's virtual address space. If the `-f` option is present, instructions are read from the target's object file instead. The `-f` option is enabled by default if the debugger is not currently attached to a live process, core file, or crash dump. The `-w` option can be used to force "window"-mode, even if the address is the start of a known function. The size of the window defaults to ten instructions; the number of instructions can be specified explicitly using the `-n` option.

`::disasms`

List the available disassembler modes. When a target is initialized, mdb will attempt to select the appropriate disassembler mode. The user can change the mode to any of the modes listed using the `::dismode` dcmd.

`::dismode [ mode ]`

`$V [ mode ]`

Get or set the disassembler mode. If no argument is specified, print the current disassembler mode. If a *mode* argument is specified, switch the disassembler to the specified mode. The list of available disassemblers can be displayed using the `::disasms` dcmd.

`::dmods [ -l ] [ module-name ]`

List the loaded debugger modules. If the `-l` option is specified, the list of the dcmds and walkers associated with each dmod is printed below its name. The output can be restricted to a particular dmod by specifying its name as an additional argument.

`[ address ] ::dump [ -eqrstu ] [ -f | -p ]`

`[ -g bytes ] [ -w paragraphs ]`

Print a hexadecimal and ASCII memory dump of the 16-byte aligned region of memory containing the address specified by dot. If a repeat count is specified for `::dump`, this is interpreted as a number of bytes to dump rather than a number of iterations. The `::dump` dcmd also recognizes the following options:

- `-e` Adjusts for endian-ness. The `-e` option assumes 4-byte words. The `-g` option can be used to change the default word size.
- `-f` Reads data from the object file location corresponding to the given virtual address instead of from the target's virtual address space. The `-f` option is enabled by default if the debugger is not currently attached to a live process, core file, or crash dump.

<code>-g bytes</code>	Displays bytes in groups of <i>bytes</i> . The default group size is 4 bytes. The group size must be a power of two that divides the line width.
<code>-p</code>	Interprets <i>address</i> as a physical address location in the target's address space instead of a virtual address.
<code>-q</code>	Does not print an ASCII decoding of the data.
<code>-r</code>	Numbers lines relative to the start address instead of with the explicit address of each line. This option implies the <code>-u</code> option.
<code>-s</code>	Elides repeated lines.
<code>-t</code>	Only reads from and displays the contents of the specified addresses, instead of reading and printing entire lines.
<code>-u</code>	Unaligns output instead of aligning the output at a paragraph boundary.
<code>-w paragraphs</code>	Displays paragraphs at 16-byte paragraphs per line. The default number of <i>paragraphs</i> is one. The maximum value accepted for <code>-w</code> is 16.

`::echo [ string | value ...]`

Print the arguments separated by blanks and terminated by a NEWLINE to standard output. Expressions enclosed in `$ [ ]` will be evaluated to a value and printed in the default base.

`::eval command`

Evaluate and execute the specified string as a command. If the command contains metacharacters or whitespace, it should be enclosed in double or single quotes.

`::events [ -av ]`

`$b [ -av ]`

Display the list of software event specifiers. Each event specifier is assigned a unique ID number that can be used to delete or modify it at a later time. The debugger may also have its own internal events enabled for tracing. These events will only be displayed if the `-a` option is present. If the `-v` option is present, a more verbose display, including the reason for any specifier inactivity, will be shown. Here is some sample output:

```
> ::events
  ID S TA HT LM Description                Action
-----
[ 1 ] - T  1  0 stop on SIGINT              -
[ 2 ] - T  0  0 stop on SIGQUIT            -
[ 3 ] - T  0  0 stop on SIGILL            -
...
[ 11] - T  0  0 stop on SIGXCPU             -
[ 12] - T  0  0 stop on SIGXFSZ           -
[ 13] -   2  0 stop at libc`printf        ::echo printf
>
```

The following table explains the meaning of each column. A summary of this information is available using `::help events`.

mdb(1)

ID	The event specifier identifier. The identifier will be shown in square brackets [ ] if the specifier is enabled, in parentheses ( ) if the specifier is disabled, or in angle brackets < > if the target program is currently stopped on an event that matches the given specifier.
S	<p>The event specifier state. The state will be one of the following symbols:</p> <ul style="list-style-type: none"><li>- The event specifier is idle. When no target program is running, all specifiers are idle. When the target program is running, a specifier may be idle if it cannot be evaluated (for example, a deferred breakpoint in a shared object that is not yet loaded).</li><li>+ The event specifier is active. When the target is continued, events of this type will be detected by the debugger.</li><li>* The event specifier is armed. This state means that the target is currently running with instrumentation for this type of event. This state is only visible if the debugger is attached to a running program with the <code>-o nostop</code> option.</li><li>! The event specifier was not armed due to an operating system error. The <code>::events -v</code> option can be used to display more information about the reason the instrumentation failed.</li></ul>
TA	<p>The Temporary, Sticky, and Automatic event specifier properties. One or more of the following symbols may be shown:</p> <ul style="list-style-type: none"><li>t The event specifier is temporary, and will be deleted the next time the target stops, regardless of whether it is matched.</li><li>T The event specifier is sticky, and will be not be deleted by <code>::delete all</code> or <code>:z</code>. The specifier can be deleted by explicitly specifying its id number to <code>::delete</code>.</li><li>d The event specifier will be automatically disabled when the hit count is equal to the hit limit.</li><li>D The event specifier will be automatically deleted when the hit count is equal to the hit limit.</li><li>s The target will automatically stop when the hit count is equal to the hit limit.</li></ul>

HT	The current hit count. This column displays the number of times the corresponding software event has occurred in the target since the creation of this event specifier.
LM	The current hit limit. This column displays the limit on the hit count at which the auto-disable, auto-delete, or auto-stop behavior will take effect. These behaviors can be configured using the <code>::evset dcmd</code> , described below.
Description	A description of the type of software event that is matched by the given specifier.
Action	The callback string to execute when the corresponding software event occurs. This callback is executed as if it had been typed at the command prompt.

`[id] ::evset [+/-dDestT] [-c cmd] [-n count] id ...`

Modify the properties of one or more software event specifiers. The properties are set for each specifier identified by the optional expression preceding the `dcmd` and an optional list of arguments following the `dcmd`. The argument list is interpreted as a list of decimal integers, unless an explicit radix is specified. The `::evset dcmd` recognizes the following options:

- d Disables the event specifier when the hit count reaches the hit limit. If the `+d` form of the option is given, this behavior is disabled. Once an event specifier is disabled, the debugger will remove any corresponding instrumentation and will ignore the corresponding software events until the specifier is subsequently re-enabled. If the `-n` option is not present, the specifier is disabled immediately.
- D Deletes the event specifier when the hit count reaches the hit limit. If the `+D` form of the option is given, this behavior is disabled. The `-D` option takes precedence over the `-d` option. The hit limit can be configured using the `-n` option.
- e Enables the event specifier. If the `+e` form of the option is given, the specifier is disabled.
- s Stops the target program when the hit count reaches the hit limit. If the `+s` form of the option is given, this behavior is disabled. The `-s` behavior tells the debugger to act as if the `::cont` were issued following each execution of the specifier's callback, except for the *N*th execution, where *N* is the current value of the specifier's hit limit. The `-s` option takes precedence over both the `-D` option and the `-d` option.
- t Marks the event specifier as temporary. Temporary specifiers are automatically deleted the next time the target stops, regardless of whether it stopped as the result of a software event corresponding to the given specifier. If the `+t` form of the option is given, the temporary marker is removed. The `-t` option takes precedence over the `-T` option.

mdb(1)

-T Marks the event specifier as sticky. Sticky specifiers will not be deleted by `::delete all` or `:z`. They can be deleted by specifying the corresponding specifier ID as an explicit argument to `::delete`. If the `+T` form of the option is given, the sticky property is removed. The default set of event specifiers are all initially marked sticky.

-c Executes the specified *cmd* string each time the corresponding software event occurs in the target program. The current callback string can be displayed using `::events`.

-n Sets the current value of the hit limit to *count*. If no hit limit is currently set and the `-n` option does not accompany `-s` or `D`, the hit limit will be set to one.

A summary of this information is available using `::help evset`.

`::files`  
*\$f*  
Print a list of the known source files (symbols of type `STT_FILE` present in the various target symbol tables).

`[flt] ::fltbp [+/-dDestT] [-c cmd] [-n count] flt ...`  
Trace the specified machine faults. The faults are identified using an optional fault number preceding the *dcmd*, or a list of fault names or numbers (see `<sys/fault.h>`) following the *dcmd*. The `-d`, `-D`, `-e`, `-s`, `-t`, `-T`, `-c`, and `-n` options have the same meaning as they do for the `::evset dcmd`.

`[ thread ] ::fpregs`  
`[ thread ] $x, $X, $y, $Y`  
Print the floating-point register set of the representative thread. If a thread is specified, the floating point registers of that thread are displayed. The thread expression should be one of the thread identifiers described under `Thread Support`, above.

`::formats`  
List the available output format characters for use with the `/`, `\`, `?`, and `=` formatting *dcmds*. The formats and their use is described under `Formatting dcmds`, above.

`::grep command`  
Evaluate the specified command string, and then print the old value of `dot` if the new value of `dot` is non-zero. If the *command* contains whitespace or metacharacters, it must be quoted. The `::grep dcmd` can be used in pipelines to filter a list of addresses.

`::help [ dcmd-name ]`  
With no arguments, the `::help dcmd` prints a brief overview of the help facilities available in `mdb`. If a *dcmd-name* is specified, `mdb` will print a usage summary for that *dcmd*.

*signal* :i  
If the target is a live user process, ignore the specified signal and allow it to be delivered transparently to the target. All event specifiers that are tracing delivery of

the specified signal will be deleted from the list of traced events. By default, the set of ignored signals is initialized to the complement of the set of signals that cause a process to dump core by default (see `signal.h(3HEAD)`), except for `SIGINT`, which is traced by default.

`$i`

Display the list of signals that are ignored by the debugger and that will be handled directly by the target. More information on traced signals can be obtained using the `::events` dcmd.

`::kill`

`:k`

Forcibly terminate the target if it is a live user process. The target will also be forcibly terminated when the debugger exits if it was created by the debugger using `::run`.

`$l`

Print the LWPID of the representative thread, if the target is a user process.

`$L`

Print the LWPIDs of each LWP in the target, if the target is a user process.

`[ address ] ::list type member [ variable-name ]`

Walk through the elements of a linked list data structure and print the address of each element in the list. The address of the first element in the list can be specified using an optional address. Otherwise, the list is assumed to start at the current value of dot. The type parameter must name a C struct or union type and is used to describe the type of the list elements so that `mdb` can read in objects of the appropriate size. The member parameter is used to name the *member of type* that contains a pointer to the next list element. The `::list` dcmd will continue iterating until a `NULL` pointer is encountered, the first element is reached again (a circular list), or an error occurs while reading an element. If the optional *variable-name* is specified, the specified variable will be assigned the value returned at each step of the walk when `mdb` invokes the next stage of a pipeline. The `::list` dcmd may only be used with objects that contain symbolic debugging information designed for use with `mdb`. Refer to `NOTES, Symbolic Debugging Information`, below for more information.

`::load [ -s ] module-name`

Load the specified dmod. The module name may be given as an absolute or relative path. If *module-name* is a simple name (that is, does not contain a `'/'`), `mdb` will search for it in the module library path. Modules with conflicting names may not be loaded; the existing module must be unloaded first. If the `-s` option is present, `mdb` will remain silent and not issue any error messages if the module is not found or could not be loaded.

`::log [ -d | [ -e ] filename ]`

`$> [ filename ]`

Enable or disable the output log. `mdb` provides an interactive logging facility where both the input commands and standard output can be logged to a file while still interacting with the user. The `-e` option enables logging to the specified file, or

## mdb(1)

re-enables logging to the previous log file if no filename is given. The `-d` option disables logging. If the `$(dcmd)` is used, logging is enabled if a filename argument is specified; otherwise, logging is disabled. If the specified log file already exists, `mdb` appends any new log output to the file.

`::map command`

Map the value of `dot` to a corresponding value using the *command* specified as a string argument, and then print the new value of `dot`. If the command contains whitespace or metacharacters, it must be quoted. The `::map dcmd` can be used in pipelines to transform the list of addresses into a new list of addresses.

`[ address ] ::mappings [ name ]`

`[ address ] $m [ name ]`

Print a list of each mapping in the target's virtual address space, including the address, size, and description of each mapping. If the `dcmd` is preceded by an *address*, `mdb` will only show the mapping that contains the given address. If a string *name* argument is given, `mdb` will only show the mapping matching that description.

`::next [ SIG ]`

`::e [ SIG ]`

Step the target program one instruction, but step over subroutine calls. If an optional signal name or number (see `signal.h(3HEAD)`) is specified as an argument, the signal is immediately delivered to the target as part of resuming its execution. If no target program is currently running, `::next` will start a new program running as if by `::run` and stop at the first instruction.

`[ address ] ::nm [ -DPdghnopuvx ] [ -t types ]`

`[ -f format ] [ object ]`

Print the symbol tables associated with the current target. If an optional address preceding the `dcmd` is specified, only the symbol table entry for the symbol corresponding to *address* is displayed. If an *object* is specified, only the symbol table for this load object is displayed. The `::nm dcmd` also recognizes the following options:

<code>-D</code>	Prints <code>.dynsym</code> (dynamic symbol table) instead of <code>.symtab</code> .
<code>-P</code>	Prints the private symbol table instead of <code>.symtab</code> .
<code>-d</code>	Prints value and size fields in decimal.
<code>-g</code>	Prints only global symbols.
<code>-h</code>	Suppresses the header line.
<code>-n</code>	Sorts symbols by name.
<code>-o</code>	Prints value and size fields in octal.
<code>-p</code>	Prints symbols as a series of <code>::nmadd</code> commands. This option can be used with <code>-P</code> to produce a macro file that can be subsequently read into the debugger with <code>\$(&lt;</code> .

-u	Prints only undefined symbols.																				
-v	Sorts symbols by value.																				
-x	Prints value and size fields in hexadecimal.																				
-t <i>type</i> [, <i>type</i> ... ]	Prints only symbols of the specified type(s). The valid <i>type</i> argument strings are: <table> <tr><td>noty</td><td>STT_NOTYPE</td></tr> <tr><td>objt</td><td>STT_OBJECT</td></tr> <tr><td>func</td><td>STT_FUNC</td></tr> <tr><td>sect</td><td>STT_SECTION</td></tr> <tr><td>file</td><td>STT_FILE</td></tr> <tr><td>comm</td><td>STT_COMMON</td></tr> <tr><td>tls</td><td>STT_TLS</td></tr> <tr><td>regi</td><td>STT_SPARC_REGISTER</td></tr> </table>	noty	STT_NOTYPE	objt	STT_OBJECT	func	STT_FUNC	sect	STT_SECTION	file	STT_FILE	comm	STT_COMMON	tls	STT_TLS	regi	STT_SPARC_REGISTER

obj	object which defines symbol																				

*value* ::nmadd [ -fo ] [ -e *end* ] [ -s *size* ] *name*

Add the specified symbol *name* to the private symbol table. mdb provides a private, configurable symbol table that can be used to interpose on the target's symbol table, as described under Symbol Name Resolution above. The ::nmadd cmd also recognizes the following options:

-e	Sets the size of the symbol to <i>end - value</i> .
-f	Sets the type of the symbol to STT_FUNC.
-o	Sets the type of the symbol to STT_OBJECT.

## mdb(1)

`-s` Sets the size of the symbol to *size*.

`::nm del name`  
Delete the specified symbol *name* from the private symbol table.

`::objects [ -v ]`  
Print a map of the target's virtual address space, showing only those mappings that correspond to the primary mapping (usually the text section) of each of the known load objects. The `-v` option displays the version of each load object. Version information is not available for all load objects. Load objects without version information will be listed as having a version of "Unknown" in the output for the `-v` option.

`::offset of type member`  
Print the offset of the specified *member* of the specified *type*. The *type* should be the name of a C structure. The offset is printed in bytes, unless the member is a bit-field, in which case the offset may be printed in bits. The output is always suffixed with the appropriate units for clarity. The type name may use the backquote (`) scoping operator described under Symbol Name Resolution, above. The `::offset of` dcmd may only be used with objects that contain symbolic debugging information designed for use with mdb. Refer to NOTES, Symbolic Debugging Information, below for more information.

`address ::print [ -aCdilptx ] [ -c lim ]`  
`[ -l lim ] [ type [ member ... ] ]`  
Print the data structure at the specified virtual *address* using the given *type* information. The *type* parameter may name a C struct, union, enum, fundamental integer type, or a pointer to any of these types. If the type name contains whitespace (for example, "struct foo"), it must be enclosed in single or double quotes. The type name may use the backquote (`) scoping operator described under Symbol Name Resolution, above. If the type is a structured type, the `::print` dcmd will recursively print each member of the struct or union. If the *type* argument is not present and a static or global STT\_OBJECT symbol matches the address, `::print` will infer the appropriate type automatically. If the *type* argument is specified, it may be followed by an optional list of *member* expressions, in which case only those members and submembers of the specified *type* are displayed. If *type* contains other structured types, each member string may refer to a sub-structure element by forming a list of member names separated by period (.) delimiters. The `::print` dcmd may only be used with objects that contain symbolic debugging information designed for use with mdb. Refer to NOTES, Symbolic Debugging Information, below for more information. After displaying the data structure, `::print` increments dot by the size of *type* in bytes.

If the `-a` option is present, the address of each member is displayed. If the `-p` option is present, `::print` interprets *address* as a physical memory address instead of a virtual memory address. If the `-t` option is present, the type of each member is displayed. If the `-d` or `-x` options are present, all integers are displayed in decimal (`-d`) or hexadecimal (`-x`). By default, a heuristic is used to determine if the value should be displayed in decimal or hexadecimal. The number of characters in a character array that will be read and displayed as a string can be limited with the

-c option. If the -C option is present, no limit is enforced. The number of elements in a standard array that will be read and displayed can be limited with the -l option. If the -L option is present, no limit is enforced and all array elements are shown. The default values for -c and -l can be modified using ::set or the -o command-line option as described under OPTIONS.

If the -i option is specified, the address value is interpreted as an immediate value to be printed. You must give a type with which to interpret the value. If the type is smaller than 64 bits, the immediate value is interpreted as if it were the size of the type. The -i option cannot be used in conjunction with the -p option. If the -a option is given, the addresses shown are byte offsets starting at zero.

::quit

\$q

Quit the debugger.

[ *thread* ] ::regs

[ *thread* ] \$r

Print the general purpose register set of the representative thread. If a thread is specified, the general purpose register set of that thread is displayed. The thread expression should be one of the thread identifiers described under Thread Support, above.

::release [ -a ]

:R [ -a ]

Release the previously attached process or core file. If the -a option is present, the process is released and left stopped and abandoned. It can subsequently be continued by `prun(1)` (see `proc(1)`) or it can be resumed by applying `mdb` or another debugger. By default, a released process is forcibly terminated if it was created by `mdb` using ::run, or it is released and set running if it was attached to by `mdb` using the -p option or using the ::attach or :A dcmts.

::run [ *args* ... ]

:r [ *args* ... ]

Start a new target program running with the specified arguments and attach to it. The arguments are not interpreted by the shell. If the debugger is already examining a live running program, it will first detach from this program as if by ::release.

::set [ -wF ] [ +/-o *option* ] [ -s *distance* ] [ -I *path* ]

[ -L *path* ] [ -P *prompt* ]

Get or set miscellaneous debugger properties. If no options are specified, the current set of debugger properties is displayed. The ::set dcmt recognizes the following options:

- F Forcibly takes over the next user process that ::attach is applied to, as if `mdb` had been executed with the -F option on the command line.
- I Sets the default path for locating macro files. The path argument may contain any of the special tokens described for the -I command-line option under OPTIONS.

## mdb(1)

- L Sets the default path for locating debugger modules. The path argument may contain any of the special tokens described for the -I command-line option under OPTIONS.
  - o Enables the specified debugger option. If the +o form is used, the option is disabled. The option strings are described along with the -o command-line option under OPTIONS.
  - P Sets the command prompt to the specified prompt string.
  - s Sets the symbol matching distance to the specified distance. Refer to the description of the -s command-line option under OPTIONS for more information.
  - w Re-opens the target for writing, as if mdb had been executed with the -w option on the command line.
- `::showrev [-pv]`  
Display revision information for the hardware and software. With no options specified, general system information is displayed. The -v option displays version information for all load objects, whereas the -p option displays the version information only for the load objects that have been installed on the system as part of a patch. Version information is not available for all load objects. Load objects without version information will be omitted from the output for the -p option and will be listed as having a version of "Unknown" in the output for the -v option.
- `[signal] ::sigbp [+/-dDestT] [-c cmd] [-n count] SIG ...`  
`[signal] :t [+/-dDestT] [-c cmd] [-n count] SIG ...`  
Trace delivery of the specified signals. The signals are identified using an optional signal number preceding the dcmd, or a list of signal names or numbers (see `signal.h(3HEAD)`) following the dcmd. The -d, -D, -e, -s, -t, -T, -c, and -n options have the same meaning as they do for the `::evset dcmd`. Initially, the set of signals that cause the process to dump core by default (see `signal.h(3HEAD)`) and SIGINT are traced.
- `::sizeof type`  
Print the size of the specified *type* in bytes. The *type* parameter may name a C struct, union, enum, fundamental integer type, or a pointer to any of these types. The type name may use the backquote (`) scoping operator described under *Symbol Name Resolution*, above. The `::sizeof dcmd` may only be used with objects that contain symbolic debugging information designed for use with mdb. Refer to *NOTES, Symbolic Debugging Information*, below for more information.
- `[ address ] ::stack [ count ]`  
`[ address ] $c [ count ]`  
Print a C stack backtrace. If the dcmd is preceded by an explicit *address*, a backtrace beginning at this virtual memory address is displayed. Otherwise the stack of the representative thread is displayed. If an optional count value is given as an argument, no more than *count* arguments are displayed for each stack frame in the output.
- `::status`  
Print a summary of information related to the current target.

`::step [ over | out ] [ SIG ]`

`:s [ SIG ]`

`:u [ SIG ]`

Step the target program one instruction. If an optional signal name or number (see `signal.h(3HEAD)`) is specified as an argument, the signal is immediately delivered to the target as part of resuming its execution. If the optional “over” argument is specified, `::step` will step over subroutine calls. The `::step over` argument is the same as the `::next` dcmd. If the optional “out” argument is specified, the target program will continue until the representative thread returns from the current function. If no target program is currently running, `::step out` will start a new program running as if by `::run` and stop at the first instruction. The `:s` dcmd is the same as `::step`. The `:u` dcmd is the same as `::step out`.

`[ syscall ] ::sysbp [ +/-dDestT ] [ -io ] [ -c cmd ]`  
`[ -n count ] syscall...`

Trace entry to or exit from the specified system calls. The system calls are identified using an optional system call number preceding the dcmd, or a list of system call names or numbers (see `<sys/syscall.h>`) following the dcmd. If the `-i` option is specified (the default), the event specifiers trigger on entry into the kernel for each system call. If the `-o` option is specified, the event specifiers trigger on exit out from the kernel. The `-d`, `-D`, `-e`, `-s`, `-t`, `-T`, `-c`, and `-n` options have the same meaning as they do for the `::evset` dcmd.

*thread* `::tls symbol`

Print the address of the storage for the specified thread-local storage (TLS) symbol in the context of the specified thread. The thread expression should be one of the thread identifiers described under `Thread Support`, above. The symbol name may use any of the scoping operators described under `Symbol Name Resolution`, above.

`::typeset [ +/-t ] variable-name . . .`

Set attributes for named variables. If one or more variable names are specified, they are defined and set to the value of dot. If the `-t` option is present, the user-defined tag associated with each variable is set. If the `+t` option is present, the tag is cleared. If no variable names are specified, the list of variables and their values is printed.

`::unload module-name`

Unload the specified dmod. The list of active dmods may be printed using the `::dmods` dcmd. Built-in modules may not be unloaded. Modules that are busy (that is, provide dcmds that are currently executing) may not be unloaded.

`::unset variable-name . . .`

Unset (remove) the specified variable(s) from the list of defined variables. Some variables exported by `mdb` are marked as persistent, and may not be unset by the user.

`::vars [ -npt ]`

Print a listing of named variables. If the `-n` option is present, the output is restricted to variables that currently have non-zero values. If the `-p` option is present, the variables are printed in a form suitable for re-processing by the debugger using the

## mdb(1)

`$< dcmd`. This option can be used to record the variables to a macro file and then restore these values later. If the `-t` option is present, only the tagged variables are printed. Variables can be tagged using the `-t` option of the `::typeset dcmd`.

`::version`  
Print the debugger version number.

`address ::vtop [-a as]`  
Print the physical address mapping for the specified virtual address, if possible. The `::vtop dcmd` is only available when examining a kernel target, or when examining a user process inside a kernel crash dump (after a `::context dcmd` has been issued).

When examining a kernel target from the kernel context, the `-a` option can be used to specify the address (*as*) of an alternate address space structure that should be used for the virtual to physical translation. By default, the kernel's address space is used for translation. This option is available for active address spaces even when the dump content only contains kernel pages.

`[ address ] ::walk walker-name [ variable-name ]`  
Walk through the elements of a data structure using the specified walker. The available walkers can be listed using the `::walkers dcmd`. Some walkers operate on a global data structure and do not require a starting address. For example, walk the list of proc structures in the kernel. Other walkers operate on a specific data structure whose address must be specified explicitly. For example, given a pointer to an address space, walk the list of segments. When used interactively, the `::walk dcmd` will print the address of each element of the data structure in the default base. The `dcmd` can also be used to provide a list of addresses for a pipeline. The walker name may use the backquote (```) scoping operator described under `dcmd` and Walker Name Resolution, above. If the optional *variable-name* is specified, the specified variable will be assigned the value returned at each step of the walk when `mdb` invokes the next stage of the pipeline.

`::walkers`  
List the available walkers and print a brief description for each one.

`::whence [-v] name . . .`  
`::which [-v] name . . .`  
Print the dmod that exports the specified `dcmds` and walkers. These `dcmds` can be used to determine which dmod is currently providing the global definition of the given `dcmd` or walker. Refer to the section on `dcmd` and Walker Name Resolution above for more information on global name resolution. The `-v` option will cause the `dcmd` to print the alternate definitions of each `dcmd` and walker in order of precedence.

`addr [ ,len ] ::wp [ +/-dDestT ] [ -rwx ] [ -c cmd ]`  
`[ -n count ]`  
`addr [ ,len ] :a [ cmd . . . ]`  
`addr [ ,len ] :p [ cmd . . . ]`  
`addr [ ,len ] :w [ cmd . . . ]`  
Set a watchpoint at the specified address. The length in bytes of the watched region may be set by specifying an optional repeat count preceding the `dcmd`. If no length

is explicitly set, the default is one byte. The `:wp dcmd` allows the watchpoint to be configured to trigger on any combination of read (`-r` option), write (`-w` option), or execute (`-x` option) access. The `-d`, `-D`, `-e`, `-s`, `-t`, `-T`, `-c`, and `-n` options have the same meaning as they do for the `:evset dcmd`. The `:a dcmd` sets a read access watchpoint at the specified address. The `:p dcmd` sets an execute access watchpoint at the specified address. The `:w dcmd` sets a write access watchpoint at the specified address. The arguments following the `:a`, `:p`, and `:w` dcms are concatenated together to form the callback string. If this string contains meta-characters, it must be quoted.

`::xdata`

List the external data buffers exported by the current target. External data buffers represent information associated with the target that can not be accessed through standard target facilities (that is, an address space, symbol table, or register set). These buffers may be consumed by dcms; for more information, refer to the *Solaris Modular Debugger Guide*.

`:z`

Delete all event specifiers from the list of traced software events. Event specifiers can also be deleted using `::delete`.

**OPTIONS** The following options are supported:

- `-A` Disables automatic loading of `mdb` modules. By default, `mdb` attempts to load debugger modules corresponding to the active shared libraries in a user process or core file, or to the loaded kernel modules in the live operating system or an operating system crash dump.
- `-f` Forces raw file debugging mode. By default, `mdb` attempts to infer whether the object and core file operands refer to a user executable and core dump or to a pair of operating system crash dump files. If the file type cannot be inferred, the debugger will default to examining the files as plain binary data. The `-f` option forces `mdb` to interpret the arguments as a set of raw files to examine.
- `-F` Forcibly takes over the specified user process, if necessary. By default, `mdb` refuses to attach to a user process that is already under the control of another debugging tool, such as `truss(1)`. With the `-F` option, `mdb` attaches to these processes anyway. This may produce unexpected interactions between `mdb` and the other tools attempting to control the process.
- `-I path` Sets default path for locating macro files. Macro files are read using the `$<` or `$<<` dcms. The path is a sequence of directory names delimited by colon (`:`) characters. The `-I include path` and `-L library path` (see below) may also contain any of the following tokens:
  - `%i` Expands to the current instruction set architecture (ISA) name ('sparc', 'sparcv9', or 'i386').

## mdb(1)

	<p><code>%o</code> Expands to the old value of the path being modified. This is useful for appending or prepending directories to an existing path.</p> <p><code>%p</code> Expands to the current platform string (either <code>uname -i</code> or the platform string stored in the process core file or crash dump).</p> <p><code>%r</code> Expands to the pathname of the root directory. An alternate root directory may be specified using the <code>-R</code> option. If no <code>-R</code> option is present, the root directory is derived dynamically from the path to the <code>mdb</code> executable itself. For example, if <code>/bin/mdb</code> is executed, the root directory will be <code>.</code>. If <code>/net/hostname/bin/mdb</code> were executed, the root directory would be derived as <code>/net/hostname</code>.</p> <p><code>%t</code> Expands to the name of the current target. This will either be the literal string <code>'proc'</code> (a user process or user process core file), <code>'kvm'</code> (a kernel crash dump or the live operating system), or <code>'raw'</code> (a raw file).</p>
	<p>The default include path for 32-bit <code>mdb</code> is:</p> <pre>%r/usr/platform/%p/lib/adb:%r/usr/lib/adb</pre>
	<p>The default include path for 64-bit <code>mdb</code> is:</p> <pre>%r/usr/platform/%p/lib/adb/%i:%r/usr/lib/adb/%i</pre>
<code>-k</code>	<p>Forces kernel debugging mode. By default, <code>mdb</code> attempts to infer whether the object and core file operands refer to a user executable and core dump, or to a pair of operating system crash dump files. The <code>-k</code> option forces <code>mdb</code> to assume these files are operating system crash dump files. If no object or core operand is specified, but the <code>-k</code> option is specified, <code>mdb</code> defaults to an object file of <code>/dev/ksyms</code> and a core file of <code>/dev/kmem</code>. Read access to <code>/dev/kmem</code> is restricted to group <code>sys</code>. Write access requires ALL privileges.</p>
<code>-L path</code>	<p>Sets default path for locating debugger modules. Modules are loaded automatically on startup or using the <code>::load dcmd</code>. The path is a sequence of directory names delimited by colon (<code>:</code>) characters. The <code>-L</code> library path may also contain any of the tokens shown for <code>-I</code> above.</p>
<code>-m</code>	<p>Disables demand-loading of kernel module symbols. By default, <code>mdb</code> processes the list of loaded kernel modules and performs demand loading of per-module symbol tables. If the <code>-m</code> option is</p>

specified, `mdb` will not attempt to process the kernel module list or provide per-module symbol tables. As a result, `mdb` modules corresponding to active kernel modules will not be loaded on startup.

`-M` Preloads all kernel module symbols. By default, `mdb` performs demand-loading for kernel module symbols: the complete symbol table for a module is read when an address is that module's text or data section is referenced. With the `-M` option, `mdb` loads the complete symbol table of all kernel modules during startup.

`-o option` Enables the specified debugger option. If the `+o` form of the option is used, the specified *option* is disabled. Unless noted below, each option is off by default. `mdb` recognizes the following *option* arguments:

`adb`

Enables stricter `adb(1)` compatibility. The prompt will be set to the empty string and many `mdb` features, such as the output pager, will be disabled.

`array_mem_limit=limit`

Sets the default limit on the number of array members that `::print` will display. If *limit* is the special token `none`, all array members will be displayed by default.

`array_str_limit=limit`

Sets the default limit on the number of characters that `::print` will attempt to display as an ASCII string when printing a char array. If *limit* is the special token `none`, the entire char array will be displayed as a string by default.

`follow_exec_mode=mode`

Sets the debugger behavior for following an `exec(2)` system call. The *mode* should be one of the following named constants:

`ask` If `stdout` is a terminal device, the debugger stops after the `exec(2)` system call has returned and then prompts the user to decide whether to follow the `exec` or `stop`. If `stdout` is not a terminal device, the `ask` mode defaults to `stop`.

`follow` The debugger follows the `exec` by automatically continuing the target process and resetting all of its mappings and symbol tables based on the new executable. The `follow` behavior is discussed in more detail under `NOTES, Interaction with Exec`, below.

`stop` The debugger stops following return from the `exec` system call. The `stop` behavior is discussed in more detail under `NOTES, Interaction with Exec`,

## mdb(1)

below.

### `follow_fork_mode=mode`

Sets the debugger behavior for following a `fork(2)`, `fork1(2)`, or `vfork(2)` system call. The *mode* should be one of the following named constants:

- `ask` If `stdout` is a terminal device, the debugger stops after the `fork(2)` system call has returned and then prompts the user to decide whether to follow the parent or child. If `stdout` is not a terminal device, the `ask` mode defaults to `parent`.
- `parent` The debugger follows the parent process, and detaches from the child process and sets it running.
- `child` The debugger follows the child process, and detaches from the parent process and sets it running.

### `ignoreeof`

The debugger will not exit when an EOF sequence (^D) is entered at the terminal. The `::quit` dcmd must be used to quit.

### `nostop`

Does not stop a user process when attaching to it when the `-p` option is specified or when the `::attach` or `:A` dcmds are applied. The `nostop` behavior is described in more detail under NOTES, Process Attach and Release, below.

### `pager`

Enables the output pager (default).

### `repeatlast`

If a NEWLINE is entered as the complete command at the terminal, `mdb` repeats the previous command with the current value of `dot`. This option is implied by `-o adb`.

### `showlmid`

`mdb` provides support for symbol naming and identification in user applications that make use of link maps other than `LM_ID_BASE` and `LM_ID_LDSO`, as described in Symbol Name Resolution, above. Symbols on link maps other than `LM_ID_BASE` or `LM_ID_LDSO` will be shown as `Lmlmid`library`symbol`, where `lmid` is the link-map ID in the default output radix (16). The user may optionally configure `mdb` to show the link-map ID scope of all symbols and objects, including those associated with `LM_ID_BASE` and `LM_ID_LDSO`, by enabling the `showlmid` option. Built-in dcmds that deal with object file names will display link-map IDs according to the value of `showlmid` above, including `::nm`, `::mappings`, `$m`, and `::objects`.

<code>-p <i>pid</i></code>	Attaches to and stops the specified process-id. <code>mdb</code> will use the <code>/proc/<i>pid</i>/object/a.out</code> file as the executable file pathname.
<code>-P <i>prompt</i></code>	Sets the command prompt. The default prompt is <code>'&gt;'</code> .
<code>-R <i>root</i></code>	Sets root directory for pathname expansion. By default, the root directory is derived from the pathname of the <code>mdb</code> executable itself. The root directory is substituted in place of the <code>%r</code> token during pathname expansion.
<code>-s <i>distance</i></code>	Sets the symbol matching distance for address-to-symbol-name conversions to the specified <i>distance</i> . By default, <code>mdb</code> sets the distance to zero, which enables a smart-matching mode. Each ELF symbol table entry includes a value <i>V</i> and size <i>S</i> , representing the size of the function or data object in bytes. In smart mode, <code>mdb</code> matches an address <i>A</i> with the given symbol if <i>A</i> is in the range [ <i>V</i> , <i>V</i> + <i>S</i> ). If any non-zero distance is specified, the same algorithm is used, but <i>S</i> in the expression above is always the specified absolute distance and the symbol size is ignored.
<code>-S</code>	Suppresses processing of the user's <code>~/ .mdbContext</code> file. By default, <code>mdb</code> reads and processes the macro file <code>.mdbContext</code> if one is present in the user's home directory, as defined by <code>\$HOME</code> . If the <code>-S</code> option is present, this file will not be read.
<code>-u</code>	Forces user debugging mode. By default, <code>mdb</code> attempts to infer whether the object and core file operands refer to a user executable and core dump, or to a pair of operating system crash dump files. The <code>-u</code> option forces <code>mdb</code> to assume these files are not operating system crash dump files.
<code>-V <i>version</i></code>	Sets disassembler version. By default, <code>mdb</code> attempts to infer the appropriate disassembler version for the debug target. The disassembler can be set explicitly using the <code>-V</code> option. The <code>::disasms dcmd</code> lists the available disassembler versions.
<code>-w</code>	Opens the specified object and core files for writing.
<code>-y</code>	Sends explicit terminal initialization sequences for tty mode. Some terminals, such as <code>cmdt001(1)</code> , require explicit initialization sequences to switch into a tty mode. Without this initialization sequence, terminal features such as standout mode may not be available to <code>mdb</code> .

## OPERANDS

The following operands are supported:

<i>object</i>	Specifies an ELF format object file to examine. <code>mdb</code> provides the ability to examine and edit ELF format executables ( <code>ET_EXEC</code> ), ELF dynamic library files ( <code>ET_DYN</code> ), ELF relocatable object files ( <code>ET_REL</code> ), and operating system <code>unix.X</code> symbol table files.
---------------	--

## mdb(1)

	<i>core</i>	Specifies an ELF process core file (ET_CORE), or an operating system crash dump vmcore.X file. If an ELF core file operand is provided without a corresponding object file, mdb will attempt to infer the name of the executable file that produced the core using several different algorithms. If no executable is found, mdb will still execute, but some symbol information may be unavailable.
	<i>suffix</i>	Specifies the numerical suffix representing a pair of operating system crash dump files. For example, if the suffix is '3', mdb infers that it should examine the files 'unix.3' and 'vmcore.3'. The string of digits will not be interpreted as a suffix if an actual file of the same name is present in the current directory.
<b>USAGE</b>		mdb processes all input files (including scripts, object files, core files, and raw data files) in a large file aware fashion. See <code>largefile(5)</code> for more information about the processing of large files, which are files greater than or equal to 2 Gbytes (2 <sup>31</sup> bytes).
<b>EXIT STATUS</b>		The following exit values are returned: 0           Debugger completed execution successfully. 1           A fatal error occurred. 2           Invalid command line options were specified.
<b>ENVIRONMENT VARIABLES</b>	<i>HISTSIZE</i>	This variable is used to determine the maximum length of the command history list. If this variable is not present, the default length is 128.
	<i>HOME</i>	This variable is used to determine the pathname of the user's home directory, where a <code>.mdbContext</code> file may reside. If this variable is not present, no <code>.mdbContext</code> processing will occur.
	<i>SHELL</i>	This variable is used to determine the pathname of the shell used to process shell escapes requested using the <code>!</code> meta-character. If this variable is not present, <code>/bin/sh</code> is used.
<b>FILES</b>	<code>\$HOME/.mdbContext</code>	User mdb initialization file. The <code>.mdbContext</code> file, if present, is processed after the debug target has been initialized, but before module auto-loading is performed or any commands have been read from standard input.
	<code>/dev/kmem</code>	Kernel virtual memory image device. This device special file is used as the core file when examining the live operating system.
	<code>/dev/ksyms</code>	Kernel symbol table device. This device special file is used as the object file when examining the live operating system.
	<code>/proc/pid/*</code>	Process information files that are read when examining and controlling user processes.

/usr/lib/adb

/usr/platform/*platform-name*/lib/adb

Default directories for macro files that are read with the `$<` and `$<<` dcmds.

*platform-name* is the name of the platform, derived either from information in a core file or crash dump, or from the current machine as if by `uname -i` (see [uname\(1\)](#)).

/usr/lib/mdb

/usr/platform/*platform-name*/lib/mdb

Default directories for debugger modules that are loaded using the `:load` dcmd.

*platform-name* is the name of the platform, derived either from information in a core file or crash dump, or from the current machine as if by `uname -i` (see [uname\(1\)](#)).

*Linker and Libraries Guide*

*Solaris Modular Debugger Guide*

**WARNINGS**

**Use of the Error Recovery Mechanism**

The debugger and its dmods execute in the same address space, and thus it is quite possible that a buggy dmod can cause `mdb` to dump core or otherwise misbehave. The `mdb` resume capability, described above under [Signal Handling](#), provides a limited recovery mechanism for these situations. However, it is not possible for `mdb` to know definitively whether the dmod in question has corrupted only its own state, or the debugger's global state. Therefore a resume operation cannot be guaranteed to be safe, or to prevent a subsequent crash of the debugger. The safest course of action following a resume is to save any important debug information, and then quit and restart the debugger.

**Use of the Debugger to Modify the Live Operating System**

The use of the debugger to modify (that is, write to) the address space of live running operating system is extremely dangerous, and may result in a system panic in the event the user damages a kernel data structure.

**NOTES**

**Limitations on Examining Process Core Files**

`mdb` does not provide support for examining process core files that were generated by a release of Solaris preceding Solaris 2.6. When debugging core files generated by a release of Solaris 9 or an earlier release, symbol information may not be available.

mdb(1)

Since the text section and read-only data is not present in those core files, the symbol information may not match the data present in the process at the time it dumped core. In releases later than Solaris 9, text sections and read-only data are included in core files by default. Users can configure their processes to exclude that information from core files using `coreadm(1M)`. Thus, the information presented by `mdb` for those core files may not match the data that was present at the time the process dumped core. Core files from Solaris x86 systems may not be examined on Solaris SPARC systems, and vice-versa.

**Limitations on Examining Crash Dump Files**

Crash dumps from Solaris 7 and earlier releases may only be examined with the aid of the `libkvm` from the corresponding operating system release. If a crash dump from one operating system release is examined using the `dmods` from a different operating system release, changes in the kernel implementation may prevent some `dcmds` or `walkers` from working properly. `mdb` will issue a warning message if it detects this condition. Crash dumps from Solaris x86 systems may not be examined on Solaris SPARC systems, and vice-versa.

**Relationship Between 32-bit and 64-bit Debugger**

`mdb` provides support for debugging both 32-bit and 64-bit programs. Once it has examined the target and determined its data model, `mdb` automatically re-executes the `mdb` binary that has the same data model as the target, if necessary. This approach simplifies the task of writing debugger modules, because the modules that are loaded will use the same data model as the primary target. Only the 64-bit debugger may be used to debug 64-bit target programs. The 64-bit debugger can only be used on a system that is running the 64-bit operating environment.

The debugger may also need to re-execute itself when debugging a 32-bit process that execs a 64-bit process, or vice-versa. The handling of this situation is discussed in more detail under *Interaction with Exec*, below.

**Interaction with Exec**

When a controlled process performs a successful `exec(2)`, the behavior of the debugger is controlled by the `::set -o follow_exec_mode` option, as described above. If the debugger and victim process have the same data model, then the `"stop"` and `"follow"` modes determine whether `mdb` automatically continues the target or returns to the debugger prompt following the `exec`. If the debugger and victim process have a different data model, then the `"follow"` behavior causes `mdb` to automatically re-exec the `mdb` binary with the appropriate data model and to re-attach to the process, still stopped on return from the `exec`. Not all debugger state is preserved across this re-exec.

If a 32-bit victim process execs a 64-bit program, then `"stop"` returns to the command prompt, but the debugger is no longer able to examine the process because it is now using the 64-bit data model. To resume debugging, execute the `::release -a dcmd`, quit `mdb`, and then execute `mdb -p pid` to re-attach the 64-bit debugger to the process.

If a 64-bit victim process execs a 32-bit program, then `"stop"` will return to the command prompt, but the debugger will only provide limited capabilities for examining the new process. All built-in `dcmds` will work as advertised, but loadable `dcmds` will not since they do not perform data model conversion of structures. The user should release and re-attach the debugger to the process as described above in order to restore full debugging capabilities.

**Interaction with Job Control**

If the debugger is attached to a process that is stopped by job control (that is, it stopped in response to `SIGTSTP`, `SIGTTIN`, or `SIGTTOU`), the process may not be able to be set running again when it is continued by a `continue` dcmd. If the victim process is a member of the same session (that is, it shares the same controlling terminal as `mdb`), `mdb` attempts to bring the associated process group to the foreground and to continue the process with `SIGCONT` to resume it from job control stop. When `mdb` is detached from such a process, it restores the process group to the background before exiting. If the victim process is not a member of the same session, `mdb` cannot safely bring the process group to the foreground, so it continues the process with respect to the debugger, but the process remains stopped by job control. `mdb` prints a warning in this case, and the user must issue an “`fg`” command from the appropriate shell in order to resume the process.

**Process Attach and Release**

When `mdb` attaches to a running process, the process is stopped and remains stopped until one of the `continue` dcmds is applied, or the debugger quits. If the `-o nostop` option is enabled prior to attaching the debugger to a process with `-p`, or prior to issuing an `::attach` or `:A` command, `mdb` attaches to the process but does not stop it. While the process is still running, it may be inspected as usual (albeit with inconsistent results) and breakpoints or other tracing flags may be enabled. If the `:c` or `::cont` dcmds are executed while the process is running, the debugger waits for the process to stop. If no traced software events occur, the user can send an interrupt (`^C`) after `:c` or `::cont` to force the process to stop and return control to the debugger.

`mdb` releases the current running process (if any) when the `:R`, `::release`, `:r`, `::run`, `$g`, or `::quit` dcmds are executed, or when the debugger terminates as the result of an EOF or signal. If the process was originally created by the debugger using `:r` or `::run`, it will be forcibly terminated as if by `SIGKILL` when it is released. If the process was already running prior to attaching `mdb` to it, it will be set running again when it is released. A process may be released and left stopped and abandoned using the `::release -a` option.

**Symbolic Debugging Information**

The `::list`, `::offsetof`, `::print`, and `::sizeof` dcmds require that one or more load objects contain compressed symbolic debugging information suitable for use with `mdb`. This information is currently only available for certain Solaris kernel modules.

**Developer Information**

The *Solaris Modular Debugger Guide* provides a more detailed description of `mdb` features, as well as information for debugger module developers.

The header file `<sys/mdb_modapi.h>` contains prototypes for the functions in the MDB Module API, and the `SUNWmdbdm` package provides source code for an example module in the directory `/usr/demo/mdb`.

## mesg(1)

<b>NAME</b>	mesg – permit or deny messages						
<b>SYNOPSIS</b>	<b>mesg</b> [-n   -y   n   y]						
<b>DESCRIPTION</b>	The <code>mesg</code> utility will control whether other users are allowed to send messages via <code>write(1)</code> , <code>talk(1)</code> , or other utilities to a terminal device. The terminal device affected is determined by searching for the first terminal in the sequence of devices associated with standard input, standard output, and standard error, respectively. With no arguments, <code>mesg</code> reports the current state without changing it. Processes with appropriate privileges may be able to send messages to the terminal independent of the current state.						
<b>OPTIONS</b>	The following options are supported:  -n   n      Denies permission to other users to send message to the terminal. See <code>write(1)</code> .  -y   y      Grants permission to other users to send messages to the terminal.						
<b>ENVIRONMENT VARIABLES</b>	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>mesg</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .						
<b>EXIT STATUS</b>	The following exit values are returned:  0            if messages are receivable.  1            if messages are not receivable.  2            on error.						
<b>FILES</b>	<code>/dev/tty*</code> terminal devices <code>/dev/pts/*</code> terminal devices						
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1" data-bbox="444 1281 1412 1415"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsu</td></tr><tr><td>Interface Stability</td><td>Standard</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu	Interface Stability	Standard
ATTRIBUTE TYPE	ATTRIBUTE VALUE

<b>SEE ALSO</b>	<code>talk(1)</code> , <code>write(1)</code> , <code>attributes(5)</code> , <code>environ(5)</code> , <code>standards(5)</code>						

NAME	message – puts its arguments on FMLI message line
SYNOPSIS	<p><b>message</b> [-t] [ -b [num]] [-o] [-w] [string]</p> <p><b>message</b> [-f] [ -b [num]] [-o] [-w] [string]</p> <p><b>message</b> [-p] [ -b [num]] [-o] [-w] [string]</p>
DESCRIPTION	<p>The message command puts <i>string</i> out on the FMLI message line. If there is no string, the <i>stdin</i> input to message will be used. The output of message has a duration (length of time it remains on the message line). The default duration is "transient": it or one of two other durations can be requested with the mutually-exclusive options below.</p> <p>Messages displayed with message -p will replace (change the value of) any message currently displayed or stored via use of the permanentmsg descriptor. Likewise, message -f will replace any message currently displayed or stored via use of the framemsg descriptor. If more than one message in a frame definition file is specified with the -p option, the last one specified will be the permanent duration message.</p> <p>The <i>string</i> argument should always be the last argument.</p>
OPTIONS	<p>-t        Explicitly defines a message to have transient duration. Transient messages remain on the message line only until the user presses another key or a CHECKWORLD occurs. The descriptors itemmsg , fieldmsg , invalidmsg , choicemsg , the default-if-not-defined value of oninterrupt , and FMLI generated error messages (that is, from syntax errors) also output transient duration messages. Transient messages take precedence over both frame messages and permanent messages.</p> <p>-f        Defines a message to have "frame" duration. Frame messages remain on the message line as long as the frame in which they are defined is current. The descriptor framemsg also outputs a frame duration message. Frame messages take precedence over permanent messages.</p> <p>-p        Defines a message to have "permanent" duration. Permanent messages remain on the message line for the length of the FMLI session, unless explicitly replaced by another permanent message or temporarily superseded by a transient message or frame message. A permanent message is not affected by navigating away from, or by closing, the frame which generated the permanent message. The descriptor permanentmsg also outputs a permanent duration message.</p> <p>-b[num]   Rings the terminal bell <i>num</i> times, where <i>num</i> is an integer from 1 to 10. The default value is 1. If the terminal has no bell, the screen will flash <i>num</i> times instead, if possible.</p> <p>-o        Forces message to duplicate its message to <i>stdout</i> .</p> <p>-w        Turns on the working indicator.</p>

## message(1F)

### EXAMPLES

**EXAMPLE 1** A sample output of message on the message line:

When a value entered in a field is invalid, ring the bell 3 times and then display Invalid Entry: Try again! on the message line:

```
invalidmsg=`message -b 3 "Invalid Entry: Try again!"`
```

Display a message that tells the user what is being done:

```
done=`message EDITOR has been set in your environment` close
```

Display a message on the message line and *stdout* for each field in a form (a pseudo-"field duration" message).

```
fieldmsg=`message -o -f "Enter a filename."`
```

Display a blank transient message (effect is to "remove" a permanent or frame duration message).

```
done=`message "" nop
```

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

### SEE ALSO

`sleep(1)`, `attributes(5)`

### NOTES

If `message` is coded more than once on a single line, it may appear that only the right-most instance is interpreted and displayed. Use `sleep(1)` between uses of `message` in this case, to display multiple messages.

`message -f` should not be used in a stand-alone backquoted expression or with the `init` descriptor because the frame is not yet current when these are evaluated.

In cases where ``message -f "string" `` is part of a stand-alone backquoted expression, the context for evaluation of the expression is the previously current frame. The previously current frame can be the frame that issued the `open` command for the frame containing the backquoted expression, or it can be a frame given as an argument when `fml` was invoked. That is, the previously current frame is the one whose frame message will be modified.

Permanent duration messages are displayed when the user navigates to the command line.

<b>NAME</b>	mixerctl – audio mixer control command line application	
<b>SYNOPSIS</b>	<code>/usr/sbin/mixerctl [-a   -d <i>dev</i>] [-iv] [-e   -o]</code>	
<b>DESCRIPTION</b>	Some audio devices support the audio mixer functionality. See <code>mixer(7I)</code> for a complete description of the audio mixer. The <code>mixerctl</code> command is used to control the mode of the audio mixer and to get information about the audio mixer and the audio device. See <code>audio(7I)</code> for details.	
<b>OPTIONS</b>	The following options are supported. If none are specified, option <code>-i</code> is assumed:	
	<code>-a</code>	The command applies to all audio devices.
	<code>-d <i>dev</i></code>	The <i>dev</i> argument specifies an alternate audio control device for the command to use.
	<code>-e</code>	Enables the audio mixer function if the audio device supports it. If supported, the audio mixer may be enabled at any time. The command silently ignores the enable option if the audio mixer is already enabled.
	<code>-i</code>	Prints the audio device type information for the device and indicates whether the audio device uses the audio mixer. If the device does use the audio mixer, this option displays the audio mixer's mode.
	<code>-o</code>	Turns off the audio mixer function if the audio device supports it. If supported, the audio mixer may be turned off if only one process has the device opened with the <code>O_RDWR</code> flag, or, if two different processes have the device opened, one with the <code>O_RDONLY</code> flag and the other with the <code>O_WRONLY</code> flag. (See <code>open(2)</code> .) The command silently ignores the disable option if the audio mixer function is already disabled.
	<code>-v</code>	Verbose mode. Prints the <code>audio_info_t</code> structure for the device, along with the device type information. This option implies the <code>-i</code> option.
<b>ENVIRONMENT VARIABLES</b>	AUDIODEV	If the <code>-d</code> and <code>-a</code> options are not specified, the AUDIODEV environment variable is consulted. If set, AUDIODEV will contain the full path name of the user's default audio device. The default audio device will be converted into a control device, and then used. If the AUDIODEV variable is not set, <code>/dev/audioctl</code> is used.
<b>FILES</b>	<code>/dev/audioctl</code>  <code>/dev/sound/{0...n}ctl</code>	

mixerctl(1)

<b>NAME</b>	mkdir – make directories
<b>SYNOPSIS</b>	<b>mkdir</b> [-m <i>mode</i> ] [-p] <i>dir...</i>
<b>DESCRIPTION</b>	<p>The <b>mkdir</b> command creates the named directories in mode 777 (possibly altered by the file mode creation mask <b>umask(1)</b>).</p> <p>Standard entries in a directory (for instance, the files “.”, for the directory itself, and “..”, for its parent) are made automatically. <b>mkdir</b> cannot create these entries by name. Creation of a directory requires write permission in the parent directory.</p> <p>The owner-ID and group-ID of the new directories are set to the process’s effective user-ID and group-ID, respectively. <b>mkdir</b> calls the <b>mkdir(2)</b> system call.</p>
<b>setgid and mkdir</b>	<p>To change the <b>setgid</b> bit on a newly created directory, you must use <b>chmod g+s</b> or <b>chmod g-s</b> after executing <b>mkdir</b>.</p> <p>The <b>setgid</b> bit setting is inherited from the parent directory.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <p><b>-m <i>mode</i></b>            This option allows users to specify the mode to be used for new directories. Choices for modes can be found in <b>chmod(1)</b>.</p> <p><b>-p</b>                        With this option, <b>mkdir</b> creates <i>dir</i> by creating all the non-existing parent directories first. The mode given to intermediate directories will be the difference between 777 and the bits set in the file mode creation mask. The difference, however, must be at least 300 (write and execute permission for the user).</p>
<b>OPERANDS</b>	<p>The following operand is supported:</p> <p><i>dir</i>                      A path name of a directory to be created.</p>
<b>USAGE</b>	See <b>largefile(5)</b> for the description of the behavior of <b>mkdir</b> when encountering files greater than or equal to 2 Gbyte ( 2 <sup>31</sup> bytes).
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Using <b>mkdir</b></p> <p>The following example:</p> <pre>example% mkdir -p ltr/jd/jan</pre> <p>creates the subdirectory structure <b>ltr/jd/jan</b>.</p>
<b>ENVIRONMENT VARIABLES</b>	See <b>environ(5)</b> for descriptions of the following environment variables that affect the execution of <b>mkdir</b> : <b>LANG</b> , <b>LC_ALL</b> , <b>LC_CTYPE</b> , <b>LC_MESSAGES</b> , and <b>NLSPATH</b> .
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <p>0                        All the specified directories were created successfully or the <b>-p</b> option was specified and all the specified directories now exist.</p> <p>&gt;0                      An error occurred.</p>

mkdir(1)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	enabled
Interface Stability	Standard

<b>NAME</b>	mkmsgs – create message files for use by gettext
<b>SYNOPSIS</b>	<b>mkmsgs</b> [-o] [-i <i>locale</i> ] <i>inputstrings</i> <i>msgfile</i>
<b>DESCRIPTION</b>	<p>The <code>mkmsgs</code> utility is used to create a file of text strings that can be accessed using the text retrieval tools (see <code>gettext(1)</code>, <code>srchtxt(1)</code>, <code>exstr(1)</code>, and <code>gettext(3C)</code>). It will take as input a file of text strings for a particular geographic locale (see <code>setlocale(3C)</code>) and create a file of text strings in a format that can be retrieved by both <code>gettext(1)</code> and <code>gettext(3C)</code>. By using the <code>-i</code> option, you can install the created file under the <code>/usr/lib/locale/locale/LC_MESSAGES</code> directory (<code>locale</code> corresponds to the language in which the text strings are written).</p> <p><i>inputstrings</i> is the name of the file that contains the original text strings. <i>msgfile</i> is the name of the output file where <code>mkmsgs</code> writes the strings in a format that is readable by <code>gettext(1)</code> and <code>gettext(3C)</code>. The name of <i>msgfile</i> can be up to 14 characters in length, but may not contain either <code>\0</code> (null) or the ASCII code for <code>/</code> (slash) or <code>:</code> (colon).</p> <p>The input file contains a set of text strings for the particular geographic locale. Text strings are separated by a newline character. Nongraphic characters must be represented as alphabetic escape sequences. Messages are transformed and copied sequentially from <i>inputstrings</i> to <i>msgfile</i>. To generate an empty message in <i>msgfile</i>, leave an empty line at the correct place in <i>inputstrings</i>.</p> <p>Strings can be changed simply by editing the file <i>inputstrings</i>. New strings must be added only at the end of the file; then a new <i>msgfile</i> file must be created and installed in the correct place. If this procedure is not followed, the retrieval function will retrieve the wrong string and software compatibility will be broken.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-o</code> Overwrite <i>msgfile</i>, if it exists.</li> <li><code>-i locale</code> Install <i>msgfile</i> in the <code>/usr/lib/locale/locale/LC_MESSAGES</code> directory. Only someone who is super user or a member of group <code>bin</code> can create or overwrite files in this directory. Directories under <code>/usr/lib/locale</code> will be created if they do not exist.</li> </ul>
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Using the <code>mkmsgs</code> command.</p> <p>The following example shows an input message source file <code>C.str</code>:</p> <pre>File %s:\t cannot be opened\n %s: Bad directory\n . . . write error\n . .</pre>

## mkmsgs(1)

**EXAMPLE 1** Using the `mkmsgs` command. (Continued)

**EXAMPLE 2** Using Input Strings From `C.str` to Create Text Strings in a File

The following command uses the input strings from `C.str` to create text strings in the appropriate format in the file `UX` in the current directory:

```
example% mkmsgs C.str UX
```

**EXAMPLE 3** Using Input Strings From `FR.str` to Create Text Strings in a File

The following command uses the input strings from `FR.str` to create text strings in the appropriate format in the file `UX` in the directory `/usr/lib/locale/fr/LC_MESSAGES`:

```
example% mkmsgs -i fr FR.str UX
```

These text strings would be accessed if you had set the environment variable `LC_MESSAGES=fr` and then invoked one of the text retrieval tools listed at the beginning of the `DESCRIPTION` section.

**FILES** `/usr/lib/locale/locale/LC_MESSAGES/*`  
message files created by `mkmsgs`

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWloc

**SEE ALSO** `exstr(1)`, `gettxt(1)`, `srchtxt(1)`, `gettxt(3C)`, `setlocale(3C)`, `attributes(5)`

<b>NAME</b>	mkstr – create an error message file by massaging C source files
<b>SYNOPSIS</b>	<code>/usr/ucb/mkstr [-] messagefile prefix filename...</code>
<b>DESCRIPTION</b>	<p>The <code>mkstr</code> utility creates files of error messages. You can use <code>mkstr</code> to make programs with large numbers of error diagnostics much smaller, and to reduce system overhead in running the program — as the error messages do not have to be constantly swapped in and out.</p> <p><code>mkstr</code> processes each of the specified <i>filenames</i>, placing a massaged version of the input file in a file with a name consisting of the specified <i>prefix</i> and the original source file name. A typical example of using <code>mkstr</code> would be:</p> <pre>mkstr pistrings processed *.c</pre> <p>This command would cause all the error messages from the C source files in the current directory to be placed in the file <code>pistrings</code> and processed copies of the source for these files to be placed in files whose names are prefixed with <i>processed</i>.</p> <p>To process the error messages in the source to the message file, <code>mkstr</code> keys on the string <code>'error ('</code> in the input stream. Each time it occurs, the C string starting at the <code>'</code> is placed in the message file followed by a null character and a NEWLINE character; the null character terminates the message so it can be easily used when retrieved, the NEWLINE character makes it possible to sensibly <code>cat</code> the error message file to see its contents. The massaged copy of the input file then contains a <code>lseek</code> pointer into the file which can be used to retrieve the message, that is:</p> <pre>char efilename[ ] = "/usr/lib/pi_strings"; int efil = -1;  error(a1, a2, a3, a4) {     char     buf[256];     if (efil &lt; 0) {          efil = open(efilename, 0);         if (efil &lt; 0) { oops:             perror (efilename);             exit (1);         }     }     if (lseek(efil, (long) a1, 0)     read(efil, buf, 256) &lt;= 0)         goto oops;     printf(buf, a2, a3, a4); } </pre>
<b>OPTIONS</b>	<p>– Place error messages at the end of the specified message file for recompiling part of a large <code>mkstr</code>ed program.</p>

<b>NAME</b>	mktemp – make temporary filename
<b>SYNOPSIS</b>	<b>mktemp</b> [-dtqu] [-p <i>directory</i> ] [ <i>template</i> ]
<b>DESCRIPTION</b>	<p>The <code>mktemp</code> utility makes a temporary filename. To do this, <code>mktemp</code> takes the specified filename template and overwrites a portion of it to create a unique filename. See <b>OPERANDS</b>.</p> <p>The template is passed to <code>mktemp(3C)</code> for directories or <code>mkstemp(3C)</code> for ordinary files.</p> <p>If <code>mktemp</code> can successfully generate a unique filename, the file (or directory) is created with file permissions such that it is only readable and writable by its owner (unless the <code>-u</code> flag is given) and the filename is printed to standard output.</p> <p><code>mktemp</code> allows shell scripts to safely use temporary files. Traditionally, many shell scripts take the name of the program with the <code>PID</code> as a suffix and used that as a temporary filename. This kind of naming scheme is predictable and the race condition it creates is easy for an attacker to win. A safer, though still inferior approach is to make a temporary directory using the same naming scheme. While this guarantees that a temporary file is not subverted, it still allows a simple denial of service attack. Use <code>mktemp</code> instead.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-d                               Make a directory instead of a file.</li> <li>-p <i>directory</i>                Use the specified directory as a prefix when generating the temporary filename. The directory is overridden by the user's <code>TMPDIR</code> environment variable if it is set. This option implies the <code>-t</code> flag.</li> <li>-q                               Fail silently if an error occurs. This is useful if a script does not want error output to go to standard error.</li> <li>-t                               Generate a path rooted in a temporary directory. This directory is chosen as follows: If the user's <code>TMPDIR</code> environment variable is set, the directory contained therein is used. Otherwise, if the <code>-p</code> flag was given the specified directory is used. If none of the above apply, <code>/tmp</code> is used. In this mode, the template (if specified) should be a directory component (as opposed to a full path) and thus should not contain any forward slashes.</li> <li>-u                               Operate in unsafe mode. The temp file is unlinked before <code>mktemp</code> exits. This is slightly better than <code>mktemp(3C)</code>, but still introduces a race condition. Use of this option is discouraged.</li> </ul>
<b>OPERANDS</b>	The following operands are supported:

## mktemp(1)

*template*

*template* can be any filename with one or more Xs appended to it, for example /tmp/tfile.XXXXXX.

If *template* is not specified, a default of tmp.XXXXXX is used and the -t flag is implied.

### EXAMPLES

#### EXAMPLE 1 Using mktemp

The following example illustrates a simple use of `mktemp` in a `sh(1)` script. In this example, the script quits if it cannot get a safe temporary file.

```
TMPFILE=`mktemp /tmp/example.XXXXXX`
if [ -z "$TMPFILE" ]; then exit 1; fi
echo "program output" >> $TMPFILE
```

#### EXAMPLE 2 Using mktemp to Support TMPDIR

The following example uses `mktemp` to support for a user's `TMPDIR` environment variable:

```
TMPFILE=`mktemp -t example.XXXXXX`
if [ -z "$TMPFILE" ]; then exit 1; fi
echo "program output" >> $TMPFILE
```

#### EXAMPLE 3 Using mktemp Without Specifying the Name of the Temporary File

The following example uses `mktemp` without specifying the name of the temporary file. In this case the -t flag is implied.

```
TMPFILE=`mktemp`
if [ -z "$TMPFILE" ]; then exit 1; fi
echo "program output" >> $TMPFILE
```

#### EXAMPLE 4 Using mktemp with a Default Temporary Directory Other than /tmp

The following example creates the temporary file in `/extra/tmp` unless the user's `TMPDIR` environment variable specifies otherwise:

```
TMPFILE=`mktemp -p /extra/tmp example.XXXXXX`
if [ -z "$TMPFILE" ]; then exit 1; fi
echo "program output" >> $TMPFILE
```

#### EXAMPLE 5 Using mktemp to Remove a File

The following example attempts to create two temporary files. If creation of the second temporary file fails, `mktemp` removes the first file before exiting:

```
TMP1=`mktemp -t example.1.XXXXXX`
if [ -z "$TMP1" ]; then exit 1; fi
TMP2=`mktemp -t example.2.XXXXXX`
if [ -z "$TMP2" ]; then
    rm -f $TMP1
```

**EXAMPLE 5** Using mktemp to Remove a File *(Continued)*

```

        exit 1
    fi

```

**EXAMPLE 6** Using mktemp

The following example does not exit if `mktemp` is unable to create the file. That part of the script has been protected.

```

TMPFILE=`mktemp -q -t example.XXXXXX`
if [ ! -z "$TMPFILE" ]
then
    # Safe to use $TMPFILE in this block
    echo data > $TMPFILE
    ...
    rm -f $TMPFILE
fi

```

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `mktemp` with the `-t` option: `TMPDIR`.

**EXIT STATUS**

The following exit values are returned:

```

0          Successful completion.
1          An error occurred.

```

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Evolving

**SEE ALSO**

[sh\(1\)](#), [mkstemp\(3C\)](#), [mktemp\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**NOTES**

The `mktemp` utility appeared in OpenBSD 2.1. The Solaris implementation uses only as many 'Xs' as are significant for `mktemp(3C)` and `mkstemp(3C)`.

moe(1)

<b>NAME</b>	moe – manifest the optimal expansion of a pathname
<b>SYNOPSIS</b>	<b>moe</b> [-c] [-32   -64 ] [-s   -v ] <i>path</i>
<b>DESCRIPTION</b>	<p>The <b>moe</b> utility manifests the optimal expansion of a pathname containing reserved runtime linker tokens. These tokens can be used to define dependencies, filtees and runpaths within dynamic objects. The expansion of these tokens at runtime, provides a flexible mechanism for selecting objects and search paths that perform best on this machine. See <a href="#">ld.so.1(1)</a>.</p> <p>For example, the token \$HWCAP can be employed to represent filters and dependencies. The runtime interpretation of this token can result in a family of objects that are analyzed to determine their applicability for loading with a process. The objects are sorted based on the hardware capabilities that each object requires to execute. <b>moe</b> returns the name of the object optimally suited for execution on the current platform.</p> <p><b>moe</b> analyzes a pathname by passing the supplied <i>path</i> to <code>dlopen(3C)</code>, together with the <code>RTLD_FIRST</code> flag. Reserved token expansion is therefore carried out by <code>ld.so.1</code> as the expansion would occur in an executing process. Although multiple objects can be analyzed as a result of the <code>dlopen()</code> call, the <code>RTLD_FIRST</code> flag insures only the optimal object is processed.</p> <p>By default, <b>moe</b> analyzes the specified <i>path</i> twice. The first analysis looks for 32-bit objects. The second analysis, if applicable, looks for 64-bit objects. Typically, 32-bit objects and 64-bit objects are isolated to different directories. These directories are frequently named to reflect the class of object the directory contains. The multiple passes of <b>moe</b> catch any instances where 32-bit objects and 64-bit objects occupy the same directory. Multiple passes also provide flexibility when the pathname that is specified does not convey to the user the class of object the directory might contain.</p> <p>For a complete description of the reserved token expansion carried out by the runtime linker, refer to the <i>Linker and Libraries Guide</i>.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"><li>-32      Only analyze 32-bit objects.</li><li>-64      Only analyze 64-bit objects.</li><li>-c        Prefix each pathname with the class of the object.</li><li>-s        Silent. No optimal name, or error diagnostics are displayed. Only an error return is made available. This option is only meaningful with the -32 and -64 options. The -s option can not be used with the -v option.</li><li>-v        Verbose. If no optimal expansion name can be determined, an error diagnostic is written to standard error. The -v option can not be used with the -s option.</li></ul>
<b>OPERANDS</b>	<p>The following operand is supported:</p> <ul style="list-style-type: none"><li><i>path</i>      The pathname to be expanded.</li></ul>

**EXAMPLES** The following example uses moe to display the optimal expansion of objects in the directory `/usr/lib/libc`. This directory contains a family of Intel objects that are built to use various hardware capabilities.

```
% moe '/usr/lib/libc/$HWCAP'
/usr/lib/libc/libc_hwcap.so.1
```

The `-c` option can be used to clarify the class of the optimal object.

```
% moe -c '/usr/lib/libc/$HWCAP'
32-bit: /usr/lib/libc/libc_hwcap.so.1
```

The following example uses moe to display the optimal expansion of objects under the `/opt/ISV/cpu` directory hierarchy. These directories contain a family of SPARC objects that are built for various platforms.

```
% moe -c -64 '/opt/ISV/$ISALIST/isa.so.1'
64-bit: /opt/ISV/sparcv9/isa.so.1
```

The `-v` can be used to diagnose the instance where an optimal name is not returned. An attempt to inspect the previous pathname as a 32-bit object, would result in the following diagnostic being produced.

```
% moe -c -v -32 '/opt/ISV/$ISALIST/isa.so.1'
32-bit: /opt/ISV/sparcv9/isa.so.1: wrong ELF class: ELFCLASS64
```

**EXIT STATUS** When the `-32` or `-64` options are in effect, a successful optimal expansion returns 0, otherwise non-zero. Without the `-32` or `-64` options in effect, the return value is always 0.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Stable

**SEE ALSO** `ld.so.1(1)`, `optisa(1)`, `isalist(1)`, `dlopen(3C)`, `attributes(5)`

*Linker and Libraries Guide*

## more(1)

<b>NAME</b>	more, page – browse or page through a text file
<b>SYNOPSIS</b>	<pre><b>/usr/bin/more</b> [-cdfllrsuw] [-lines] [ + <i>linenumber</i>] [ +/ <i>pattern</i>] [<i>file...</i>] <b>/usr/bin/page</b> [-cdfllrsuw] [-lines] [ + <i>linenumber</i>] [ +/ <i>pattern</i>] [<i>file...</i>] <b>/usr/xpg4/bin/more</b> [-cdeisu] [-n <i>number</i>] [-p <i>command</i>] [-t <i>tagstring</i>] [<i>file...</i>] <b>/usr/xpg4/bin/more</b> [-cdeisu] [-n <i>number</i>] [ + <i>command</i>] [-t <i>tagstring</i>] [<i>file...</i>]</pre>
<b>DESCRIPTION</b>	<p>The more utility is a filter that displays the contents of a text file on the terminal, one screenful at a time. It normally pauses after each screenful. <code>/usr/bin/more</code> then prints <code>--More--</code> and <code>/usr/xpg4/bin/more</code> then prints <i>file</i> at the bottom of the screen. If more is reading from a file rather than a pipe, the percentage of characters displayed so far is also shown.</p> <p>The more utility scrolls up to display one more line in response to a RETURN character. more displays another screenful in response to a SPACE character. Other commands are listed below.</p> <p>The page utility clears the screen before displaying the next screenful of text. page only provides a one-line overlap between screens.</p> <p>The more utility sets the terminal to NOECHO mode, so that the output can be continuous. Commands that you type do not normally show up on your terminal, except for the / and ! commands.</p> <p>The <code>/usr/bin/more</code> utility exits after displaying the last specified file. <code>/usr/xpg4/bin/more</code> prompts for a command at the last line of the last specified file.</p> <p>If the standard output is not a terminal, more acts just like <code>cat(1)</code>, except that a header is printed before each file in a series.</p>
<b>OPTIONS</b>	<p>The following options are supported for both <code>/usr/bin/more</code> and <code>/usr/xpg4/bin/more</code>:</p> <ul style="list-style-type: none"><li>-c Clears before displaying. Redraws the screen instead of scrolling for faster displays. This option is ignored if the terminal does not have the ability to clear to the end of a line.</li><li>-d Displays error messages rather than ringing the terminal bell if an unrecognized command is used. This is helpful for inexperienced users.</li><li>-s Squeeze. Replaces multiple blank lines with a single blank line. This is helpful when viewing <code>nroff(1)</code> output on the screen.</li></ul>
<b>/usr/bin/more</b>	<p>The following options are supported for <code>/usr/bin/more</code> only:</p> <ul style="list-style-type: none"><li>-f Does not fold long lines. This is useful when lines contain nonprinting characters or escape sequences, such as those generated when <code>nroff(1)</code> output is piped through <code>ul(1)</code>.</li></ul>

-l	Does not treat FORMFEED characters (Control-I) as page breaks. If -l is not used, <code>more</code> pauses to accept commands after any line containing a ^L character (Control-I). Also, if a file begins with a FORMFEED, the screen is cleared before the file is printed.
-r	Normally, <code>more</code> ignores control characters that it does not interpret in some way. The -r option causes these to be displayed as ^C where C stands for any such control character.
-u	Suppresses generation of underlining escape sequences. Normally, <code>more</code> handles underlining, such as that produced by <code>nroff(1)</code> , in a manner appropriate to the terminal. If the terminal can perform underlining or has a stand-out mode, <code>more</code> supplies appropriate escape sequences as called for in the text file.
-w	Normally, <code>more</code> exits when it comes to the end of its input. With -w, however, <code>more</code> prompts and waits for any key to be struck before exiting.
-lines	Displays the indicated number of <i>lines</i> in each screenful, rather than the default (the number of lines in the terminal screen less two).
+linenumber	Start up at <i>linenumber</i> .
+ /pattern	Start up two lines above the line containing the regular expression <i>pattern</i> . <i>Note</i> : Unlike editors, this construct should <i>not</i> end with a '/'. If it does, then the trailing slash is taken as a character in the search pattern.

**/usr/xpg4/bin/more**

The following options are supported for `/usr/xpg4/bin/more` only:

-e	Exits immediately after writing the last line of the last file in the argument list.
-i	Performs pattern matching in searches without regard to case.
-n <i>number</i>	Specifies the number of lines per screenful. The <i>number</i> argument is a positive decimal integer. The -n option overrides any values obtained from the environment.
-p <i>command</i> + <i>command</i>	For each file examined, initially executes the <code>more</code> command in the <i>command</i> argument. If the command is a positioning command, such as a line number or a regular expression search, set the current position to represent the final results of the command, without writing any intermediate lines of the file. For example, the two commands:  <pre>more -p 1000j file more -p 1000G file</pre>

more(1)

are equivalent and start the display with the current position at line 1000, bypassing the lines that *j* would write and scroll off the screen if it had been issued during the file examination. If the positioning command is unsuccessful, the first line in the file will be the current position.

- t *tagstring* Writes the screenful of the file containing the tag named by the *tagstring* argument. See the `ctags(1)` utility.
- u Treats a backspace character as a printable control character, displayed as a ^H (Control-h), suppressing backspacing and the special handling that produces underlined or standout-mode text on some terminal types. Also, does not ignore a carriage-return character at the end of a line.

If both the -t *tagstring* and -p *command* (or the obsolescent +*command*) options are given, the -t *tagstring* is processed first.

## USAGE

**Environment** more uses the terminal's `terminfo(4)` entry to determine its display characteristics.

more looks in the environment variable MORE for any preset options. For instance, to page through files using the -c mode by default, set the value of this variable to -c. (Normally, the command sequence to set up this environment variable is placed in the `.login` or `.profile` file).

**Commands** The commands take effect immediately. It is not necessary to type a carriage return unless the command requires a *file*, *command*, *tagstring*, or *pattern*. Up to the time when the command character itself is given, the user may type the line kill character to cancel the numerical argument being formed. In addition, the user may type the erase character to redisplay the '- -MORE- - (xx%)' or *file* message.

In the following commands, *i* is a numerical argument (1 by default).

- i*SPACE Display another screenful, or *i* more lines if *i* is specified.
- i*RETURN Display another line, or *i* more lines, if specified.
- i*b  
*i*^B (Control-b) Skip back *i* screenfuls and then print a screenful.
- i*d  
*i*^D (Control-d) Scroll forward one half screenful or *i* more lines. If *i* is specified, the count becomes the default for subsequent d and u commands.
- i*F Skip *i* screens full and then print a screenful.
- h Help. Give a description of all the more commands.
- ^L (Control-l) Refresh.

<i>in</i>	Search for the <i>i</i> th occurrence of the last <i>pattern</i> entered.
<i>q</i> <i>Q</i>	Exit from <i>more</i> .
<i>is</i>	Skip <i>i</i> lines and then print a screenful.
<i>v</i>	Drop into the <i>vi</i> editor at the current line of the current file.
<i>iz</i>	Same as <i>SPACE</i> , except that <i>i</i> , if present, becomes the new default number of lines per screenful.
<i>=</i>	Display the current line number.
<i>i/pattern</i>	Search forward for the <i>i</i> th occurrence of the regular expression <i>pattern</i> . Display the screenful starting two lines before the line that contains the <i>i</i> th match for the regular expression <i>pattern</i> , or the end of a pipe, whichever comes first. If <i>more</i> is displaying a file and there is no match, its position in the file remains unchanged. Regular expressions can be edited using erase and kill characters. Erasing back past the first column cancels the search command.
<i>!command</i>	Invoke a shell to execute <i>command</i> . The characters <i>%</i> and <i>!</i> , when used within <i>command</i> are replaced with the current filename and the previous shell command, respectively. If there is no current filename, <i>%</i> is not expanded. Prepend a backslash to these characters to escape expansion.
<i>:f</i>	Display the current filename and line number.
<i>i:n</i>	Skip to the <i>i</i> th next filename given in the command line, or to the last filename in the list if <i>i</i> is out of range.
<i>i:p</i>	Skip to the <i>i</i> th previous filename given in the command line, or to the first filename if <i>i</i> is out of range. If given while <i>more</i> is positioned within a file, go to the beginning of the file. If <i>more</i> is reading from a pipe, <i>more</i> simply rings the terminal bell.
<i>:q</i> <i>:Q</i>	Exit from <i>more</i> (same as <i>q</i> or <i>Q</i> ).
<b>/usr/bin/more</b>	The following commands are available only in <i>/usr/bin/more</i> :
<i>'</i>	Single quote. Go to the point from which the last search started. If no search has been performed in the current file, go to the beginning of the file.
<i>.</i>	Dot. Repeat the previous command.
<i>^ \</i>	Halt a partial display of text. <i>more</i> stops sending output, and displays the usual <i>--More--</i> prompt. Some output is lost as a result.
<b>/usr/xpg4/bin/more</b>	The following commands are available only in <i>/usr/xpg4/bin/more</i> :
<i>i^F</i>	(Control-f) Skip <i>i</i> screens full and print a screenful. (Same as <i>if</i> .)

more(1)

<b>^G</b>	(Control-g) Display the current line number (same as =).
<b>iG</b>	Go to line number <i>i</i> with the default of the first line in the file.
<b>iG</b>	Go to line number <i>i</i> with the default of the Last line in the file.
<b>ij</b>	Display another line, or <i>i</i> more lines, if specified. (Same as <i>i</i> RETURN.)
<b>ik</b>	Scroll backwards one or <i>i</i> lines, if specified.
<b>mletter</b>	Mark the current position with the name <i>letter</i> .
<b>N</b>	Reverse direction of search.
<b>r</b>	Refresh the screen.
<b>R</b>	Refresh the screen, discarding any buffered input.
<b>iü</b>	
<b>i^U</b>	(Control-u) Scroll backwards one half a screen of <i>i</i> lines, if specified. If <i>i</i> is specified, the count becomes the new default for subsequent <b>d</b> and <b>u</b> commands.
<b>ZZ</b>	Exit from more (same as <b>q</b> ).
<b>:e file</b>	Examine (display) a new file. If no <i>file</i> is specified, the current file is redisplayed.
<b>:t tagstring</b>	Go to the tag named by the <i>tagstring</i> argument and scroll/rewrite the screen with the tagged line in the current position. See the <b>ctags</b> utility.
<b>' letter</b>	Return to the position that was previously marked with the name <i>letter</i> .
<b>''</b>	Return to the position from which the last move of more than a screenful was made. Defaults to the beginning of the file.
<b>i?[!]pattern</b>	Search backward in the file for the <i>i</i> th line containing the <i>pattern</i> . The <b>!</b> specifies to search backward for the <i>i</i> th line that does not contain the <i>pattern</i> .
<b>i/!pattern</b>	Search forward in the file for the <i>i</i> th line that does not contain the <i>pattern</i> .
<b>![command]</b>	Invoke a shell or the specified command.

**Large File Behavior**

See **largefile(5)** for the description of the behavior of more and page when encountering files greater than or equal to 2 Gbyte ( 2<sup>31</sup> bytes).

**ENVIRONMENT VARIABLES**

See **environ(5)** for descriptions of the following environment variables that affect the execution of more: **LANG**, **LC\_ALL**, **LC\_COLLATE** (/usr/xpg4/bin/more only), **LC\_CTYPE**, **LC\_MESSAGES**, **NLSPATH**, and **TERM**.

**/usr/xpg4/bin/more**

The following environment variables also affect the execution of /usr/xpg4/bin/more:

- COLUMNS** Overrides the system selected horizontal screen size.
- EDITOR** Used by the v command to select an editor.
- LINES** Overrides the system selected vertical screen size. The -n option has precedence over LINES in determining the number of lines in a screen.
- MORE** A string specifying options as described in the OPTIONS section, above. As in a command line, The options must be separated by blank characters and each option specification must start with a -. Any command line options are processed after those specified in MORE as though the command line were: `more $MORE options operands`

**EXIT STATUS**

The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**FILES**

/usr/lib/more.help help file for /usr/bin/more and /usr/bin/page only.

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

**/usr/bin/more  
/usr/bin/page**

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Not enabled

**/usr/xpg4/bin/more**

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
CSI	Enabled
Interface Stability	Standard

**SEE ALSO**

cat(1), csh(1), ctags(1), man(1), nroff(1), script(1), sh(1), ul(1), environ(4), terminfo(4), attributes(5), environ(5), largefile(5), standards(5)

**NOTES**

**/usr/bin/more**

Skipping backwards is too slow on large files.

more(1)

**/usr/xpg4/bin/more**

This utility will not behave correctly if the terminal is not set up properly.

<b>NAME</b>	mp – text to PDL (Page Description Language) pretty print filter
<b>SYNOPSIS</b>	<pre>mp [-A4] [-C] [-D target_printer_name] [-F] [-L locale_name]   [-P target_spool_printer] [-PS] [-US] [-a] [-c chars] [-d] [-e] [-ff]   [-fp] [-l] [-ll] [-m] [-M] [-n] [-o] [-p prologue] [-s subject]   [-tm] [-ts] [-u config_file_path] [-v] [-w words] [-z point_size] [-?]   [filename...]</pre>
<b>DESCRIPTION</b>	<p>The mp program, when called without the -D or -P option, reads each <i>filename</i> in sequence and generates a prettified version of the contents in PostScript™ format, sent to standard output. If no filename argument is provided, mp reads the standard input. If the standard input is a terminal, input is terminated by an EOF signal, usually Control-d.</p> <p>The -D and -P options require the target printer name as an argument and produce the Page Description Language (PDL) of the target printer. The -D option causes the PDL to output to stdout and the -P option causes the PDL to be directly spooled to the printer. In the absence of these options, mp will product default PostScript output.</p> <p>The mp program accepts international text files of various Solaris locales and produces output which is proper for the specified locale. The output will also contain proper text layout. For instance, the output will contain bidirectional text rendering, and also shaping, since the complex text layout (CTL) is supported in mp.</p> <p>Mail items, news articles, ordinary ASCII files, complete mail folders, and digests are all acceptable input formats for mp. The output format includes grayscale lozenges, or the outline of the same dimensions as the lozenges, containing banner information at the top and bottom of every page.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a                      Formats the file as a news article. The top banner contains the text: "Article from <i>newsgroup</i>", where <i>newsgroup</i> is the first news group found on the "Newsgroups:" line.</li> <li>-A4                     Uses A4 paper size (8.26 x 11.69 inches).</li> <li>-c <i>chars</i>             The maximum number of characters to extract from the <i>gecos</i> field of the user's <i>/etc/passwd</i> entry. The default is 18.</li> <li>-C                      Instead of using "\nFrom" to denote the start of new mail messages, mp will look for (and use) the value of the Content-Length: mail header. If the Content-Length doesn't take you to the next "\nFrom", then it is wrong, and mp falls back to looking for the next "\nFrom" in the mail folder.</li> <li>-d                      Formats the file as a digest.</li> </ul>

## mp(1)

-D <i>target_printer_name</i>	Produces the PDL for the target printer. Requires X Print Server connection. <i>target_printer_name</i> can be either <i>printer_name@machine[:display_number]</i> or just <i>printer_name</i> . In the first form, mp tries to connect to the X Print Server display <i>machine[:display_number]</i> with the target printer as <i>printer_name</i> .
-e	Assumes the ELM mail frontend intermediate file format. Used when printing messages from within ELM (using the "p" command), especially for printing tagged messages. This option must be specified in your ELM option setup.
-ff	Formats the file for use with a Filofax personal organizer.
-fp	Formats the file for use with a Franklin Planner personal organizer.
-F	Instead of printing who the mail article is <i>for</i> , the top header will contain who the mail article is <i>from</i> . A useful option for people with their own personal printer.
-l	Formats output in landscape mode. Two pages of text will be printed per sheet of paper.
-ll	Formats output in landscape mode. One page of text will be printed per sheet of paper. This is useful for printing files with longer than normal lines.
-L <i>localename</i>	Provides the locale of the file to be printed. If this command line option is not present, then mp looks for the <code>MP_LANG</code> environment variable. If that is not present, the <code>LANG</code> environment variable is used. If none of these options are present, mp tries to determine the locale it is running in. If it cannot determine the locale, mp assumes it is running in the C locale.
-m	Formats the file as a mail folder, printing multiple messages.
-M	Forces mp to use the <code>mp.conf</code> file for printing output even if a <code>prolog.ps</code> file exists for that locale. Useful when printing to non-native PostScript printers.
-n	Turns off the gray bars and associated information from header and footer. Used to get output similar to output of ' <code>lp filename</code> '.
-o	Formats the file as an ordinary ASCII file.

<code>-p <i>prologue</i></code>	Employs the file <i>prologue</i> as the PostScript/Xprt prologue file, overriding any previously defined file names. This file specifies the format of the print output. For PostScript output, the <i>prologue</i> file will have a <code>.ps</code> extension. For <code>xprt</code> clients (when the <code>-D</code> option is specified), this file will have an <code>.xpr</code> extension. These files are defined in the SUPPLIED PROLOGUE FILES section below.
<code>-P <i>target_spool_printer</i></code>	Spools the PDL to the target printer. No output is sent to stdout. Requires X Print Server connection. <i>target_spool_printer</i> can be either <i>printer_name@machine[:display_number]</i> or just <i>printer_name</i> . In the first form, <code>mp</code> tries to connect to the display <i>machine[:display_number]</i> with the target printer as <i>printer_name</i> .
<code>-PS</code>	If the mail or digest message just has PostScript as the text of the message, this is normally just passed straight through. Specifying this option causes PostScript to be printed as text.
<code>-s <i>subject</i></code>	Uses <i>subject</i> as the new subject for the printout. If you are printing ordinary ASCII files that have been specified on the command line, the subject will default to the name of each of these files.
<code>-tm</code>	Formats the file for use with the Time Manager personal organizer.
<code>-ts</code>	Formats the file for use with the Time/System International personal organizer.
<code>-US</code>	Uses US paper size (8.5 x 11 inches). This is the default paper size.
<code>-u <i>config_file_path</i></code>	Specifies an alternate configuration file to the default file <code>/usr/lib/lp/locale/locale_name/mp/mp.conf</code> . The absolute file path name must be used.
<code>-v</code>	Prints the version number of this release of <code>mp</code> .
<code>-w <i>words</i></code>	The maximum number of words to extract from the <code>gecos</code> field of the user's <code>/etc/passwd</code> entry. The default is 3.
<code>-z <i>point_size</i></code>	Prints the output text in the point size specified by <i>point_size</i> . The internal default is 12 points for portrait printing and 9 points for landscape printing.

## mp(1)

	- ?	Prints the usage line for mp. Notice that the ? character must be escaped if using <code>csch(1)</code> .
<b>OPERANDS</b>	The following operand is supported: <i>filename</i> The name of the file to be read.	
<b>EXAMPLES</b>	<p>The mp print filter can be used to print files in any locale that is installed in the user's machine.</p> <p><b>EXAMPLE 1</b> Printing Japanese text files</p> <p>Japanese text files encoded in the euc codeset can be printed in any non-Japanese PostScript printers by entering:</p> <pre>example% mp -L ja_JP.eucJP -M ja_JP_eucJP.txt   lp</pre> <p>Here, the -L option specifies the locale and the -M option invokes the mp.conf configuration file instead of the default prolog.ps file. In the case of ja_JP.eucJP, both /usr/lib/lp/locale/ja_JP.eucJP/mp/mp.conf and /usr/openwin/lib/locale/ja_JP.eucJP/print/prolog.ps files are present. Therefore, the -M option is used to override the precedence of the default prolog.ps file. Using mp.conf as the configuration file makes it possible to print to any PostScript printer.</p> <p>The encoding of the locale specified by the -L option and that of the text file to be printed have to be the same. In the above Japanese file example, if the text file is encoded in Shift-JIS, use the following command, since the locale ja_JP.PCK is encoded in SJIS:</p> <pre>example% mp -L ja_JP.PCK -M SJIS.txt   lp</pre> <p><b>EXAMPLE 2</b> Running in Xprt mode</p> <p>If an X Print Server daemon (/usr/openwin/bin/Xprt) is running in any system in the network, mp can be invoked as follows, enabling it to output in any Page Description Language supported by Xprt (the default value of <i>display_number</i> is 2100):</p> <pre>example% setenv XPSEVERLIST "machine1[:display_number1] \                                   machine2[:display_number2] machine3[:display_number3]"</pre> <p>OR</p> <pre>example% setenv XPDISPLAY machine_name[:display_number]</pre>	

**EXAMPLE 2** Running in Xprt mode (Continued)

Using the options `-D printer_name[@machine[:display_number]]` or `-P printer_name[@machine[:display_number]]` gives the greatest precedence and `mp` tries to connect to Xprt running on `machine[:display_number]` with `printer_name`. When not specified, the default `display_number` value is 2100. If this fails, `printer_name` is tried with an Xprt display obtained from the following logic. The following is also valid if you enter only `-D printer_name` or `-P printer_name` on the command line.

`mp` checks XPSERVERLIST for a list of space-separated Xprt servers until it finds one which supports the `printer_name` argument. If none is found, `mp` checks the XPDISPLAY environment variable, which is of the form `machine[:display_number]`. If that is also not set or not valid, `mp` tries to connect to the default display, :2100. If that is also not successful, `mp` exits with an error message.

To pipe the data to the target printer when XPSERVERLIST or XPDISPLAY is set, enter:

```
example% mp -D printer_name -L ja_JP.eucJP \
-M ja_JP_eucJP.txt | lp -d printer_name
```

For direct spooling when working in Xprt client mode, use the `-P` option:

```
example% mp -P printer_name -L ja_JP.eucJP -M ja_JP_eucJP.txt
```

**EXAMPLE 3** Turning off the header and footer

Use the `-n` option to turn off the `mp` header and footer:

```
example% mp -n mytext.txt | lp
```

**EXAMPLE 4** Printing long text lines

Use the `-ll` option to print text files with longer than 80 column lines in landscape mode:

```
example% mp -ll mytext.txt | lp
```

**EXAMPLE 5** Specifying print point size

Use the `-z` option to specify any point size, in this case, 20 points:

```
example% mp -z 20 mytext.txt | lp
```

**ENVIRONMENT  
VARIABLES**

**XPSERVERLIST** If the arguments to `-D` or `-P` is of the form `printer_name@machine[:display_number]`, XPSERVERLIST is used only if the `machine[:display_number]` does not support `printer_name`.

mp(1)

	<p>XPSERVERLIST contains a space-separated list of Xprt displays to which to connect the printer. mp goes through the list sequentially to get an Xprt server that can support the given printer, exiting at the first instance where mp finds a display to which to connect. If this is not set, the environment variable XPDISPLAY is used instead.</p>				
XPDISPLAY	<p>If the -D or -P option is specified in the command line with just the <i>printer_name</i> argument and no XPSERVERLIST variable is set in the environment, the XPDISPLAY variable is used to determine the <i>machine[:display_number]</i> running the X Print Server to connect the client. If XPDISPLAY is also not set, the print server startup script starts an Xprt server at port 2100 of the machine in which the client is running. The script terminates the print server once the job is over. If XPDISPLAY is set, the mp client tries to contact the print server running at XPDISPLAY. In this case, no attempt is made to start the server if it is not running.</p>				
MP_PROLOGUE	<p>Used to determine the directory where the page formatting files (.xpr or .ps) are kept. These files determine page decorations, number of logical pages per physical page, landscape or portrait format, and so forth. In the absence of MP_PROLOGUE, the default location of the directory is /usr/lib/lp/locale/C/mp.</p>				
MP_LANG LANG	<p>If neither of the -D or -P options is specified, a prologue file is prepended to the output to be printed. The prologue file is called /usr/openwin/lib/locale/<i>localename</i>/print/prolog.ps or /usr/lib/lp/locale/<i>localename</i>/mp/prolog.ps, where <i>localename</i> is the value of the MP_LANG or LANG environment variable, if present. If both variables are present, the file /usr/openwin/lib/locale/<i>localename</i>/print/prolog.ps is given preference due to backward compatibility reasons. If either of these files are not present, and the -D option is not specified, a configuration file of the locale called /usr/lib/lp/locale/<i>localename</i>/mp/mp.conf is used as the source of the configuration information that substitutes the prologue information for printing. The presence of prolog.ps disables mp.conf for backward compatibility.</p>				
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <table><tr><td>0</td><td>Successful completion.</td></tr><tr><td>1</td><td>An error occurred.</td></tr></table>	0	Successful completion.	1	An error occurred.
0	Successful completion.				
1	An error occurred.				
<b>SUPPLIED PROLOGUE FILES</b>	<p>The following prologue files are provided. Files with .ps extensions are for the PostScript output. Files with .xpr extensions are for the Print Server client. .xpr files are created for 300dpi printers and will scale to other resolution values.</p>				

mp.common.ps	Common prologue file for all other .ps files in this directory.
mp.pro.ps mp.pro.xpr	Used by default.
mp.pro.ff.ps mp.pro.ff.xpr	Used if the -ff option is in effect.
mp.pro.fp.ps mp.pro.fp.xpr	Used if the -fp option is in effect.
mp.pro.tm.ps mp.pro.tm.xpr	Used if the -tm option is in effect.
mp.pro.ts.ps mp.pro.ts.xpr	Used if the -ts option is in effect.
mp.pro.alt.ps mp.pro.alt.xpr	An alternative modification of the default prologue file which outputs the page number in the right corner of the bottom banner.
mp.pro.l.ps mp.pro.l.xpr	Prologue file used for landscape outputs.
mp.pro.ll.ps mp.pro.ll.xpr	Prologue file used for landscape outputs, when printing files with longer than normal lines.
mp.pro.altl.ps mp.pro.altl.xpr	Alternate prologue file used for landscape outputs.
<b>FILES</b>	
.cshrc	Initialization file for <a href="#">csh(1)</a> .
.mailrc	Initialization file for <a href="#">mail(1)</a> .
/usr/bin/mp	Executable.
/usr/lib/lp/locale/C/mp/mp.conf	Default configuration file.
/usr/lib/lp/locale/C/mp/mp.common.ps	Common prologue file for all other .ps files in this directory. Not for .xpr files.
/usr/lib/lp/locale/C/mp/mp.pro.ps /usr/lib/lp/locale/C/mp/mp.pro.xpr	Default prologue files for mail printing.
/usr/lib/lp/locale/C/mp/mp.pro.l.ps /usr/lib/lp/locale/C/mp/mp.pro.l.xpr	Default prologue files for landscape format.

## mp(1)

`/usr/lib/lp/locale/C/mp/mp.pro.ll.ps`  
`/usr/lib/lp/locale/C/mp/mp.pro.ll.xpr`  
Default prologue files for landscape format with one column per page. Useful when printing files with long lines.

`/usr/lib/lp/locale/C/mp/mp.pro.alt1.ps`  
`/usr/lib/lp/locale/C/mp/mp.pro.alt1.xpr`  
Alternate prologue files for landscape format.

`/usr/lib/lp/locale/C/mp/mp.pro.alt.ps`  
`/usr/lib/lp/locale/C/mp/mp.pro.alt.xpr`  
Alternative "default" prologue files. Insert page numbers in the bottom right corner of each page.

`/usr/lib/lp/locale/C/mp/mp.pro.ff.ps`  
`/usr/lib/lp/locale/C/mp/mp.pro.ff.xpr`  
Default prologue files for Filofax format.

`/usr/lib/lp/locale/C/mp/mp.pro.fp.ps`  
`/usr/lib/lp/locale/C/mp/mp.pro.fp.xpr`  
Default prologue files for Franklin Planner format.

`/usr/lib/lp/locale/C/mp/mp.pro.tm.ps`  
`/usr/lib/lp/locale/C/mp/mp.pro.tm.xpr`  
Default prologue files for Time Manager format.

`/usr/lib/lp/locale/C/mp/mp.pro.ts.ps`  
`/usr/lib/lp/locale/C/mp/mp.pro.ts.xpr`  
Default prologue files for Time/System International format.

`/usr/openwin/lib/locale/localename/print/prolog.ps`  
`/usr/lib/lp/locale/localename/mp/prolog.ps`  
Default locale-specific prologued file as an alternative to the `mp.conf` file. See ENVIRONMENT VARIABLES for more detail on the relationship.

The structure and format for `mp.conf` and `.xpr` files are documented in the *International Language Environments Guide*. Refer to this document if you need to use alternate fonts, including Printer Resident Fonts, or if you want to make changes to output format.

*International Language Environments Guide*

<b>NAME</b>	mpss.so.1 – shared object for setting preferred page size
<b>SYNOPSIS</b>	<b>mpss.so.1</b>
<b>DESCRIPTION</b>	<p>The <code>mpss.so.1</code> shared object provides a means by which the preferred stack and/or heap page size can be selectively configured for launched processes and their descendants. To enable <code>mpss.so.1</code>, the following string needs to be present in the environment (see <a href="#">ld.so.1(1)</a>) along with one or more MPSS (Multiple Page Size Support) environment variables:</p> <pre>LD_PRELOAD=\$LD_PRELOAD:mpss.so.1</pre>
<b>ENVIRONMENT VARIABLES</b>	<p>Once preloaded, the <code>mpss.so.1</code> shared object reads the following environment variables to determine any preferred page size requirements and any processes these may be specific to.</p> <p><code>MPSSHEAP=<i>size</i></code>  <code>MPSSSTACK=<i>size</i></code></p> <p><code>MPSSCFGFILE=<i>config-file</i></code></p> <p><code>MPSSHEAP</code> and <code>MPSSSTACK</code> specify the preferred page sizes for the heap and stack, respectively. The specified page size(s) are applied to all created processes.</p> <p><i>size</i> must be a supported page size (see <a href="#">pagesize(1)</a>) or 0, in which case the system will select an appropriate page size (see <a href="#">memcntl(2)</a>).</p> <p><i>size</i> can be qualified with K, M, G, or T to specify Kilobytes, Megabytes, Gigabytes, or Terabytes respectively.</p> <p><i>config-file</i> is a text file which contains one or more <code>mpss</code> configuration entries of the form:</p> <pre><i>exec-name exec-args :heap-size :stack-size</i></pre> <p><i>exec-name</i> specifies the name of an application or executable. The corresponding preferred page size(s) are set for newly created processes (see <a href="#">getexecname(3C)</a>) that match the first <i>exec-name</i> found in the file.</p> <p><i>exec-name</i> can be a full pathname, a base name or a pattern string. See <a href="#">File Name Generation in sh(1)</a> for a discussion of pattern matching.</p> <p><i>exec-args</i> is an optionally specified pattern string to match against arguments. Preferred page size(s) are set only if <i>exec-args</i> is not specified or occurs within the arguments to <i>exec-name</i>.</p> <p>If <i>heap-size</i> and/or <i>stack-size</i> are not specified, the corresponding preferred page size(s) will not be set.</p>

MPSSCFGFILE takes precedence over MPSSHEAP and MPSSSTACK. When MPSSCFGFILE is not set, preferred page size settings are taken from file `/etc/mpss.conf` if it exists.

`MPSSERRFILE=pathname` By default, error messages are logged via `syslog(3C)` using level `LOG_ERR` and facility `LOG_USER`. If `MPSSERRFILE` contains a valid *pathname* (such as `/dev/stderr`), error messages will be logged there instead.

#### EXAMPLES **EXAMPLE 1** Configuring preferred page sizes using MPSSCFGFILE

The following Bourne shell commands (see [sh\(1\)](#)) configure the preferred page sizes to a select set of applications with exec names that begin with `foo`, using the `MPSSCFGFILE` environment variable. The MPSS configuration file, `mpsscfcg`, is assumed to have been previously created via a text editor like [vi\(1\)](#). The `cat(1)` command is only dumping out the contents.

```
example$ LD_PRELOAD=$LD_PRELOAD:mpss.so.1
example$ MPSSCFGFILE=mpsscfcg
example$ export LD_PRELOAD MPSSCFGFILE
example$ cat $MPSSCFGFILE
foo*:512K:64K
```

Once the application has been started, `pmap` (see [proc\(1\)](#)) can be used to view the actual page sizes configured:

```
example$ foobar &
example$ pmap -s `pgrep foobar`
```

If the desired page size is not configured (shown in the `pmap` output), it may be due to errors in the MPSS configuration file or environment variables. Check the error log (by default: `/var/adm/messages`) for errors.

If no errors can be found, resource or alignment constraints may be responsible. See the NOTES section.

#### **EXAMPLE 2** Configuring preferred page sizes using MPSSHEAP and MPSSSTACK

The following Bourne shell commands configure 512K heap and 64K stack preferred page sizes for all applications using the `MPSSHEAP` and `MPSSSTACK` environment variables.

```
example$ LD_PRELOAD=$LD_PRELOAD:mpss.so.1
example$ MPSSHEAP=512K
example$ MPSSSTACK=64K
example$ export LD_PRELOAD MPSSHEAP MPSSSTACK
```

**EXAMPLE 3** Precedence rules (continuation from Example 2)

The preferred page size configuration in `MPSSCFGFILE` overrides `MPS SHEAP` and `MPS STACK`. Appending the following commands to those in Example 2 would mean that all applications will be configured with 512K heap and 64K stack preferred page sizes with the exception of those applications, the `ls` command, and all applications beginning with `ora` that have `ora1` as an argument, in the configuration file.

```
example$ MPSSCFGFILE=mpsscfig2
example$ export MPSSCFGFILE
example$ cat $MPSSCFGFILE
ls::
ora* ora1:4m:4m
```

**FILES** `/usr/lib/ld/map.bssalign` A template link-editor `mapfile` for aligning bss (see NOTES).  
`/etc/mpss.conf` Configuration file

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu (32-bit)
	SUNWesxu (64-bit)
Interface Stability	Evolving

**SEE ALSO** `cat(1)`, `ld(1)`, `ld.so.1(1)`, `pagesize(1)`, `ppgsz(1)`, `proc(1)`, `sh(1)`, `vi(1)`, `exec(2)`, `fork(2)`, `memcntl(2)`, `getexecname(3C)`, `getpagesize(3C)`, `syslog(3C)`, `proc(4)`, `attributes(5)`

**NOTES** The heap and stack preferred page sizes are inherited. A child process has the same preferred page sizes as its parent. On `exec(2)`, the preferred page sizes are set back to the default system page size unless a preferred page size has been configured via the `mpss` shared object.

`ppgsz(1)`, a `proc` tool, can also be used to set the preferred stack and/or heap page sizes. It cannot selectively configure the page size for descendants based on name matches.

See also NOTES under `ppgsz(1)`.

## msgfmt(1)

<b>NAME</b>	msgfmt – create a message object from a message file																						
<b>SYNOPSIS</b>	<b>msgfmt</b> [-D <i>dir</i>   --directory= <i>dir</i> ] [-f   --use-fuzzy] [-g] [-o <i>output-file</i>   --output-file= <i>output-file</i> ] [-s] [--strict] [-v] [--verbose] <i>filename.po</i> ...																						
<b>DESCRIPTION</b>	<p>The msgfmt utility creates message object files from portable object files (<i>filename.po</i>), without changing the portable object files.</p> <p>The .po file contains messages displayed to users by system commands or by application programs. .po files can be edited. The messages in these files can be rewritten in any language supported by the system.</p> <p>The <a href="#">xgettext(1)</a> command can be used to create .po files from script or programs.</p> <p>msgfmt interprets data as characters according to the current setting of the LC_CTYPE locale category or according to the codeset specified in the .po file.</p>																						
<b>OPTIONS</b>	<p>The following options are supported:</p> <table><tr><td>-D <i>dir</i></td><td></td></tr><tr><td>--directory=<i>dir</i></td><td>Adds <i>dir</i> to the list for input files search.</td></tr><tr><td>-f</td><td></td></tr><tr><td>--use-fuzzy</td><td>Uses fuzzy entries in output. If this option is not specified, fuzzy entries are not included into the output. These options are ignored if Solaris message catalogs are processed.</td></tr><tr><td>-g</td><td>Directs the utility to generate the GNU-compatible message catalog file. This option cannot be specified with the -s option.</td></tr><tr><td>-o <i>output-file</i></td><td></td></tr><tr><td>--output=<i>output-file</i></td><td>Specifies the output file name as <i>output-file</i>. All domain directives and duplicate msgids in the .po file are ignored.</td></tr><tr><td>-s</td><td>Directs the utility to generate the Solaris message catalog file. This option cannot be specified with the -g option.</td></tr><tr><td>--strict</td><td>Directs the utility to append the suffix .mo to the generating message object file name if it doesn't have this suffix. This option is ignored if Solaris message catalogs are processed.</td></tr><tr><td>-v</td><td></td></tr><tr><td>--verbose</td><td>Verbose. Lists duplicate message identifiers if Solaris message catalog files are processed. Message strings are not redefined.</td></tr></table>	-D <i>dir</i>		--directory= <i>dir</i>	Adds <i>dir</i> to the list for input files search.	-f		--use-fuzzy	Uses fuzzy entries in output. If this option is not specified, fuzzy entries are not included into the output. These options are ignored if Solaris message catalogs are processed.	-g	Directs the utility to generate the GNU-compatible message catalog file. This option cannot be specified with the -s option.	-o <i>output-file</i>		--output= <i>output-file</i>	Specifies the output file name as <i>output-file</i> . All domain directives and duplicate msgids in the .po file are ignored.	-s	Directs the utility to generate the Solaris message catalog file. This option cannot be specified with the -g option.	--strict	Directs the utility to append the suffix .mo to the generating message object file name if it doesn't have this suffix. This option is ignored if Solaris message catalogs are processed.	-v		--verbose	Verbose. Lists duplicate message identifiers if Solaris message catalog files are processed. Message strings are not redefined.
-D <i>dir</i>																							
--directory= <i>dir</i>	Adds <i>dir</i> to the list for input files search.																						
-f																							
--use-fuzzy	Uses fuzzy entries in output. If this option is not specified, fuzzy entries are not included into the output. These options are ignored if Solaris message catalogs are processed.																						
-g	Directs the utility to generate the GNU-compatible message catalog file. This option cannot be specified with the -s option.																						
-o <i>output-file</i>																							
--output= <i>output-file</i>	Specifies the output file name as <i>output-file</i> . All domain directives and duplicate msgids in the .po file are ignored.																						
-s	Directs the utility to generate the Solaris message catalog file. This option cannot be specified with the -g option.																						
--strict	Directs the utility to append the suffix .mo to the generating message object file name if it doesn't have this suffix. This option is ignored if Solaris message catalogs are processed.																						
-v																							
--verbose	Verbose. Lists duplicate message identifiers if Solaris message catalog files are processed. Message strings are not redefined.																						

If GNU-compatible message files are processed, this option detects and diagnoses input file anomalies which might represent translation errors. The `msgid` and `msgstr` strings are studied and compared. It is considered abnormal if one string starts or ends with a newline while the other does not. Also, if the string represents a format string used in a `printf`-like function, both strings should have the same number of `%` format specifiers, with matching types. If the flag `c-format` appears in the special comment `'#'` for this entry, a check is performed.

**USAGE** The format of portable object files (`.po` files) is defined as follows. Each `.po` file contains one or more lines, with each line containing either a comment or a statement. Comments start the line with a pound sign (`#`) and end with the newline character. All comments (except special comments described later) and empty lines are ignored. The format of a statement is:

*directive value*

Each *directive* starts at the beginning of the line and is separated from *value* by white space (such as one or more space or tab characters). *value* consists of one or more quoted strings separated by white space. Use any of the following types of directives for the Solaris message file:

`domain domainname`  
`msgid message_identifier`  
`msgstr message_string`

For a GNU-compatible message file, use any of the following types of directives:

`domain domainname`  
`msgid message_identifier`  
`msgid_plural untranslated_string_plural`  
`msgstr message_string`  
`msgstr[n] message_string`

The behavior of the `domain` directive is affected by the options used. See **OPTIONS** for the behavior when the `-o` or `--output-file` options are specified. If the `-o` or `--output-file` options are not specified, the behavior of the `domain` directive is as follows:

- All `msgid`s from the beginning of each `.po` file to the first `domain` directive are put into a default message object file. The default message object file is named `messages.mo`, if the Solaris message catalog file format is used to generate the message object file or if the `--strict` option is specified. Otherwise, the default message object file is named `messages`.

## msgfmt(1)

- When `msgfmt` encounters a `domain domainname` directive in the `.po` file, all following `msgid`s until the next `domain` directive are put into the message object file, named `domainname.mo`, if the Solaris message catalog file format is used to generate the message object file or if the `--strict` option is specified. Otherwise, the `msgid`s are put into the message object file named `domainname`.
- Duplicate `msgid`s are defined in the scope of each domain. That is, a `msgid` is considered a duplicate only if the identical `msgid` exists in the same domain.
- All duplicate `msgid`s are ignored.

The `msgid` directive specifies the value of a message identifier associated with the directive that follows it. The `msgid_plural` directive specifies the plural form message specified to the plural message handling functions `ngettext()`, `dngettext()`, or `dcngettext()`. The *message\_identifier* string identifies a target string to be used at retrieval time. Each statement containing a `msgid` directive must be followed by a statement containing a `msgstr` directive or `msgstr[n]` directives.

The `msgstr` directive specifies the target string associated with the *message\_identifier* string declared in the immediately preceding `msgid` directive.

The directive `msgstr[n]` (where  $n = 0, 1, 2, \dots$ ) specifies the target string to be used with plural form handling functions `ngettext()`, `dngettext()`, and `dcngettext()`.

Message strings can contain the escape sequences `\n` for newline, `\t` for tab, `\v` for vertical tab, `\b` for backspace, `\r` for carriage return, `\f` for formfeed, `\\` for backslash, `\"` for double quote, `\a` for alarm, `\ddd` for octal bit pattern, and `\xDD` for hexadecimal bit pattern.

Comments for a GNU-compatible message file should be in one of the following formats (the `msgfmt` utility will ignore these comments when processing Solaris message files):

```
# translator-comments
# . automatic-comments
# : reference..
# , flag
```

The `'#:'` comments indicate the location of the `msgid` string in the source files in *filename:line* format. The `'#'`, `'#.'`, and `'#:'` comments are informative only and are silently ignored by the `msgfmt` utility. The `'#,'` comments require one or more flags separated by the comma character. The following *flags* can be specified:

fuzzy	This flag can be inserted by the translator. It shows that the <code>msgstr</code> string might not be a correct translation (anymore). Only the translator can judge if the translation requires further modification or is acceptable as is. Once satisfied with the
-------	--

translation, the translator removes this fuzzy flag. If this flag is specified, the `msgfmt` utility will not generate the entry for the immediately following `msgid` in the output message catalog.

`c-format`

`no-c-format`

The `c-format` flag indicates that the `msgid` string is used as a format string by `printf`-like functions. In case the `c-format` flag is given for a string, the `msgfmt` utility does some more tests to check the validity of the translation.

In the GNU-compatible message file, the `msgid` entry with empty string ("" ) is called the header entry and treated specially. If the message string for the header entry contains `nplurals=value`, the value indicates the number of plural forms. For example, if `nplurals=4`, there are four plural forms. If `nplurals` is defined, the same line should contain `plural=expression`, separated by a semicolon character. The *expression* is a C language expression to determine which version of `msgstr[n]` is to be used based on the value of *n*, the last argument of `ngettext()`, `dngettext()`, or `dcngettext()`. For example,

```
nplurals=2; plural= n == 1 ? 0 : 1
```

indicates that there are two plural forms in the language. `msgstr[0]` is used if `n == 1`, otherwise `msgstr[1]` is used. For another example:

```
nplurals=3; plural= n == 1 ? 0 : n == 2 ? 1 : 2
```

indicates that there are three plural forms in the language. `msgstr[0]` is used if `n == 1`, `msgstr[1]` is used if `n == 2`, otherwise `msgstr[2]` is used.

If the header entry contains a `charset=codeset` string, the *codeset* is used to indicate the codeset to be used to encode the message strings. If the output string's codeset is different from the message string's codeset, codeset conversion from the message string's codeset to the output string's codeset will be performed upon the call of `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, and `dcngettext()` for the GNU-compatible message catalogs. The output string's codeset is determined by the current locale's codeset (the return value of `nl_langinfo(CODESET)`) by default, and can be changed by the call of `bind_textdomain_codeset()`.

## Message catalog file format

The `msgfmt` utility can generate the message object both in Solaris message catalog file format and in GNU-compatible message catalog file format. If the `-s` option is specified and the input file is a Solaris `.po` file, the `msgfmt` utility generates the message object in Solaris message catalog file format. If the `-g` option is specified and the input file is a GNU `.po` file, the `msgfmt` utility generates the message object in GNU-compatible message catalog file format. If neither the `-s` nor `-g` option is specified, the `msgfmt` utility determines the message catalog file format as follows:

- If the `.po` file contains a valid GNU header entry (having an empty string for `msgid`), the `msgfmt` utility uses the GNU-compatible message catalog file format.
- Otherwise, the `msgfmt` utility uses the Solaris message catalog file format.

msgfmt(1)

If the `msgfmt` utility determined that the Solaris message catalog file format is used, as above, but found the `.po` file contains directives that are specific to the GNU-compatible message catalog file format, such as `msgid_plural` and `msgstr[n]`, the `msgfmt` utility handles those directives as invalid specifications.

## EXAMPLES

### EXAMPLE 1 Creating message objects from message files

In this example, `module1.po` and `module2.po` are portable message objects files.

```
example% cat module1.po
# default domain "messages.mo"
msgid "msg 1"
msgstr "msg 1 translation"
#
domain "help_domain"
msgid "help 2"
msgstr "help 2 translation"
#
domain "error_domain"
msgid "error 3"
msgstr "error 3 translation"
example% cat module2.po
# default domain "messages.mo"
msgid "mesg 4"
msgstr "mesg 4 translation"
#
domain "error_domain"
msgid "error 5"
msgstr "error 5 translation"
#
domain "window_domain"
msgid "window 6"
msgstr "window 6 translation"
```

The following command will produce the output files `messages.mo`, `help_domain.mo`, and `error_domain.mo` in Solaris message catalog file format:

```
example% msgfmt module1.po
```

The following command will produce the output files `messages.mo`, `help_domain.mo`, `error_domain.mo`, and `window_domain.mo` in Solaris message catalog file format:

```
example% msgfmt module1.po module2.po
```

The following command will produce the output file `hello.mo` in Solaris message catalog file format:

```
example% msgfmt -o hello.mo module1.po module2.po
```

## ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environmental variables that affect the execution of `msgfmt`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWloc
CSI	Enabled

**SEE ALSO** `xgettext(1)`, `gettext(3C)`, `setlocale(3C)`, `attributes(5)`, `environ(5)`

**NOTES** Installing message catalogs under the C locale is pointless, since they are ignored for the sake of efficiency.

## mt(1)

<b>NAME</b>	mt – magnetic tape control
<b>SYNOPSIS</b>	<b>mt</b> [-f <i>tapename</i> ] <i>command</i> ... [ <i>count</i> ]
<b>DESCRIPTION</b>	The <b>mt</b> utility sends commands to a magnetic tape drive. If -f <i>tapename</i> is not specified, the environment variable <b>TAPE</b> is used. If <b>TAPE</b> does not exist, <b>mt</b> uses the device <code>/dev/rmt/0n</code> .
<b>OPTIONS</b>	The following option is supported:  -f <i>tapename</i> Specifies the raw tape device.
<b>OPERANDS</b>	The following operands are supported:  <i>count</i> The number of times that the requested operation is to be performed. By default, <b>mt</b> performs <i>command</i> once. Multiple operations of <i>command</i> may be performed by specifying <i>count</i> .  <i>command</i> Available commands that can be sent to a magnetic tape drive. Only as many characters as are required to uniquely identify a <i>command</i> need be specified.  eof weof                        Writes <i>count</i> EOF marks at the current position on the tape.  fsf                         Forward spaces over <i>count</i> EOF marks. The tape is positioned on the first block of the file.  fsr                         Forward spaces <i>count</i> records.  bsf                         Back spaces over <i>count</i> EOF marks. The tape is positioned on the beginning-of-tape side of the EOF mark.  bsr                         Back spaces <i>count</i> records.  nbsf                        Back spaces <i>count</i> files. The tape is positioned on the first block of the file. This is equivalent to <i>count</i> +1 <i>bsf</i> 's followed by one <i>fsf</i> .  asf                         Specifies absolute space to <i>count</i> file number. This is equivalent to a <i>rewind</i> followed by a <i>fsf count</i> .  If <i>count</i> is specified with any of the following commands, the <i>count</i> is ignored and the command is performed only once.  eom                         Spaces to the end of recorded media on the tape. This is useful for appending files onto previously written tapes.  rewind                     Rewinds the tape.

offline	
rewoffl	Rewinds the tape and, if appropriate, takes the drive unit off-line by unloading the tape.
status	Prints status information about the tape unit.
retension	Rewinds the cartridge tape completely, then winds it forward to the end of the reel and back to beginning-of-tape to smooth out tape tension.
reserve	Allows the tape drive to remain reserved after closing the device. The drive must then be explicitly released.
release	Re-establishes the default behavior of releasing at close.
forcereserve	Breaks the reservation of the tape drive held by another host and then reserves the tape drive. This command can be executed only with super-user privileges.
erase	Erases the entire tape. <i>Caution:</i> Some tape drives have option settings where only portions of the tape may be erased. Be sure to select the correct setting to erase the whole tape. Erasing a tape may take a long time depending on the device and/or tape. Refer to the device specific manual for time details.
config	Reads the drives current configuration from the driver and displays it in <code>st.conf</code> format. See <code>st(7D)</code> for definition of fields and there meanings.

<b>EXIT STATUS</b>	0	All operations were successful.
	1	Command was unrecognized or <code>mt</code> was unable to open the specified tape drive.
	2	An operation failed.

**FILES** /dev/rmt/\* magnetic tape interface

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO** `tar(1)`, `tcopy(1)`, `ar.h(3HEAD)`, `environ(4)`, `attributes(5)`, `mtio(7I)`, `st(7D)`

mt(1)

**BUGS** | Not all devices support all options. Some options are hardware-dependent. Refer to the corresponding device manual page.

mt is architecture sensitive. Heterogeneous operation (that is, SPARC to x86 or the reverse) is not supported.

<b>NAME</b>	mv – move files
<b>SYNOPSIS</b>	<pre> /usr/bin/mv [-fi] source target_file /usr/bin/mv [-fi] source... target_dir /usr/xpg4/bin/mv [-fi] source target_file /usr/xpg4/bin/mv [-fi] source... target_dir </pre>
<b>DESCRIPTION</b>	<p>In the first synopsis form, the mv utility moves the file named by the <i>source</i> operand to the destination specified by the <i>target_file</i>. <i>source</i> and <i>target_file</i> may not have the same name. If <i>target_file</i> does not exist, mv creates a file named <i>target_file</i>. If <i>target_file</i> exists, its contents are overwritten. This first synopsis form is assumed when the final operand does not name an existing directory.</p> <p>In the second synopsis form, mv moves each file named by a <i>source</i> operand to a destination file in the existing directory named by the <i>target_dir</i> operand. The destination path for each <i>source</i> is the concatenation of the target directory, a single slash character (/), and the last path name component of the <i>source</i>. This second form is assumed when the final operand names an existing directory.</p> <p>If mv determines that the mode of <i>target_file</i> forbids writing, it will print the mode (see <code>chmod(2)</code>), ask for a response, and read the standard input for one line. If the response is affirmative, the mv occurs, if permissible; otherwise, the command exits. Notice that the mode displayed may not fully represent the access permission if <i>target</i> is associated with an ACL. When the parent directory of <i>source</i> is writable and has the sticky bit set, one or more of the following conditions must be true:</p> <ul style="list-style-type: none"> <li>■ the user must own the file</li> <li>■ the user must own the directory</li> <li>■ the file must be writable by the user</li> <li>■ the user must be a privileged user</li> </ul> <p>If <i>source</i> is a file and <i>target_file</i> is a link to another file with links, the other links remain and <i>target_file</i> becomes a new file.</p> <p>If <i>source</i> and <i>target_file/target_dir</i> are on different file systems, mv copies the source and deletes the original. Any hard links to other files are lost. mv will attempt to duplicate the source file characteristics to the target, that is, the owner and group id, permission modes, modification and access times, ACLs, and extended attributes, if applicable. For symbolic links, mv will preserve only the owner and group of the link itself.</p> <p>If unable to preserve owner and group id, mv will clear <code>S_ISUID</code> and <code>S_ISGID</code> bits in the target. mv will print a diagnostic message to stderr if unable to clear these bits, though the exit code will not be affected. mv may be unable to preserve extended attributes if the target file system does not have extended attribute support. <code>/usr/xpg4/bin/mv</code> will print a diagnostic message to stderr for all other failed attempts to duplicate file characteristics. The exit code will not be affected.</p> <p>In order to preserve the source file characteristics, users must have the appropriate file access permissions. This includes being super-user or having the same owner id as the destination file.</p>

## mv(1)

**OPTIONS** The following options are supported:

- f mv will move the file(s) without prompting even if it is writing over an existing *target*. Note that this is the default if the standard input is not a terminal.
- i mv will prompt for confirmation whenever the move would overwrite an existing *target*. An affirmative answer means that the move should proceed. Any other answer prevents mv from overwriting the *target*.

**/usr/bin/mv** Specifying both the -f and the -i options is not considered an error. The -f option will override the -i option.

**/usr/xpg4/bin/mv** Specifying both the -f and the -i options is not considered an error. The last option specified will determine the behavior of mv.

**OPERANDS** The following operands are supported:

- source* A path name of a file or directory to be moved.
- target\_file* A new path name for the file or directory being moved.
- target\_dir* A path name of an existing directory into which to move the input files.

**USAGE** See `largefile(5)` for the description of the behavior of mv when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**ENVIRONMENT VARIABLES** See `environ(5)` for descriptions of the following environment variables that affect the execution of mv: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**EXIT STATUS** The following exit values are returned:

- 0 All input files were moved successfully.
- >0 An error occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

**/usr/bin/mv**

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled
Interface Stability	Stable

**/usr/xpg4/bin/mv**

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
CSI	Enabled

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Standard

**SEE ALSO** [cp\(1\)](#), [cpio\(1\)](#), [ln\(1\)](#), [rm\(1\)](#), [setfacl\(1\)](#), [chmod\(2\)](#), [attributes\(5\)](#), [environ\(5\)](#), [fsattr\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

**NOTES** A `--` permits the user to mark explicitly the end of any command line options, allowing `mv` to recognize filename arguments that begin with a `-`. As an aid to BSD migration, `mv` will accept `-` as a synonym for `--`. This migration aid may disappear in a future release.

nawk(1)

<b>NAME</b>	nawk – pattern scanning and processing language
<b>SYNOPSIS</b>	<pre> /usr/bin/nawk [-F ERE] [-v assignment] 'program'   -f progfile... [argument...] /usr/xpg4/bin/awk [-F ERE] [-v assignment...] 'program'   -f progfile... [argument...] </pre>
<b>DESCRIPTION</b>	<p>The /usr/bin/nawk and /usr/xpg4/bin/awk utilities execute <i>programs</i> written in the nawk programming language, which is specialized for textual data manipulation. A nawk <i>program</i> is a sequence of patterns and corresponding actions. The string specifying <i>program</i> must be enclosed in single quotes (') to protect it from interpretation by the shell. The sequence of pattern - action statements can be specified in the command line as <i>program</i> or in one, or more, file(s) specified by the -f <i>progfile</i> option. When input is read that matches a pattern, the action associated with the pattern is performed.</p> <p>Input is interpreted as a sequence of records. By default, a record is a line, but this can be changed by using the RS built-in variable. Each record of input is matched to each pattern in the <i>program</i>. For each pattern matched, the associated action is executed.</p> <p>The nawk utility interprets each input record as a sequence of fields where, by default, a field is a string of non-blank characters. This default white-space field delimiter (blanks and/or tabs) can be changed by using the FS built-in variable or the -F <i>ERE</i> option. The nawk utility denotes the first field in a record \$1, the second \$2, and so forth. The symbol \$0 refers to the entire record; setting any other field causes the reevaluation of \$0. Assigning to \$0 resets the values of all fields and the NF built-in variable.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-F <i>ERE</i>                 Define the input field separator to be the extended regular expression <i>ERE</i>, before any input is read (can be a character).</li> <li>-f <i>progfile</i>           Specifies the pathname of the file <i>progfile</i> containing a nawk program. If multiple instances of this option are specified, the concatenation of the files specified as <i>progfile</i> in the order specified is the nawk program. The nawk program can alternatively be specified in the command line as a single argument.</li> <li>-v <i>assignment</i>        The <i>assignment</i> argument must be in the same form as an <i>assignment</i> operand. The assignment is of the form <i>var=value</i>, where <i>var</i> is the name of one of the variables described below. The specified assignment occurs before executing the nawk program, including the actions associated with BEGIN patterns (if any). Multiple occurrences of this option can be specified.</li> </ul>
<b>OPERANDS</b>	<p>The following operands are supported:</p> <ul style="list-style-type: none"> <li><i>program</i>               If no -f option is specified, the first operand to nawk is the text of the nawk program. The application supplies the <i>program</i> operand as a single argument to nawk . If the text does not end in a newline character, nawk interprets the text as if it did.</li> </ul>

*argument*

Either of the following two types of *argument* can be intermixed:

*file*

A pathname of a file that contains the input to be read, which is matched against the set of patterns in the program. If no *file* operands are specified, or if a *file* operand is `-`, the standard input is used.

*assignment*

An operand that begins with an underscore or alphabetic character from the portable character set, followed by a sequence of underscores, digits and alphabets from the portable character set, followed by the `=` character specifies a variable assignment rather than a pathname. The characters before the `=` represent the name of a `nawk` variable. If that name is a `nawk` reserved word, the behavior is undefined. The characters following the equal sign is interpreted as if they appeared in the `nawk` program preceded and followed by a double-quote (`"`) character, as a `STRING` token, except that if the last character is an unescaped backslash, it is interpreted as a literal backslash rather than as the first character of the sequence `"\"`. The variable is assigned the value of that `STRING` token. If the value is considered a *numericstring*, the variable is assigned its numeric value. Each such variable assignment is performed just before the processing of the following *file*, if any. Thus, an assignment before the first *file* argument is executed after the `BEGIN` actions (if any), while an assignment after the last *file* argument is executed before the `END` actions (if any). If there are no *file* arguments, assignments are executed before processing the standard input.

**INPUT FILES**

Input files to the `nawk` program from any of the following sources:

- any *file* operands or their equivalents, achieved by modifying the `nawk` variables `ARGV` and `ARGC`
- standard input in the absence of any *file* operands
- arguments to the `getline` function

must be text files. Whether the variable `RS` is set to a value other than a newline character or not, for these files, implementations support records terminated with the specified separator up to `{LINE_MAX}` bytes and may support longer records.

If `-F progfile` is specified, the files named by each of the *progfile* option-arguments must be text files containing an `nawk` program.

The standard input are used only if no *file* operands are specified, or if a *file* operand is `-`.

**EXTENDED DESCRIPTION**

A `nawk` program is composed of pairs of the form:

```
pattern { action }
```

## nawk(1)

Either the pattern or the action (including the enclosing brace characters) can be omitted. Pattern-action statements are separated by a semicolon or by a newline.

A missing pattern matches any record of input, and a missing action is equivalent to an action that writes the matched record of input to standard output.

Execution of the `nawk` program starts by first executing the actions associated with all `BEGIN` patterns in the order they occur in the program. Then each *file* operand (or standard input if no files were specified) is processed by reading data from the file until a record separator is seen (a newline character by default), splitting the current record into fields using the current value of `FS`, evaluating each pattern in the program in the order of occurrence, and executing the action associated with each pattern that matches the current record. The action for a matching pattern is executed before evaluating subsequent patterns. Last, the actions associated with all `END` patterns is executed in the order they occur in the program.

### Expressions in nawk

Expressions describe computations used in *patterns* and *actions*. In the following table, valid expression operations are given in groups from highest precedence first to lowest precedence last, with equal-precedence operators grouped between horizontal lines. In expression evaluation, where the grammar is formally ambiguous, higher precedence operators are evaluated before lower precedence operators. In this table *expr*, *expr1*, *expr2*, and *expr3* represent any expression, while *lvalue* represents any entity that can be assigned to (that is, on the left side of an assignment operator).

Syntax	Name	Type of Result	Associativity
$( expr )$	Grouping	type of <i>expr</i>	n/a
$\$expr$	Field reference	string	n/a
$++ lvalue$	Pre-increment	numeric	n/a
$-- lvalue$	Pre-decrement	numeric	n/a
$lvalue ++$	Post-increment	numeric	n/a
$lvalue --$	Post-decrement	numeric	n/a
$expr \wedge expr$	Exponentiation	numeric	right
$! expr$	Logical not	numeric	n/a
$+ expr$	Unary plus	numeric	n/a
$- expr$	Unary minus	numeric	n/a
$expr * expr$	Multiplication	numeric	left
$expr / expr$	Division	numeric	left
$expr \% expr$	Modulus	numeric	left
$expr + expr$	Addition	numeric	left

<b>Syntax</b>	<b>Name</b>	<b>Type of Result</b>	<b>Associativity</b>
<i>expr - expr</i>	Subtraction	numeric	left
<i>expr expr</i>	String concatenation	string	left
<i>expr &lt; expr</i>	Less than	numeric	none
<i>expr &lt;= expr</i>	Less than or equal to	numeric	none
<i>expr != expr</i>	Not equal to	numeric	none
<i>expr == expr</i>	Equal to	numeric	none
<i>expr &gt; expr</i>	Greater than	numeric	none
<i>expr &gt;= expr</i>	Greater than or equal to	numeric	none
<i>expr ~ expr</i>	ERE match	numeric	none
<i>expr !~ expr</i>	ERE non-match	numeric	none
<i>expr in array</i>	Array membership	numeric	left
<i>( index ) in array</i>	Multi-dimension array membership	numeric	left
<i>expr &amp;&amp; expr</i>	Logical AND	numeric	left
<i>expr    expr</i>	Logical OR	numeric	left
<i>expr1 ? expr2 : expr3</i>	Conditional expression	type of selected <i>expr2</i> or <i>expr3</i>	right
<i>lvalue ^= expr</i>	Exponentiation assignment	numeric	right
<i>lvalue %= expr</i>	Modulus assignment	numeric	right
<i>lvalue *= expr</i>	Multiplication assignment	numeric	right
<i>lvalue /= expr</i>	Division assignment	numeric	right
<i>lvalue += expr</i>	Addition assignment	numeric	right
<i>lvalue -= expr</i>	Subtraction assignment	numeric	right
<i>lvalue = expr</i>	Assignment	type of <i>expr</i>	right

## nawk(1)

Each expression has either a string value, a numeric value or both. Except as stated for specific contexts, the value of an expression is implicitly converted to the type needed for the context in which it is used. A string value is converted to a numeric value by the equivalent of the following calls:

```
setlocale(LC_NUMERIC, "");  
numeric_value = atof(string_value);
```

A numeric value that is exactly equal to the value of an integer is converted to a string by the equivalent of a call to the `sprintf` function with the string `%d` as the `fmt` argument and the numeric value being converted as the first and only `expr` argument. Any other numeric value is converted to a string by the equivalent of a call to the `sprintf` function with the value of the variable `CONVFMT` as the `fmt` argument and the numeric value being converted as the first and only `expr` argument.

A string value is considered to be a *numeric string* in the following case:

1. Any leading and trailing blank characters is ignored.
2. If the first unignored character is a `+` or `-`, it is ignored.
3. If the remaining unignored characters would be lexically recognized as a `NUMBER` token, the string is considered a *numeric string*.

If a `-` character is ignored in the above steps, the numeric value of the *numeric string* is the negation of the numeric value of the recognized `NUMBER` token. Otherwise the numeric value of the *numeric string* is the numeric value of the recognized `NUMBER` token. Whether or not a string is a *numeric string* is relevant only in contexts where that term is used in this section.

When an expression is used in a Boolean context, if it has a numeric value, a value of zero is treated as false and any other value is treated as true. Otherwise, a string value of the null string is treated as false and any other value is treated as true. A Boolean context is one of the following:

- the first subexpression of a conditional expression.
- an expression operated on by logical NOT, logical AND, or logical OR.
- the second expression of a `for` statement.
- the expression of an `if` statement.
- the expression of the `while` clause in either a `while` or `do . . . while` statement.
- an expression used as a pattern (as in Overall Program Structure).

The `nawk` language supplies arrays that are used for storing numbers or strings. Arrays need not be declared. They are initially empty, and their sizes changes dynamically. The subscripts, or element identifiers, are strings, providing a type of associative array capability. An array name followed by a subscript within square brackets can be used as an *lvalue* and as an expression, as described in the grammar. Unsubscripted array names are used in only the following contexts:

- a parameter in a function definition or function call.

- the NAME token following any use of the keyword `in`.

A valid array *index* consists of one or more comma-separated expressions, similar to the way in which multi-dimensional arrays are indexed in some programming languages. Because `nawk` arrays are really one-dimensional, such a comma-separated list is converted to a single string by concatenating the string values of the separate expressions, each separated from the other by the value of the `SUBSEP` variable.

Thus, the following two index operations are equivalent:

```
var[expr1, expr2, ... exprn]
var[expr1 SUBSEP expr2 SUBSEP ... SUBSEP exprn]
```

A multi-dimensioned *index* used with the `in` operator must be put in parentheses. The `in` operator, which tests for the existence of a particular array element, does not create the element if it does not exist. Any other reference to a non-existent array element automatically creates it.

## Variables and Special Variables

Variables can be used in an `nawk` program by referencing them. With the exception of function parameters, they are not explicitly declared. Uninitialized scalar variables and array elements have both a numeric value of zero and a string value of the empty string.

Field variables are designated by a `$` followed by a number or numerical expression. The effect of the field number *expression* evaluating to anything other than a non-negative integer is unspecified. Uninitialized variables or string values need not be converted to numeric values in this context. New field variables are created by assigning a value to them. References to non-existent fields (that is, fields after `$NF`) produce the null string. However, assigning to a non-existent field (for example, `$(NF+2) = 5`) increases the value of `NF`, create any intervening fields with the null string as their values and cause the value of `$0` to be recomputed, with the fields being separated by the value of `OFS`. Each field variable has a string value when created. If the string, with any occurrence of the decimal-point character from the current locale changed to a period character, is considered a *numeric string* (see *Expressions in nawk* above), the field variable also has the numeric value of the *numeric string*.

## `/usr/bin/nawk,` `/usr/xpg4/bin/awk`

`nawk` sets the following special variables that are supported by both `/usr/bin/nawk` and `/usr/xpg4/bin/awk`:

<code>ARGC</code>	The number of elements in the <code>ARGV</code> array.
<code>ARGV</code>	An array of command line arguments, excluding options and the <i>program</i> argument, numbered from zero to <code>ARGC-1</code> .

## nawk(1)

	<p>The arguments in <code>ARGV</code> can be modified or added to; <code>ARGC</code> can be altered. As each input file ends, <code>nawk</code> treats the next non-null element of <code>ARGV</code>, up to the current value of <code>ARGC-1</code>, inclusive, as the name of the next input file. Setting an element of <code>ARGV</code> to null means that it is not treated as an input file. The name <code>-</code> indicates the standard input. If an argument matches the format of an <i>assignment</i> operand, this argument is treated as an assignment rather than a <i>file</i> argument.</p>
ENVIRON	<p>The variable <code>ENVIRON</code> is an array representing the value of the environment. The indices of the array are strings consisting of the names of the environment variables, and the value of each array element is a string consisting of the value of that variable. If the value of an environment variable is considered a <i>numeric string</i>, the array element also has its numeric value.</p> <p>In all cases where <code>nawk</code> behavior is affected by environment variables (including the environment of any commands that <code>nawk</code> executes via the <code>system</code> function or via pipeline redirections with the <code>print</code> statement, the <code>printf</code> statement, or the <code>getline</code> function), the environment used is the environment at the time <code>nawk</code> began executing.</p>
FILENAME	<p>A pathname of the current input file. Inside a <code>BEGIN</code> action the value is undefined. Inside an <code>END</code> action the value is the name of the last input file processed.</p>
FNR	<p>The ordinal number of the current record in the current file. Inside a <code>BEGIN</code> action the value is zero. Inside an <code>END</code> action the value is the number of the last record processed in the last file processed.</p>
FS	<p>Input field separator regular expression; a space character by default.</p>
NF	<p>The number of fields in the current record. Inside a <code>BEGIN</code> action, the use of <code>NF</code> is undefined unless a <code>getline</code> function without a <i>var</i> argument is executed previously. Inside an <code>END</code> action, <code>NF</code> retains the value it had for the last record read, unless a subsequent, redirected, <code>getline</code> function without a <i>var</i> argument is performed prior to entering the <code>END</code> action.</p>
NR	<p>The ordinal number of the current record from the start of input. Inside a <code>BEGIN</code> action the value is zero. Inside an <code>END</code> action the value is the number of the last record processed.</p>
OFMT	<p>The <code>printf</code> format for converting numbers to strings in output statements <code>"%.6g"</code> by default. The result of the conversion is unspecified if the value of <code>OFMT</code> is not a floating-point format specification.</p>

OFS	The <code>print</code> statement output field separator; a space character by default.
ORS	The <code>print</code> output record separator; a newline character by default.
LENGTH	The length of the string matched by the <code>match</code> function.
RS	The first character of the string value of <code>RS</code> is the input record separator; a newline character by default. If <code>RS</code> contains more than one character, the results are unspecified. If <code>RS</code> is null, then records are separated by sequences of one or more blank lines. Leading or trailing blank lines do not produce empty records at the beginning or end of input, and the field separator is always newline, no matter what the value of <code>FS</code> .
RSTART	The starting position of the string matched by the <code>match</code> function, numbering from 1. This is always equivalent to the return value of the <code>match</code> function.
SUBSEP	The subscript separator string for multi-dimensional arrays. The default value is 1

**/usr/xpg4/bin/awk**

The following variable is supported for `/usr/xpg4/bin/awk` only:

CONVFMT	The <code>printf</code> format for converting numbers to strings (except for output statements, where <code>OFMT</code> is used). The default is <code>% . 6g</code> .
---------	--

**Regular Expressions**

The `nawk` utility makes use of the extended regular expression notation (see `regex(5)`) except that it allows the use of C-language conventions to escape special characters within the EREs, namely `\`, `\a`, `\b`, `\f`, `\n`, `\r`, `\t`, `\v`, and those specified in the following table. These escape sequences are recognized both inside and outside bracket expressions. Note that records need not be separated by newline characters and string constants can contain newline characters, so even the `\n` sequence is valid in `nawk` EREs. Using a slash character within the regular expression requires escaping as shown in the table below:

Escape Sequence	Description	Meaning
<code>\"</code>	Backslash quotation-mark	Quotation-mark character
<code>\/</code>	Backslash slash	Slash character
<code>\ddd</code>	A backslash character followed by the longest sequence of one, two, or three octal-digit characters (01234567). If all of the digits are 0, (that is, representation of the NULL character), the behavior is undefined.	The character encoded by the one-, two- or three-digit octal integer. Multi-byte characters require multiple, concatenated escape sequences, including the leading <code>\</code> for each byte.

nawk(1)

---

<code>\c</code>	A backslash character followed by any character not described in this table or special characters ( <code>\\</code> , <code>\a</code> , <code>\b</code> , <code>\f</code> , <code>\n</code> , <code>\r</code> , <code>\t</code> , <code>\v</code> ).	Undefined
-----------------	--	-----------

---

A regular expression can be matched against a specific field or string by using one of the two regular expression matching operators, `~` and `! ~`. These operators interpret their right-hand operand as a regular expression and their left-hand operand as a string. If the regular expression matches the string, the `~` expression evaluates to the value 1, and the `! ~` expression evaluates to the value 0. If the regular expression does not match the string, the `~` expression evaluates to the value 0, and the `! ~` expression evaluates to the value 1. If the right-hand operand is any expression other than the lexical token `ERE`, the string value of the expression is interpreted as an extended regular expression, including the escape conventions described above. Notice that these same escape conventions also are applied in the determining the value of a string literal (the lexical token `STRING`), and is applied a second time when a string literal is used in this context.

When an `ERE` token appears as an expression in any context other than as the right-hand of the `~` or `! ~` operator or as one of the built-in function arguments described below, the value of the resulting expression is the equivalent of:

```
$0 ~ /ere/
```

The `ere` argument to the `gsub`, `match`, `sub` functions, and the `fs` argument to the `split` function (see `String Functions`) is interpreted as extended regular expressions. These can be either `ERE` tokens or arbitrary expressions, and are interpreted in the same manner as the right-hand side of the `~` or `! ~` operator.

An extended regular expression can be used to separate fields by using the `-F ERE` option or by assigning a string containing the expression to the built-in variable `FS`. The default value of the `FS` variable is a single space character. The following describes `FS` behavior:

1. If `FS` is a single character:
  - If `FS` is the space character, skip leading and trailing blank characters; fields are delimited by sets of one or more blank characters.
  - Otherwise, if `FS` is any other character `c`, fields are delimited by each single occurrence of `c`.
2. Otherwise, the string value of `FS` is considered to be an extended regular expression. Each occurrence of a sequence matching the extended regular expression delimits fields.

Except in the `gsub`, `match`, `split`, and `sub` built-in functions, regular expression matching is based on input records. That is, record separator characters (the first character of the value of the variable `RS`, a newline character by default) cannot be embedded in the expression, and no expression matches the record separator character. If the record separator is not a newline character, newline characters

embedded in the expression can be matched. In those four built-in functions, regular expression matching are based on text strings. So, any character (including the newline character and the record separator) can be embedded in the pattern and an appropriate pattern will match any character. However, in all nawk regular expression matching, the use of one or more NUL characters in the pattern, input record or text string produces undefined results.

**Patterns** A *pattern* is any valid *expression*, a range specified by two expressions separated by comma, or one of the two special patterns BEGIN or END.

**Special Patterns** The nawk utility recognizes two special patterns, BEGIN and END. Each BEGIN pattern is matched once and its associated action executed before the first record of input is read (except possibly by use of the `getline` function in a prior BEGIN action) and before command line assignment is done. Each END pattern is matched once and its associated action executed after the last record of input has been read. These two patterns have associated actions.

BEGIN and END do not combine with other patterns. Multiple BEGIN and END patterns are allowed. The actions associated with the BEGIN patterns are executed in the order specified in the program, as are the END actions. An END pattern can precede a BEGIN pattern in a program.

If an nawk program consists of only actions with the pattern BEGIN, and the BEGIN action contains no `getline` function, nawk exits without reading its input when the last statement in the last BEGIN action is executed. If an nawk program consists of only actions with the pattern END or only actions with the patterns BEGIN and END, the input is read before the statements in the END actions are executed.

**Expression Patterns** An expression pattern is evaluated as if it were an expression in a Boolean context. If the result is true, the pattern is considered to match, and the associated action (if any) is executed. If the result is false, the action is not executed.

**Pattern Ranges** A pattern range consists of two expressions separated by a comma. In this case, the action is performed for all records between a match of the first expression and the following match of the second expression, inclusive. At this point, the pattern range can be repeated starting at input records subsequent to the end of the matched range.

**Actions** An action is a sequence of statements. A statement may be one of the following:

```
if ( expression ) statement [ else statement ]
while ( expression ) statement
do statement while ( expression )
for ( expression ; expression ; expression ) statement
for ( var in array ) statement
delete array[subscript] #delete an array element
break
continue
{ [ statement ] . . . }
expression          # commonly variable = expression
print [ expression-list ] [ >expression ]
printf format [ ,expression-list ] [ >expression ]
next                # skip remaining patterns on this input line
```

## nawk(1)

```
exit [expr] # skip the rest of the input; exit status is expr
return [expr]
```

Any single statement can be replaced by a statement list enclosed in braces. The statements are terminated by newline characters or semicolons, and are executed sequentially in the order that they appear.

The `next` statement causes all further processing of the current input record to be abandoned. The behavior is undefined if a `next` statement appears or is invoked in a `BEGIN` or `END` action.

The `exit` statement invokes all `END` actions in the order in which they occur in the program source and then terminate the program without reading further input. An `exit` statement inside an `END` action terminates the program without further execution of `END` actions. If an expression is specified in an `exit` statement, its numeric value is the exit status of `nawk`, unless subsequent errors are encountered or a subsequent `exit` statement with an expression is executed.

### Output Statements

Both `print` and `printf` statements write to standard output by default. The output is written to the location specified by `output_redirection` if one is supplied, as follows:

```
> expression >> expression | expression
```

In all cases, the *expression* is evaluated to produce a string that is used as a full pathname to write into (for `>` or `>>`) or as a command to be executed (for `|`). Using the first two forms, if the file of that name is not currently open, it is opened, creating it if necessary and using the first form, truncating the file. The output then is appended to the file. As long as the file remains open, subsequent calls in which *expression* evaluates to the same string value simply appends output to the file. The file remains open until the `close` function, which is called with an expression that evaluates to the same string value.

The third form writes output onto a stream piped to the input of a command. The stream is created if no stream is currently open with the value of *expression* as its command name. The stream created is equivalent to one created by a call to the `popen(3C)` function with the value of *expression* as the *command* argument and a value of `w` as the *mode* argument. As long as the stream remains open, subsequent calls in which *expression* evaluates to the same string value writes output to the existing stream. The stream will remain open until the `close` function is called with an expression that evaluates to the same string value. At that time, the stream is closed as if by a call to the `pclose` function.

These output statements take a comma-separated list of *expression s* referred in the grammar by the non-terminal symbols `expr_list`, `print_expr_list` or `print_expr_list_opt`. This list is referred to here as the *expression list*, and each member is referred to as an *expression argument*.

The `print` statement writes the value of each expression argument onto the indicated output stream separated by the current output field separator (see variable `OFS` above), and terminated by the output record separator (see variable `ORS` above). All

expression arguments is taken as strings, being converted if necessary; with the exception that the `printf` format in `OFMT` is used instead of the value in `CONVFMT`. An empty expression list stands for the whole input record (`$0`).

The `printf` statement produces output based on a notation similar to the File Format Notation used to describe file formats in this document. Output is produced as specified with the first expression argument as the string `format` and subsequent expression arguments as the strings `arg1` to `argn`, inclusive, with the following exceptions:

1. The *format* is an actual character string rather than a graphical representation. Therefore, it cannot contain empty character positions. The space character in the *format* string, in any context other than a *flag* of a conversion specification, is treated as an ordinary character that is copied to the output.
2. If the character set contains a Delta character and that character appears in the *format* string, it is treated as an ordinary character that is copied to the output.
3. The *escape sequences* beginning with a backslash character is treated as sequences of ordinary characters that are copied to the output. Note that these same sequences is interpreted lexically by `nawk` when they appear in literal strings, but they is not treated specially by the `printf` statement.
4. A *field width* or *precision* can be specified as the `*` character instead of a digit string. In this case the next argument from the expression list is fetched and its numeric value taken as the field width or precision.
5. The implementation does not precede or follow output from the `d` or `u` conversion specifications with blank characters not specified by the *format* string.
6. The implementation does not precede output from the `o` conversion specification with leading zeros not specified by the *format* string.
7. For the `c` conversion specification: if the argument has a numeric value, the character whose encoding is that value is output. If the value is zero or is not the encoding of any character in the character set, the behavior is undefined. If the argument does not have a numeric value, the first character of the string value will be output; if the string does not contain any characters the behavior is undefined.
8. For each conversion specification that consumes an argument, the next expression argument will be evaluated. With the exception of the `c` conversion, the value will be converted to the appropriate type for the conversion specification.
9. If there are insufficient expression arguments to satisfy all the conversion specifications in the *format* string, the behavior is undefined.
10. If any character sequence in the *format* string begins with a `%` character, but does not form a valid conversion specification, the behavior is unspecified.

Both `print` and `printf` can output at least `{LINE_MAX}` bytes.

## Functions

The `nawk` language has a variety of built-in functions: arithmetic, string, input/output and general.

nawk(1)

**Arithmetic Functions**

The arithmetic functions, except for `int`, are based on the ISO C standard. The behavior is undefined in cases where the ISO C standard specifies that an error be returned or that the behavior is undefined. Although the grammar permits built-in functions to appear with no arguments or parentheses, unless the argument or parentheses are indicated as optional in the following list (by displaying them within the [ ] brackets), such use is undefined.

- `atan2(y,x)`      Return arctangent of  $y/x$ .
- `cos(x)`          Return cosine of  $x$ , where  $x$  is in radians.
- `sin(x)`          Return sine of  $x$ , where  $x$  is in radians.
- `exp(x)`          Return the exponential function of  $x$ .
- `log(x)`          Return the natural logarithm of  $x$ .
- `sqrt(x)`          Return the square root of  $x$ .
- `int(x)`          Truncate its argument to an integer. It will be truncated toward 0 when  $x > 0$ .
- `rand()`            Return a random number  $n$ , such that  $0 \leq n < 1$ .
- `srand([expr])`    Set the seed value for `rand` to *expr* or use the time of day if *expr* is omitted. The previous seed value will be returned.

**String Functions**

The string functions in the following list shall be supported. Although the grammar permits built-in functions to appear with no arguments or parentheses, unless the argument or parentheses are indicated as optional in the following list (by displaying them within the [ ] brackets), such use is undefined.

- `gsub(ere, repl[, in])`      Behave like `sub` (see below), except that it will replace all occurrences of the regular expression (like the `ed` utility `global substitute`) in  $\$0$  or in the *in* argument, when specified.
- `index(s,t)`          Return the position, in characters, numbering from 1, in string  $s$  where string  $t$  first occurs, or zero if it does not occur at all.
- `length([(s)])`      Return the length, in characters, of its argument taken as a string, or of the whole record,  $\$0$ , if there is no argument.
- `match(s, ere)`      Return the position, in characters, numbering from 1, in string  $s$  where the extended regular expression *ere* occurs, or zero if it does not occur at all. `RSTART` will be set to the starting position (which is the

<code>split(s,a[,fs])</code>	<p>same as the returned value), zero if no match is found; RLENGTH will be set to the length of the matched string, -1 if no match is found.</p> <p>Split the string <i>s</i> into array elements <i>a</i>[1], <i>a</i>[2], . . . , <i>a</i>[<i>n</i>], and return <i>n</i>. The separation will be done with the extended regular expression <i>fs</i> or with the field separator FS if <i>fs</i> is not given. Each array element will have a string value when created. If the string assigned to any array element, with any occurrence of the decimal-point character from the current locale changed to a period character, would be considered a <i>numeric string</i>; the array element will also have the numeric value of the <i>numeric string</i>. The effect of a null string as the value of <i>fs</i> is unspecified.</p>
<code>sprintf(fmt,expr,expr,...)</code>	<p>Format the expressions according to the printf format given by <i>fmt</i> and return the resulting string.</p>
<code>sub(ere,repl[,in])</code>	<p>Substitute the string <i>repl</i> in place of the first instance of the extended regular expression <i>ERE</i> in string <i>in</i> and return the number of substitutions. An ampersand ( &amp; ) appearing in the string <i>repl</i> will be replaced by the string from <i>in</i> that matches the regular expression. For each occurrence of backslash ( \ ) encountered when scanning the string <i>repl</i> from beginning to end, the next character is taken literally and loses its special meaning (for example, \&amp; will be interpreted as a literal ampersand character). Except for &amp; and \, it is unspecified what the special meaning of any such character is. If <i>in</i> is specified and it is not an <i>lvalue</i> the behavior is undefined. If <i>in</i> is omitted, nawk will substitute in the current record (\$0) .</p>
<code>substr(s,m[,n])</code>	<p>Return the at most <i>n</i>-character substring of <i>s</i> that begins at position <i>m</i>, numbering from 1. If <i>n</i> is missing, the length of the substring will be limited by the length of the string <i>s</i>.</p>

nawk(1)

<code>tolower(s)</code>	Return a string based on the string <i>s</i> . Each character in <i>s</i> that is an upper-case letter specified to have a <code>tolower</code> mapping by the <code>LC_CTYPE</code> category of the current locale will be replaced in the returned string by the lower-case letter specified by the mapping. Other characters in <i>s</i> will be unchanged in the returned string.
<code>toupper(s)</code>	Return a string based on the string <i>s</i> . Each character in <i>s</i> that is a lower-case letter specified to have a <code>toupper</code> mapping by the <code>LC_CTYPE</code> category of the current locale will be replaced in the returned string by the upper-case letter specified by the mapping. Other characters in <i>s</i> will be unchanged in the returned string.

All of the preceding functions that take *ERE* as a parameter expect a pattern or a string valued expression that is a regular expression as defined below.

### Input/Output and General Functions

The input/output and general functions are:

<code>close (expression)</code>	Close the file or pipe opened by a <code>print</code> or <code>printf</code> statement or a call to <code>getline</code> with the same string-valued <i>expression</i> . If the close was successful, the function will return 0; otherwise, it will return non-zero.
<code>expression   getline [var]</code>	Read a record of input from a stream piped from the output of a command. The stream will be created if no stream is currently open with the value of <i>expression</i> as its command name. The stream created will be equivalent to one created by a call to the <code>popen</code> function with the value of <i>expression</i> as the <i>command</i> argument and a value of <code>r</code> as the <i>mode</i> argument. As long as the stream remains open, subsequent calls in which <i>expression</i> evaluates to the same string value will read subsequent records from the file. The stream will remain open until the <code>close</code> function is called with an expression that evaluates to the same string value. At that time, the stream will be closed as if by a call to the <code>pclose</code> function. If <i>var</i> is missing, <code>\$0</code> and <code>NF</code> will be set; otherwise, <i>var</i> will be set.

<pre>getline</pre>	<p>The <code>getline</code> operator can form ambiguous constructs when there are operators that are not in parentheses (including concatenate) to the left of the <code> </code> (to the beginning of the expression containing <code>getline</code>). In the context of the <code>\$</code> operator, <code> </code> behaves as if it had a lower precedence than <code>\$</code>. The result of evaluating other operators is unspecified, and all such uses of portable applications must be put in parentheses properly.</p>
<pre>getline var</pre>	<p>Set <code>\$0</code> to the next input record from the current input file. This form of <code>getline</code> will set the <code>NF</code>, <code>NR</code>, and <code>FNR</code> variables.</p>
<pre>getline [var] &lt; expression</pre>	<p>Set variable <code>var</code> to the next input record from the current input file. This form of <code>getline</code> will set the <code>FNR</code> and <code>NR</code> variables.</p> <p>Read the next record of input from a named file. The <code>expression</code> will be evaluated to produce a string that is used as a full pathname. If the file of that name is not currently open, it will be opened. As long as the stream remains open, subsequent calls in which <code>expression</code> evaluates to the same string value will read subsequent records from the file. The file will remain open until the <code>close</code> function is called with an expression that evaluates to the same string value. If <code>var</code> is missing, <code>\$0</code> and <code>NF</code> will be set; otherwise, <code>var</code> will be set.</p> <p>The <code>getline</code> operator can form ambiguous constructs when there are binary operators that are not in parentheses (including concatenate) to the right of the <code>&lt;</code> (up to the end of the expression containing the <code>getline</code>). The result of evaluating such a construct is unspecified, and all such uses of portable applications must be put in parentheses properly.</p>
<pre>system(expression)</pre>	<p>Execute the command given by <code>expression</code> in a manner equivalent to the <code>system(3C)</code> function and return the exit status of the command.</p>

nawk(1)

All forms of `getline` will return 1 for successful input, 0 for end of file, and -1 for an error.

Where strings are used as the name of a file or pipeline, the strings must be textually identical. The terminology “same string value” implies that “equivalent strings”, even those that differ only by space characters, represent different files.

### User-defined Functions

The nawk language also provides user-defined functions. Such functions can be defined as:

```
function name (args, . . .) { statements }
```

A function can be referred to anywhere in an nawk program; in particular, its use can precede its definition. The scope of a function will be global.

Function arguments can be either scalars or arrays; the behavior is undefined if an array name is passed as an argument that the function uses as a scalar, or if a scalar expression is passed as an argument that the function uses as an array. Function arguments will be passed by value if scalar and by reference if array name. Argument names will be local to the function; all other variable names will be global. The same name will not be used as both an argument name and as the name of a function or a special nawk variable. The same name must not be used both as a variable name with global scope and as the name of a function. The same name must not be used within the same scope both as a scalar variable and as an array.

The number of parameters in the function definition need not match the number of parameters in the function call. Excess formal parameters can be used as local variables. If fewer arguments are supplied in a function call than are in the function definition, the extra parameters that are used in the function body as scalars will be initialized with a string value of the null string and a numeric value of zero, and the extra parameters that are used in the function body as arrays will be initialized as empty arrays. If more arguments are supplied in a function call than are in the function definition, the behavior is undefined.

When invoking a function, no white space can be placed between the function name and the opening parenthesis. Function calls can be nested and recursive calls can be made upon functions. Upon return from any nested or recursive function call, the values of all of the calling function’s parameters will be unchanged, except for array parameters passed by reference. The `return` statement can be used to return a value. If a `return` statement appears outside of a function definition, the behavior is undefined.

In the function definition, newline characters are optional before the opening brace and after the closing brace. Function definitions can appear anywhere in the program where a *pattern-action* pair is allowed.

### USAGE

The `index`, `length`, `match`, and `substr` functions should not be confused with similar functions in the ISO C standard; the nawk versions deal with characters, while the ISO C standard deals with bytes.

Because the concatenation operation is represented by adjacent expressions rather than an explicit operator, it is often necessary to use parentheses to enforce the proper evaluation precedence.

See `largefile(5)` for the description of the behavior of `nawk` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**EXAMPLES**

The `nawk` program specified in the command line is most easily specified within single-quotes (for example, `'program'`) for applications using `sh`, because `nawk` programs commonly contain characters that are special to the shell, including double-quotes. In the cases where a `nawk` program contains single-quote characters, it is usually easiest to specify most of the program as strings within single-quotes concatenated by the shell with quoted single-quote characters. For example:

```
nawk '/\''/ { print "quote:", $0 }
```

prints all lines from the standard input containing a single-quote character, prefixed with `quote:`.

The following are examples of simple `nawk` programs:

**EXAMPLE 1** Write to the standard output all input lines for which field 3 is greater than 5:

```
$3 > 5
```

**EXAMPLE 2** Write every tenth line:

```
(NR % 10) == 0
```

**EXAMPLE 3** Write any line with a substring matching the regular expression:

```
/(G|D)(2[0-9][[:alpha:]]*)/
```

**EXAMPLE 4** Print any line with a substring containing a G or D, followed by a sequence of digits and characters:

This example uses character classes `digit` and `alpha` to match language-independent digit and alphabetic characters, respectively.

```
/(G|D)([[:digit:]][[:alpha:]]*)/
```

**EXAMPLE 5** Write any line in which the second field matches the regular expression and the fourth field does not:

```
$2 ~ /xyz/ && $4 !~ /xyz/
```

**EXAMPLE 6** Write any line in which the second field contains a backslash:

```
$2 ~ /\
```

nawk(1)

**EXAMPLE 7** Write any line in which the second field contains a backslash (alternate method):

Notice that backslash escapes are interpreted twice, once in lexical processing of the string and once in processing the regular expression.

```
$2 ~ "\\\""
```

**EXAMPLE 8** Write the second to the last and the last field in each line, separating the fields by a colon:

```
{OFS=":";print $(NF-1), $NF}
```

**EXAMPLE 9** Write the line number and number of fields in each line:

The three strings representing the line number, the colon and the number of fields are concatenated and that string is written to standard output.

```
{print NR ":" NF}
```

**EXAMPLE 10** Write lines longer than 72 characters:

```
{length($0) > 72}
```

**EXAMPLE 11** Write first two fields in opposite order separated by the OFS:

```
{ print $2, $1 }
```

**EXAMPLE 12** Same, with input fields separated by comma or space and tab characters, or both:

```
BEGIN { FS = ",[\\t]*|[\\t]+" }  
      { print $2, $1 }
```

**EXAMPLE 13** Add up first column, print sum and average:

```
      {s += $1 }  
END {print "sum is ", s, " average is", s/NR}
```

**EXAMPLE 14** Write fields in reverse order, one per line (many lines out for each line in):

```
{ for (i = NF; i > 0; --i) print $i }
```

**EXAMPLE 15** Write all lines between occurrences of the strings "start" and "stop":

```
/start/, /stop/
```

**EXAMPLE 16** Write all lines whose first field is different from the previous one:

```
$1 != prev { print; prev = $1 }
```

**EXAMPLE 17** Simulate the echo command:

```
BEGIN {
    for (i = 1; i < ARGV; ++i)
        printf "%s%s", ARGV[i], i==ARGV-1?"\n":""
}
```

**EXAMPLE 18** Write the path prefixes contained in the PATH environment variable, one per line:

```
BEGIN {
    n = split (ENVIRON["PATH"], path, ":")
    for (i = 1; i <= n; ++i)
        print path[i]
}
```

**EXAMPLE 19** Print the file "input", filling in page numbers starting at 5:

If there is a file named `input` containing page headers of the form

Page#

and a file named `program` that contains

```
/Page/{ $2 = n++; }
{ print }
```

then the command line

```
nawk -f program n=5 input
```

will print the file `input`, filling in page numbers starting at 5.

## ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect execution: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

`LC_NUMERIC` Determine the radix character used when interpreting numeric input, performing conversions between numeric and string values and formatting numeric output. Regardless of locale, the period character (the decimal-point character of the POSIX locale) is the decimal-point character recognized in processing `awk` programs (including assignments in command-line arguments).

## EXIT STATUS

The following exit values are returned:

0 All input files were processed successfully.  
>0 An error occurred.

The exit status can be altered within the program by using an `exit` expression.

nawk(1)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

`/usr/bin/nawk`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

`/usr/xpg4/bin/awk`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4

**SEE ALSO** [awk\(1\)](#), [ed\(1\)](#), [egrep\(1\)](#), [grep\(1\)](#), [lex\(1\)](#), [sed\(1\)](#), [popen\(3C\)](#), [printf\(3C\)](#), [system\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [regex\(5\)](#), [XPG4\(5\)](#)

Aho, A. V., B. W. Kernighan, and P. J. Weinberger, *The AWK Programming Language*, Addison-Wesley, 1988.

**DIAGNOSTICS** If any *file* operand is specified and the named file cannot be accessed, `nawk` will write a diagnostic message to standard error and terminate without any further action.

If the program specified by either the *program* operand or a *progfile* operand is not a valid `nawk` program (as specified in `EXTENDED DESCRIPTION`), the behavior is undefined.

**NOTES** Input white space is not preserved on output if fields are involved.

There are no explicit conversions between numbers and strings. To force an expression to be treated as a number add 0 to it; to force it to be treated as a string concatenate the null string (" ") to it.

<b>NAME</b>	nca, snca – the Solaris Network Cache and Accelerator (NCA)	
<b>DESCRIPTION</b>	<p>The Solaris Network Cache and Accelerator (“NCA”) is a kernel module designed to provide improved web server performance. The kernel module, <code>ncakmod</code>, services HTTP requests. To improve the performance of servicing HTTP requests, the NCA kernel module maintains an in-kernel cache of web pages. If the NCA kernel module cannot service the request itself, it passes the request to the <code>httpd</code> daemon (<code>httpd</code>). It uses either a sockets interface, with family type designated <code>PF_NCA</code>, or a private Solaris doors interface that is based on the Solaris doors RPC mechanism, to pass the request.</p> <p>To use the sockets interface, the web server must open a socket of family type <code>PF_NCA</code>. The <code>PF_NCA</code> family supports only <code>SOCK_STREAM</code> and protocol 0, otherwise an error occurs.</p> <p>The following features are not presently supported:</p> <ul style="list-style-type: none"> <li>■ You cannot initiate a connection from a <code>PF_NCA</code> type socket. The <code>connect(3SOCKET)</code> interface on <code>PF_NCA</code> will fail.</li> <li>■ System calls that are associated with type <code>SO_DGRAM</code>, such as <code>send()</code>, <code>sendto()</code>, <code>sendmsg()</code>, <code>recv()</code>, <code>recvfrom()</code>, and <code>recvmsg()</code>, will fail.</li> <li>■ You cannot set TCP or IP options on a <code>PF_NCA</code> type socket through <code>setsockopt(3SOCKET)</code>.</li> </ul> <p>The NCA cache consistency is maintained by honoring HTTP headers that deal with a given content type and expiration date, much the same way as a proxy cache.</p> <p>For configuration information, see <i>System Administration Guide: IP Services</i></p> <p>When native <code>PF_NCA</code> socket support does not exist in the web server, the <code>ncad_addr(4)</code> interface must be used to provide NCA support in that web server.</p> <p>NCA is intended to be run on a dedicated web server. Running other large processes while running NCA might cause undesirable behavior.</p> <p>NCA supports the logging of in-kernel cache hits. See <code>ncalogd.conf(4)</code>. NCA stores logs in a binary format. Use the <code>ncab2clf(1)</code> utility to convert the log from a binary format to the Common Log File format.</p>	
<b>FILES</b>	<p><code>/etc/nca/ncakmod.conf</code></p> <p><code>/etc/nca/ncalogd.conf</code></p> <p><code>/etc/nca/nca.if</code></p> <p><code>/etc/hostname.{0-9}</code></p> <p><code>/etc/hosts</code></p>	<p>Lists configuration parameters for NCA.</p> <p>Lists configuration parameters for NCA logging.</p> <p>Lists the physical interfaces on which NCA will run.</p> <p>Lists all physical interfaces configured on the server.</p> <p>Lists all host names associated with the server. Entries in this file must match with</p>

nca(1)

entries in `/etc/hostname.{0-9}` for NCA to function.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

<b>NAME</b>	ncab2clf – convert binary log file to Common Log File format
<b>SYNOPSIS</b>	<code>/usr/bin/ncab2clf [-Dhv] [-i <i>input-file</i>] [-o <i>output-file</i>] [-b <i>size</i>] [-n <i>number</i>] [-s <i>datetime</i>]</code>
<b>DESCRIPTION</b>	The <code>ncab2clf</code> command is used to convert the log file generated by the Solaris Network Cache and Accelerator (“NCA”) from binary format, to Common Log File (“CLF”) format. If no <i>input-file</i> is specified, <code>ncab2clf</code> uses <code>stdin</code> . If no <i>output-file</i> is specified, the output goes to <code>stdout</code> .
<b>OPTIONS</b>	<p><code>-b</code> Specifies the binary-log-file blocking in kilobytes; the default is 64 Kbyte.</p> <p><code>-D</code> Specifies that direct I/O be disabled.</p> <p><code>-h</code> Prints usage message.</p> <p><code>-i <i>input-file</i></code> Specifies the input file.</p> <p><code>-n <i>number</i></code> Output <i>number</i> CLF records.</p> <p><code>-o <i>output-file</i></code> Specifies the output file.</p> <p><code>-s <i>datetime</i></code> Skip any records before the date and time specified in <i>datetime</i>. You can specify the date and time in CLF format or in the format specified by the <code>touch(1)</code> utility. CLF format is the dominant format, so <code>ncab2clf</code> first analyzes <i>datetime</i> assuming CLF.</p> <p><code>-v</code> Provides verbose output.</p>
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Converting a Binary File to a Common Log File Format</p> <p>The following example converts the binary file <code>/var/nca/logs/nca.blf</code> to a file <code>/var/nca/logs/nca.clf</code>, which is in Common Log File format.</p> <pre>example% ncab2clf -D -i /var/nca/logs/nca.blf -o /var/nca/logs/nca.clf</pre> <p><b>EXAMPLE 2</b> Converting Multiple Log Files</p> <p>The following script may be used to convert multiple log files. The directory designated by “*” must only contain log files.</p> <pre>#!/bin/ksh for filename in * do     ncab2clf -D &lt; \$filename &gt; \$filename.clf done</pre> <p><b>EXAMPLE 3</b> Using <code>-s</code> and <code>-n</code> on a Raw Device</p> <p>The following example shows how <code>ncab2clf</code> can be used on a raw device. If not using the <code>-n</code> option, the default is to convert all records from the starting location to the end of the file. The date and time specified with <code>-s</code>, below, is in CLF format.</p>

## ncab2clf(1)

**EXAMPLE 3** Using `-s` and `-n` on a Raw Device (Continued)

```
example% ncab2clf -s '10/Apr/2001:09:23:13' -n 100 < /dev/dsk/c2t1d0s6
```

**EXIT STATUS** The following exit values are returned:

0                   The file converted successfully  
>0                   An error occurred.

*System Administration Guide: IP Services*

**NOTES** The binary log files generated by NCA can become very large. When converting these large binary files, use the `-b` option to the `ncab2clf` command to help performance.

Direct I/O is a benefit to the user if the data being written does not come in as large chunks. However, if the user wishes to convert the log file in large chunks using the `-b` option, then direct I/O should be disabled by using the `-D` option.

<b>NAME</b>	ncakmod – start or stop the NCA kernel module							
<b>SYNOPSIS</b>	<code>/etc/init.d/ncakmod start   stop</code>							
<b>DESCRIPTION</b>	<p>ncakmod is used to start or stop the Solaris Network Cache and Accelerator (“NCA”) kernel module.</p> <p>When the <code>start</code> option is specified at the command-line, the NCA kernel module will be activated for all physical interfaces listed in the <code>nca.if</code> file. When the <code>ncakmod</code> command is invoked with the <code>stop</code> option, the NCA kernel module will print the following message:</p> <pre>To stop NCA, please set the status configuration parameter to disable in ncakmod.conf and then reboot your system. See the ncakmod.conf(4) manual page for more information.</pre> <p>Note that in order to properly stop NCA on your system, you must first edit the <code>ncakmod.conf(4)</code> file and set the status field to “disable,” then reboot your system.</p>							
<b>OPTIONS</b>	<code>start</code>	Starts the NCA kernel module.						
	<code>stop</code>	Describes the current method for stopping the NCA feature.						
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Starting and Stopping the NCA Feature</p> <p>The following command is used to start the NCA feature:</p> <pre>example% /etc/init.d/ncakmod start</pre>							
<b>FILES</b>	<code>/etc/init.d/ncakmod</code>	The NCA kernel module startup script.						
	<code>/etc/nca/ncakmod.conf</code>	Specifies configuration options for the NCA kernel module.						
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:

## newform(1)

<b>NAME</b>	newform – change the format of a text file
<b>SYNOPSIS</b>	<b>newform</b> [-s] [-itabspec] [-otabspec] [-bn] [-en] [-pn] [-an] [-f] [-cchar] [-ln] [filename...]
<b>DESCRIPTION</b>	<p>newform reads lines from the named <i>filenames</i>, or the standard input if no input file is named, and reproduces the lines on the standard output. Lines are reformatted in accordance with command line options in effect.</p> <p>Except for <i>-s</i>, command line options may appear in any order, may be repeated, and may be intermingled with the optional <i>filenames</i>. Command line options are processed in the order specified. This means that option sequences like “-e15 -160” will yield results different from “-160 -e15”. Options are applied to all <i>filenames</i> on the command line.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <p><i>-s</i> Shears off leading characters on each line up to the first tab and places up to 8 of the sheared characters at the end of the line. If more than 8 characters (not counting the first tab) are sheared, the eighth character is replaced by a * and any characters to the right of it are discarded. The first tab is always discarded.</p> <p>An error message and program exit will occur if this option is used on a file without a tab on each line. The characters sheared off are saved internally until all other options specified are applied to that line. The characters are then added at the end of the processed line.</p> <p>For example, to convert a file with leading digits, one or more tabs, and text on each line, to a file beginning with the text, all tabs after the first expanded to spaces, padded with spaces out to column 72 (or truncated to column 72), and the leading digits placed starting at column 73, the command would be:</p> <pre>newform -s -i -l -a -e filename</pre> <p><i>-itabspec</i> Input tab specification: expands tabs to spaces, according to the tab specifications given. <i>Tabspec</i> recognizes all tab specification forms described in <a href="#">tabs(1)</a>. In addition, <i>tabspec</i> may be -, in which newform assumes that the tab specification is to be found in the first line read from the standard input (see <a href="#">fspec(4)</a>). If no <i>tabspec</i> is given, <i>tabspec</i> defaults to -8. A <i>tabspec</i> of -0 expects no tabs; if any are found, they are treated as -1.</p> <p><i>-otabspec</i> Output tab specification: replaces spaces by tabs, according to the tab specifications given. The tab specifications are the same as for <i>-itabspec</i>. If no <i>tabspec</i> is given, <i>tabspec</i> defaults to -8. A <i>tabspec</i> of -0 means that no spaces will be converted to tabs on output.</p>

- bn** Truncate *n* characters from the beginning of the line when the line length is greater than the effective line length (see **-ln**). Default is to truncate the number of characters necessary to obtain the effective line length. The default value is used when **-b** with no *n* is used. This option can be used to delete the sequence numbers from a COBOL program as follows:
- ```
newform -l11 -b7 filename
```
- en** Same as **-bn** except that characters are truncated from the end of the line.
- pn** Prefix *n* characters (see **-cchar**) to the beginning of a line when the line length is less than the effective line length. Default is to prefix the number of characters necessary to obtain the effective line length.
- an** Same as **-pn** except characters are appended to the end of a line.
- f** Write the tab specification format line on the standard output before any other lines are output. The tab specification format line which is printed will correspond to the format specified in the last **-o** option. If no **-o** option is specified, the line which is printed will contain the default specification of **-8**.
- cchar** Change the prefix/append character to *char*. Default character for *char* is a space.
- ln** Set the effective line length to *n* characters. If *n* is not entered, **-l** defaults to 72. The default line length without the **-l** option is 80 characters. Note: Tabs and backspaces are considered to be one character (use **-i** to expand tabs to spaces).
- The **-l11** must be used to set the effective line length shorter than any existing line in the file so that the **-b** option is activated.

**OPERANDS** The following operand is supported:

*filename* Input file

**EXIT STATUS** The following exit values are returned:

0 Successful operation.

1 Operation failed.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
|----------------|-----------------|

newform(1)

|              |         |
|--------------|---------|
| Availability | SUNWesu |
|--------------|---------|

**SEE ALSO** [csplit\(1\)](#), [tabs\(1\)](#), [fspec\(4\)](#), [attributes\(5\)](#)

**DIAGNOSTICS** All diagnostics are fatal.

usage: . . .  
newform was called with a bad option.

"not -s format"  
There was no tab on one line.

"can't open file"  
Self-explanatory.

"internal line too long"  
A line exceeds 512 characters after being expanded in the internal work buffer.

"tabspec in error"  
A tab specification is incorrectly formatted, or specified tab stops are not ascending.

"tabspec indirection illegal"  
A *tabspec* read from a file (or standard input) may not contain a *tabspec* referencing another file (or standard input).

**NOTES** newform normally only keeps track of physical characters; however, for the `-i` and `-o` options, newform will keep track of backspaces in order to line up tabs in the appropriate logical columns.

newform will not prompt the user if a *tabspec* is to be read from the standard input (by use of `-i-` or `-o-`).

If the `-f` option is used, and the last `-o` option specified was `-o-`, and was preceded by either a `-o-` or a `-i-`, the tab specification format line will be incorrect.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Command</b>      | <p>The <code>newgrp</code> command logs a user into a new group by changing a user's real and effective group ID. The user remains logged in and the current directory is unchanged. The execution of <code>newgrp</code> always replaces the current shell with a new shell, even if the command terminates with an error (unknown group).</p> <p>Any variable that is not exported is reset to null or its default value. Exported variables retain their values. System variables (such as <code>PS1</code>, <code>PS2</code>, <code>PATH</code>, <code>MAIL</code>, and <code>HOME</code>), are reset to default values unless they have been exported by the system or the user. For example, when a user has a primary prompt string (<code>PS1</code>) other than <code>\$</code> (default) and has not exported <code>PS1</code>, the user's <code>PS1</code> will be set to the default prompt string <code>\$</code>, even if <code>newgrp</code> terminates with an error. Note that the shell command <code>export</code> (see <a href="#">sh(1)</a> and <a href="#">set(1)</a>) is the method to export variables so that they retain their assigned value when invoking new shells.</p> <p>With no operands and options, <code>newgrp</code> changes the user's group IDs (real and effective) back to the group specified in the user's password file entry. This is a way to exit the effect of an earlier <code>newgrp</code> command.</p> <p>A password is demanded if the group has a password and the user is not listed in <code>/etc/group</code> as being a member of that group. The only way to create a password for a group is to use <a href="#">passwd(1)</a>, then cut and paste the password from <code>/etc/shadow</code> to <code>/etc/group</code>. Group passwords are antiquated and not often used.</p> |
| <b>sh Built-in</b>  | Equivalent to <code>exec newgrp argument</code> where <i>argument</i> represents the options and/or operand of the <code>newgrp</code> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                     | <p>On this man page, <a href="#">ksh(1)</a> commands that are preceded by one or two * (asterisks) are treated specially in the following ways:</p> <ol style="list-style-type: none"> <li>1. Variable assignment lists preceding the command remain in effect when the command completes.</li> <li>2. I/O redirections are processed after variable assignments.</li> <li>3. Errors cause a script that contains them to abort.</li> <li>4. Words, following a command preceded by ** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## newgrp(1)

file name generation are not performed.

**OPTIONS** The following option is supported:

-1 | -            Change the environment to what would be expected if the user actually logged in again as a member of the new group.

**OPERANDS** The following operands are supported:

*group*            A group name from the group database or a non-negative numeric group ID. Specifies the group ID to which the real and effective group IDs will be set. If *group* is a non-negative numeric string and exists in the group database as a group name (see `getgrnam(3C)`), the numeric group ID associated with that group name will be used as the group ID.

*argument*        `sh` and `ksh` only. Options and/or operand of the `newgrp` command.

**ENVIRONMENT VARIABLES** See `environ(5)` for descriptions of the following environment variables that affect the execution of `newgrp`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS** If `newgrp` succeeds in creating a new shell execution environment, whether or not the group identification was changed successfully, the exit status will be the exit status of the shell. Otherwise, the following exit value is returned:

>0            An error occurred.

**FILES**            `/etc/group`        system's group file  
`/etc/passwd`      system's password file

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Standard        |

**SEE ALSO** `login(1)`, `ksh(1)`, `set(1)`, `sh(1)`, `intro(3)`, `getgrnam(3C)`, `group(4)`, `passwd(4)`, `attributes(5)`, `environ(5)`, `standards(5)`

| <b>NAME</b>                  | news – print news items                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |         |     |         |

| <b>SYNOPSIS</b>              | <b>news</b> [-a] [-n] [-s] [ <i>items</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |     |         |
| <b>DESCRIPTION</b>           | <p>news is used to keep the user informed of current events. By convention, these events are described by files in the directory <code>/var/news</code>.</p> <p>When invoked without arguments, news prints the contents of all current files in <code>/var/news</code>, most recent first, with each preceded by an appropriate header. news stores the “currency” time as the modification date of a file named <code>.news_time</code> in the user’s home directory (the identity of this directory is determined by the environment variable <code>\$HOME</code>); only files more recent than this currency time are considered “current.”</p>                                                                                                                                                                  |                |                 |              |         |     |         |
| <b>OPTIONS</b>               | <p>-a        Print all items, regardless of currency. In this case, the stored time is not changed.</p> <p>-n        Report the names of the current items without printing their contents, and without changing the stored time.</p> <p>-s        report how many current items exist, without printing their names or contents, and without changing the stored time. It is useful to include such an invocation of news in one’s <code>.profile</code> file, or in the system’s <code>/etc/profile</code>.</p> <p>All other arguments are assumed to be specific news items that are to be printed.</p> <p>If a <i>delete</i> is typed during the printing of a news item, printing stops and the next item is started. Another <i>delete</i> within one second of the first causes the program to terminate.</p> |                |                 |              |         |     |         |
| <b>ENVIRONMENT VARIABLES</b> | See <code>environ(5)</code> for a description of the <code>LC_CTYPE</code> environment variable that affects the execution of news.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |         |     |         |

| <b>NAME</b>        | newtask – create new task and optionally change project                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>    | <b>newtask</b> [-p <i>project</i> ] [-v] [-c <i>pid</i>   [-F1] [ <i>command...</i> ]]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b> | <p>The <b>newtask</b> command executes the user's default shell or a specified command, placing the executed command in a new task owned by the specified project. The user's default shell is the one specified in the <code>passwd</code> database, and is determined using <code>getpwnam()</code>.</p> <p>Alternatively, <b>newtask</b> can be used to cause an already running process to enter a newly created task. A project for the new task can also be specified in this form of the command. This might be desirable for processes that are mission critical and cannot be restarted in order to put them into a new project.</p> <p>In the case that extended accounting is active, the <b>newtask</b> command can additionally cause the creation of a task accounting record marking the completion of the preceding system task.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-c <i>pid</i> Cause a running process to enter a newly created task. A project for the new task can also be specified using the -p option. The invoking user must either own the process or have super-user privileges.</li><li>If the project is being changed, the process owner must be a member of the specified project, or the invoking user must have super-user privileges. When the project is changed for a running process, its pool binding as well as resource controls are modified to match the configuration of the new project. Controls not explicitly specified in the project entry is preserved.</li><li>This option is incompatible with the -F and -1 options.</li><li>-F Creates a finalized task, within which further <b>newtask</b> or <b>settaskid(2)</b> invocations would fail. Finalized tasks can be useful at some sites for simplifying the attribution of resource consumption.</li><li>-1 Changes the environment to what would be expected if the user actually logged in again as a member of the new project.</li><li>-p Changes the project ID of the new task to that associated with the given project name. The invoking user must be a valid member of the requested project, or must have super-user privileges, for the command to succeed. If no project name is specified, the new task is started in the invoking user's current project.</li><li>-v Verbose: displays the system task id as the new system task is begun.</li></ul> |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <ul style="list-style-type: none"><li><i>project</i> The project to which resource usage by the created task should be charged. The requested project must be defined in the project databases defined in <code>nsswitch.conf(4)</code>.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

*command* The command to be executed as the new task. If no command is given, the user's login shell is invoked. (If the login shell is not available, /bin/sh is invoked.)

**EXAMPLES** **EXAMPLE 1** Creating a New Shell

The following example creates a new shell in the `canada` project, displaying the task id:

```
example$ id -p
uid=565(gh) gid=10(staff) projid=10(default)
example$ newtask -v -p canada
38
example$ id -p
uid=565(gh) gid=10(staff) projid=82(canada)
```

**EXAMPLE 2** Running the `date` Command

The following example runs the `date` command in the `russia` project:

```
example$ newtask -p russia date
Tue Aug 31 11:12:10 PDT 1999
```

**EXAMPLE 3** Changing the Project of an Existing Process

The following example changes the project of the existing process with a pid of 9999 to `russia`:

```
example$ newtask -c 9999 -p russia
```

**EXIT STATUS** The following exit values are returned:

- 0 Successful execution.
- 1 A fatal error occurred during execution.
- 2 Invalid command line options were specified.

**FILES** /etc/project Local database containing valid project definitions for this machine.

/proc/pid/\* Process information and control files.

**ATTRIBUTES** See `attributes(5)` for a description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|

| <b>csH Builtin</b>           | <b>nice</b> [-increment   +increment] [command]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b>           | <p>The nice utility invokes <i>command</i>, requesting that it be run with a different system scheduling priority. The <a href="#">prioctl(1)</a> command is a more general interface to scheduler functions.</p> <p>The invoking process (generally the user’s shell) must be in a scheduling class that supports nice.</p> <p>If the C shell (see <a href="#">csh(1)</a>) is used, the full path of the command must be specified. Otherwise, the csh built-in version of nice will be invoked. See <a href="#">csH Builtin</a> below.</p>                                                                                                                    |
| <b>/usr/bin/nice</b>         | If nice executes commands with arguments, it uses the default shell /usr/bin/sh (see <a href="#">sh(1)</a> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>/usr/xpg4/bin/nice</b>    | If nice executes commands with arguments, it uses /usr/xpg4/bin/sh (see <a href="#">ksh(1)</a> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>csH Builtin</b>           | nice is also a csh built-in command with behavior different from the utility versions. See <a href="#">csh(1)</a> for description.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>OPTIONS</b>               | <p>The following options are supported:</p> <p><i>-increment</i>   <i>-n increment</i></p> <p><i>increment</i> is a positive or negative decimal integer that has the same effect on the execution of the utility as if the utility had called the nice() function with the numeric value of the <i>increment</i> option-argument. See <a href="#">nice(2)</a>. nice() errors, other than EINVAL, are ignored. If not specified, an increment of 10 is assumed.</p> <p>The super-user may run commands with priority higher than normal by using a negative increment such as -10. A negative <i>increment</i> assigned by an unprivileged user is ignored.</p> |
| <b>OPERANDS</b>              | <p>The following operands are supported:</p> <p><i>command</i>            The name of a command that is to be invoked. If <i>command</i> names any of the special built-in utilities (see <a href="#">shell_builtins(1)</a>), the results are undefined.</p> <p><i>argument</i>           Any string to be supplied as an argument when invoking <i>command</i>.</p>                                                                                                                                                                                                                                                                                            |
| <b>ENVIRONMENT VARIABLES</b> | See <a href="#">environ(5)</a> for descriptions of the following environment variables that affect the execution of nice: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, PATH, and NLSPATH.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>EXIT STATUS</b>           | If <i>command</i> is invoked, the exit status of nice will be the exit status of <i>command</i> . Otherwise, nice will exit with one of the following values:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

- 1-125 An error occurred.
- 126 *command* was found but could not be invoked.

| <b>NAME</b>                  | nis+, NIS+, nis – a new version of the network information name service                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b>           | <p>NIS+ is a new version of the network information nameservice. This version differs in several significant ways from version 2, which is referred to as NIS or YP in earlier releases. Specific areas of enhancement include the ability to scale to larger networks, security, and the administration of the service.</p> <p>The man pages for NIS+ are broken up into three basic categories. Those in section 1 are the user commands that are most often executed from a shell script or directly from the command line. Section 1M man pages describe utility commands that can be used by the network administrator to administer the service itself. The NIS+ programming API is described by man pages in section 3NSL.</p> <p>All commands and functions that use NIS version 2 are prefixed by the letters <i>yp</i> as in <i>ypmatch(1)</i>, <i>ypcat(1)</i>, <i>yp_match(3NSL)</i>, and <i>yp_first(3NSL)</i>. Commands and functions that use the new replacement software NIS+ are prefixed by the letters <i>nis</i> as in <i>nismatch(1)</i>, <i>nischown(1)</i>, <i>nis_list(3NSL)</i>, and <i>nis_add_entry(3NSL)</i>. A complete list of NIS+ commands is in the LIST OF COMMANDS section.</p> <p>This man page introduces the NIS+ terminology. It also describes the NIS+ namespace, authentication, and authorization policies.</p> |
| <b>NIS+ NAMESPACE</b>        | The naming model of NIS+ is based upon a tree structure. Each node in the tree corresponds to an NIS+ object. There are six types of NIS+ objects: <i>directory</i> , <i>table</i> , <i>group</i> , <i>link</i> , <i>entry</i> , and <i>private</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>NIS+ Directory Object</b> | Each NIS+ namespace will have at least one NIS+ directory object. An NIS+ directory is like a UNIX file system directory which contains other NIS+ objects including NIS+ directories. The NIS+ directory that forms the root of the NIS+ namespace is called the root directory. There are two special NIS+ directories: <i>org_dir</i> and <i>groups_dir</i> . The <i>org_dir</i> directory consists of all the system-wide administration tables, such as <i>passwd</i> , <i>hosts</i> , and <i>mail_aliases</i> . The <i>groups_dir</i> directory consists of NIS+ group objects which are used for access control. The collection of <i>org_dir</i> , <i>groups_dir</i> and their parent directory is referred to as an NIS+ domain. NIS+ directories can be arranged in a tree-like structure so that the NIS+ namespace can match the organizational or administrative hierarchy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>NIS+ Table Object</b>     | NIS+ tables (not files), contained within NIS+ directories, store the actual information about some particular type. For example, the <i>hosts</i> system table stores information about the IP address of the hosts in that domain. NIS+ tables are multicolumn and the tables can be searched through any of the searchable columns. Each table object defines the schema for its table. The NIS+ tables consist of NIS+ entry objects. For each entry in the NIS+ table, there is an NIS+ entry object. NIS+ entry objects conform to the schema defined by the NIS+ table object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>NIS+ Group Object</b>     | NIS+ group objects are used for access control at group granularity. NIS+ group objects, contained within the <i>groups_dir</i> directory of a domain, contain a list of all the NIS+ principals within a certain NIS+ group. An NIS+ principal is a user or a machine making NIS+ requests.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>NIS+ Link Object</b> | <p>NIS+ link objects are like UNIX symbolic file-system links and are typically used for shortcuts in the NIS+ namespace.</p> <p>Refer to <code>nis_objects(3NSL)</code> for more information about the NIS+ objects.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>NIS+ NAMES</b>       | <p>The NIS+ service defines two forms of names, <i>simple</i> names and <i>indexed</i> names. Simple names are used by the service to identify NIS+ objects contained within the NIS+ namespace. Indexed names are used to identify NIS+ entries contained within NIS+ tables. Furthermore, entries within NIS+ tables are returned to the caller as NIS+ objects of type <i>entry</i>. NIS+ objects are implemented as a union structure which is described in the file <code>&lt;rpcsvc/nis_object.x&gt;</code>. The differences between the various types and the meanings of the components of these objects are described in <code>nis_objects(3NSL)</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Simple Names</b>     | <p>Simple names consist of a series of labels that are separated by the '.' (dot) character. Each label is composed of printable characters from the ISO Latin 1 set. Each label can be of any nonzero length, provided that the fully qualified name is fewer than <code>NIS_MAXNAMELEN</code> octets including the separating dots. (See <code>&lt;rpcsvc/nis.h&gt;</code> for the actual value of <code>NIS_MAXNAMELEN</code> in the current release.) Labels that contain special characters (see <code>Grammar</code>) must be quoted.</p> <p>The NIS+ namespace is organized as a singly rooted tree. Simple names identify nodes within this tree. These names are constructed such that the leftmost label in a name identifies the leaf node and all of the labels to the right of the leaf identify that object's parent node. The parent node is referred to as the leaf's <i>directory</i>. This is a naming directory and should not be confused with a file system directory.</p> <p>For example, the name <i>example.simple.name</i> is a simple name with three labels, where <i>example</i> is the leaf node in this name, the directory of this leaf is <i>simple.name</i> which by itself is a simple name. The leaf of which is <i>simple</i> and its directory is simply <i>name</i>.</p> <p>The function <code>nis_leaf_of(3NSL)</code> returns the first label of a simple name. The function <code>nis_domain_of(3NSL)</code> returns the name of the directory that contains the leaf. Iterative use of these two functions can break a simple name into each of its label components.</p> <p>The name '.' (dot) is reserved to name the <i>global root</i> of the namespace. For systems that are connected to the Internet, this global root will be served by a Domain Name Service. When an NIS+ server is serving a root directory whose name is not '.' (dot) this directory is referred to as a <i>local root</i>.</p> <p>NIS+ names are said to be <i>fully qualified</i> when the name includes all of the labels identifying all of the directories, up to the global root. Names without the trailing dot are called <i>partially</i> qualified.</p> |
| <b>Indexed Names</b>    | <p>Indexed names are compound names that are composed of a search criterion and a simple name. The search criterion component is used to select entries from a table; the simple name component is used to identify the NIS+ table that is to be searched. The search criterion is a series of column names and their desired values enclosed in bracket '[' ]' characters. These criteria take the following form:</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

nis+(1)

[*column\_name=value, column\_name =value, ...* ]

A search criterion is combined with a simple name to form an indexed name by concatenating the two parts, separated by a ','(comma) character as follows.

[ *search-criterion* ] , *table.directory*

When multiple column name/value pairs are present in the search criterion, only those entries in the table that have the appropriate value in all columns specified are returned. When no column name/value pairs are specified in the search criterion, [ ] , *all* entries in the table are returned.

#### Grammar

The following text represents a context-free grammar that defines the set of legal NIS+ names. The terminals in this grammar are the characters '.' (dot), '[' (open bracket), ']' (close bracket), ',' (comma), '=' (equals) and whitespace. Angle brackets ('<' and '>'), which delineate non-terminals, are not part of the grammar. The character '|' (vertical bar) is used to separate alternate productions and should be read as "this production OR this production".

|                         |     |                                                                                                                                                                          |
|-------------------------|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>name</i>             | ::= | .   <simple name>   <indexed name>                                                                                                                                       |
| <i>simple name</i>      | ::= | <string>.   <string>.<simple name>                                                                                                                                       |
| <i>indexed name</i>     | ::= | <search criterion>,<simple name>                                                                                                                                         |
| <i>search criterion</i> | ::= | [ <attribute list> ]                                                                                                                                                     |
| <i>attribute list</i>   | ::= | <attribute>   <attribute>,<attribute list>                                                                                                                               |
| <i>attribute</i>        | ::= | <string> = <string>                                                                                                                                                      |
| <i>string</i>           | ::= | ISO Latin 1 character set except the character '/' (slash). The initial character may not be a terminal character or the characters '@' (at), '+' (plus), or '-' hyphen. |

Terminals that appear in strings must be quoted with "" (double quote). The "" character may be quoted by quoting it with itself "" "".

#### Name Expansion

The NIS+ service only accepts fully qualified names. However, since such names may be unwieldy, the NIS+ commands in section 1 employ a set of standard expansion rules that will attempt to fully qualify a partially qualified name. This expansion is actually done by the NIS+ library function `nis_getnames(3NSL)` which generates a list of names using the default NIS+ directory search path or the `NIS_PATH` environment variable. The default NIS+ directory search path includes all the names in its path. `nis_getnames()` is invoked by the functions `nis_lookup(3NSL)` and `nis_list(3NSL)` when the `EXPAND_NAME` flag is used.

The `NIS_PATH` environment variable contains an ordered list of simple names. The names are separated by the ':' (colon) character. If any name in the list contains colons, the colon should be quoted as described in the Grammar section. When the list is exhausted, the resolution function returns the error `NIS_NOTFOUND`. This may mask the fact that the name existed but a server for it was unreachable. If the name presented to the list or lookup interface is fully qualified, the `EXPAND_NAME` flag is ignored.

In the list of names from the `NIS_PATH` environment variable, the '\$' (dollar sign) character is treated specially. Simple names that end with the label '\$' have this character replaced by the default directory (see `nis_local_directory(3NSL)`). Using "\$" as a name in this list results in this name being replaced by the list of directories between the default directory and the global root that contain at least two labels.

Below is an example of this expansion. Given the default directory of *some.long.domain.name.*, and the `NIS_PATH` variable set to `fred.bar.:org_dir.$:$`. This path is initially broken up into the list:

```
1      fred.bar.
2      org_dir.$
3      $
```

The dollar sign in the second component is replaced by the default directory. The dollar sign in the third component is replaced with the names of the directories between the default directory and the global root that have at least two labels in them. The effective path value becomes:

```
1      fred.bar.
2a     org_dir.some.long.domain.name.
3a     some.long.domain.name.
3b     long.domain.name.
3c     domain.name.
```

Each of these simple names is appended to the partially qualified name that was passed to the `nis_lookup(3NSL)` or `nis_list(3NSL)` interface. Each is tried in turn until `NIS_SUCCESS` is returned or the list is exhausted.

If the `NIS_PATH` variable is not set, the path "\$" is used.

The library function `nis_getnames(3NSL)` can be called from user programs to generate the list of names that would be attempted. The program `nisdefaults(1)` with the `-s` option can also be used to show the fully expanded path.

## Concatenation Path

Normally, all the entries for a certain type of information are stored within the table itself. However, there are times when it is desirable for the table to point to other tables where entries can be found. For example, you may want to store all the IP

nis+(1)

addresses in the host table for their own domain, and yet want to be able to resolve hosts in some other domain without explicitly specifying the new domain name. NIS+ provides a mechanism for concatenating different but related tables with a "NIS+ Concatenation Path". With a concatenation path, you can create a sort of flat namespace from a hierarchical structure. You can also create a table with no entries and just point the hosts or any other table to its parent domain. Notice that with such a setup, you are moving the administrative burden of managing the tables to the parent domain. The concatenation path will slow down the request response time because more tables and more servers are searched. It will also decrease the availability if all the servers are incapacitated for a particular directory in the table path.

The NIS+ Concatenation Path is also referred to as the "table path". This path is set up at table creation time through `nistbladm(1)`. You can specify more than one table to be concatenated and they will be searched in the given order. Notice that the NIS+ client libraries, by default, will not follow the concatenation path set in site-specific tables. Refer to `nis_list(3NSL)` for more details.

#### Namespaces

The NIS+ service defines two additional *disjoint* namespaces for its own use. These namespaces are the NIS+ *Principal* namespace, and the NIS+ *Group* namespace. The names associated with the group and principal namespaces are syntactically identical to simple names. However, the information they represent *cannot* be obtained by directly presenting these names to the NIS+ interfaces. Instead, special interfaces are defined to map these names into NIS+ names so that they may then be resolved.

#### Principal Names

NIS+ principal names are used to uniquely identify users and machines that are making NIS+ requests. These names have the form:

*principal.domain*

Here *domain* is the fully qualified name of an NIS+ directory where the named principal's credentials can be found. See *Directories and Domains* for more information on domains. Notice that in this name, *principal*, is not a leaf in the NIS+ namespace.

Credentials are used to map the identity of a host or user from one context such as a process UID into the NIS+ context. They are stored as records in an NIS+ table named *cred*, which always appears in the *org\_dir* subdirectory of the directory named in the principal name.

This mapping can be expressed as a replacement function:

```
principal.domain -> [cname=principal.domain ] , cred.org_dir.domain
```

This latter name is an NIS+ name that can be presented to the `nis_list(3NSL)` interface for resolution. NIS+ principal names are administered using the `nisaddcred(1M)` command.

The *cred* table contains five columns named *cname*, *auth\_name*, *auth\_type*, *public\_data*, and *private\_data*. There is one record in this table for each identity mapping for an NIS+ principal. The current service supports three types of mappings:

|         |                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LOCAL   | This mapping is used to map from the UID of a given process to the NIS+ principal name associated with that UID. If no mapping exists, the name <i>nobody</i> is returned. When the effective UID of the process is 0 (for example, the superuser), the NIS+ name associated with the host is returned. Notice that UIDs are sensitive to the context of the machine on which the process is executing. |
| DES     | This mapping is used to map to and from a Secure RPC "netname" into an NIS+ principal name. See <i>secure_rpc(3NSL)</i> for more information on netnames. Notice that since netnames contain the notion of a domain, they span NIS+ directories.                                                                                                                                                        |
| DHnnn-m | Example: DH640-0, DH1024-0. Analogous to DES mappings, these are used to map netnames and NIS+ principal names for extended Diffie-Hellman keys. See <i>nisauthconf(1M)</i> for further information.                                                                                                                                                                                                    |

The NIS+ client library function *nis\_local\_principal(3NSL)* uses the *cred.org\_dir* table to map the UNIX notion of an identity, a process' UID, into an NIS+ principal name. Shell programs can use the program *nisdefaults(1)* with the *-p* switch to return this information.

Mapping from UIDs to an NIS+ principal name is accomplished by constructing a query of the form:

```
[auth_type=LOCAL, auth_name=uid], cred.org_dir.default-domain.
```

This query will return a record containing the NIS+ principal name associated with this UID, in the machine's default domain.

The NIS+ service uses the DES mapping to map the names associated with Secure RPC requests into NIS+ principal names. RPC requests that use Secure RPC include the *netname* of the client making the request in the RPC header. This netname has the form:

```
unix.UID@domain
```

The service constructs a query using this name of the form:

```
[auth_type=DES, auth_name=netname], cred.org_dir.domain.
```

where the domain part is extracted from the netname rather than using the default domain. This query is used to look up the mapping of this netname into an NIS+ principal name in the domain where it was created.

nis+(1)

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                | <p>This mechanism of mapping UID and netnames into an NIS+ principal name guarantees that a client of the NIS+ service has only one principal name. This principal name is used as the basis for authorization which is described below. All objects in the NIS+ namespace and all entries in NIS+ tables must have an owner specified for them. This owner field always contains an NIS+ principal name.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Group Names</b>             | <p>Like NIS+ principal names, NIS+ group names take the form:</p> <pre>group_name.domain</pre> <p>All objects in the NIS+ namespace and all entries in NIS+ tables may optionally have a <i>group owner</i> specified for them. This group owner field, when filled in, always contains the fully qualified NIS+ group name.</p> <p>The NIS+ client library defines several interfaces (<code>nis_groups(3NSL)</code>) for dealing with NIS+ groups. These interfaces internally map NIS+ group names into an NIS+ simple name which identifies the NIS+ group object associated with that group name. This mapping can be shown as follows:</p> <pre>group.domain -&gt; group.groups_dir.domain</pre> <p>This mapping eliminates collisions between NIS+ group names and NIS+ directory names. For example, without this mapping, a directory with the name <i>engineering.foo.com.</i>, would make it impossible to have a group named <i>engineering.foo.com.</i>. This is due to the restriction that within the NIS+ namespace, a name unambiguously identifies a single object. With this mapping, the NIS+ <i>group</i> name <i>engineering.foo.com.</i> maps to the NIS+ <i>object</i> name <i>engineering.groups_dir.foo.com.</i></p> <p>The contents of a group object is a list of NIS+ principal names, and the names of other NIS+ groups. See <code>nis_groups(3NSL)</code> for a more complete description of their use.</p> |
| <b>NIS+ SECURITY</b>           | <p>NIS+ defines a security model to control access to information managed by the service. The service defines access rights that are selectively granted to individual clients or groups of clients. Principal names and group names are used to define clients and groups of clients that may be granted or denied access to NIS+ information. These principals and groups are associated with NIS+ domains as defined below.</p> <p>The security model also uses the notion of a class of principals called <i>nobody</i>, which contains all clients, whether or not they have authenticated themselves to the service. The class <i>world</i> includes any client who has been authenticated.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Directories and Domains</b> | <p>Some directories within the NIS+ namespace are referred to as NIS+ <i>Domains</i>. Domains are those NIS+ directories that contain the subdirectories <i>groups_dir</i> and <i>org_dir</i>. Further, the subdirectory <i>org_dir</i> should contain the table named <i>cred</i>. NIS+ Group names and NIS+ Principal names <i>always</i> include the NIS+ domain name after their first label.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |      |                                                                                                                                                                                                                                    |        |                                                                                                                                                                                                                                                                     |        |                                                                                                                                                                                                                                                                                                                                                          |

| <b>Authentication</b> | <p>The NIS+ name service uses Secure RPC for the integrity of the NIS+ service. This requires that users of the service and their machines must have a Secure RPC key pair associated with them. This key is initially generated with either the <code>nisaddcred(1M)</code> or <code>nisclient(1M)</code> commands and modified with the <code>chkey(1)</code> or <code>nispasswd(1)</code> commands.</p> <p>The use of Secure RPC allows private information to be stored in the name service that will not be available to untrusted machines or users on the network.</p> <p>In addition to the Secure RPC key, users need a mapping of their UID into an NIS+ principal name. This mapping is created by the system administrator using either the <code>nisclient(1M)</code> or the <code>nisaddcred(1M)</code> command.</p> <p>Users that will be using machines in several NIS+ domains must insure that they have a <i>local</i> credential entry in each of those domains. This credential should be created with the NIS+ principal name of the user in the user's "home" domain. For the purposes of NIS+ and Secure RPC, the home domain is defined to be the one where the user's Secure RPC key pair is located.</p> <p>Although extended Diffie-Hellman keys use an alternative to Secure RPC, administration is done through the same commands. See <code>nisauthconf(1M)</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |      |                                                                                                                                                                                                                                    |        |                                                                                                                                                                                                                                                                     |        |                                                                                                                                                                                                                                                                                                                                                          |
| <b>Authorization</b>  | <p>The NIS+ service defines four access rights that can be granted or denied to clients of the service. These rights are <i>read</i>, <i>modify</i>, <i>create</i>, and <i>destroy</i>. These rights are specified in the object structure at creation time and may be modified later with the <code>nischmod(1)</code> command. In general, the rights granted for an object apply only to that object. However, for purposes of authorization, rights granted to clients reading <i>directory</i> and <i>table</i> objects are granted to those clients for all of the objects "contained" by the parent object. This notion of containment is abstract. The objects do not actually contain other objects within them. Notice that <i>group</i> objects do contain the list of principals within their definition.</p> <p>Access rights are interpreted as follows:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;">read</td> <td>This right grants read access to an object. For directory and table objects, having read access on the parent object conveys read access to all of the objects that are direct children of a directory, or entries within a table.</td> </tr> <tr> <td>modify</td> <td>This right grants modification access to an existing object. Read access is not required for modification. However, in many applications, one will need to read an object before modifying it. Such modify operations will fail unless read access is also granted.</td> </tr> <tr> <td>create</td> <td>This right gives a client permission to create new objects where one had not previously existed. It is only used in conjunction with directory and table objects. Having create access for a table allows a client to add additional entries to the table. Having create access for a directory allows a client to add new objects to an NIS+ directory.</td> </tr> </table> | read | This right grants read access to an object. For directory and table objects, having read access on the parent object conveys read access to all of the objects that are direct children of a directory, or entries within a table. | modify | This right grants modification access to an existing object. Read access is not required for modification. However, in many applications, one will need to read an object before modifying it. Such modify operations will fail unless read access is also granted. | create | This right gives a client permission to create new objects where one had not previously existed. It is only used in conjunction with directory and table objects. Having create access for a table allows a client to add additional entries to the table. Having create access for a directory allows a client to add new objects to an NIS+ directory. |
| read                  | This right grants read access to an object. For directory and table objects, having read access on the parent object conveys read access to all of the objects that are direct children of a directory, or entries within a table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |      |                                                                                                                                                                                                                                    |        |                                                                                                                                                                                                                                                                     |        |                                                                                                                                                                                                                                                                                                                                                          |
| modify                | This right grants modification access to an existing object. Read access is not required for modification. However, in many applications, one will need to read an object before modifying it. Such modify operations will fail unless read access is also granted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |      |                                                                                                                                                                                                                                    |        |                                                                                                                                                                                                                                                                     |        |                                                                                                                                                                                                                                                                                                                                                          |

Having create access for a directory allows a client to add new objects to an NIS+ directory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |      |                                                                                                                                                                                                                                    |        |                                                                                                                                                                                                                                                                     |        |                                                                                                                                                                                                                                                                                                                                                          |

nis+(1)

*destroy* This right gives a client permission to destroy or remove an existing object or entry. When a client attempts to destroy an entry or object by removing it, the service first checks to see if the table or directory containing that object grants the client destroy access. If it does, the operation proceeds, if the containing object does not grant this right then the object itself is checked to see if it grants this right to the client. If the object grants the right, then the operation proceeds; otherwise the request is rejected.

Each of these rights may be granted to any one of four different categories.

*owner* A right may be granted to the *owner* of an object. The owner is the NIS+ principal identified in the owner field. The owner can be changed with the `nischown(1)` command. Notice that if the owner does not have modification access rights to the object, the owner cannot change any access rights to the object, unless the owner has modification access rights to its parent object.

*group owner* A right may be granted to the *group owner* of an object. This grants the right to any principal that is identified as a member of the group associated with the object. The group owner may be changed with the `nischgrp(1)` command. The object owner need not be a member of this group.

*world* A right may be granted to everyone in the *world*. This grants the right to all clients who have authenticated themselves with the service.

*nobody* A right may be granted to the *nobody* principal. This has the effect of granting the right to any client that makes a request of the service, regardless of whether they are authenticated or not.

Notice that for bootstrapping reasons, directory objects that are NIS+ domains, the *org\_dir* subdirectory and the *cred* table within that subdirectory must have `read` access to the *nobody* principal. This makes navigation of the namespace possible when a client is in the process of locating its credentials. Granting this access does not allow the contents of other tables within *org\_dir* to be read (such as the entries in the password table) unless the table itself gives "real" access rights to the *nobody* principal.

### Directory Authorization

Additional capabilities are provided for granting access rights to clients for directories. These rights are contained within the *object access rights* (OAR) structure of the directory. This structure allows the NIS+ service to grant rights that are not granted by the directory object to be granted for objects contained by the directory of a specific type.

An example of this capability is a directory object which does not grant create access to all clients, but does grant create access in the OAR structure for *group* type objects to clients who are members of the NIS+ group associated with the directory. In this example the only objects that could be created as children of the directory would have to be of the type *group*.

Another example is a directory object that grants create access only to the owner of the directory, and then additionally grants create access through the OAR structure for objects of type *table*, *link*, *group*, and *private* to any member of the directory's group. This has the effect of giving nearly complete create access to the group with the exception of creating subdirectories. This restricts the creation of new NIS+ domains because creating a domain requires creating both a *groups\_dir* and *org\_dir* subdirectory.

Notice that there is currently no command line interface to set or change the OAR of the directory object.

### Table Authorization

As with directories, additional capabilities are provided for granting access to entries within tables. Rights granted to a client by the access rights field in a table object apply to the table object and all of the entry objects "contained" by that table. If an access right is not granted by the table object, it may be granted by an entry within the table. This holds for all rights except *create*.

For example, a table may not grant read access to a client performing a `nis_list(3NSL)` operation on the table. However, the access rights field of entries within that table may grant read access to the client. Notice that access rights in an entry are granted to the owner and group owner of the *entry* and not the owner or group of the table. When the list operation is performed, all entries that the client has read access to are returned. Those entries that do not grant read access are not returned. If none of the entries that match the search criterion grant read access to the client making the request, no entries are returned and the result status contains the `NIS_NOTFOUND` error code.

Access rights that are granted by the rights field in an entry are granted for the entire entry. However, in the table object an additional set of access rights is maintained for each column in the table. These rights apply to the equivalent column in the entry. The rights are used to grant access when neither the table nor the entry itself grant access. The access rights in a column specification apply to the owner and group owner of the entry rather than the owner and group owner of the table object.

When a read operation is performed, if read access is not granted by the table and is not granted by the entry but *is* granted by the access rights in a column, that entry is returned with the correct values in all columns that are readable and the string `*NP*` (No Permission) in columns where read access is not granted.

As an example, consider a client that has performed a list operation on a table that does not grant read access to that client. Each entry object that satisfied the search criterion specified by the client is examined to see if it grants read access to the client. If it does, it is included in the returned result. If it does not, then each column is checked to see if it grants read access to the client. If any columns grant read access to the client, data in those columns is returned. Columns that do not grant read access have their contents replaced by the string `*NP*`. If none of the columns grant read access, then the entry is not returned.

nis+(1)

**Protocol Operation  
Authorization**

Most NIS+ operations have implied access control through the permissions on the objects that they manipulate. For example, in order to read an entry in a table, you must have read permission on that entry. However, some NIS+ operations by default perform no access checking at all and so are allowed for anyone.

| <i>Operation</i> | <i>Example of commands that use the operation</i> |
|------------------|---------------------------------------------------|
| NIS_CHECKPOINT   | nisping -C                                        |
| NIS_CPTIME       | nisping, rpc.nisd                                 |
| NIS_MKDIR        | nismkdir                                          |
| NIS_PING         | nisping, rpc.nisd                                 |
| NIS_RMDIR        | nisrmdir                                          |
| NIS_SERVSTATE    | nisbackup, nisrestore                             |
| NIS_STATUS       | nisstat, rpc.nispasswd                            |

See [nisopaccess\(1\)](#) for a description of how to enforce access control to these NIS+ operations.

**LIST OF  
COMMANDS  
NIS+ User  
Commands**

The following lists all commands and programming functions related to NIS+:

|                                |                                                                  |
|--------------------------------|------------------------------------------------------------------|
| <a href="#">nisaddent(1M)</a>  | add /etc files and NIS maps into their corresponding NIS+ tables |
| <a href="#">niscat(1)</a>      | display NIS+ tables and objects                                  |
| <a href="#">nischgrp(1)</a>    | change the group owner of a NIS+ object                          |
| <a href="#">nischmod(1)</a>    | change access rights on a NIS+ object                            |
| <a href="#">nischown(1)</a>    | change the owner of a NIS+ object                                |
| <a href="#">nischttl(1)</a>    | change the time to live value of a NIS+ object                   |
| <a href="#">nisdefaults(1)</a> | display NIS+ default values                                      |
| <a href="#">niserror(1)</a>    | display NIS+ error messages                                      |
| <a href="#">nisgrep(1)</a>     | utilities for searching NIS+ tables                              |
| <a href="#">nisgrpadm(1)</a>   | NIS+ group administration command                                |
| <a href="#">nisln(1)</a>       | symbolically link NIS+ objects                                   |
| <a href="#">nislsl(1)</a>      | list the contents of a NIS+ directory                            |
| <a href="#">nismatch(1)</a>    | utilities for searching NIS+ tables                              |
| <a href="#">nismkdir(1)</a>    | create NIS+ directories                                          |
| <a href="#">nisopaccess(1)</a> | access control for protocol operations                           |
| <a href="#">nispasswd(1)</a>   | change NIS+ password information                                 |

|                                     |                               | nis+(1)                                                               |
|-------------------------------------|-------------------------------|-----------------------------------------------------------------------|
|                                     | <code>nisrm(1)</code>         | remove NIS+ objects from the namespace                                |
|                                     | <code>nisrmdir(1)</code>      | remove NIS+ directories                                               |
|                                     | <code>nisshowcache(1M)</code> | NIS+ utility to print out the contents of the shared cache file       |
|                                     | <code>nistbladm(1)</code>     | NIS+ table administration command                                     |
|                                     | <code>nistest(1)</code>       | return the state of the NIS+ namespace using a conditional expression |
| <b>NIS+ Administrative Commands</b> | <code>aliasadm(1M)</code>     | manipulate the NIS+ aliases map                                       |
|                                     | <code>nis_cachemgr(1M)</code> | NIS+ utility to cache location information about NIS+ servers         |
|                                     | <code>nisaddcred(1M)</code>   | create NIS+ credentials                                               |
|                                     | <code>nisaddent(1M)</code>    | create NIS+ tables from corresponding /etc files or NIS+ maps         |
|                                     | <code>nisauthconf(1M)</code>  | configure extended Diffie-Hellman keys                                |
|                                     | <code>nisbackup(1M)</code>    | backup NIS+ directories                                               |
|                                     | <code>nisclient(1M)</code>    | initialize NIS+ credentials for NIS+ principals                       |
|                                     | <code>nisd(1M)</code>         | NIS+ service daemon                                                   |
|                                     | <code>nisd_resolv(1M)</code>  | NIS+ service daemon                                                   |
|                                     | <code>nisinit(1M)</code>      | NIS+ client and server initialization utility                         |
|                                     | <code>nislog(1M)</code>       | display the contents of the NIS+ transaction log                      |
|                                     | <code>nisping(1M)</code>      | send ping to NIS+ servers                                             |
|                                     | <code>nispopulate(1M)</code>  | populate the NIS+ tables in a NIS+ domain                             |
|                                     | <code>nisprefadm(1M)</code>   | NIS+ utility to set server preferences for NIS+ clients               |
|                                     | <code>nisrestore(1M)</code>   | restore NIS+ directory backup                                         |
|                                     | <code>nisserver(1M)</code>    | set up NIS+ servers                                                   |
|                                     | <code>nissetup(1M)</code>     | initialize a NIS+ domain                                              |
|                                     | <code>nisshowcache(1M)</code> | NIS+ utility to print out the contents of the shared cache file       |
|                                     | <code>nisstat(1M)</code>      | report NIS+ server statistics                                         |
|                                     | <code>nisupdkeys(1M)</code>   | update the public keys in a NIS+ directory object                     |

| <code>nis_verifygroup(3NSL)</code>       | NIS+ group manipulation functions                                                                  |
| <code>nisfiles(4)</code>                 | NIS+ database files and directory structure                                                        |
| <code>&lt;rpcsvc/nis_object.x&gt;</code> | protocol description of an NIS+ object                                                             |
| <code>&lt;rpcsvc/nis.x&gt;</code>        | defines the NIS+ protocol using the RPC language as described in the <i>ONC+ Developer's Guide</i> |

nis+(1)

<rpcsvc/nis.h>

should be included by all clients of the NIS+ service

**SEE ALSO** [nischown\(1\)](#), [nisdefaults\(1\)](#), [nismatch\(1\)](#), [nisopaccess\(1\)](#), [nispasswd\(1\)](#), [newkey\(1M\)](#), [nisaddcred\(1M\)](#), [nisauthconf\(1M\)](#), [nisclient\(1M\)](#), [nispopulate\(1M\)](#), [nisserver\(1M\)](#), [nis\\_add\\_entry\(3NSL\)](#), [nis\\_domain\\_of\(3NSL\)](#), [nis\\_getnames\(3NSL\)](#), [nis\\_groups\(3NSL\)](#), [nis\\_leaf\\_of\(3NSL\)](#), [nis\\_list\(3NSL\)](#), [nis\\_local\\_directory\(3NSL\)](#), [nis\\_lookup\(3NSL\)](#), [nis\\_objects\(3NSL\)](#)

*System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)*  
Describes how to make the transition from NIS to NIS+.

*ONC+ Developer's Guide*

Describes the application programming interfaces for networks including NIS+.

*System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)*  
Describes how to plan for and configure an NIS+ namespace.

*System Administration Guide: IP Services*

Describes IPv6 extensions to Solaris name services.

**NOTES** NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>NAME</b>        | niscat – display NIS+ tables and objects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <b>niscat</b> [-AhLMv] [-s <i>sep</i> ] <i>tablename</i> ...<br><b>niscat</b> [-ALMP] -o <i>name</i> ...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | In the first synopsis, <i>niscat</i> displays the contents of the NIS+ tables named by <i>tablename</i> . In the second synopsis, it displays the internal representation of the NIS+ objects named by <i>name</i> .<br><br>Columns without values in the table are displayed by two adjacent separator characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>OPTIONS</b>     | The following options are supported:<br><ul style="list-style-type: none"> <li>-A               Displays the data within the table and all of the data in tables in the initial table's concatenation path.</li> <li>-h               Displays the header line prior to displaying the table. The header consists of the '#' (hash) character followed by the name of each column. The column names are separated by the table separator character.</li> <li>-L               Follows links. When this option is specified, if <i>tablename</i> or <i>name</i> names a LINK type object, the link is followed and the object or table named by the link is displayed.</li> <li>-M               Master server only. This option specifies that the request should be sent to the master server of the named data. This guarantees that the most up-to-date information is seen at the possible expense of increasing the load on the master server and increasing the possibility of the NIS+ server being unavailable or busy for updates.</li> <li>-o <i>name</i>       Displays the internal representation of the named NIS+ object(s). If <i>name</i> is an indexed name (see <i>nismatch(1)</i>), then each of the matching entry objects is displayed. This option is used to display access rights and other attributes of individual columns.</li> <li>-P               Follows concatenation path. This option specifies that the request should follow the concatenation path of a table if the initial search is unsuccessful. This option is only useful when using an indexed name for <i>name</i> and the -o option.</li> <li>-s <i>sep</i>        This option specifies the character to use to separate the table columns. If no character is specified, the default separator for the table is used.</li> <li>-v               Displays binary data directly. This option displays columns containing binary data on the standard output. Without this option binary data is displayed as the string *BINARY*.</li> </ul> |

niscat(1)

## EXAMPLES

### EXAMPLE 1 Displaying the contents of the hosts table

```
example% niscat -h hosts.org_dir
# cname  name  addr  comment
client1  client1  192.168.201.100  Joe Smith
crunchy  crunchy  192.168.201.44  Jane Smith
crunchy  softy  192.168.201.44
```

The string `*NP*` is returned in those fields where the user has insufficient access rights.

### EXAMPLE 2 Displaying on the standard output

Display the `passwd.org_dir` on the standard output.

```
example% niscat passwd.org_dir
```

### EXAMPLE 3 Displaying table contents

Display the contents of table `frodo` and the contents of all tables in its concatenation path.

```
example% niscat -A frodo
```

### EXAMPLE 4 Displaying table entries

Display the entries in the table `groups.org_dir` as NIS+ objects. Notice that the brackets are protected from the shell by single quotes.

```
example% niscat -o '[ ]groups.org_dir'
```

### EXAMPLE 5 Displaying the table object

Display the table object of the `passwd.org_dir` table.

```
example% niscat -o passwd.org_dir
```

The previous example displays the `passwd` table object and not the `passwd` table. The table object includes information such as the number of columns, column type, searchable or not searchable separator, access rights, and other defaults.

### EXAMPLE 6 Displaying the directory object

Display the directory object for `org_dir`, which includes information such as the access rights and replica information.

```
example% niscat -o org_dir
```

## ENVIRONMENT VARIABLES

`NIS_PATH`

If this variable is set, and the NIS+ table name is not fully qualified, each directory specified will be searched until the table is found (see [nisdefaults\(1\)](#)).

**EXIT STATUS** niscat returns the following values:

- 0 Successful completion
- 1 An error occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

**SEE ALSO** `nis+(1)`, `nisdefaults(1)`, `nismatch(1)`, `nistbladm(1)`, `nis_objects(3NSL)`, `nis_tables(3NSL)`, `attributes(5)`

**NOTES** NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

| <b>NAME</b>        | nischgrp – change the group owner of a NIS+ object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <b>nischgrp</b> [-AfLP] <i>group name...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | <p>nischgrp changes the group owner of the NIS+ objects or entries specified by <i>name</i> to the specified NIS+ <i>group</i>. Entries are specified using indexed names (see <a href="#">nismatch(1)</a>). If <i>group</i> is not a fully qualified NIS+ group name, it will be resolved using the directory search path (see <a href="#">nisdefaults(1)</a>).</p> <p>The only restriction on changing an object's group owner is that you must have modify permissions for the object.</p> <p>This command will fail if the master NIS+ server is not running.</p> <p>The NIS+ server will check the validity of the group name prior to effecting the modification.</p>                                                                                                                                                       |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-A        Modify all entries in all tables in the concatenation path that match the search criterion specified in <i>name</i>. This option implies the -P switch.</li><li>-f        Force the operation and fail silently if it does not succeed.</li><li>-L        Follow links and change the group owner of the linked object or entries rather than the group owner of the link itself.</li><li>-P        Follow the concatenation path within a named table. This option only makes sense when either <i>name</i> is an indexed name or the -L switch is also specified and the named object is a link pointing to entries.</li></ul>                                                                                                      |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Using the nischgrp Command</p> <p>The following two examples show how to change the group owner of an object to a group in a different domain, and how to change it to a group in the local domain, respectively.</p> <pre>example% nischgrp newgroup.remote.domain. object example% nischgrp my-buds object</pre> <p>This example shows how to change the group owner for a password entry.</p> <pre>example% nischgrp admins ' [uid=99],passwd.org_dir'</pre> <p>In the previous example, <i>admins</i> is a NIS+ group in the same domain.</p> <p>The next two examples change the group owner of the object or entries pointed to by a link, and the group owner of all entries in the <i>hobbies</i> table.</p> <pre>example% nischgrp -L my-buds linkname example% nischgrp my-buds ' [],hobbies'</pre> |

nischgrp(1)

**ENVIRONMENT  
VARIABLES**

NIS\_PATH

If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see [nisdefaults\(1\)](#)).

**EXIT STATUS**

The following exit values are returned:

0 Successful operation.

1 Operation failed.

**ATTRIBUTES**

See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

**SEE ALSO**

[nis+\(1\)](#), [nischmod\(1\)](#), [nischown\(1\)](#), [nisdefaults\(1\)](#), [nisgrpadm\(1\)](#), [nismatch\(1\)](#), [nis\\_objects\(3NSL\)](#), [attributes\(5\)](#)

**NOTES**

NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

## nischmod(1)

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>NAME</b>        | nischmod – change access rights on a NIS+ object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <b>nischmod</b> [-AfLP] <i>mode name...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | <p>nischmod changes the access rights (mode) of the NIS+ objects or entries specified by <i>name</i> to <i>mode</i>. Entries are specified using indexed names (see <a href="#">nismatch(1)</a>). Only principals with modify access to an object may change its mode.</p> <p><i>mode</i> has the following form:</p> <p><i>rights</i> [, <i>rights</i> ] . . .</p> <p><i>rights</i> has the form:</p> <p>[ <i>who</i> ] <i>op permission</i> [ <i>op permission</i> ] . . .</p> <p><i>who</i> is a combination of:</p> <ul style="list-style-type: none"><li>n Nobody's permissions.</li><li>o Owner's permissions.</li><li>g Group's permissions.</li><li>w World's permissions.</li><li>a All, or owg.</li></ul> <p>If <i>who</i> is omitted, the default is a.</p> <p><i>op</i> is one of:</p> <ul style="list-style-type: none"><li>+ To grant the <i>permission</i>.</li><li>- To revoke the <i>permission</i>.</li><li>= To set the permissions explicitly.</li></ul> <p><i>permission</i> is any combination of:</p> <ul style="list-style-type: none"><li>r Read.</li><li>m Modify.</li><li>c Create.</li><li>d Destroy.</li></ul> <p>Unlike the system <a href="#">chmod(1)</a> command, this command does not accept an octal notation.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-A Modify all entries in all tables in the concatenation path that match the search criteria specified in <i>name</i>. This option implies the -P switch.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

- f Force the operation and fail silently if it does not succeed.
- L Follow links and change the permission of the linked object or entries rather than the permission of the link itself.
- P Follow the concatenation path within a named table. This option is only applicable when either *name* is an indexed name or the -L switch is also specified and the named object is a link pointing to an entry.

**EXAMPLES** **EXAMPLE 1** Using the `nischmod` Command

This example gives everyone read access to an object. (that is, access for owner, group, and all).

```
example% nischmod a+r object
```

This example denies create and modify privileges to group and unauthenticated clients (`nobody`).

```
example% nischmod gn-cm object
```

In this example, a complex set of permissions are set for an object.

```
example% nischmod o=rmdc,g=rm,w=rc,n=r object
```

This example sets the permissions of an entry in the password table so that the group owner can modify them.

```
example% nischmod g+m '[uid=55],passwd.org_dir'
```

The next example changes the permissions of a linked object.

```
example% nischmod -L w+mr linkname
```

**ENVIRONMENT VARIABLES**

**NIS\_PATH** If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see `nisdefaults(1)`).

**EXIT STATUS**

The following exit values are returned:

- 0 Successful operation.
- 1 Operation failed.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

| <b>NAME</b>                  | nischown – change the owner of a NIS+ object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>              | <b>nischown</b> [-AfLP] <i>owner name...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b>           | <p>nischown changes the owner of the NIS+ objects or entries specified by <i>name</i> to <i>owner</i>. Entries are specified using indexed names (see <a href="#">nismatch(1)</a>). If <i>owner</i> is not a fully qualified NIS+ principal name (see <a href="#">nisaddcred(1M)</a>), the default domain (see <a href="#">nisdefaults(1)</a>) will be appended to it.</p> <p>The only restriction on changing an object's owner is that you must have modify permissions for the object. Note: If you are the current owner of an object and you change ownership, you may not be able to regain ownership unless you have modify access to the new object.</p> <p>The command will fail if the master NIS+ server is not running.</p> <p>The NIS+ server will check the validity of the name before making the modification.</p> |
| <b>OPTIONS</b>               | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-A        Modify all entries in all tables in the concatenation path that match the search criteria specified in <i>name</i>. It implies the -P option.</li> <li>-f        Force the operation and fail silently if it does not succeed.</li> <li>-L        Follow links and change the owner of the linked object or entries rather than the owner of the link itself.</li> <li>-P        Follow the concatenation path within a named table. This option is only meaningful when either <i>name</i> is an indexed name or the -L option is also specified and the named object is a link pointing to entries.</li> </ul>                                                                                                                      |
| <b>EXAMPLES</b>              | <p><b>EXAMPLE 1</b> Using the nischown Command</p> <p>The following two examples show how to change the owner of an object to a principal in a different domain, and to change it to a principal in the local domain, respectively.</p> <pre>example% nischown bob.remote.domain. object example% nischown skippy object</pre> <p>The next example shows how to change the owner of an entry in the passwd table.</p> <pre>example% nischown bob.remote.domain. '[uid=99],passwd.org_dir'</pre> <p>This example shows how to change the object or entries pointed to by a link.</p> <pre>example% nischown -L skippy linkname</pre>                                                                                                                                                                                                |
| <b>ENVIRONMENT VARIABLES</b> | <p><b>NIS_PATH</b>                      If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see <a href="#">nisdefaults(1)</a>).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>EXIT STATUS</b>           | The following exit values are returned:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>NAME</b>        | nischttl – change the time to live value of a NIS+ object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <b>nischttl</b> [-AfLP] <i>time name...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>nischttl changes the time to live value (ttl) of the NIS+ objects or entries specified by <i>name</i> to <i>time</i>. Entries are specified using indexed names (see <a href="#">nismatch(1)</a>).</p> <p>The time to live value is used by object caches to expire objects within their cache. When an object is read into the cache, this value is added to the current time in seconds yielding the time when the cached object would expire. The object may be returned from the cache until the current time is earlier than the calculated expiration time. When the expiration time has been reached, the object will be flushed from the cache.</p> <p>The time to live <i>time</i> may be specified in seconds or in days, hours, minutes, seconds format. The latter format uses a suffix letter of d, h, m, or s to identify the units of time. See the examples below for usage.</p> <p>The command will fail if the master NIS+ server is not running.</p> <p>Setting a high ttl value allows objects to stay persistent in caches for a longer period of time and can improve performance. However, when an object changes, in the worst case, the number of seconds in this attribute must pass before that change is visible to all clients. Setting a ttl value of 0 means that the object should not be cached at all.</p> <p>A high ttl value is a week, a low value is less than a minute. Password entries should have ttl values of about 12 hours (easily allows one password change per day), entries in the RPC table can have ttl values of several weeks (this information is effectively unchanging).</p> <p>Only directory and group objects are cached in this implementation.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-A        Modify all tables in the concatenation path that match the search criterion specified in <i>name</i>. This option implies the -P switch.</li> <li>-f        Force the operation and fail silently if it does not succeed.</li> <li>-L        Follow links and change the time to live of the linked object or entries rather than the time to live of the link itself.</li> <li>-P        Follow the concatenation path within a named table. This option only makes sense when either <i>name</i> is an indexed name or the -L switch is also specified and the named object is a link pointing to entries.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Changing the ttl of an Object</p> <p>The following example shows how to change the ttl of an object using the seconds format and the days, hours, minutes, seconds format. The ttl of the second object is set to 1 day and 12 hours.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## nischttl(1)

**EXAMPLE 1** Changing the ttl of an Object (Continued)

```
example% nischttl 184000 object
example% nischttl 1d12h object
```

**EXAMPLE 2** Changing the ttl for a password Entry

This example shows how to change the ttl for a password entry.

```
example% nischttl 1h30m '[uid=99],passwd.org_dir'
```

**EXAMPLE 3** Changing the ttl of Entries Pointed to by a Link

The next two examples change the ttl of the object or entries pointed to by a link, and the ttl of all entries in the hobbies table.

```
example% nischttl -L 12h linkname
example% nischttl 3600 '[],hobbies'
```

### ENVIRONMENT VARIABLES

**NIS\_PATH** If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found. See [nisdefaults\(1\)](#).

### EXIT STATUS

The following exit values are returned:

0 Successful operation.  
1 Operation failed.

### ATTRIBUTES

See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

### SEE ALSO

| <b>NAME</b>        | <code>nisdefaults</code> – display NIS+ default values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <code>nisdefaults</code> [-adghprstv]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | The <code>nisdefaults</code> utility prints the default values that are returned by calls to the NIS+ local name functions (see <code>nis_local_names(3NSL)</code> ). With no options specified, all defaults will be printed in a verbose format. With options, only that option is displayed in a terse form suitable for shell scripts. See the example below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>OPTIONS</b>     | The following options are supported: <ul style="list-style-type: none"> <li>-a        Print all defaults in a terse format.</li> <li>-d        Print the default domain name.</li> <li>-g        Print the default group name.</li> <li>-h        Print the default host name.</li> <li>-p        Print the default principal name.</li> <li>-r        Print the default access rights with which new objects will be created.</li> <li>-s        Print the default directory search path.</li> <li>-t        Print the default time to live value.</li> <li>-v        Print the defaults in a verbose format. This prepends an identifying string to the output.</li> </ul>                                                                                                                                                                                   |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Printing NIS+ defaults</p> <p>The following prints the NIS+ defaults for a root process on machine <code>example</code> in the <code>foo.bar.</code> domain:</p> <pre>example# nisdefaults Principal Name   :   example.foo.bar. Domain Name     :   foo.bar. Host Name       :   example.foo.bar. Group Name      : Access Rights   :   - - - -rmcdr- - -r - - - Time to live    :   12:00:00 Search Path     :   foo.bar.</pre> <p><b>EXAMPLE 2</b> Setting a variable in the shell script</p> <p>This example sets a variable in a shell script to the default domain:</p> <pre>DOMAIN=`nisdefaults -d`</pre> <p><b>EXAMPLE 3</b> Printing the default time to live in verbose format</p> <p>This example prints out the default time to live in a verbose format:</p> <pre>example% nisdefaults -tv Time to live    :   12:00:00</pre> |

nisdefaults(1)

## ENVIRONMENT VARIABLES

**EXAMPLE 4** Printing the time to live in terse format

This example prints out the time to live in the terse format:

```
example% nisdefaults -t
43200
```

Several environment variables affect the defaults associated with a process.

**NIS\_DEFAULTS**

This variable contains a defaults string that will override the NIS+ standard defaults. The defaults string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.

*ttl=time*

This token sets the default time to live for objects that are created. The value *time* is specified in the format as defined by the [nischttl\(1\)](#) command. The default value is 12 hours.

*owner=ownername*

This token specifies that the NIS+ principal *ownername* should own created objects. The default for this value is the principal who is executing the command.

*group=groupname*

This token specifies that the group *groupname* should be the group owner for created objects. The default is NULL.

*access=rights*

This token specifies the set of access rights that are to be granted for created objects. The value *rights* is specified in the format as defined by the [nischmod\(1\)](#) command. The default value is:  
- - - -rmdr- - -r- - -.

**NIS\_GROUP**

This variable contains the name of the local NIS+ group. If the name is not fully qualified, the default domain will be appended to it.

**NIS\_PATH**

This variable overrides the default NIS+ directory search path. It contains an ordered list of directories separated by ':' (colon) characters. The '\$' (dollar sign) character is treated specially. Directory names that end in '\$' have the default domain appended to them, and a

nisdefaults(1)

'\$' by itself is replaced by the list of directories between the default domain and the global root that are at least two levels deep. The default NIS+ directory search path is '\$'.

Refer to the Name Expansion subsection in [nis+\(1\)](#) for more details.

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

**SEE ALSO** [nischmod\(1\)](#), [nischttl\(1\)](#), [nis+\(1\)](#), [nis\\_local\\_names\(3NSL\)](#), [attributes\(5\)](#)

**NOTES** NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

niserror(1)

**NAME** niserror – display NIS+ error messages

**SYNOPSIS** **niserror** *error-num*

**DESCRIPTION** niserror prints the NIS+ error associated with status value *error-num* on the standard output. It is used by shell scripts to translate NIS+ error numbers that are returned into text messages.

**EXAMPLES** **EXAMPLE 1** Using niserror

The following example prints the error associated with the error number 20:

```
example% niserror 20
Not Found, no such name
```

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| <b>DESCRIPTION</b> | <p>The <code>nisgrpadm</code> utility is used to administer NIS+ groups. This command administers both groups and the groups' membership lists. <code>nisgrpadm</code> can create, destroy, or list NIS+ groups. <code>nisgrpadm</code> can be used to administer a group's membership list. It can add or delete principals to the group, or test principals for membership in the group.</p> <p>The names of NIS+ groups are syntactically similar to names of NIS+ objects but they occupy a separate namespace. A group named <code>a.b.c.d.</code> is represented by a NIS+ group object named <code>a.groups_dir.b.c.d.</code>; the functions described here all expect the name of the group, not the name of the corresponding group object.</p> <p>There are three types of group members:</p> <ul style="list-style-type: none"> <li>■ An <i>explicit</i> member is just a NIS+ principal-name. For example:<br/><code>wickedwitch.west.oz.</code></li> <li>■ An <i>implicit</i> ("domain") member, written <code>*.west.oz.</code>, means that all principals in the given domain belong to this member. No other forms of wildcarding are allowed; <code>wickedwitch.*.oz.</code> is invalid, as is <code>wickedwitch.west.*.</code>. Note that principals in subdomains of the given domain are <i>not</i> included.</li> <li>■ A <i>recursive</i> ("group") member, written <code>@cowards.oz.</code>, refers to another group; all principals that belong to that group are considered to belong here.</li> </ul> <p>Any member may be made <i>negative</i> by prefixing it with a minus sign ('-'). A group may thus contain explicit, implicit, recursive, negative explicit, negative implicit, and negative recursive members.</p> <p>A principal is considered to belong to a group if it belongs to at least one non-negative group member of the group and belongs to no negative group members.</p> <p>Principal names <i>must</i> be fully qualified, whereas groups can be abbreviated on all operations <i>except</i> <code>create</code>.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a                Adds the list of NIS+ principals specified to <i>group</i>. The principal name should be fully qualified.</li> <li>-c                Creates <i>group</i> in the NIS+ namespace. The NIS+ group name should be fully qualified.</li> <li>-d                Destroys (removes) <i>group</i> from the namespace.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## nisgrpadm(1)

|                              |                                                                                                                                                                                                                                                                                                                       |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-D defaults</code>     | When creating objects, this option specifies a different set of defaults to be used during this operation. The <i>defaults</i> string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below. |
| <code>ttl=time</code>        | This token sets the default time to live for objects that are created by this command. The value <i>time</i> is specified in the format as defined by the <code>nischttl(1)</code> command. The default value is 12 hours.                                                                                            |
| <code>owner=ownername</code> | This token specifies that the NIS+ principal <i>ownername</i> should own the created object. Normally this value is the same as the principal who is executing the command.                                                                                                                                           |
| <code>group=groupname</code> | This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default value is NULL.                                                                                                                                                                             |
| <code>access=rights</code>   | This token specifies the set of access rights that are to be granted for the given object. The value <i>rights</i> is specified in the format as defined by the <code>nischmod(1)</code> command. The default value is<br>- - - -rmcdr- - -r- - -.                                                                    |
| <code>-l</code>              | Lists the membership list of the specified <i>group</i> . (See <code>-M</code> option.)                                                                                                                                                                                                                               |
| <code>-M</code>              | Master server only. Sends the lookup to the master server of the named data. This guarantees that the most up to date information is seen at the possible expense that the master server may be busy. Note that the <code>-M</code> flag is applicable only with the <code>-l</code> flag.                            |
| <code>-r</code>              | Removes the list of principals specified from <i>group</i> . The principal name should be fully qualified.                                                                                                                                                                                                            |
| <code>-s</code>              | Work silently. Results are returned using the exit status of the command. This status can be translated into a text string using the <code>niserror(1)</code> command.                                                                                                                                                |
| <code>-t</code>              | Displays whether the principals specified are members in <i>group</i> .                                                                                                                                                                                                                                               |

### EXAMPLES

**Administering  
Groups****EXAMPLE 1** Creating a group

This example shows how to create a group in the `foo.com.` domain:

```
example% nisgrpadm -c my_buds.foo.com.
```

**EXAMPLE 2** How to remove a group

This example shows how to remove the group from the current domain.

```
example% nisgrpadm -d fred's_group
```

**Administering  
Members****EXAMPLE 3** Adding to the group

This example shows how one would add two principals, `bob` and `betty`, to the group `my_buds.foo.com.`:

```
example% nisgrpadm -a my_buds.foo.com. bob.bar.com. betty.foo.com.
```

**EXAMPLE 4** How to remove a principal from the group

This example shows how to remove `betty` from `fred's_group`:

```
example% nisgrpadm -r fred's_group betty.foo.com.
```

**ENVIRONMENT  
VARIABLES****NIS\_DEFAULTS**

This variable contains a defaults string that will override the NIS+ standard defaults.

**NIS\_PATH**

If this variable is set, and the NIS+ group name is not fully qualified, each directory specified will be searched until the group is found (see [nisdefaults\(1\)](#)).

**ATTRIBUTES**

See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

**SEE ALSO**

[nis+\(1\)](#), [nischgrp\(1\)](#), [nischmod\(1\)](#), [nischttl\(1\)](#), [nisdefaults\(1\)](#), [niserror\(1\)](#), [nis\\_groups\(3NSL\)](#), [attributes\(5\)](#)

**DIAGNOSTICS****NIS\_SUCCESS**

On success, this command returns an exit status of 0.

**NIS\_PERMISSION**

When you do not have the needed access right to change the group, the command returns this error.

**NIS\_NOTFOUND**

This is returned when the group does not exist.

**NIS\_TRYAGAIN**

This error is returned when the server for the group's domain is currently checkpointing or otherwise in a read-only state. The command should be retried at a later date.

## nisgrpadm(1)

NIS\_MODERROR

This error is returned when the group was modified by someone else during the execution of the command. Reissue the command and optionally recheck the group's membership list.

**NOTES** NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

| <b>NAME</b>        | <code>nisln</code> – symbolically link NIS+ objects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <code>nisln [-L] [-D <i>defaults</i>] <i>name linkname</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | <p>The <code>nisln</code> command links a NIS+ object named <i>name</i> to a NIS+ name <i>linkname</i>. If <i>name</i> is an indexed name (see <code>nismatch(1)</code>), the link points to entries within a NIS+ table. Clients wishing to look up information in the name service can use the <code>FOLLOW_LINKS</code> flag to force the client library to follow links to the name they point to. Further, all of the NIS+ administration commands accept the <code>-L</code> switch indicating they should follow links (see <code>nis_names(3NSL)</code> for a description of the <code>FOLLOW_LINKS</code> flag).</p> <p>When creating the link, <code>nisln</code> verifies that the linked object exists. Once created, the linked object may be deleted or replaced and the link will not be affected. At that time, the link will become invalid and attempts to follow it will return <code>NIS_LINKNAMEERROR</code> to the client. When the path attribute in tables specifies a link rather than another table, the link will be followed if the flag <code>FOLLOW_LINKS</code> was present in the call to <code>nis_list()</code> (see <code>nis_tables(3NSL)</code>) and ignored if the flag is not present. If the flag is present and the link is no longer valid, a warning is sent to the system logger and the link is ignored.</p>                                                                                                                                                                                                                                                                                                              |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-D <i>defaults</i></code>      Specify a different set of defaults to be used for the creation of the link object. The <i>defaults</i> string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.</p> <p style="padding-left: 2em;"><code>t<sub>tl</sub>=<i>time</i></code><br/> This token sets the default time to live for objects that are created by this command. The value <i>time</i> is specified in the format as defined by the <code>nischttl(1)</code> command. The default is 12 hours.</p> <p style="padding-left: 2em;"><code>owner=<i>ownername</i></code><br/> This token specifies that the NIS+ principal <i>ownername</i> should own the created object. The default for this value is the principal who is executing the command.</p> <p style="padding-left: 2em;"><code>group=<i>groupname</i></code><br/> This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default is <code>NULL</code>.</p> <p style="padding-left: 2em;"><code>access=<i>rights</i></code><br/> This token specifies the set of access rights that are to be granted for the given object. The value <i>rights</i> is specified in the format as defined by the <code>nischmod(1)</code> command. The default value is <code>—rmcdr—r—</code>.</p> <p><code>-L</code>      When present, this option specifies that this command should follow links. If <i>name</i> is itself a link, then this command will follow</p> |

## nisl(1)

it to the linked object that it points to. The new link will point to that linked object rather than to *name*.

### EXAMPLES

#### EXAMPLE 1 Creating a link

In this example, we create a link in the domain `foo.com.` named `hosts` that points to the object `hosts.bar.com.`:

```
example% nisl hosts.bar.com. hosts.foo.com.
```

#### EXAMPLE 2 Making a link that points to an entry in the hosts table

In this example, we make a link `example.foo.com.` that points to an entry in the hosts table in `eng.foo.com.`:

```
example% nisl '[name=example],hosts.eng.foo.com.' example.foo.com.
```

### ENVIRONMENT VARIABLES

`NIS_PATH` If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see [nisdefaults\(1\)](#)).

### EXIT STATUS

The following exit values are returned:

0 Successful operation.  
1 Operation failed.

### ATTRIBUTES

See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

### SEE ALSO

### NOTES

NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

| <b>NAME</b>                  | nisl – list the contents of a NIS+ directory                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>              | <b>nisl</b> [-dglLmMR] [ <i>name</i> ...]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b>           | For each <i>name</i> that is a NIS+ directory, <b>nisl</b> lists the contents of the directory. For each <i>name</i> that is a NIS+ object other than a directory, <b>nisl</b> simply echos the name. If no <i>name</i> is specified, the first directory in the search path is listed. See <a href="#">nisdefaults(1)</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>OPTIONS</b>               | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-d        Treat NIS+ directories like other NIS+ objects, rather than listing their contents.</li> <li>-g        Display group owner instead of owner when listing in long format.</li> <li>-l        List in long format. This option displays additional information about the objects such as their type, creation time, owner, and access rights.</li> </ul> <p>The access rights are listed in the following order in long mode: nobody, owner, group owner, and world.</p> <ul style="list-style-type: none"> <li>-L        This option specifies that links are to be followed. If <i>name</i> actually points to a link, it is followed to the linked object.</li> <li>-m        Display modification time instead of creation time when listing in long format.</li> <li>-M        Master only. This specifies that information is to be returned from the master server of the named object. This guarantees that the most up to date information is seen at the possible expense that the master server may be busy.</li> <li>-R        List directories recursively. This option will reiterate the list for each subdirectory found in the process of listing each <i>name</i>.</li> </ul> |
| <b>ENVIRONMENT VARIABLES</b> | <p><b>NIS_PATH</b>                      If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found. See <a href="#">nisdefaults(1)</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>EXIT STATUS</b>           | <p>The following exit values are returned:</p> <ul style="list-style-type: none"> <li>0        Successful operation.</li> <li>1        Operation failed.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>ATTRIBUTES</b>            | See <a href="#">attributes(5)</a> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>NAME</b>        | nismatch, nisgrep – utilities for searching NIS+ tables                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <pre> <b>nismatch</b> [-AchMoPv] [-s <i>sep</i>] <i>key tablename</i> <b>nismatch</b> [-AchMoPv] [-s <i>sep</i>] <i>colname = key... tablename</i> <b>nismatch</b> [-AchMoPv] [-s <i>sep</i>] <i>indexedname</i> <b>nisgrep</b> [-AchiMov] [-s <i>sep</i>] <i>keypat tablename</i> <b>nisgrep</b> [-AchiMov] [-s <i>sep</i>] <i>colname = keypat... tablename</i> </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>The utilities <code>nismatch</code> and <code>nisgrep</code> can be used to search NIS+ tables. The command <code>nisgrep</code> differs from the <code>nismatch</code> command in its ability to accept regular expressions <i>keypat</i> for the search criteria rather than simple text matches.</p> <p>Because <code>nisgrep</code> uses a callback function, it is not constrained to searching only those columns that are specifically made searchable at the time of table creation. This makes it more flexible, but slower, than <code>nismatch</code>.</p> <p>In <code>nismatch</code>, the server does the searching, whereas in <code>nisgrep</code> the server returns all the readable entries and then the client does the pattern-matching.</p> <p>In both commands, the parameter <i>tablename</i> is the NIS+ name of the table to be searched. If only one key or key pattern is specified without the column name, then it is applied searching the first column. Specific named columns can be searched by using the <i>colname=key</i> syntax. When multiple columns are searched, only entries that match in all columns are returned. This is the equivalent of a logical join operation.</p> <p><code>nismatch</code> accepts an additional form of search criteria, <i>indexedname</i>, which is a NIS+ indexed name of the form:</p> <pre>[ <i>colname=value</i>, . . . ], <i>tablename</i></pre> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-A All data. Return the data within the table and all of the data in tables in the initial table's concatenation path.</li> <li>-c Print only a count of the number of entries that matched the search criteria.</li> <li>-h Display a header line before the matching entries that contains the names of the table's columns</li> <li>-i Ignore upper/lower case distinction during comparisons.</li> <li>-M Master server only. Send the lookup to the master server of the named data. This guarantees that the most up to date information is seen at the possible expense that the master server may be busy.</li> <li>-o Display the internal representation of the matching NIS+ object(s).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## nismatch(1)

- P Follow concatenation path. Specify that the lookup should follow the concatenation path of a table if the initial search is unsuccessful.
- s *sep* This option specifies the character to use to separate the table columns. If no character is specified, the default separator for the table is used.
- v Verbose. Do not suppress the output of binary data when displaying matching entries. Without this option binary data is displayed as the string \*BINARY\*.

### EXAMPLES **EXAMPLE 1** Searching a table for a username

This example searches a table named `passwd` in the `org_dir` subdirectory of the `zotz.com.` domain. It returns the entry that has the username of `skippy`. In this example, all the work is done on the server:

```
example% nismatch name=skippy passwd.org_dir.zotz.com.
```

### **EXAMPLE 2** Finding users using specific shells

This example is similar to the one above, except that it uses `nisgrep` to find all users in the table named `passwd` that are using either `ksh(1)` or `csch(1)`:

```
example% nisgrep 'shell=[ck]sh' passwd.org_dir.zotz.com.
```

### ENVIRONMENT VARIABLES

`NIS_PATH` If this variable is set, and the NIS+ table name is not fully qualified, each directory specified will be searched until the table is found (see [nisdefaults\(1\)](#)).

### EXIT STATUS

The following exit values are returned:

- 0 Successfully matches some entries.
- 1 Successfully searches the table and no matches are found.
- 2 An error condition occurs. An error message is also printed.

### ATTRIBUTES

See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

### SEE ALSO

[niscat\(1\)](#), [nisdefaults\(1\)](#), [nisls\(1\)](#), [nistbladm\(1\)](#), [nis\\_objects\(3NSL\)](#), [attributes\(5\)](#)

### DIAGNOSTICS

No memory An attempt to allocate some memory for the search failed.

nismatch(1)

*tablename* is not a table

The object with the name *tablename* was not a table object.

Can't compile regular expression

The regular expression in *keypat* was malformed.

column not found: *colname*

The column named *colname* does not exist in the table named *tablename*.

**NOTES** NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

| <b>DESCRIPTION</b>                       | <p>The <code>nismkdir</code> command creates new NIS+ subdirectories within an existing domain. It can also be used to create replicated directories. Without options, this command will create a subdirectory with the same master and the replicas as its parent directory.</p> <p>It is advisable to use <code>nisserver(1M)</code> to create an NIS+ domain which consists of the specified directory along with the <code>org_dir</code> and <code>groups_dir</code> subdirectories.</p> <p>The two primary aspects that are controlled when making a directory are its access rights, and its degree of replication.</p> <p>A host that serves a NIS+ directory must be a NIS+ client in a directory above the one it is serving. The exceptions to this rule are the root NIS+ servers, which are both clients and servers of the same NIS+ directory.</p> <p>When the host's default domain is different from the default domain on the client where the command is executed, the hostname supplied as an argument to the <code>-s</code> or <code>-m</code> options must be fully qualified.</p> <p>Special per-server and per-directory access restrictions may apply when this command updates the serving lists of the affected NIS+ servers. See <code>nisopaccess(1)</code>.</p> |                                 |                                                                                                                                                                                                                                                                                          |                                          |                                                                                                                                                                                                                                  |                                     |                                                                                                                                                                        |                                     |                                                                                                                                           |

The default value is 12h (12 hours).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                 |                                                                                                                                                                                                                                                                                          |                                          |                                                                                                                                                                                                                                  |                                     |                                                                                                                                                                        |                                     |                                                                                                                                           |
| <code>owner=<i>ownername</i></code>      | This token specifies that the NIS+ principal <i>ownername</i> should own the created object. The default for this value is the principal who is executing the command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                 |                                                                                                                                                                                                                                                                                          |                                          |                                                                                                                                                                                                                                  |                                     |                                                                                                                                                                        |                                     |                                                                                                                                           |
| <code>group=<i>groupname</i></code>      | This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default value is NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                 |                                                                                                                                                                                                                                                                                          |                                          |                                                                                                                                                                                                                                  |                                     |                                                                                                                                                                        |                                     |                                                                                                                                           |

`access=rights`

This token specifies the set of access rights that are to be granted for the given object. The value *rights* is specified in the format as defined by the `nischmod(1)` command. The default value is

```
-- -- -rmcdr- - -r- - -.
```

`-m hostname`

If the directory named by *dirname* does not exist, then a new directory that is *not* replicated is created with host *hostname* as its master server.

If the directory name by *dirname* does exist, then the host named by *hostname* is made its master server.

`-s hostname`

Specify that the host *hostname* will be a replica for an existing directory named *dirname*.

**OPERANDS**

The following operand is supported:

*dirname*

The fully qualified NIS+ name of the directory that has to be created.

**EXAMPLES****EXAMPLE 1** Using the `nismkdir` Command

To create a new directory `bar.foo.com.` under the `foo.com.` domain that shares the same master and replicas as the `foo.com.` directory one would use the command:

```
example% nismkdir bar.foo.com.
```

To create a new directory `bar.foo.com.` that is not replicated under the `foo.com.` domain one would use the command:

```
example% nismkdir -m myhost.foo.com. bar.foo.com.
```

To add a replica server of the `bar.foo.com.` directory, one would use the command:

```
example% nismkdir -s replica.foo.com. bar.foo.com.
```

**ENVIRONMENT VARIABLES**`NIS_DEFAULTS`

This variable contains a defaults string that will override the NIS+ standard defaults. If the `-D` switch is used those values will then override both the `NIS_DEFAULTS` variable and the standard defaults.

`NIS_PATH`

If this variable is set, and the NIS+ directory name is not fully qualified, each directory specified will be searched until the directory is found (see `nisdefaults(1)`).

**EXIT STATUS**

The following exit values are returned:

0 Successful operation.

nismkdir(1)

1            Operation failed.

**ATTRIBUTES**    See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

**SEE ALSO**    [nis+\(1\)](#), [nischmod\(1\)](#), [nischttl\(1\)](#), [nisdefaults\(1\)](#), [nislsl\(1\)](#), [nisopaccess\(1\)](#), [nismkdir\(1\)](#), [nisserver\(1M\)](#), [attributes\(5\)](#)

**NOTES**        NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

| <b>NAME</b>        | nisopaccess – NIS+ operation access control administration command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                  |                                                   |                |            |            |                   |           |          |          |                   |           |          |               |                       |            |                         |

| <b>SYNOPSIS</b>    | <p><b>nisopaccess</b> [-v] <i>directory operation rights</i></p> <p><b>nisopaccess</b> [-v] [-r] <i>directory operation</i></p> <p><b>nisopaccess</b> [-v] [-l] <i>directory [operation]</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                  |                                                   |                |            |            |                   |           |          |          |                   |           |          |               |                       |            |                         |
| <b>DESCRIPTION</b> | <p>Most NIS+ operations have implied access control through the permissions on the objects that they manipulate. For example, in order to read an entry in a table, you must have read permission on that entry. However, some NIS+ operations by default perform no access checking at all and are allowed to all:</p> <table border="0" style="width: 100%;"> <thead> <tr> <th style="text-align: left;"><i>Operation</i></th> <th style="text-align: left;"><i>Example of commands that use the operation</i></th> </tr> </thead> <tbody> <tr> <td>NIS_CHECKPOINT</td> <td>nisping -C</td> </tr> <tr> <td>NIS_CPTIME</td> <td>nisping, rpc.nisd</td> </tr> <tr> <td>NIS_MKDIR</td> <td>nismkdir</td> </tr> <tr> <td>NIS_PING</td> <td>nisping, rpc.nisd</td> </tr> <tr> <td>NIS_RMDIR</td> <td>nisrmdir</td> </tr> <tr> <td>NIS_SERVSTATE</td> <td>nisbackup, nisrestore</td> </tr> <tr> <td>NIS_STATUS</td> <td>nisstat, rpc.nispasswdd</td> </tr> </tbody> </table> <p>The <code>nisopaccess</code> command can be used to enforce access control on these operations on a per NIS+ directory basis.</p> <p>The <i>directory</i> argument should be the fully qualified name, including the trailing dot, of the NIS+ directory to which <code>nisopaccess</code> will be applied. As a short-hand method, if the directory name does not end in a trailing dot, for example “org_dir”, then the domain name is appended. The domain name is also appended to partial paths such as “org_dir.xyz”.</p> <p>You can use upper or lower case for the <i>operation</i> argument. However, you cannot mix cases. The “NIS_” prefix may be omitted. For example, NIS_PING can be specified as NIS_PING, nis_ping, PING, or ping.</p> <p>The <i>rights</i> argument is specified in the format defined by the <code>nischmod(1)</code> command. Since only the read (“r”) rights are used to determine who has the right to perform the operation, the modify and delete rights may be used to control who can change access to the operation.</p> <p>The access checking performed for each operation is as follows. When an operation requires access be checked on all directories served by its <code>rpc.nisd(1M)</code>, access is denied if even one of the directories prohibits the operation.</p> | <i>Operation</i> | <i>Example of commands that use the operation</i> | NIS_CHECKPOINT | nisping -C | NIS_CPTIME | nisping, rpc.nisd | NIS_MKDIR | nismkdir | NIS_PING | nisping, rpc.nisd | NIS_RMDIR | nisrmdir | NIS_SERVSTATE | nisbackup, nisrestore | NIS_STATUS | nisstat, rpc.nispasswdd |
| <i>Operation</i>   | <i>Example of commands that use the operation</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                  |                                                   |                |            |            |                   |           |          |          |                   |           |          |               |                       |            |                         |

|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NIS_CHECKPOINT | Check specified directory, or all directories if there is no directory argument, as is the case when NIS_CHECKPOINT is issued by the "nisping -Ca" command. Return NIS_PERMISSION when access is denied.                                                                                                                                                                                                                                                                                                                            |
| NIS_CPTIME     | Check specified directory. It returns 0 when access is denied.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| NIS_MKDIR      | Check parent of specified directory. Returns NIS_PERMISSION when access is denied.<br><br>If the parent directory is not available locally, that is, it is not served by this <code>rpc.nisd(1M)</code> , NIS_MKDIR access is allowed, though the operation will be executed only if this <code>rpc.nisd</code> is a known replica of the directory.<br><br>You should note that the NIS_MKDIR operation does not create a NIS+ directory; it adds a directory to the serving list for this <code>rpc.nisd</code> , if appropriate. |
| NIS_PING       | Check specified directory. No return value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| NIS_RMDIR      | Check specified directory. NIS_PERMISSION is returned when access denied.<br><br>The NIS_RMDIR operation does not remove a NIS+ directory; it deletes the directory from the serving list for this <code>rpc.nisd</code> , if appropriate.                                                                                                                                                                                                                                                                                          |
| NIS_SERVSTATE  | Check access on all directories served by this <code>rpc.nisd</code> . If access is denied for a tag, "<permission denied>" is returned instead of the tag value.                                                                                                                                                                                                                                                                                                                                                                   |
| NIS_STATUS     | Same as for NIS_SERVSTATE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

Notice that older clients may not supply authentication information for some of the operations listed above. These clients are treated as "nobody" when access checking is performed.

The access control is implemented by creating a NIS+ table called "proto\_op\_access" in each NIS+ directory to which access control should be applied. The table can be manipulated using normal NIS+ commands. However, `nisopaccess` is the only supported interface for NIS+ operation access control.

### OPTIONS

The following options are supported:

- l List the access control for a single operation, or for all operations that have access control enabled.
- r Remove access control for a certain operation on the specified directory.

`-v` Verbose mode.

**EXAMPLES****EXAMPLE 1** Enabling Access Control for the NIS\_PING Operation

To enable access control for the NIS\_PING operation on "org\_dir. `domainname` ." such that only the owner of the directory can perform a NIS\_PING, or change the NIS\_PING rights:

```
example% nisopaccess org_dir NIS_PING o=rmcd,g=,w=,n=
```

**EXAMPLE 2** Listing the Access to NIS\_PING

To list the access to the NIS\_PING operation for org\_dir:

```
example% nisopaccess -l org_dir NIS_PING
```

```
NIS_PING ----rmcd----- owner.dom.ain. group.dom.ain.
```

**EXAMPLE 3** Removing Access Control for NIS\_PING

To remove access control for NIS\_PING on org\_dir:

```
example% nisopaccess -r org_dir NIS_PING
```

**EXIT STATUS**

The following exit values are returned:

0 Successful operation.

other Operation failed. The status is usually the return status from a NIS+ command such as nistbladm.

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

**SEE ALSO**

[nis+\(1\)](#), [nischmod\(1\)](#), [nistbladm\(1\)](#), [rpc.nisd\(1M\)](#), [attributes\(5\)](#)

**NOTES**

NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

| <b>NAME</b>        | nispasswd – change NIS+ password information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <pre>nispasswd [-ghs] [-D domainname] [username] nispasswd -a nispasswd [-D domainname] [ -d [username]] nispasswd [-l] [-f] [-n min] [-x max] [-w warn] [-D domainname] username</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p>The <code>nispasswd</code> utility changes a password, <code>gecos</code> (<code>finger</code>) field (<code>-g</code> option), home directory (<code>-h</code> option), or login shell (<code>-s</code> option) associated with the <code>username</code> (invoker by default) in the NIS+ <code>passwd</code> table.</p> <p>Additionally, the command can be used to view or modify aging information associated with the user specified if the invoker has the right NIS+ privileges.</p> <p><code>nispasswd</code> uses secure RPC to communicate with the NIS+ server, and therefore, never sends unencrypted passwords over the communication medium.</p> <p><code>nispasswd</code> does not read or modify the local password information stored in the <code>/etc/passwd</code> and <code>/etc/shadow</code> files.</p> <p>When used to change a password, <code>nispasswd</code> prompts non-privileged users for their old password. It then prompts for the new password twice to forestall typing mistakes. When the old password is entered, <code>nispasswd</code> checks to see if it has “aged” sufficiently. If “aging” is insufficient, <code>nispasswd</code> terminates; see <code>getspnam(3C)</code>.</p> <p>The old password is used to decrypt the username’s secret key. If the password does not decrypt the secret key, <code>nispasswd</code> prompts for the old secure-RPC password. It uses this password to decrypt the secret key. If this fails, it gives the user one more chance. The old password is also used to ensure that the new password differs from the old by at least three characters. Assuming aging is sufficient, a check is made to ensure that the new password meets construction requirements described below. When the new password is entered a second time, the two copies of the new password are compared. If the two copies are not identical, the cycle of prompting for the new password is repeated twice. The new password is used to re-encrypt the user’s secret key. Hence, it also becomes their secure-RPC password. Therefore, the secure-RPC password is no longer a different password from the user’s password.</p> <p>Passwords must be constructed to meet the following requirements:</p> <ul style="list-style-type: none"><li>■ Each password must have at least six characters. Only the first eight characters are significant.</li><li>■ Each password must contain at least two alphabetic characters and at least one numeric or special character. In this case, “alphabetic” refers to all upper or lower case letters.</li><li>■ Each password must differ from the user’s login <code>username</code> and any reverse or circular shift of that login <code>username</code>. For comparison purposes, an upper case letter and its corresponding lower case letter are equivalent.</li></ul> |

- New passwords must differ from the old by at least three characters. For comparison purposes, an upper case letter and its corresponding lower case letter are equivalent.

Network administrators, who own the NIS+ password table, may change any password attributes if they establish their credentials (see [keylogin\(1\)](#)) before invoking `nispasswd`. Hence, `nispasswd` does not prompt these privileged-users for the old password and they are not forced to comply with password aging and password construction requirements.

Any user may use the `-d` option to display password attributes for his or her own login name. The format of the display will be:

```
username status mm/dd/yy min max warn
```

or, if password aging information is not present,

```
username status
```

where

|                 |                                                                                                                                                                                                                             |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>username</i> | The login ID of the user.                                                                                                                                                                                                   |
| <i>status</i>   | The password status of <i>username</i> : "PS" stands for password exists or locked, "LK" stands for locked, and "NP" stands for no password.                                                                                |
| <i>mm/dd/yy</i> | The date password was last changed for <i>username</i> . (Note that all password aging dates are determined using Greenwich Mean Time (Universal Time) and, therefore, may differ by as much as a day in other time zones.) |
| <i>min</i>      | The minimum number of days required between password changes for <i>username</i> .                                                                                                                                          |
| <i>max</i>      | The maximum number of days the password is valid for <i>username</i> .                                                                                                                                                      |
| <i>warn</i>     | The number of days relative to <i>max</i> before the password expires that the <i>username</i> will be warned.                                                                                                              |

The use of `nispasswd` is strongly discouraged. It is a wrapper around the [passwd\(1\)](#) command.

Using [passwd\(1\)](#) with the `-r nisplus` option will achieve the same result and will be consistent across all the different name services available. This is the recommended way to change the password in NIS+.

The login program, file access display programs (for example, `ls -l`), and network programs that require user passwords, for example, [rlogin\(1\)](#), [ftp\(1\)](#), and so on, use the standard [getpwnam\(3C\)](#) and [getspnam\(3C\)](#) interfaces to get password information. These programs will get the NIS+ password information, which is modified by `nispasswd`, only if the `passwd:` entry in the `/etc/nsswitch.conf` file includes `nisplus`. See [nsswitch.conf\(4\)](#) for more details.

## nispasswd(1)

### OPTIONS

The following options are supported:

- a Shows the password attributes for all entries. This will show only the entries in the NIS+ passwd table in the local domain that the invoker is authorized to "read".
- d [*username*] Displays password attributes for the caller or the user specified if the invoker has the right privileges.
- D *domainname* Consults the `passwd.org_dir` table in *domainname*. If this option is not specified, the default *domainname* returned by `nis_local_directory()` will be used. This *domainname* is the same as that returned by `domainname(1M)`.
- f Forces the user to change password at the next login by expiring the password for *username*.
- g Changes the `gecos` (finger) information.
- h Changes the home directory.
- l Locks the password entry for *username*. Subsequently, `login(1)` would disallow logins with this NIS+ password entry.
- n *min* Sets minimum field for *username*. The *min* field contains the minimum number of days between password changes for *username*. If *min* is greater than *max*, the user may not change the password. Always use this option with the `-x` option, unless *max* is set to `-1` (aging turned off). In that case, *min* need not be set.
- s Changes the login shell. By default, only the NIS+ administrator can change the login shell. The user will be prompted for the new login shell.
- w *warn* Sets *warn* field for *username*. The *warn* field contains the number of days before the password expires that the user will be warned whenever he or she attempts to login.
- x *max* Sets maximum field for *username*. The *max* field contains the number of days that the password is valid for *username*. The aging for *username* will be turned off immediately if *max* is set to `-1`. If it is set to `0`, then the user is forced to change the password at the next login session and aging is turned off.

### EXIT STATUS

The following exit values are returned:

- 0 Success.
- 1 Permission denied.
- 2 Invalid combination of options.
- 3 Unexpected failure. NIS+ passwd table unchanged.
- 4 NIS+ passwd table missing.

- 5 NIS+ is busy. Try again later.
- 6 Invalid argument to option.
- 7 Aging is disabled.
- 8 No memory.
- 9 System error.
- 10 Account expired.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

**SEE ALSO** `keylogin(1)`, `login(1)`, `nis+(1)`, `nistbladm(1)`, `passwd(1)`, `rlogin(1)`, `domainname(1M)`, `nisserver(1M)`, `getpwnam(3C)`, `getspnam(3C)`, `nis_local_directory(3NSL)`, `nsswitch.conf(4)`, `passwd(4)`, `shadow(4)`, `attributes(5)`

**NOTES** NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

## nisrm(1)

| <b>NAME</b>                  | nisrm – remove NIS+ objects from the namespace                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                                                                                                                                              |                |                 |              |          |

| <b>SYNOPSIS</b>              | <b>nisrm</b> [-if] <i>name</i> ...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                              |                |                 |              |          |
| <b>DESCRIPTION</b>           | The <b>nisrm</b> command removes NIS+ objects named <i>name</i> from the NIS+ namespace.<br><br>This command will fail if the NIS+ master server is not running.<br><br>This command will not remove directories. See <a href="#">nisrmdir(1)</a> . Nor will it remove non-empty tables. See <a href="#">nistbladm(1)</a> .                                                                                                                                                                                                                                |                                                                                                                                                                              |                |                 |              |          |
| <b>OPTIONS</b>               | The following options are supported:<br><br>-i        Interactive mode. Like the system <a href="#">rm(1)</a> command the <b>nisrm</b> command will ask for confirmation prior to removing an object. If the name specified by <i>name</i> is a non-fully qualified name this option is forced on. This prevents the removal of unexpected objects.<br><br>-f        Force. The removal is attempted, and if it fails for permission reasons, a <a href="#">nischmod(1)</a> is attempted and the removal retried. If the command fails, it fails silently. |                                                                                                                                                                              |                |                 |              |          |
| <b>OPERANDS</b>              | The following operand is supported:<br><br><i>name</i> A NIS+ named object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                              |                |                 |              |          |
| <b>EXAMPLES</b>              | <b>EXAMPLE 1</b> Using the <b>nisrm</b> Command<br><br>Remove the objects <i>foo</i> , <i>bar</i> , and <i>baz</i> from the namespace:<br><br>example% <b>nisrm foo bar baz</b>                                                                                                                                                                                                                                                                                                                                                                            |                                                                                                                                                                              |                |                 |              |          |
| <b>ENVIRONMENT VARIABLES</b> | <b>NIS_PATH</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found. See <a href="#">nisdefaults(1)</a> . |                |                 |              |          |
| <b>EXIT STATUS</b>           | The following exit values are returned:<br><br>0        Successful operation.<br><br>1        Operation failed.                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                                                                                                                                                              |                |                 |              |          |

| <b>DESCRIPTION</b> | <p><code>nisrmdir</code> deletes existing NIS+ subdirectories. It can remove a directory outright, or simply remove replicas from serving a directory.</p> <p>This command modifies the object that describes the directory <i>dirname</i>, and then notifies each replica to remove the directory named <i>dirname</i>. If the notification of any of the affected replicas fails, the directory object is returned to its original state unless the <code>-f</code> option is present.</p> <p>This command will fail if the NIS+ master server is not running.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-i</code> Interactive mode. Like the system <code>rm(1)</code> command the <code>nisrmdir</code> command will ask for confirmation prior to removing a directory. If the name specified by <i>dirname</i> is a non-fully qualified name this option is forced on. This prevents the removal of unexpected directories.</p> <p><code>-f</code> Force the command to succeed even though it may not be able to contact the affected replicas. This option should be used when a replica is known to be down and will not be able to respond to the removal notification. When the replica is finally rebooted it will read the updated directory object, note that it is no longer a replica for that directory, and stop responding to lookups on that directory. Cleanup of the files that held the now removed directory can be accomplished manually by removing the appropriate files in the <code>/var/nis</code> directory. See <code>nisfiles(4)</code> for more information.</p> <p><code>-s hostname</code> Specify that the host <i>hostname</i> should be removed as a replica for the directory named <i>dirname</i>. If this option is not present <i>all</i> replicas and the master server for a directory are removed and the directory is removed from the namespace.</p> <p>Special per-server and per-directory access restrictions may apply when this command updates the serving lists of the affected NIS+ servers. For more information, see <code>nisopaccess(1)</code>.</p> |
| <b>OPERANDS</b>    | <p>The following operand is supported:</p> <p><i>dirname</i> An existing NIS+ directory.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Using the <code>nisrmdir</code> Command</p> <p>To remove a directory <code>bar</code> under the <code>foo.com.</code> domain, one would use the command:</p> <pre>example% nisrmdir bar.foo.com.</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**EXAMPLE 1** Using the `nismdir` Command (Continued)

To remove a replica that is serving directory `bar.foo.com`, one would use the command:

```
example% nismdir -s replica.foo.com bar.foo.com.
```

To force the removal of directory `bar.foo.com` from the namespace, one would use the command:

```
example% nismdir -f bar.foo.com.
```

#### ENVIRONMENT VARIABLES

`NIS_PATH` If this variable is set, and the NIS+ directory name is not fully qualified, each directory specified will be searched until the directory is found. See [nisdefaults\(1\)](#).

#### EXIT STATUS

The following exit values are returned:

0 Successful operation.  
1 Operation failed.

#### ATTRIBUTES

See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

#### SEE ALSO

[nis+\(1\)](#), [nisdefaults\(1\)](#), [nisopaccess\(1\)](#), [nism\(1\)](#), [nisfiles\(4\)](#), [attributes\(5\)](#)

#### NOTES

NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

| <b>DESCRIPTION</b> | <p>The <code>nistbladm</code> command is used to administer NIS+ tables. There are five primary operations that it performs: creating and deleting tables, adding entries to, modifying entries within, and removing entries from tables.</p> <p>Though NIS+ does not place restrictions on the size of tables or entries, the size of data has an impact on the performance and the disk space requirements of the NIS+ server. NIS+ is not designed to store huge pieces of data, such as files; instead, pointers to files should be stored in NIS+.</p> <p>NIS+ design is optimized to support 10,000 objects with a total size of 10M bytes. If the requirements exceed the above, it is suggested that the domain hierarchy be created, or the data stored in the tables be pointers to the actual data, instead of the data itself.</p> <p>When creating tables, a table type, <code>type</code>, and a list of column definitions must be provided.</p> <p><code>type</code> is a string that is stored in the table and later used by the service to verify that entries being added to it are of the correct type.</p> <p>Syntax for column definitions is:</p> <pre>colname=[flags][,access]</pre> <p><code>flags</code> is a combination of:</p> <ul style="list-style-type: none"><li>S        Searchable. Specifies that searches can be done on the column's values (see <a href="#">nismatch(1)</a>).</li><li>I        Case-insensitive (only makes sense in combination with S). Specifies that searches should ignore case.</li><li>C        Crypt. Specifies that the column's values should be encrypted.</li></ul> |

- B Binary data (does not make sense in combination with *S*). If not set, the column's values are expected to be null terminated ASCII strings.
- X XDR encoded data (only makes sense in combination with *B*).

*access* is specified in the format as defined by the `nischmod(1)` command.

When manipulating entries, this command takes two forms of entry name. The first uses a series of space separated *colname=value* pairs that specify column values in the entry. The second is a NIS+ indexed name, *indexedname*, of the form:

```
[ colname=value, . . . ],tablename
```

## OPTIONS

The following options are supported:

- a | A Adds entries to a NIS+ table. The difference between the lowercase 'a' and the uppercase 'A' is in the treatment of preexisting entries. The entry's contents are specified by the *column=value* pairs on the command line. Values for all columns must be specified when adding entries to a table.
- Normally, NIS+ reports an error if an attempt is made to add an entry to a table that would overwrite an entry that already exists. This prevents multiple parties from adding duplicate entries and having one of them get overwritten. If you wish to force the add, the uppercase 'A' specifies that the entry is to be added, even if it already exists. This is analogous to a modify operation on the entry.
- c Creates a table named *tablename* in the namespace. The table that is created must have at least one column and at least one column must be searchable.
- d *tablename* Destroys the table named *tablename*. The table that is being destroyed must be empty. The table's contents can be deleted with the `-R` option below.
- e | E Edits the entry in the table that is specified by *indexdname*. *indexdname* must uniquely identify a single entry. It is possible to edit the value in a column that would change the indexed name of an entry.
- The change (*colname=value*) may affect other entries in the table if the change results in an entry whose indexed name is different from *indexedname* and which matches that of another existing entry. In this case, the `-e` option will fail and an error will be reported. The `-E` option will force the replacement of the existing entry by the new entry (effectively removing two old entries and adding a new one).

| -m                              | A synonym for -E. This option has been superseded by the -E option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                          |                                                                                                                                                                                                                               |                                 |                                                                                                                                                                             |                                 |                                                                                                                                           |                               |                                                                                                                       |
| -r  R                           | Removes entries from a table. The xentry is specified by either a series of <i>column=value</i> pairs on the command line, or an indexed name that is specified as <i>entryname</i> . The difference between the interpretation of the lowercase 'r' versus the uppercase 'R' is in the treatment of non-unique entry specifications. Normally the NIS+ server will disallow an attempt to remove an entry when the search criterion specified for that entry resolves to more than one entry in the table. However, it is sometimes desirable to remove more than one entry, as when you are attempting to remove all of the entries from a table. In this case, using the uppercase 'R' will force the NIS+ server to remove all entries matching the passed search criterion. If that criterion is null and no column values specified, then all entries in the table will be removed.                                                                                                                                                                                                                                                                                                                                                 |                          |                                                                                                                                                                                                                               |                                 |                                                                                                                                                                             |                                 |                                                                                                                                           |                               |                                                                                                                       |
| -u                              | Updates attributes of a table. This allows the concatenation path (-p), separation character (specified with the (-s)), column access rights, and table type string (-t) of a table to be changed. Neither the number of columns, nor the columns that are searchable may be changed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                          |                                                                                                                                                                                                                               |                                 |                                                                                                                                                                             |                                 |                                                                                                                                           |                               |                                                                                                                       |
| -D <i>defaults</i>              | When creating objects, this option specifies a different set of defaults to be used during this operation. The <i>defaults</i> string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.<br><br><table><tr><td><i>t</i>tl=<i>time</i></td><td>This token sets the default time to live for objects that are created by this command. The value <i>time</i> is specified in the format as defined by the <a href="#">nischttl(1)</a> command. The default value is 12 hours.</td></tr><tr><td><i>o</i>wner=<i>ownername</i></td><td>This token specifies that the NIS+ principal <i>ownername</i> should own the created object. Normally this value is the same as the principal who is executing the command.</td></tr><tr><td><i>g</i>roup=<i>groupname</i></td><td>This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default value is NULL.</td></tr><tr><td><i>a</i>ccess=<i>rights</i></td><td>This token specifies the set of access rights that are to be granted for the given object. The value <i>rights</i> is</td></tr></table> | <i>t</i> tl= <i>time</i> | This token sets the default time to live for objects that are created by this command. Normally this value is the same as the principal who is executing the command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                          |                                                                                                                                                                                                                               |                                 |                                                                                                                                                                             |                                 |                                                                                                                                           |                               |                                                                                                                       |
| <i>g</i> roup= <i>groupname</i> | This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default value is NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                          |                                                                                                                                                                                                                               |                                 |                                                                                                                                                                             |                                 |                                                                                                                                           |                               |                                                                                                                       |
| <i>a</i> ccess= <i>rights</i>   | This token specifies the set of access rights that are to be granted for the given object. The value <i>rights</i> is                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                          |                                                                                                                                                                                                                               |                                 |                                                                                                                                                                             |                                 |                                                                                                                                           |                               |                                                                                                                       |

nistbladm(1)

specified in the format as defined by the `nischmod(1)` command. The default value is

`- - - -rmcdr- - -r- - -`.

- `-p path` When creating or updating a table, this option specifies the table's search path. When a `nis_list()` function is invoked, the user can specify the flag `FOLLOW_PATH` to tell the client library to continue searching tables in the table's path if the search criteria used does not yield any entries. The path consists of an ordered list of table names, separated by colons. The names in the path must be fully qualified.
- `-s sep` When creating or updating a table, this option specifies the table's separator character. The separator character is used by `niscat(1)` when displaying tables on the standard output. Its purpose is to separate column data when the table is in ASCII form. The default value is a space.
- `-t type` When updating a table, this option specifies the table's type string.

## EXAMPLES

### EXAMPLE 1 Creating an Unmodifiable Table

This example creates a table named `hobbies` in the directory `foo.com`. of the type `hobby_tbl` with two searchable columns, `name` and `hobby`.

```
example% nistbladm -c hobby_tbl name=S,\
          a+r,o+m hobby=S,a+r hobbies.foo.com.
```

The column `name` has read access for all (that is, owner, group, and world) and modify access for only the owner. The column `hobby` is readable by all, but not modifiable by anyone.

In this example, if the access rights had not been specified, the table's access rights would have come from either the standard defaults or the `NIS_DEFAULTS` variable (see below).

### EXAMPLE 2 Adding Entries to the Table

To add entries to this table:

```
example% nistbladm -a name=bob hobby=skiing hobbies.foo.com.
example% nistbladm -a name=sue hobby=skiing hobbies.foo.com.
example% nistbladm -a name=ted hobby=swimming hobbies.foo.com.
```

### EXAMPLE 3 Adding the Concatenation Path

In the following example, the common root domain is `foo.com` (NIS+ requires at least two components to define the root domain) and the concatenation path for the subdomains `bar` and `baz` are added:

## nistbladm(1)

### EXAMPLE 3 Adding the Concatenation Path *(Continued)*

```
example% nistbladm -u -p hobbies.bar.foo.com.:hobbies.baz.foo.com. hobbies
```

### EXAMPLE 4 Deleting Skiers from the List

To delete the skiers from our list:

```
example% nistbladm -R hobby=skiing hobbies.foo.com.
```

Note: The use of the `-r` option would fail because there are two entries with the value of `skiing`.

### EXAMPLE 5 Naming a Column with no Flags Set

To create a table with a column that is named with no flags set, you supply only the name and the equals (=) sign as follows:

```
example% nistbladm -c notes_tbl name=S,a+r,o+m note= notes.foo.com.
```

This example created a table, named `notes.foo.com.`, of type `notes_tbl` with two columns name and note. The note column is not searchable.

### EXAMPLE 6 Protecting Terminal Characters

When entering data for columns in the form of a *value* string, it is essential that terminal characters be protected by single or double quotes. These are the characters equals (=), comma (,), left bracket ([), right bracket (]), and space ( ). These characters are parsed by NIS+ within an indexed name. These characters are protected by enclosing the entire value in double quote (") characters as follows:

```
example% nistbladm -a fullname="Joe User" nickname=Joe nicknames
```

If there is any doubt about how the string will be parsed, it is better to enclose it in quotes.

## ENVIRONMENT VARIABLES

NIS\_DEFAULTS

This variable contains a defaults string that will be override the NIS+ standard defaults. If the `-D` switch is used those values will then override both the `NIS_DEFAULTS` variable and the standard defaults.

NIS\_PATH

If this variable is set, and the NIS+ table name is not fully qualified, each directory specified will be searched until the table is found. See `nisdefaults(1)`.

## EXIT STATUS

The following exit values are returned:

0 Successful operation.

1            Operation failed.

**ATTRIBUTES**    See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

**SEE ALSO**    `nis+(1)`, `niscat(1)`, `nischmod(1)`, `nischown(1)`, `nischttl(1)`, `nisdefaults(1)`, `nismatch(1)`, `nissetup(1M)`, `attributes(5)`

**NOTES**        NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

**WARNINGS**    To modify one of the entries, say, for example, from “bob” to “robert”:

```
example% nistbladm -m name=robert [name=bob],hobbies
```

Notice that “[name=bob],hobbies” is an indexed name, and that the characters '[' (open bracket) and ']' (close bracket) are interpreted by the shell. When typing entry names in the form of NIS+ indexed names, the name must be protected by using single quotes.

It is possible to specify a set of defaults such that you cannot read or modify the table object later.

## nistest(1)

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>DESCRIPTION</b> | nistest provides a way for shell scripts and other programs to test for the existence, type, and access rights of objects and entries. Entries are named using indexed names. See <a href="#">nismatch(1)</a> . With the -c option, directory names can be compared to test where they lie in relation to each other in the namespace.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>OPTIONS</b>     | The following options are supported:<br><br>-a <i>rights</i> This option is used to verify that the current process has the desired or required access rights on the named object or entries. The access rights are specified in the same way as the <a href="#">nischmod(1)</a> command.<br><br>-A                    All data. This option specifies that the data within the table and all of the data in tables in the initial table's concatenation path be returned. This option is only valid when using indexed names or following links.<br><br>-L                    Follow links. If the object named by <i>object</i> or the tablename component of <i>indexedname</i> names a LINK type object, the link is followed when this switch is present.<br><br>-M                    Master server only. This option specifies that the lookup should be sent to the master server of the named data. This guarantees that the most up to date information is seen at the possible expense that the master server may be busy.<br><br>-P                    Follow concatenation path. This option specifies that the lookup should follow the concatenation path of a table if the initial search is unsuccessful. This option is only valid when using indexed names or following links.<br><br>-t <i>type</i> This option tests the type of <i>object</i> . The value of <i>type</i> can be one of the following:<br><br>D            Return true if the object is a directory object.<br>G            Return true if the object is a group object.<br>L            Return true if the object is a link object.<br>P            Return true if the object is a private object.<br>T            Return true if the object is a table object.<br><br>-c                    Test whether or not two directory names have a certain relationship to each other, for example, higher than (ht) or lower than (lt). The complete list of values for <i>op</i> can be displayed by |

using the `-c` option with no arguments.

**EXAMPLES** **EXAMPLE 1** Using the `nistest` Command

When testing for access rights, `nistest` returns success (0) if the specified rights are granted to the current user. Thus, testing for access rights:

```
example% nistest -a w=mr skippy.domain
```

Tests that all authenticated NIS+ clients have read and modify access to the object named `skippy.domain`.

Testing for access on a particular entry in a table can be accomplished using the indexed name syntax. The following example tests to see if an entry in the password table can be modified:

```
example% nistest -a o=m '[uid=99],passwd.org_dir'
```

To test if a directory lies higher in the namespace than another directory, use the `-c` option with an `op` of `ht` (higher than) as in the following example (which would return true):

```
example% nistest -c dom.com. ht lower.dom.com.
```

**ENVIRONMENT VARIABLES**

`NIS_PATH` If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found. See `nisdefaults(1)`.

**EXIT STATUS**

The following exit values are returned:

- 0 Successful operation.
- 1 Failure due to object not present, not of specified type, and/or no such access.
- 2 Failure due to illegal usage.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

**SEE ALSO**

`nis+(1)`, `nischmod(1)`, `nisdefaults(1)`, `nismatch(1)`, `attributes(5)`

**NOTES**

NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

| <b>DESCRIPTION</b> | <p>The nl utility reads lines from the named <i>file</i>, or the standard input if no <i>file</i> is named, and reproduces the lines on the standard output. Lines are numbered on the left in accordance with the command options in effect.</p> <p>nl views the text it reads in terms of logical pages. Line numbering is reset at the start of each logical page. A logical page consists of a header, a body, and a footer section. Empty sections are valid. Different line numbering options are independently available for header, body, and footer. For example, -bt (the default) numbers non-blank lines in the body section and does not number any lines in the header and footer sections.</p> <p>The start of logical page sections are signaled by input lines containing nothing but the following delimiter character(s):</p> <table border="1"><thead><tr><th>Line contents</th><th>Start Of</th></tr></thead><tbody><tr><td>\\:\\:</td><td>header</td></tr><tr><td>\\:\\:</td><td>body</td></tr><tr><td>\\:</td><td>footer</td></tr></tbody></table> <p>Unless optioned otherwise, nl assumes the text being read is in a single logical page body.</p> | Line contents  | Start Of                                                                                                    | \\:\\: | header           | \\:\\: | body                        | \\: | footer            |
| Line contents      | Start Of                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                                                                                                             |        |                  |        |                             |     |                   |

Recognized <i>types</i> and their meanings are:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                                                                                                             |        |                  |        |                             |     |                   |
| a                  | number all lines                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                                                                                                             |        |                  |        |                             |     |                   |
| t                  | number all non-empty lines.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                                                                                                             |        |                  |        |                             |     |                   |
| n                  | no line numbering                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                                                                                                             |        |                  |        |                             |     |                   |

|            |                 |                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | <i>pexp</i>     | number only lines that contain the regular expression specified in <i>exp</i> . See NOTES below.                                                                                                                                                                                                                                                                                                 |
|            |                 | Default <i>type</i> for logical page body is <i>t</i> (text lines numbered).                                                                                                                                                                                                                                                                                                                     |
| - <i>f</i> | <i>type</i>     | Same as <i>-btype</i> except for footer. Default <i>type</i> for logical page footer is <i>n</i> (no lines numbered).                                                                                                                                                                                                                                                                            |
| - <i>d</i> | <i>delim</i>    | The two delimiter characters specifying the start of a logical page section may be changed from the default characters ( <i>\ :</i> ) to two user-specified characters. If only one character is entered, the second character remains the default character ( <i>:</i> ). No space should appear between the <i>-d</i> and the delimiter characters. To enter a backslash, use two backslashes. |
| - <i>h</i> | <i>type</i>     | Same as <i>-btype</i> except for header. Default <i>type</i> for logical page header is <i>n</i> (no lines numbered).                                                                                                                                                                                                                                                                            |
| - <i>i</i> | <i>incr</i>     | <i>incr</i> is the increment value used to number logical page lines. Default <i>incr</i> is 1.                                                                                                                                                                                                                                                                                                  |
| - <i>l</i> | <i>num</i>      | <i>num</i> is the number of blank lines to be considered as one. For example, <i>-l2</i> results in only the second adjacent blank being numbered (if the appropriate <i>-ha</i> , <i>-ba</i> , and/or <i>-fa</i> option is set). Default <i>num</i> is 1.                                                                                                                                       |
| - <i>n</i> | <i>format</i>   | <i>format</i> is the line numbering format. Recognized values are:<br><i>ln</i> left justified, leading zeroes suppressed<br><i>rn</i> right justified, leading zeroes suppressed<br><i>rz</i> right justified, leading zeroes kept<br>Default <i>format</i> is <i>rn</i> (right justified).                                                                                                     |
| - <i>p</i> |                 | Do not restart numbering at logical page delimiters.                                                                                                                                                                                                                                                                                                                                             |
| - <i>s</i> | <i>sep</i>      | <i>sep</i> is the character(s) used in separating the line number and the corresponding text line. Default <i>sep</i> is a TAB.                                                                                                                                                                                                                                                                  |
| - <i>v</i> | <i>startnum</i> | <i>startnum</i> is the initial value used to number logical page lines. Default <i>startnum</i> is 1.                                                                                                                                                                                                                                                                                            |
| - <i>w</i> | <i>width</i>    | <i>width</i> is the number of characters to be used for the line number. Default <i>width</i> is 6.                                                                                                                                                                                                                                                                                              |

**OPERANDS** The following operand is supported:

*file* A path name of a text file to be line-numbered.

nl(1)

**EXAMPLES** **EXAMPLE 1** An example of the nl command

The command:

```
example% nl -v10 -i10 -d!+ filename1
```

will cause the first line of the page body to be numbered 10, the second line of the page body to be numbered 20, the third 30, and so forth. The logical page delimiters are !+.

**ENVIRONMENT VARIABLES** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of nl: LANG, LC\_ALL, LC\_COLLATE, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**FILES** /usr/lib/locale/locale/LC\_COLLATE/CollTable  
Collation table generated by localedef  
/usr/lib/locale/locale/LC\_COLLATE/coll.so  
Shared object containing string transformation library routines

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

/usr/bin/nl

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWesu         |

/usr/xpg4/bin/nl

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWxcu4        |
| Interface Stability | Standard        |

**SEE ALSO** [pr\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [regex\(5\)](#), [regexp\(5\)](#), [standards\(5\)](#)

**NOTES** Internationalized Regular Expressions are used in the POSIX and "C" locales. In other locales, Internationalized Regular Expressions are used if the following two conditions are met:

- /usr/lib/locale/locale/LC\_COLLATE/CollTable is present.
- /usr/lib/locale/locale/LC\_COLLATE/coll.so is not present.

Otherwise, Simple Regular Expressions are used.

Internationalized Regular Expressions are explained on [regex\(5\)](#). Simple Regular Expressions are explained on [regexp\(5\)](#).

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>DESCRIPTION</b> | <p>The nm utility displays the symbol table of each ELF object file that is specified by <i>file</i>.</p> <p>If no symbolic information is available for a valid input file, the nm utility will report that fact, but not consider it an error condition.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OPTIONS</b>     | <p>The output of nm may be controlled using the following options:</p> <ul style="list-style-type: none"> <li>-A               Writes the full path name or library name of an object on each line.</li> <li>-C               Demangles C++ symbol names before printing them out.</li> <li>-D               Displays the SHT_DYNSYM symbol information. This is the symbol table used by ld.so.1 and is present even in stripped dynamic executables. By default, the SHT_SYMTAB symbol table is displayed.</li> <li>-e               See NOTES below.</li> <li>-f               See NOTES below.</li> <li>-g               Writes only external (global) symbol information.</li> <li>-h               Does not display the output heading data.</li> <li>-l               Distinguishes between WEAK and GLOBAL symbols by appending a * to the key letter for WEAK symbols.</li> <li>-n               Sorts external symbols by name before they are printed.</li> <li>-o               Prints the value and size of a symbol in octal instead of decimal (equivalent to -t o).</li> <li>-p               Produces easy to parse, terse output. Each symbol name is preceded by its value (blanks if undefined) and one of the letters: <ul style="list-style-type: none"> <li>A            Absolute symbol.</li> <li>B            bss (uninitialized data space) symbol.</li> <li>C            COMMON symbol.</li> <li>D            Data object symbol.</li> <li>F            File symbol.</li> <li>N            Symbol has no type.</li> <li>L            Thread-Local storage symbol.</li> <li>S            Section symbol.</li> </ul> </li> </ul> |

|                         | Options may be used in any order, either singly or in combination, and may appear anywhere in the command line. When conflicting options are specified (such as <code>-v</code> and <code>-n</code> , or <code>-o</code> and <code>-x</code> ) the first is taken and the second ignored with a warning message to the user. (See <code>-R</code> for exception.) |                                                                                                                                                             |
| <b>OPERANDS</b>         | The following operand is supported:                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                             |

|                        |                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------|-------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | <i>file</i>                                                 | A path name of an object file, executable file or object-file library.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>OUTPUT</b>          | This section describes the nm utility's output options.     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Standard Output</b> | For each symbol, the following information will be printed: |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                        | Index                                                       | The index of the symbol. (The index appears in brackets.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                        | Value                                                       | The value of the symbol is one of the following: <ul style="list-style-type: none"> <li>■ A section offset for defined symbols in a relocatable file.</li> <li>■ Alignment constraints for symbols whose section index is SHN_COMMON.</li> <li>■ A virtual address in executable and dynamic library files.</li> </ul>                                                                                                                                                                                                                                                 |
|                        | Size                                                        | The size in bytes of the associated object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                        | Type                                                        | A symbol is of one of the following types: <ul style="list-style-type: none"> <li>NOTYPE           No type was specified.</li> <li>OBJECT           A data object such as an array or variable.</li> <li>FUNC             A function or other executable code.</li> <li>REGI             A register symbol (SPARC only).</li> <li>SECTION          A section symbol.</li> <li>FILE             Name of the source file.</li> <li>COMMON           An uninitialized common block.</li> <li>TLS              A variable associated with Thread-Local storage.</li> </ul> |
|                        | Bind                                                        | The symbol's binding attributes. <ul style="list-style-type: none"> <li>LOCAL symbols    Have a scope limited to the object file containing their definition.</li> <li>GLOBAL symbols   Are visible to all object files being combined.</li> <li>WEAK symbols     Are essentially global symbols with a lower precedence than GLOBAL.</li> </ul>                                                                                                                                                                                                                       |
|                        | Other                                                       | A symbol's visibility. <p>The lower 3 bits of the <code>st_other</code> member of the <code>Elf32_Sym</code> structure, defined in <code>&lt;sys/elf.h&gt;</code>, are currently used and can be one of:</p> <pre>#define STV_DEFAULT      0 #define STV_INTERNAL     1 #define STV_HIDDEN       2 #define STV_PROTECTED    3</pre>                                                                                                                                                                                                                                    |

## nm(1)

|             |                                                                                                                                                         |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| Shndx       | Except for three special values, this is the section header table index in relation to which the symbol is defined. The following special values exist: |
| ABS         | Indicates the symbol's value will not change through relocation.                                                                                        |
| COMMON      | Indicates an unallocated block and the value provides alignment constraints.                                                                            |
| UNDEF       | Indicates an undefined symbol.                                                                                                                          |
| Name        | The name of the symbol.                                                                                                                                 |
| Object Name | The name of the object or library if <code>-A</code> is specified.                                                                                      |

If the `-P` option is specified, the previous information is displayed using the following portable format. The three versions differ depending on whether `-t d`, `-t o`, or `-t x` was specified, respectively:

```
"%s%s %s %d %d\n", library/object name, name, type, value, size "%s%s %s %o %o\n", library/object name, name, type, value, size "%s%s %s %x %x\n", library/object name, name, type, value, size
```

where *library/object name* is formatted as follows:

- If `-A` is not specified, *library/object name* is an empty string.
- If `-A` is specified and the corresponding *file* operand does not name a library:  

```
"%s: ", file
```
- If `-A` is specified and the corresponding *file* operand names a library. In this case, *object file* names the object file in the library containing the symbol being described:  

```
"%s [%s] : ", file, object file
```

If `-A` is not specified, then if more than one *file* operand is specified or if only one *file* operand is specified and it names a library, `nm` will write a line identifying the object containing the following symbols before the lines containing those symbols, in the form:

- If the corresponding *file* operand does not name a library:  

```
"%s:\n", file
```
- If the corresponding *file* operand names a library; in this case, *object file* is the name of the file in the library containing the following symbols:  

```
"%s [%s] :\n", file, object file
```

If `-P` is specified, but `-t` is not, the format is as if `-t x` had been specified.

| <b>ENVIRONMENT VARIABLES</b>  | See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>nm</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_COLLATE</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |           |                     |          |

| <b>NOTES</b>                  | The following options are obsolete because of changes to the object file format and will be deleted in a future release.<br>-e           Prints only external and static symbols. The symbol table now contains only static and external symbols. Automatic symbols no longer appear in the symbol table. They do appear in the debugging information produced by <code>cc -g</code> , which may be examined using <code>dump(1)</code> .<br>-f           Produces full output. Redundant symbols (such as <code>.text</code> , <code>.data</code> , and <code>so forth</code> ), which existed previously, do not exist and producing full output will be identical to the default output.<br>-T           By default, <code>nm</code> prints the entire name of the symbols listed. Since symbol names have been moved to the last column, the problem of overflow is removed and it is no longer necessary to truncate the symbol name. |                |                 |              |           |                     |          |

## nohup(1)

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>NAME</b>        | nohup – run a command immune to hangups                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <pre>/usr/bin/nohup <i>command</i> [<i>argument...</i>]<br/>/usr/bin/nohup -p [-Fa] <i>pid</i> [<i>pid...</i>]<br/>/usr/bin/nohup -g [-Fa] <i>gpid</i> [<i>gpid...</i>]<br/>/usr/xpg4/bin/nohup <i>command</i> [<i>argument...</i>]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p>The nohup utility invokes the named <i>command</i> with the arguments supplied. When the <i>command</i> is invoked, nohup arranges for the SIGHUP signal to be ignored by the process.</p> <p>When invoked with the <code>-p</code> or <code>-g</code> flags, nohup arranges for processes already running as identified by a list of process IDs or a list of process group IDs to become immune to hangups.</p> <p>The nohup utility can be used when it is known that <i>command</i> will take a long time to run and the user wants to log out of the terminal. When a shell exits, the system sends its children SIGHUP signals, which by default cause them to be killed. All stopped, running, and background jobs will ignore SIGHUP and continue running, if their invocation is preceded by the nohup command or if the process programmatically has chosen to ignore SIGHUP.</p> <pre>/usr/bin/nohup<br/>Processes run by /usr/bin/nohup are immune to SIGHUP (hangup) and<br/>SIGQUIT (quit) signals.</pre> <pre>/usr/bin/nohup -p [-Fa]<br/>Processes specified by ID are made immune to SIGHUP and SIGQUIT, and all<br/>output to the controlling terminal is redirected to nohup.out. If -F is specified,<br/>nohup will force control of each process. If -a is specified, nohup will change the<br/>signal disposition of SIGHUP and SIGQUIT even if the process has installed a<br/>handler for either signal.</pre> <pre>/usr/bin/nohup -g [-Fa]<br/>Every process in the same process group as the processes specified by ID are made<br/>immune to SIGHUP and SIGQUIT, and all output to the controlling terminal is<br/>redirected to nohup.out. If -F is specified, nohup will force control of each<br/>process. If -a is specified, nohup will change the signal disposition of SIGHUP and<br/>SIGQUIT even if the process has installed a handler for either signal.</pre> <pre>/usr/xpg4/bin/nohup<br/>Processes run by /usr/xpg4/bin/nohup are immune to SIGHUP.</pre> <p>The nohup utility does not arrange to make processes immune to a SIGTERM (terminate) signal, so unless they arrange to be immune to SIGTERM or the shell makes them immune to SIGTERM, they will receive it.</p> <p>If nohup.out is not writable in the current directory, output is redirected to \$HOME/nohup.out. If a file is created, the file will have read and write permission (600, see <a href="#">chmod(1)</a>). If the standard error is a terminal, it is redirected to the</p> |

standard output, otherwise it is not redirected. The priority of the process run by nohup is not altered.

**OPTIONS** The following options are supported:

- a Always changes the signal disposition of target processes. This option is valid only when specified with -p or -g.
- F Force. Grabs the target processes even if another process has control. This option is valid only when specified with -p or -g.
- g Operates on a list of process groups. This option is not valid with -p.
- p Operates on a list of processes. This option is not valid with -g.

**OPERANDS** The following operands are supported:

- pid* A decimal process ID to be manipulated by nohup -p.
- pgid* A decimal process group ID to be manipulated by nohup -g.
- command* The name of a command that is to be invoked. If the *command* operand names any of the special [shell\\_builtins\(1\)](#) utilities, the results are undefined.
- argument* Any string to be supplied as an argument when invoking the *command* operand.

**EXAMPLES** **EXAMPLE 1** Applying nohup to pipelines or command lists

It is frequently desirable to apply nohup to pipelines or lists of commands. This can be done only by placing pipelines and command lists in a single file, called a shell script. One can then issue:

```
example$ nohup sh file
```

and the nohup applies to everything in *file*. If the shell script *file* is to be executed often, then the need to type sh can be eliminated by giving *file* execute permission.

Add an ampersand and the contents of *file* are run in the background with interrupts also ignored (see [sh\(1\)](#)):

```
example$ nohup file &
```

**EXAMPLE 2** Applying nohup -p to a process

```
example$ long_running_command &
example$ nohup -p `pgrep long_running_command`
```

**EXAMPLE 3** Applying nohup -g to a process group

```
example$ make &
example$ ps -o sid -p $$
SID
```

## nohup(1)

**EXAMPLE 3** Applying nohup -g to a process group (Continued)

```
81079
example$ nohup -g `pgrep -s 81079 make`
```

### ENVIRONMENT VARIABLES

See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of nohup: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, PATH, NLSPATH, and PATH.

**HOME** Determine the path name of the user's home directory: if the output file nohup.out cannot be created in the current directory, the nohup command will use the directory named by HOME to create the file.

### EXIT STATUS

The following exit values are returned:

126 *command* was found but could not be invoked.

127 An error occurred in nohup, or *command* could not be found

Otherwise, the exit values of nohup will be those of the *command* operand.

### FILES

nohup.out The output file of the nohup execution if standard output is a terminal and if the current directory is writable.

\$HOME/nohup.out The output file of the nohup execution if standard output is a terminal and if the current directory is not writable.

### ATTRIBUTES

See [attributes\(5\)](#) for descriptions of the following attributes:

#### /usr/bin/nohup

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | enabled         |

#### /usr/xpg4/bin/nohup

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWxcu4        |
| CSI                 | enabled         |
| Interface Stability | Standard        |

### SEE ALSO

[batch\(1\)](#), [chmod\(1\)](#), [csh\(1\)](#), [ksh\(1\)](#), [nice\(1\)](#), [pgrep\(1\)](#), [proc\(1\)](#), [ps\(1\)](#), [sh\(1\)](#), [shell\\_builtins\(1\)](#), [signal\(3C\)](#), [proc\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

### WARNINGS

If you are running the Korn shell ([ksh\(1\)](#)) as your login shell, and have nohup'ed jobs running when you attempt to log out, you will be warned with the message:

You have jobs running.

You will then need to log out a second time to actually log out. However, your background jobs will continue to run.

**NOTES** The C-shell (`cs(1)`) has a built-in command `nohup` that provides immunity from `SIGHUP`, but does not redirect output to `nohup.out`. Commands executed with `'&'` are automatically immune to `HUP` signals while in the background.

`nohup` does not recognize command sequences. In the case of the following command,

```
example$ nohup command1; command2
```

the `nohup` utility applies only to `command1`. The command,

```
example$ nohup (command1; command2)
```

is syntactically incorrect.

| <b>DESCRIPTION</b> | <p>The nroff utility formats text in the named <i>files</i> for typewriter-like devices. See also <a href="#">troff(1)</a>.</p> <p>If no <i>file</i> argument is present, nroff reads the standard input. An argument consisting of a '-' is taken to be a file name corresponding to the standard input.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |    |                                                                                  |    |                                                                                                                                                                           |    |                                                               |    |                                                          |        |                                                                      |     |                                 |            |                                                                                                                                                                                                                                      |      |                                              |     |                                                                                                                                                          |        |                                                                                     |    |                                                               |            |                                                                 |     |           |        |                      |      |            |
| <b>OPTIONS</b>     | <p>The following options are supported. Options may appear in any order so long as they appear <i>before</i> the files.</p> <table><tr><td>-e</td><td>Produces equally-spaced words in adjusted lines, using full terminal resolution.</td></tr><tr><td>-h</td><td>Uses output TAB characters during horizontal spacing to speed output and reduces output character count. TAB settings are assumed to be every 8 nominal character widths.</td></tr><tr><td>-i</td><td>Reads the standard input after the input files are exhausted.</td></tr><tr><td>-q</td><td>Does not print output that was read from an .rd request.</td></tr><tr><td>-mname</td><td>Prepends the macro file /usr/share/lib/tmac/name to the input files.</td></tr><tr><td>-nN</td><td>Numbers first generated page N.</td></tr><tr><td>-opagelist</td><td>Prints only pages whose page numbers appear in the comma-separated <i>list</i> of numbers and ranges. A range N-M means pages N through M; an initial -N means from the beginning to page N; and a final N- means from N to the end.</td></tr><tr><td>-raN</td><td>Sets register <i>a</i> (one-character) to N.</td></tr><tr><td>-sN</td><td>Stops every N pages. nroff will halt prior to every N pages (default N=1) to allow paper loading or changing, and will resume upon receipt of a NEWLINE.</td></tr><tr><td>-Tname</td><td>Prepares output for a device of the specified <i>name</i>. Known <i>names</i> are:</td></tr><tr><td>37</td><td>Teletype Corporation Model 37 terminal — this is the default.</td></tr><tr><td>lp   tn300</td><td>GE — any line printer or terminal without half-line capability.</td></tr><tr><td>300</td><td>DASI-300.</td></tr><tr><td>300-12</td><td>DASI-300 — 12-pitch.</td></tr><tr><td>300S</td><td>DASI-300S.</td></tr></table> | -e | Produces equally-spaced words in adjusted lines, using full terminal resolution. | -h | Uses output TAB characters during horizontal spacing to speed output and reduces output character count. TAB settings are assumed to be every 8 nominal character widths. | -i | Reads the standard input after the input files are exhausted. | -q | Does not print output that was read from an .rd request. | -mname | Prepends the macro file /usr/share/lib/tmac/name to the input files. | -nN | Numbers first generated page N. | -opagelist | Prints only pages whose page numbers appear in the comma-separated <i>list</i> of numbers and ranges. A range N-M means pages N through M; an initial -N means from the beginning to page N; and a final N- means from N to the end. | -raN | Sets register <i>a</i> (one-character) to N. | -sN | Stops every N pages. nroff will halt prior to every N pages (default N=1) to allow paper loading or changing, and will resume upon receipt of a NEWLINE. | -Tname | Prepares output for a device of the specified <i>name</i> . | -e                 | Produces equally-spaced words in adjusted lines, using full terminal resolution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |    |                                                                                  |    |                                                                                                                                                                           |    |                                                               |    |                                                          |        |                                                                      |     |                                 |            |                                                                                                                                                                                                                                      |      |                                              |     |                                                                                                                                                          |        |                                                                                     |    |                                                               |            |                                                                 |     |           |        |                      |      |            |
| -h                 | Uses output TAB characters during horizontal spacing to speed output and reduces output character count. TAB settings are assumed to be every 8 nominal character widths.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |    |                                                                                  |    |                                                                                                                                                                           |    |                                                               |    |                                                          |        |                                                                      |     |                                 |            |                                                                                                                                                                                                                                      |      |                                              |     |                                                                                                                                                          |        |                                                                                     |    |                                                               |            |                                                                 |     |           |        |                      |      |            |

| -opagelist         | Prints only pages whose page numbers appear in the comma-separated <i>list</i> of numbers and ranges. A range N-M means pages N through M; an initial -N means from the beginning to page N; and a final N- means from N to the end.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |    |                                                                                  |    |                                                                                                                                                                           |    |                                                               |    |                                                          |        |                                                                      |     |                                 |            |                                                                                                                                                                                                                                      |      |                                              |     |                                                                                                                                                          |        |                                                                                     |    |                                                               |            |                                                                 |     |           |        |                      |      |            |
| -raN               | Sets register <i>a</i> (one-character) to N.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |    |                                                                                  |    |                                                                                                                                                                           |    |                                                               |    |                                                          |        |                                                                      |     |                                 |            |                                                                                                                                                                                                                                      |      |                                              |     |                                                                                                                                                          |        |                                                                                     |    |                                                               |            |                                                                 |     |           |        |                      |      |            |
| -sN                | Stops every N pages. nroff will halt prior to every N pages (default N=1) to allow paper loading or changing, and will resume upon receipt of a NEWLINE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |    |                                                                                  |    |                                                                                                                                                                           |    |                                                               |    |                                                          |        |                                                                      |     |                                 |            |                                                                                                                                                                                                                                      |      |                                              |     |                                                                                                                                                          |        |                                                                                     |    |                                                               |            |                                                                 |     |           |        |                      |      |            |

| -uN     | Set the emboldening factor for the font mounted in position 3 to N. If N is missing, then set the emboldening factor to 0. |

**EXAMPLES** **EXAMPLE 1** Formatting with a macro package

The following command formats `users.guide` using the `-me` macro package, and stopping every 4 pages:

```
example% nroff -s4 -me users.guide
```

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `nroff`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**FILES**

**NOTES**

`/usr/tmp` is currently a symbolic link to `/var/tmp`.

Previous documentation incorrectly described the numeric register `yr` as being the "Last two digits of current year". `yr` is in actuality the number of years since 1900. To correctly obtain the last two digits of the current year through the year 2099, the definition given below of string register `yy` may be included in a document and subsequently used to display a two-digit year. Notice that any other available one- or two-character register name may be substituted for `yy`.

```
.\ " definition of new string register yy--last two digits of year
.\ " use yr (# of years since 1900) if it is < 100
.ie \n(yr<100 .ds yy \n(yr
.el \{
        .\ " else, subtract 100 from yr, store in yy
```

## nroff(1)

```
.nr ny \n(yr-100
.ie \n(ny>9 \{      .\" use ny if it is two digits
.ds yy \n(ny
.\" remove temporary number register ny
.rr ny \}
.el \{.ds yy 0
.\" if ny is one digit, append it to 0
.as yy \n(ny
.rr ny \} \}
```

| <b>DESCRIPTION</b>           | <p>The <code>od</code> command copies sequentially each input file to standard output and transforms the input data according to the output types specified by the <code>-t</code> or <code>-bcCDdFfOoSsvXx</code> options. If no output type is specified, the default output is as if <code>-t o2</code> had been specified. Multiple types can be specified by using multiple <code>-bcCDdFfOoSstvXx</code> options. Output lines are written for each type specified in the order in which the types are specified. If no <i>file</i> is specified, the standard input is used. The <i>[offset_string]</i> operand is mutually exclusive from the <code>-A</code>, <code>-j</code>, <code>-N</code>, and <code>-t</code> options. For the purposes of this description, the following terms are used:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;">word</td> <td>Refers to a 16-bit unit, independent of the word size of the machine.</td> </tr> <tr> <td>long word</td> <td>Refers to a 32-bit unit.</td> </tr> <tr> <td>double long word</td> <td>Refers to a 64-bit unit.</td> </tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | word                         | Refers to a 16-bit unit, independent of the word size of the machine.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | long word       | Refers to a 32-bit unit.                                              | double long word | Refers to a 64-bit unit.                                                                      |      |                 |           |                 |           |                 |          |                 |        |                 |     |                 |
| word                         | Refers to a 16-bit unit, independent of the word size of the machine.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                 |                                                                       |                  |                                                                                               |      |                 |           |                 |           |                 |          |                 |        |                 |     |                 |

| <b>OPTIONS</b>               | <p>The following options are supported:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><code>-A address_base</code></td> <td>Specifies the input offset base. The <i>address_base</i> option-argument must be a character. The characters <code>d</code>, <code>o</code> and <code>x</code> specify that the offset base will be written in decimal, octal or hexadecimal, respectively. The character <code>n</code> specifies that the offset will not be written. Unless <code>-A n</code> is specified, the output line will be preceded by the input offset, cumulative across input files, of the next byte to be written. In addition, the offset of the byte following the last byte written will be displayed after all the input data has been processed. Without the <code>-A address_base</code> option and the <i>[offset_string]</i> operand, the input offset base is displayed in octal.</td> </tr> <tr> <td><code>-b</code></td> <td>Interprets bytes in octal. This is equivalent to <code>-t o1</code>.</td> </tr> </table> <p><code>/usr/bin/od</code></p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><code>-c</code></td> <td>Displays single-byte characters. Certain non-graphic characters appear as C-language escapes:</td> </tr> <tr> <td style="padding-right: 20px;">null</td> <td><code>\0</code></td> </tr> <tr> <td>backspace</td> <td><code>\b</code></td> </tr> <tr> <td>form-feed</td> <td><code>\f</code></td> </tr> <tr> <td>new-line</td> <td><code>\n</code></td> </tr> <tr> <td>return</td> <td><code>\r</code></td> </tr> <tr> <td>tab</td> <td><code>\t</code></td> </tr> </table> <p>Others appear as 3-digit octal numbers. For example:</p> | <code>-A address_base</code> | Specifies the input offset base. The <i>address_base</i> option-argument must be a character. The characters <code>d</code> , <code>o</code> and <code>x</code> specify that the offset base will be written in decimal, octal or hexadecimal, respectively. The character <code>n</code> specifies that the offset will not be written. Unless <code>-A n</code> is specified, the output line will be preceded by the input offset, cumulative across input files, of the next byte to be written. In addition, the offset of the byte following the last byte written will be displayed after all the input data has been processed. Without the <code>-A address_base</code> option and the <i>[offset_string]</i> operand, the input offset base is displayed in octal.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                 |                                                                       |                  |                                                                                               |      |                 |           |                 |           |                 |          |                 |        |                 |     |                 |
| <code>-b</code>              | Interprets bytes in octal. This is equivalent to <code>-t o1</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                 |                                                                       |                  |                                                                                               |      |                 |           |                 |           |                 |          |                 |        |                 |     |                 |
| <code>-c</code>              | Displays single-byte characters. | return                       | <code>\r</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                 |                                                                       |                  |                                                                                               |      |                 |           |                 |           |                 |          |                 |        |                 |     |                 |
| tab                          | <code>\t</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                 |                                                                       |                  |                                                                                               |      |                 |           |                 |           |                 |          |                 |        |                 |     |                 |

od(1)

/usr/xpg4/bin/od

```
echo "hello world" | od -c
0000000  h e l l o       w o r l d \n
0000014
```

**-c** Interprets bytes as single-byte or multibyte characters according to the current setting of the LC\_CTYPE locale category. Printable multibyte characters are written in the area corresponding to the first byte of the character. The two-character sequence \*\* is written in the area corresponding to each remaining byte in the character, as an indication that the character is continued. Non-graphic characters appear the same as they would using the -C option.

**-C** Interprets bytes as single-byte or multibyte characters according to the current setting of the LC\_CTYPE locale category. Printable multibyte characters are written in the area corresponding to the first byte of the character. The two-character sequence \*\* is written in the area corresponding to each remaining byte in the character, as an indication that the character is continued. Certain non-graphic characters appear as C escapes:

```
null          \0
backspace     \b
form-feed     \f
new-line      \n
return        \r
tab           \t
```

Other non-printable characters appear as one three-digit octal number for each byte in the character.

**-d** Interprets words in unsigned decimal. This is equivalent to -t u2.

**-D** Interprets long words in unsigned decimal. This is equivalent to -t u4.

**-f** Interprets long words in floating point. This is equivalent to -t f4.

**-F** Interprets double long words in extended precision. This is equivalent to -t f8.

**-j skip** Jumps over *skip* bytes from the beginning of the input. The od command will read or seek past the first *skip* bytes in the concatenated input files. If the combined input is not at least *skip* bytes long, the od command will write a diagnostic message to standard error and exit with a non-zero exit status.

By default, the *skip* option-argument is interpreted as a decimal number. With a leading 0x or 0X, the offset is interpreted as a hexadecimal number; otherwise, with a leading 0, the offset will be interpreted as an octal number. Appending the character b, k, or m to offset will cause it to be interpreted as a multiple of 512, 1024

or 1 048 576 bytes, respectively. If the *skip* number is hexadecimal, any appended b is considered to be the final hexadecimal digit. The address is displayed starting at 0000000, and its base is not implied by the base of the *skip* option-argument.

- N *count*** Formats no more than *count* bytes of input. By default, *count* is interpreted as a decimal number. With a leading 0x or 0X, *count* is interpreted as a hexadecimal number; otherwise, with a leading 0, it is interpreted as an octal number. If *count* bytes of input (after successfully skipping, if *-j skip* is specified) are not available, it will not be considered an error. The `od` command will format the input that is available. The base of the address displayed is not implied by the base of the *count* option-argument.
- o** Interprets words in octal. This is equivalent to `-t o2`.
- O** Interprets long words in unsigned octal. This is equivalent to `-t o4`.
- s** Interprets words in signed decimal. This is equivalent to `-t d2`.
- S** Interprets long words in signed decimal. This is equivalent to `-t d4`.
- t *type\_string*** Specifies one or more output types. The *type\_string* option-argument must be a string specifying the types to be used when writing the input data. The string must consist of the type specification characters:

- a** *Named character.* Interprets bytes as named characters. Only the least significant seven bits of each byte will be used for this type specification. Bytes with the values listed in the following table will be written using the corresponding names for those characters.

The following are named characters in `od`:

| Value | Name |
|-------|------|
| \000  | nul  |
| \001  | soh  |
| \002  | stx  |
| \003  | etx  |
| \004  | eot  |
| \005  | enq  |
| \006  | ack  |
| \007  | bel  |
| \010  | bs   |
| \011  | ht   |
| \012  | lf   |
| \013  | vt   |
| \014  | ff   |
| \015  | cr   |

**c** *Character.* Interprets bytes as single-byte or multibyte characters specified by the current setting of the LC\_CTYPE locale category. Printable multibyte characters are written in the area corresponding to the first byte of the character. The two-character sequence \*\* is written in the area corresponding to each remaining byte in the character, as an indication that the character is continued. Certain non-graphic characters appear as C escapes: \0, \a, \b, \f, \n, \r, \t, \v. Other non-printable characters appear as one three-digit octal number for each byte in the character.

The type specification characters **d**, **f**, **o**, **u**, and **x** can be followed by an optional unsigned decimal integer that specifies the number of bytes to be transformed by each instance of the output type.

**f** *Floating point.* Can be followed by an optional **F**, **D**, or **L** indicating that the conversion should be applied to an item of type `float`, `double`, or `long double`, respectively.

**d**, **o**, **u**, and **x** *Signed decimal, octal, unsigned decimal, and hexadecimal,* respectively. Can be followed by an optional **C**, **S**, **I**, or **L** indicating that the conversion should be applied to an item of type `char`, `short`, `int`, or `long`, respectively.

Multiple types can be concatenated within the same *type\_string* and multiple *-t* options can be specified. Output lines are written for each type specified in the order in which the type specification characters are specified.

- v Shows all input data (verbose). Without the *-v* option, all groups of output lines that would be identical to the immediately preceding output line (except for byte offsets), will be replaced with a line containing only an asterisk (\*).
- x Interprets words in hex. This is equivalent to *-t x2*.
- X Interprets long words in hex. This is equivalent to *-t x4*.

**OPERANDS** The following operands are supported for both */usr/bin/od* and */usr/xpg4/bin/od*:

- Uses the standard input in addition to any files specified. When this operand is not given, the standard input is used only if no *file* operands are specified.

**/usr/bin/od** The following operands are supported for */usr/bin/od* only:

- file* A path name of a file to be read. If no *file* operands are specified, the standard input will be used. If there are no more than two operands, none of the *-A*, *-j*, *-N*, or *-t* options is specified, and *any* of the following are true:
1. the first character of the last operand is a plus sign (+)
  2. the first character of the second operand is numeric
  3. the first character of the second operand is *x* and the second character of the second operand is a lower-case hexadecimal character or digit
  4. the second operand is named "x"
  5. the second operand is named "."

then the corresponding operand is assumed to be an offset operand rather than a file operand.

Without the *-N* count option, the display continues until an end-of-file is reached.

```
[+] [0] offset [.] [b|B]
[+] [0] [offset] [.]
[+] [0x|x] [offset]
[+] [0x|x] offset [B]
```

The *offset\_string* operand specifies the byte offset in the file where dumping is to commence. The offset is interpreted in octal bytes by default. If *offset* begins with "0", it is interpreted in octal. If *offset* begins with

od(1)

"x" or "0x", it is interpreted in hexadecimal and any appended "b" is considered to be the final hexadecimal digit. If "." is appended, the offset is interpreted in decimal. If "b" or "B" is appended, the offset is interpreted in units of 512 bytes. If the `file` argument is omitted, the `offset` argument must be preceded by a plus sign (+). The address is displayed starting at the given offset. The radix of the address will be the same as the radix of the offset, if specified, otherwise it will be octal. Decimal overrides octal, and it is an error to specify both hexadecimal and decimal conversions in the same offset operand.

**/usr/xpg4/bin/od** The following operands are supported for `/usr/xpg4/bin/od` only:

*file* Same as `/usr/bin/od`, except only one of the first two conditions must be true.

[+] [0] *offset* [.] [b|B]

+ [*offset*] [.]

[+] [0x] [*offset*]

[+] [0x] *offset* [B]

+x [*offset*]

+x*offset* [B]

Description of *offset\_string* is the same as for `/usr/bin/od`.

**ENVIRONMENT VARIABLES** See `environ(5)` for descriptions of the following environment variables that affect the execution of `od`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, `LC_NUMERIC`, and `NLSPATH`.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

**/usr/bin/od**

| <b>SYNOPSIS</b>    | <b>on</b> [-i] [-d] [-n] <i>host command [argument] ...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |              |           |
| <b>DESCRIPTION</b> | <p>The on program is used to execute commands on another system, in an environment similar to that invoking the program. All environment variables are passed and the current working directory is preserved. To preserve the working directory, the working file system must be either already mounted on the host or be exported to it. Relative path names will only work if they are within the current file system. Absolute path names may cause problems.</p> <p>The standard input is connected to the standard input of the remote command. The standard output and the standard error from the remote command are sent to the corresponding files for the on command.</p>            |                |                 |              |           |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-d        Debug mode. Prints out some messages as work is being done.</li><li>-i        Interactive mode. Uses remote echoing and special character processing. This option is needed for programs that expect to be talking to a terminal. All terminal modes and window size changes are propagated.</li><li>-n        No Input. This option causes the remote program to get EOF when it reads from the standard input, instead of passing the standard input from the standard input of the on program. For example, -n is necessary when running commands in the background with job control.</li></ul> |                |                 |              |           |
| <b>ATTRIBUTES</b>  | <p>See attributes(5) for descriptions of the following attributes:</p> <table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWnfscu</td></tr></tbody></table>                                                                                                                                                                                                                                                                                                                                                                                                                                                        | ATTRIBUTE TYPE | ATTRIBUTE VALUE | Availability | SUNWnfscu |

| <b>DIAGNOSTICS</b> | <p>unknown host<br/>  Host name not found.</p> <p>cannot connect to server<br/>  Host down or not running the server.</p> <p>can't find<br/>  Problem finding the working directory.</p> <p>can't locate mount point<br/>  Problem finding current file system.</p> <p>RPC: Authentication error<br/>  The server requires DES authentication and you do not have a secret key registered with key serv. Perhaps you logged in without a password. Try to keylogin. If that fails, try to set your publickey with chkey.</p>                                                                                                                                                                   |                |                 |              |           |

on(1)

on *server*: RPC: can't encode arguments

The 10240 byte limit for arguments to be encoded and passed from the sending to the receiving system has been exceeded.

Other diagnostic messages may be passed back from the server.

**BUGS** When the working directory is remote mounted over NFS, a Control-Z hangs the window.

Root cannot use on.

optisa(1)

**NAME** optisa – determine which variant instruction set is optimal to use

**SYNOPSIS** **optisa** *instruction\_set...*

**DESCRIPTION** *optisa* prints which *instruction\_set* out of the ones specified in the command will perform best on this machine. In this case, “best” is defined by the order in which instruction set names are returned by *isalist(1)*. Possible values for *instruction\_set* are given in *isalist(5)*.

**ATTRIBUTES** See *attributes(5)* for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**EXIT STATUS** The following exit values are returned:

0 One of the *instruction\_set* values you specified is printed by this command.

1 There is no output; that is, this machine cannot use any *instruction\_set* that you specified with the *optisa* command.

**SEE ALSO** *isalist(1)*, *uname(1)*, *attributes(5)*, *isalist(5)*

**NOTES** *optisa* is preferable to *uname -p* or *uname -m* (see *uname(1)*) in determining which of several binary versions of a given program should be used on the given machine.

| <b>NAME</b>        | pack, pcat, unpack – compress and expand files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <p><b>pack</b> [-f] [-] file...</p> <p><b>pcat</b> file...</p> <p><b>unpack</b> file...</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p><b>pack</b> The <code>pack</code> command attempts to store the specified files in a compressed form. Wherever possible (and useful), each input file <code>file</code> is replaced by a packed file <code>file.z</code> with the same access modes, access and modified dates, and owner as those of <code>file</code>. If <code>pack</code> is successful, <code>file</code> will be removed.</p> <p>The amount of compression obtained depends on the size of the input file and the character frequency distribution. Because a decoding tree forms the first part of each <code>.z</code> file, it is usually not worthwhile to pack files smaller than three blocks, unless the character frequency distribution is very skewed, which may occur with printer plots or pictures.</p> <p>Typically, text files are reduced to 60-75% of their original size. Load modules, which use a larger character set and have a more uniform distribution of characters, show little compression, the packed versions being about 90% of the original size.</p> <p><code>pack</code> returns a value that is the number of files that it failed to compress.</p> <p>No packing will occur if:</p> <ul style="list-style-type: none"> <li>■ the file appears to be already packed</li> <li>■ the file name has more than 14 – 2 bytes</li> <li>■ the file has links</li> <li>■ the file is a directory</li> <li>■ the file cannot be opened</li> <li>■ the file is empty</li> <li>■ no disk storage blocks will be saved by packing</li> <li>■ a file called <code>file.z</code> already exists</li> <li>■ the <code>.z</code> file cannot be created</li> <li>■ an I/O error occurred during processing.</li> </ul> <p>The last segment of the file name must contain no more than 14 – 2 bytes to allow space for the appended <code>.z</code> extension. Directories cannot be compressed.</p> <p><b>pcat</b> The <code>pcat</code> command does for packed files what <code>cat(1)</code> does for ordinary files, except that <code>pcat</code> cannot be used as a filter. The specified files are unpacked and written to the standard output.</p> <p><code>pcat</code> returns the number of files it was unable to unpack. Failure may occur if:</p> <ul style="list-style-type: none"> <li>■ the file cannot be opened;</li> <li>■ the file does not appear to be the output of <code>pack</code>.</li> </ul> |

## pack(1)

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>unpack</b>   | <p>The <code>unpack</code> command expands files created by <code>pack</code>. For each <code>file</code> specified in the command, a search is made for a file called <code>file.z</code> (or just <code>file</code>, if <code>file</code> ends in <code>.z</code>). If this file appears to be a packed file, it is replaced by its expanded version. The new file has the <code>.z</code> suffix stripped from its name, and has the same access modes, access and modification dates, and owner as those of the packed file.</p> <p><code>unpack</code> returns a value that is the number of files it was unable to unpack. Failure may occur for the same reasons that it may in <code>pcat</code>, as well as for the following:</p> <ul style="list-style-type: none"><li>■ a file with the “unpacked” name already exists;</li><li>■ the unpacked file cannot be created.</li><li>■ the filename (excluding the <code>.z</code> extension) has more than 14 bytes.</li></ul> |
| <b>OPTIONS</b>  | <p>The following options are supported by <code>pack</code>:</p> <p><code>-f</code> Forces packing of <code>file</code>. This is useful for causing an entire directory to be packed even if some of the files will not benefit. Packed files can be restored to their original form using <code>unpack</code> or <code>pcat</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>OPERANDS</b> | <p>The following operands are supported:</p> <p><code>file</code> A path name of a file to be packed, unpacked, or <code>pcat</code>ed; <code>file</code> can include or omit the <code>.z</code> suffix.</p> <p><code>-</code> <code>pack</code> uses Huffman (minimum redundancy) codes on a byte-by-byte basis. If the <code>-</code> argument is used, an internal flag is set that causes the number of times each byte is used, its relative frequency, and the code for the byte to be printed on the standard output. Additional occurrences of <code>-</code> in place of <code>file</code> will cause the internal flag to be set and reset.</p>                                                                                                                                                                                                                                                                                                                            |
| <b>USAGE</b>    | <p>See <code>largefile(5)</code> for the description of the behavior of <code>pack</code>, <code>pcat</code>, and <code>unpack</code> when encountering files greater than or equal to 2 Gbyte ( <math>2^{31}</math> bytes).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>EXAMPLES</b> | <p><b>EXAMPLE 1</b> Viewing a Packed File</p> <p>To view a packed file named <code>file.z</code> use:</p> <pre>example% pcat file.z</pre> <p>or just:</p> <pre>example% pcat file</pre> <p><b>EXAMPLE 2</b> Making and Unpacked Copy:</p> <p>To make an unpacked copy, say <code>nnn</code>, of a packed file named <code>file.z</code> (without destroying <code>file.z</code>) use the command:</p> <pre>example% pcat file &gt;nnn</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

pack(1)

**ENVIRONMENT VARIABLES** See `environ(5)` for descriptions of the following environment variables that affect the execution of `pack`, `pcat`, and `unpack`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

>0 An error occurred. The number of files the command failed to pack/unpack is returned.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWesu         |
| CSI            | Enabled         |

**SEE ALSO** `cat(1)`, `compress(1)`, `zcat(1)`, `attributes(5)`, `environ(5)`, `largefile(5)`

pagesize(1)

**NAME** | pagesize – display the size or sizes of a page of memory

**SYNOPSIS** | `/usr/bin/pagesize [-a]`

**DESCRIPTION** | The pagesize utility prints the default size of a page of memory in bytes, as returned by `getpagesize(3C)`. This program is useful in constructing portable shell scripts.

**OPTIONS** | The following option is supported:

-a | Prints out all possible hardware address translation sizes supported by the system.

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** | [ppgsz\(1\)](#), `getpagesize(3C)`, `getpagesizes(3C)`, `attributes(5)`

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | pargs – print process arguments, environment variables, or auxiliary vector                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <b>pargs</b> [-aceFlx] [ <i>pid</i>   <i>core...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | <p>The pargs utility examines a target process or process core file and prints arguments, environment variables and values, or the process auxiliary vector.</p> <p>pargs outputs unprintable characters as escaped octal in the format <code>\xxx</code>, unless the character is one of the characters specified in the “Escape Sequences” section of <code>formats(5)</code>, in which case the character is printed as specified in that section.</p> <p>pargs attempts to be sensitive to the locale of the target process. If the target process and the pargs process do not share a common character encoding, pargs attempts to employ the <code>iconv(3C)</code> facility to generate a printable version of the extracted strings. In the event that such a conversion is impossible, strings are displayed as 7-bit ASCII.</p>                                                                                                                                                                                                                 |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a Prints process arguments as contained in <code>argv[]</code> (default).</li> <li>-c Treats strings in the target process as though they were encoded in 7-bit ASCII, regardless of the locale of the target. The use of <code>iconv(3C)</code> is suppressed.</li> <li>-e Prints process environment variables and values as pointed at by the <code>_environ</code> symbol or by <code>pr_envp</code> in <code>/proc/pid/psinfo</code>.</li> <li>-F Force. Grabs the target process even if another process has control.</li> <li>-l Displays the arguments as a single command line. The command line is printed in a manner suitable for interpretation by <code>/bin/sh</code>. If the arguments contain unprintable characters, or if the target process is in a different locale, a warning message is displayed. The resulting command line may not be interpreted correctly by <code>/bin/sh</code>.</li> <li>-x Prints process auxiliary vector.</li> </ul> |

| <b>NAME</b>        | passwd – change login password and password attributes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>    | <pre>passwd [-r files   -r ldap   -r nis   -r nisplus] [name] passwd [ -r files] [-egh] [name] passwd [ -r files] -s [-a] passwd [ -r files] -s [name] passwd [ -r files] [-d   -l   -u   -N] [-f] [-n min] [-w warn] [-x max] name passwd -r ldap [-egh] [name] passwd -r nis [-egh] [name] passwd -r nisplus [-egh] [-D domainname] [name] passwd -r nisplus -s [-a] passwd -r nisplus [-D domainname] -s [name] passwd -r nisplus [-l   -u   -N] [-f] [-n min] [-w warn] [-x max] [-D domainname] name</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p>The <code>passwd</code> command changes the password or lists password attributes associated with the user's login <i>name</i>. Additionally, privileged users can use <code>passwd</code> to install or change passwords and attributes associated with any login <i>name</i>.</p> <p>When used to change a password, <code>passwd</code> prompts everyone for their old password, if any. It then prompts for the new password twice. When the old password is entered, <code>passwd</code> checks to see if it has "aged" sufficiently. If "aging" is insufficient, <code>passwd</code> terminates; see <code>pwconv(1M)</code>, <code>nistbladm(1)</code>, and <code>shadow(4)</code> for additional information.</p> <p>When LDAP, NIS, or NIS+ is in effect on a system, <code>passwd</code> changes the NIS or NIS+ database. The NIS or NIS+ password can be different from the password on the local machine. If NIS or NIS+ is running, use <code>passwd -r</code> to change password information on the local machine.</p> <p>The <code>pwconv</code> command creates and updates <code>/etc/shadow</code> with information from <code>/etc/passwd</code>. <code>pwconv</code> relies on a special value of 'x' in the password field of <code>/etc/passwd</code>. This value of 'x' indicates that the password for the user is already in <code>/etc/shadow</code> and should not be modified.</p> <p>If aging is sufficient, a check is made to ensure that the new password meets construction requirements. When the new password is entered a second time, the two copies of the new password are compared. If the two copies are not identical, the cycle of prompting for the new password is repeated for, at most, two more times.</p> <p>Passwords must be constructed to meet the following requirements:</p> <ul style="list-style-type: none"> <li>■ Each password must have <code>PASSLENGTH</code> characters, where <code>PASSLENGTH</code> is defined in <code>/etc/default/passwd</code> and is set to 6. Setting <code>PASSLENGTH</code> to more than eight characters requires configuring <code>policy.conf(4)</code> with an algorithm that</li> </ul> |

## passwd(1)

supports greater than eight characters.

- Each password must meet the configured complexity constraints specified in `/etc/default/passwd`.
- Each password must not be a member of the configured dictionary as specified in `/etc/default/passwd`.
- For accounts in name services which support password history checking, if prior password history is defined, new passwords must not be contained in the prior password history.

If all requirements are met, by default, the `passwd` command consults `/etc/nsswitch.conf` to determine in which repositories to perform password update. It searches the `passwd` and `passwd_compat` entries. The sources (repositories) associated with these entries are updated. However, the password update configurations supported are limited to the following cases. Failure to comply with the configurations prevents users from logging onto the system. The password update configurations are:

- `passwd: files`
- `passwd: files ldap`
- `passwd: files nis`
- `passwd: files nisplus`
- `passwd: compat (==> files nis)`
- `passwd: compat (==> files ldap)`  
`passwd_compat: ldap`
- `passwd: compat (==> files nisplus)`  
`passwd_compat: nisplus`

Network administrators, who own the NIS+ password table, can change any password attributes.

In the `files` case, super-users (for instance, real and effective uid equal to 0, see `id(1M)` and `su(1M)`) can change any password. Hence, `passwd` does not prompt privileged users for the old password. Privileged users are not forced to comply with password aging and password construction requirements. A privileged user can create a null password by entering a carriage return in response to the prompt for a new password. (This differs from `passwd -d` because the "password" prompt is still displayed.) If NIS is in effect, superuser on the root master can change any password without being prompted for the old NIS `passwd`, and is not forced to comply with password construction requirements.

Normally, `passwd` entered with no arguments changes the password of the current user. When a user logs in and then invokes `su(1M)` to become super-user or another user, `passwd` changes the original user's password, not the password of the super-user or the new user.

Any user can use the `-s` option to show password attributes for his or her own login *name*, provided they are using the `-r nisplus` argument. Otherwise, the `-s` argument is restricted to the superuser.

The format of the display is:

```
name status mm/dd/yy min max warn
```

or, if password aging information is not present,

```
name status
```

where

|                 |                                                                                                                                                                                                           |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>name</i>     | The login ID of the user.                                                                                                                                                                                 |
| <i>status</i>   | The password status of <i>name</i> : PS stands for passworded or locked, LK stands for locked, and NP stands for no password.                                                                             |
| <i>mm/dd/yy</i> | The date password was last changed for <i>name</i> . All password aging dates are determined using Greenwich Mean Time (Universal Time) and therefore can differ by as much as a day in other time zones. |
| <i>min</i>      | The minimum number of days required between password changes for <i>name</i> . MINWEEKS is found in <code>/etc/default/passwd</code> and is set to NULL.                                                  |
| <i>max</i>      | The maximum number of days the password is valid for <i>name</i> . MAXWEEKS is found in <code>/etc/default/passwd</code> and is set to NULL.                                                              |
| <i>warn</i>     | The number of days relative to <i>max</i> before the password expires and the <i>name</i> are warned.                                                                                                     |

**Security** passwd uses pam(3PAM) for password change. It calls PAM with a service name `passwd` and uses service module type `auth` for authentication and password for password change.

Locking an account (`-l` option) does not allow its use for password based login or delayed execution (such as `at(1)`, `batch(1)`, or `cron(1M)`). The `-N` option can be used to disallow password based login, while continuing to allow delayed execution.

**OPTIONS** The following options are supported:

|                 |                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-a</code> | Shows password attributes for all entries. Use only with the <code>-s</code> option. <i>name</i> must not be provided. For the <code>nisplus</code> repository, this shows only the entries in the NIS+ password table in the local domain that the invoker is authorized to "read". For the <code>files</code> repository, this is restricted to the superuser. |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## passwd(1)

- D *domainname* Consults the `passwd.org_dir` table in *domainname*. If this option is not specified, the default *domainname* returned by `nis_local_directory(3NSL)` are used. This domain name is the same as that returned by `domainname(1M)`.
- e Changes the login shell. For the `files` repository, this only works for the superuser. Normal users can change the `ldap`, `nis`, or `nisplus` repositories. The choice of shell is limited by the requirements of `getusershell(3C)`. If the user currently has a shell that is not allowed by `getusershell`, only root can change it.
- g Changes the `gecos` (finger) information. For the `files` repository, this only works for the superuser. Normal users can change the `ldap`, `nis`, or `nisplus` repositories.
- h Changes the home directory.
- r Specifies the repository to which an operation is applied. The supported repositories are `files`, `ldap`, `nis`, or `nisplus`.
- s *name* Shows password attributes for the login *name*. For the `nisplus` repository, this works for everyone. However for the `files` repository, this only works for the superuser. It does not work at all for the `nis` repository which does not support password aging.

### Privileged User Options

Only a privileged user can use the following options:

- d Deletes password for *name* and unlocks the account. The login *name* is not prompted for password. It is only applicable to the `files` repository.
- f Forces the user to change password at the next login by expiring the password for *name*.
- l Locks password entry for *name*. See the `-d` or `-u` option for unlocking the account.
- N Makes the password entry for *name* a value that cannot be used for login, but does not lock the account. See the `-d` option for removing the value, or to set a password to allow logins.
- n *min* Sets minimum field for *name*. The *min* field contains the minimum number of days between password changes for *name*. If *min* is greater than *max*, the user can not change the password. Always use this option with the `-x` option, unless *max* is set to `-1` (aging turned off). In that case, *min* need not be set.
- u Unlocks a locked password for entry *name*. See the `-d` option for removing the locked password, or to set a password to allow logins.

- w *warn*            Sets warn field for *name*. The *warn* field contains the number of days before the password expires and the user is warned. This option is not valid if password aging is disabled.
- x *max*             Sets maximum field for *name*. The *max* field contains the number of days that the password is valid for *name*. The aging for *name* is turned off immediately if *max* is set to -1.

**OPERANDS**        The following operand is supported:

*name*                User login name.

**ENVIRONMENT  
VARIABLES**

If any of the LC\_\* variables, that is, LC\_CTYPE, LC\_MESSAGES, LC\_TIME, LC\_COLLATE, LC\_NUMERIC, and LC\_MONETARY (see `environ(5)`), are not set in the environment, the operational behavior of `passwd` for each corresponding locale category is determined by the value of the LANG environment variable. If LC\_ALL is set, its contents are used to override both the LANG and the other LC\_\* variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how `passwd` behaves.

LC\_CTYPE            Determines how `passwd` handles characters. When LC\_CTYPE is set to a valid value, `passwd` can display and handle text and filenames containing valid characters for that locale. `passwd` can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. `passwd` can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

LC\_MESSAGES        Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

**EXIT STATUS**      The `passwd` command exits with one of the following values:

- 0                    Success.
- 1                    Permission denied.
- 2                    Invalid combination of options.
- 3                    Unexpected failure. Password file unchanged.
- 4                    Unexpected failure. Password file(s) missing.
- 5                    Password file(s) busy. Try again later.
- 6                    Invalid argument to option.
- 7                    Aging option is disabled.
- 8                    No memory.

## passwd(1)

|              |                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              | 9                   | System error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|              | 10                  | Account expired.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>FILES</b> | /etc/default/passwd |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|              |                     | Default values can be set for the following flags in /etc/default/passwd. For example: MAXWEEKS=26                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|              | DICTIONBDBDIR       | The directory where the generated dictionary databases reside. Defaults to /var/passwd. If neither DICTIONLIST nor DICTIONBDBDIR is specified, the system does not perform a dictionary check.                                                                                                                                                                                                                                                                                                                                                                                          |
|              | DICTIONLIST         | DICTIONLIST can contain list of comma separated dictionary files such as DICTIONLIST=file1, file2, file3. Each dictionary file contains multiple lines and each line consists of a word and a NEWLINE character (similar to /usr/share/lib/dict/words.) You must specify full pathnames. The words from these files are merged into a database that is used to determine whether a password is based on a dictionary word. If neither DICTIONLIST nor DICTIONBDBDIR is specified, the system performs a dictionary check.<br><br>To prebuild the dictionary database, see mkpwdict(1M). |
|              | HISTORY             | Maximum number of prior password history to keep for a user. Setting the HISTORY value to zero (0), or removing the flag, causes the prior password history of all users to be discarded at the next password change by any user. The default is not to define the HISTORY flag. The maximum value is 26. Currently, this functionality is enforced only for user accounts defined in the "files" name service (local passwd(4)/shadow(4)).                                                                                                                                             |
|              | MAXREPEATS          | Maximum number of allowable consecutive repeating characters. If MAXREPEATS is not set or is zero (0), the default is no checks                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|              | MAXWEEKS            | Maximum time period that password is valid.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|              | MINALPHA            | Minimum number of alpha character required. If MINALPHA is not set, the default is 2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|              | MINDIFF             | Minimum differences required between an old and a new password. If MINDIFF is not set, the default is 3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|              | MINDIGIT            | Minimum number of digits required. If MINDIGIT is not set or is set to zero (0), the default is no checks. You cannot be specify MINDIGIT if MINNONALPHA is also specified.                                                                                                                                                                                                                                                                                                                                                                                                             |
|              | MINLOWER            | Minimum number of lower case letters required. If not set or zero (0), the default is no checks.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|             |                                                                                                                                                                                                            |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MINNONALPHA | Minimum number of non-alpha (including numeric and special) required. If MINNONALPHA is not set, the default is 1. You cannot specify MINNONALPHA if MINDIGIT or MINSPECIAL is also specified.             |
| MINWEEKS    | Minimum time period before the password can be changed.                                                                                                                                                    |
| MINSPECIAL  | Minimum number of special (non-alpha and non-digit) characters required. If MINSPECIAL is not set or is zero (0), the default is no checks. You cannot specify MINSPECIAL if you also specify MINNONALPHA. |
| MINUPPER    | Minimum number of upper case letters required. If MINUPPER is not set or is zero (0), the default is no checks.                                                                                            |
| NAMECHECK   | Enable/disable checking of the login name. The default is to do login name checking. A case insensitive value of "no" disables this feature.                                                               |
| PASSLENGTH  | Minimum length of password, in characters.                                                                                                                                                                 |
| WARNWEEKS   | Time period until warning of date of password's ensuing expiration.                                                                                                                                        |
| WHITESPACE  | Determine if whitespace characters are allowed in passwords. Valid values are YES and NO. If WHITESPACE is not set or is set to YES, whitespace characters are allowed.                                    |

/etc/oshadow

Temporary file used by passwd, passmgmt and pwconv to update the real shadow file.

/etc/passwd

Password file.

/etc/shadow

Shadow password file.

/etc/shells

Shell database.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| CSI                 | Enabled         |
| Interface Stability | See below.      |

The human readable output is Unstable. The options are Evolving.

## passwd(1)

**SEE ALSO** | [at\(1\)](#), [batch\(1\)](#), [finger\(1\)](#), [login\(1\)](#), [nistbladm\(1\)](#), [orcron\(1M\)](#), [domainname\(1M\)](#), [eeprom\(1M\)](#), [id\(1M\)](#), [mkpwdict\(1M\)](#), [passmgmt\(1M\)](#), [pwconv\(1M\)](#), [su\(1M\)](#), [useradd\(1M\)](#), [userdel\(1M\)](#), [usermod\(1M\)](#), [crypt\(3C\)](#), [getpwnam\(3C\)](#), [getspnam\(3C\)](#), [getusershell\(3C\)](#), [nis\\_local\\_directory\(3NSL\)](#), [pam\(3PAM\)](#), [loginlog\(4\)](#), [nsswitch.conf\(4\)](#), [pam.conf\(4\)](#), [passwd\(4\)](#), [policy.conf\(4\)](#), [shadow\(4\)](#), [shells\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [pam\\_authtok\\_check\(5\)](#), [pam\\_authtok\\_get\(5\)](#), [pam\\_authtok\\_store\(5\)](#), [pam\\_dhkeys\(5\)](#), [pam\\_ldap\(5\)](#), [pam\\_unix\\_account\(5\)](#), [pam\\_unix\\_auth\(5\)](#), [pam\\_unix\\_session\(5\)](#)

**NOTES** | The `pam_unix(5)` module is no longer supported. Similar functionality is provided by `pam_unix_account(5)`, `pam_unix_auth(5)`, `pam_unix_session(5)`, `pam_authtok_check(5)`, `pam_authtok_get(5)`, `pam_authtok_store(5)`, `pam_dhkeys(5)`, and `pam_passwd_auth(5)`.

The `nispaswd` and `ypaswd` commands are wrappers around `passwd`. Use of `nispaswd` and `ypaswd` is discouraged. Use `passwd -r repository_name` instead.

NIS+ might not be supported in future releases of the Solaris Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

Changing a password in the files repository clears the failed login count.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                 |                    |                 |                |                 |                      |                 |                                                                                                                                                                                                                                                                 |

| <b>SYNOPSIS</b>    | <b>paste</b> [-s] [-d <i>list</i> ] <i>file...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                 |                    |                 |                |                 |                      |                 |                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p>The <code>paste</code> utility will concatenate the corresponding lines of the given input files, and write the resulting lines to standard output.</p> <p>The default operation of <code>paste</code> will concatenate the corresponding lines of the input files. The <code>NEWLINE</code> character of every line except the line from the last input file will be replaced with a <code>TAB</code> character.</p> <p>If an EOF (end-of-file) condition is detected on one or more input files, but not all input files, <code>paste</code> will behave as though empty lines were read from the files on which EOF was detected, unless the <code>-s</code> option is specified.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                 |                    |                 |                |                 |                      |                 |                                                                                                                                                                                                                                                                 |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-d list</code> Unless a backslash character ( <code>\</code> ) appears in <i>list</i>, each character in <i>list</i> is an element specifying a delimiter character. If a backslash character appears in <i>list</i>, the backslash character and one or more characters following it are an element specifying a delimiter character as described below. These elements specify one or more delimiters to use, instead of the default <code>TAB</code> character, to replace the <code>NEWLINE</code> character of the input lines. The elements in <i>list</i> are used circularly. That is, when the list is exhausted, the first element from the list is reused.</p> <p>When the <code>-s</code> option is specified:</p> <ul style="list-style-type: none"> <li>■ The last newline character in a file will not be modified.</li> <li>■ The delimiter will be reset to the first element of <i>list</i> after each <i>file</i> operand is processed.</li> </ul> <p>When the option is not specified:</p> <ul style="list-style-type: none"> <li>■ The <code>NEWLINE</code> characters in the file specified by the last <i>file</i> will not be modified.</li> <li>■ The delimiter will be reset to the first element of <i>list</i> each time a line is processed from each file.</li> </ul> <p>If a backslash character appears in <i>list</i>, it and the character following it will be used to represent the following delimiter characters:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 10px;"><code>\n</code></td> <td>Newline character.</td> </tr> <tr> <td style="padding-right: 10px;"><code>\t</code></td> <td>Tab character.</td> </tr> <tr> <td style="padding-right: 10px;"><code>\\</code></td> <td>Backslash character.</td> </tr> <tr> <td style="padding-right: 10px;"><code>\0</code></td> <td>Empty string (not a null character). If <code>\0</code> is immediately followed by the character <code>x</code>, the character <code>X</code>, or any character defined by the <code>LC_CTYPE</code> <code>digit</code> keyword, the results are unspecified.</td> </tr> </table> | <code>\n</code> | Newline character. | <code>\t</code> | Tab character. | <code>\\</code> | Backslash character. | <code>\0</code> | Empty string (not a null character). If <code>\0</code> is immediately followed by the character <code>x</code> , the character <code>X</code> , or any character defined by the <code>LC_CTYPE</code> <code>digit</code> keyword, the results are unspecified. |

| <code>\0</code>    | Empty string (not a null character). If <code>\0</code> is immediately followed by the character <code>x</code> , the character <code>X</code> , or any character defined by the <code>LC_CTYPE</code> <code>digit</code> keyword, the results are unspecified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                 |                    |                 |                |                 |                      |                 |                                                                                                                                                                                                                                                                 |

## paste(1)

|                              | If any other characters follow the backslash, the results are unspecified.                                                                                                                                                                                                                                                                                |                |                 |              |         |     |         |                     |          |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|---------|-----|---------|---------------------|----------|
|                              | <b>-s</b> Concatenate all of the lines of each separate input file in command line order. The NEWLINE character of every line except the last line in each input file will be replaced with the TAB character, unless otherwise specified by the <b>-d</b> option.                                                                                        |                |                 |              |         |     |         |                     |          |
| <b>OPERANDS</b>              | The following operand is supported:<br><br><i>file</i> A path name of an input file. If <b>-</b> is specified for one or more of the <i>files</i> , the standard input will be used. The standard input will be read one line at a time, circularly, for each instance of <b>-</b> . Implementations support pasting of at least 12 <i>file</i> operands. |                |                 |              |         |     |         |                     |          |
| <b>USAGE</b>                 | See <code>largefile(5)</code> for the description of the behavior of <code>paste</code> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                                                                                                                                       |                |                 |              |         |     |         |                     |          |
| <b>EXAMPLES</b>              | <b>EXAMPLE 1</b> Listing a directory in one column<br>example% <code>ls   paste -d" " -</code><br><br><b>EXAMPLE 2</b> Listing a directory in four columns<br>example% <code>ls   paste - - - -</code><br><br><b>EXAMPLE 3</b> Combining pairs of lines from a file into single lines<br>example% <code>paste -s -d"\ t\ n" file</code>                   |                |                 |              |         |     |         |                     |          |
| <b>ENVIRONMENT VARIABLES</b> | See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>paste</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .                                                                                             |                |                 |              |         |     |         |                     |          |
| <b>EXIT STATUS</b>           | The following exit values are returned:<br><br>0 Successful completion.<br><br>>0 An error occurred.                                                                                                                                                                                                                                                      |                |                 |              |         |     |         |                     |          |
| <b>ATTRIBUTES</b>            | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                              |                |                 |              |         |     |         |                     |          |

| <b>NAME</b>        | patch – apply changes to files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <b>patch</b> [-b1NR] [-c   -e   -n   -u] [-d <i>dir</i> ] [-D <i>define</i> ] [-i <i>patchfile</i> ]<br>[-o <i>outfile</i> ] [-p <i>num</i> ] [-r <i>rejectfile</i> ] [ <i>file</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | <p>The <code>patch</code> command reads a source (patch) file containing any of the three forms of difference (diff) listings produced by the <code>diff(1)</code> command (normal, context or in the style of <code>ed(1)</code>) and apply those differences to a file. By default, <code>patch</code> reads from the standard input.</p> <p><code>patch</code> attempts to determine the type of the <code>diff</code> listing, unless overruled by a <code>-c</code>, <code>-e</code>, or <code>-n</code> option.</p> <p>If the patch file contains more than one patch, <code>patch</code> will attempt to apply each of them as if they came from separate patch files. (In this case the name of the patch file must be determinable for each <code>diff</code> listing.)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-b Saves a copy of the original contents of each modified file, before the differences are applied, in a file of the same name with the suffix <code>.orig</code> appended to it. If the file already exists, it will be overwritten. If multiple patches are applied to the same file, the <code>.orig</code> file will be written only for the first patch. When the <code>-o outfile</code> option is also specified, <code>file.orig</code> will not be created but, if <code>outfile</code> already exists, <code>outfile.orig</code> will be created.</li><li>-c Interprets the patch file as a context difference (the output of the command <code>diff</code> when the <code>-c</code> or <code>-C</code> options are specified).</li><li>-d <i>dir</i> Changes the current directory to <i>dir</i> before processing as described in EXTENDED DESCRIPTION.</li><li>-D <i>define</i> Marks changes with the C preprocessor construct:<br/><pre>#ifdef <i>define</i><br/>.<br/>.<br/>.<br/>#endif</pre><p>The option-argument <i>define</i> will be used as the differentiating symbol.</p></li><li>-e Interprets the patch file as an <code>ed</code> script, rather than a <code>diff</code> script.</li><li>-i <i>patchfile</i> Reads the patch information from the file named by the path name <i>patchfile</i>, rather than the standard input.</li><li>-l (The letter ell.) Causes any sequence of blank characters in the difference script to match any sequence of blank characters in the input file. Other characters will be matched exactly.</li><li>-n Interprets the script as a normal difference.</li><li>-N Ignores patches where the differences have already been applied to the file; by default, already-applied patches are rejected.</li></ul> |

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-o outfile</code>    | Instead of modifying the files (specified by the <i>file</i> operand or the difference listings) directly, writes a copy of the file referenced by each patch, with the appropriate differences applied, to <i>outfile</i> . Multiple patches for a single file will be applied to the intermediate versions of the file created by any previous patches, and will result in multiple, concatenated versions of the file being written to <i>outfile</i> .                                                                                                                                                                                                                             |
| <code>-p num</code>        | For all path names in the patch file that indicate the names of files to be patched, deletes <i>num</i> path name components from the beginning of each path name. If the path name in the patch file is absolute, any leading slashes are considered the first component (that is, <code>-p 1</code> removes the leading slashes). Specifying <code>-p 0</code> causes the full path name to be used. If <code>-p</code> is not specified, only the basename (the final path name component) is used.                                                                                                                                                                                 |
| <code>-R</code>            | Reverses the sense of the patch script. That is, assumes that the difference script was created from the new version to the old version. The <code>-R</code> option cannot be used with <code>ed</code> scripts. <code>patch</code> attempts to reverse each portion of the script before applying it. Rejected differences will be saved in swapped format. If this option is not specified, and until a portion of the patch file is successfully applied, <code>patch</code> attempts to apply each portion in its reversed sense as well as in its normal sense. If the attempt is successful, the user will be prompted to determine if the <code>-R</code> option should be set. |
| <code>-r rejectfile</code> | Overrides the default reject file name. In the default case, the reject file will have the same name as the output file, with the suffix <code>.rej</code> appended to it. See Patch Application.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>-u</code>            | Interprets the patch file as a unified context difference, that is, the output of the command <code>diff</code> when the <code>-u</code> or <code>-U</code> options are specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**OPERANDS** The following operand is supported:

*file*        A path name of a file to patch.

**USAGE** The `-R` option will not work with `ed` scripts because there is too little information to reconstruct the reverse operation.

The `-p` option makes it possible to customize a patch file to local user directory structures without manually editing the patch file. For example, if the file name in the patch file was `/curds/whey/src/blurfl/blurfl.c`:

- Setting `-p 0` gives the entire path name unmodified.
- Setting `-p 1` gives:

```
curds/whey/src/blurfl/blurfl.c
```

## patch(1)

- Without the leading slash, `-p 4` gives:

```
blurfl/blurfl.c
```

- Not specifying `-p` at all gives:

```
blurfl.c
```

When using `-b` in some file system implementations, the saving of a `.orig` file may produce unwanted results. In the case of 12-, 13-, or 14-character file names, on file systems supporting 14-character maximum file names, the `.orig` file will overwrite the new file.

### ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `patch`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, and `NLSPATH`.

### OUTPUT FILES

The output of `patch` the save files (`.orig` suffixes) and the reject files (`.rej` suffixes) will be text files.

### EXTENDED DESCRIPTION

A patch file may contain patching instructions for more than one file. File names are determined as specified in `Patch Determination`. When the `-b` option is specified, for each patched file, the original will be saved in a file of the same name with the suffix `.orig` appended to it.

For each patched file, a reject file may also be created as noted in `Patch Application`. In the absence of an `-r` option, the name of this file will be formed by appending the suffix `.rej` to the original file name.

### Patch File Format

The patch file must contain zero or more lines of header information followed by one or more patches. Each patch must contain zero or more lines of file name identification in the format produced by `diff -c`, and one or more sets of `diff` output, which are customarily called hunks.

`patch` recognizes the following expression in the header information:

Index: *pathname*                      The file to be patched is named *pathname*.

If all lines (including headers) within a patch begin with the same leading sequence of blank characters, `patch` will remove this sequence before proceeding. Within each patch, if the type of difference is context, `patch` recognizes the following expressions:

\* \* \* *filename timestamp*  
The patches arose from *filename*.

- - - *filename timestamp*  
The patches should be applied to *filename*.

Each hunk within a patch must be the `diff` output to change a line range within the original file. The line numbers for successive hunks within a patch must occur in ascending order.

**File Name Determination**

If no *file* operand is specified, `patch` performs the following steps to obtain a path name:

1. If the patch contains the strings `***` and `--`, `patch` strips components from the beginning of each path name (depending on the presence or value of the `-p` option), then tests for the existence of both files in the current directory (or directory specified with the `-d` option).
2. If both files exist, `patch` assumes that no path name can be obtained from this step. If the header information contains a line with the string `Index:`, `patch` strips components from the beginning of the path name (depending on `-p`), then tests for the existence of this file in the current directory (or directory specified with the `-d` option).
3. If an SCCS directory exists in the current directory, `patch` will attempt to perform a `get -e SCCS/s.filename` command to retrieve an editable version of the file.
4. If no path name can be obtained by applying the previous steps, or if the path names obtained do not exist, `patch` will write a prompt to standard output and request a file name interactively from standard input.

**Patch Application**

If the `-c`, `-e`, `-n`, or `-u` option is present, `patch` will interpret information within each hunk as a context difference, an `ed` difference, a normal difference, or a unified context difference, respectively. In the absence of any of these options, `patch` determines the type of difference based on the format of information within the hunk.

For each hunk, `patch` begins to search for the place to apply the patch at the line number at the beginning of the hunk, plus or minus any offset used in applying the previous hunk. If lines matching the hunk context are not found, `patch` scans both forwards and backwards at least 1000 bytes for a set of lines that match the hunk context.

If no such place is found and it is a context difference, then another scan will take place, ignoring the first and last line of context. If that fails, the first two and last two lines of context will be ignored and another scan will be made. Implementations may search more extensively for installation locations.

If no location can be found, `patch` will append the hunk to the reject file. The rejected hunk will be written in context-difference format regardless of the format of the patch file. If the input was a normal or `ed -style` difference, the reject file may contain differences with zero lines of context. The line numbers on the hunks in the reject file may be different from the line numbers in the patch file since they will reflect the approximate locations for the failed hunks in the new file rather than the old one.

If the type of patch is an `ed` diff, the implementation may accomplish the patching by invoking the `ed` command.

**EXIT STATUS**

The following exit values are returned:

- |    |                                                  |
|----|--------------------------------------------------|
| 0  | Successful completion.                           |
| 1  | One or more lines were written to a reject file. |
| >1 | An error occurred.                               |

| <b>NAME</b>        | pathchk – check path names                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <b>pathchk</b> [-p] <i>path...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | <p>The <code>pathchk</code> command will check that one or more path names are valid (that is, they could be used to access or create a file without causing syntax errors) and portable (that is, no filename truncation will result). More extensive portability checks are provided by the <code>-p</code> option.</p> <p>By default, <code>pathchk</code> will check each component of each <i>path</i> operand based on the underlying file system. A diagnostic will be written for each <i>path</i> operand that:</p> <ul style="list-style-type: none"> <li>■ is longer than <code>PATH_MAX</code> bytes.</li> <li>■ contains any component longer than <code>NAME_MAX</code> bytes in its containing directory</li> <li>■ contains any component in a directory that is not searchable</li> <li>■ contains any character in any component that is not valid in its containing directory.</li> </ul> <p>The format of the diagnostic message is not specified, but will indicate the error detected and the corresponding <i>path</i> operand.</p> <p>It will not be considered an error if one or more components of a <i>path</i> operand do not exist as long as a file matching the path name specified by the missing components could be created that does not violate any of the checks specified above.</p> |
| <b>OPTIONS</b>     | <p>The following option is supported:</p> <p><code>-p</code>        Instead of performing checks based on the underlying file system, write a diagnostic for each <i>path</i> operand that:</p> <ul style="list-style-type: none"> <li>■ is longer than <code>_POSIX_PATH_MAX</code> bytes</li> <li>■ contains any component longer than <code>_POSIX_NAME_MAX</code> bytes</li> <li>■ contains any character in any component that is not in the portable filename character set.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>OPERANDS</b>    | <p>The following operand is supported:</p> <p><i>path</i>        A path to be checked.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>USAGE</b>       | See <code>largefile(5)</code> for the description of the behavior of <code>pathchk</code> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Using the <code>pathchk</code> command</p> <p>To verify that all paths in an imported data interchange archive are legitimate and unambiguous on the current system:</p> <pre>example% pax -f archive   sed -e '/ == ./s///'   xargs pathchk if [ \$? -eq 0 ] then     pax -r -f archive else</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## pathchk(1)

**EXAMPLE 1** Using the pathchk command (Continued)

```
        echo Investigate problems before importing files.
        exit 1
    fi
```

To verify that all files in the current directory hierarchy could be moved to any system conforming to the X/Open specification that also supports the `pax(1)` command:

```
example% find . -print | xargs pathchk -p
if [ $? -eq 0 ]
then
    pax -w -f archive .
else
    echo Portable archive cannot be created.
    exit 1
fi
```

To verify that a user-supplied path names a readable file and that the application can create a file extending the given path without truncation and without overwriting any existing file:

```
example% case $- in
    *C*)   reset="";;
    *)     reset="set +C"
           set -C;;
esac
test -r "$path" && pathchk "$path.out" &&
rm "$path.out" > "$path.out"
if [ $? -ne 0 ]; then
    printf "%s: %s not found or %s.out fails \
creation checks.\n" $0 "$path" "$path"
    $reset      # reset the noclobber option in case a trap
                # on EXIT depends on it
    exit 1
fi
$reset
PROCESSING < "$path" > "$path.out"
```

The following assumptions are made in this example:

1. PROCESSING represents the code that will be used by the application to use `$path` once it is verified that `$path.out` will work as intended.
2. The state of the `noclobber` option is unknown when this code is invoked and should be set on exit to the state it was in when this code was invoked. (The `reset` variable is used in this example to restore the initial state.)
3. Note the usage of:

```
rm "$path.out" > "$path.out"
```

- a. The `pathchk` command has already verified, at this point, that `$path.out` will not be truncated.

**EXAMPLE 1** Using the pathchk command (Continued)

- b. With the `noclobber` option set, the shell will verify that `$path.out` does not already exist before invoking `rm`.
- c. If the shell succeeded in creating `$path.out`, `rm` will remove it so that the application can create the file again in the `PROCESSING` step.
- d. If the `PROCESSING` step wants the file to exist already when it is invoked, the:

```
rm "$path.out" > "$path.out"
```

should be replaced with:

```
> "$path.out"
```

which will verify that the file did not already exist, but leave `$path.out` in place for use by `PROCESSING`.

#### ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `pathchk`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

#### EXIT STATUS

The following exit values are returned:

- 0 All *path* operands passed all of the checks.
- >0 An error occurred.

#### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Standard        |

#### SEE ALSO

| <b>NAME</b>        | pathconv – search FMLI criteria for filename                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <b>pathconv</b> [-f] [-v <i>alias</i> ]<br><b>pathconv</b> [-t] [-l] [-nnum] [-v <i>string</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | The <code>pathconv</code> function converts an alias to its pathname. By default, it takes the alias as a string from the standard input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>OPTIONS</b>     | <p>-f            If -f is specified, the full path will be returned (this is the default).</p> <p>-t            If -t is specified, <code>pathconv</code> will truncate a pathname specified in <i>string</i> in a format suitable for display as a frame title. This format is a shortened version of the full pathname, created by deleting components of the path from the middle of the string until it is under <code>DISPLAYW</code> — 6 characters in length, and then inserting ellipses ( . . . ) between the remaining pieces. Ellipses are also used to show truncation at the ends of the strings if necessary, unless the -l option is given.</p> <p>-l            If -l is specified, &lt; and &gt; will be used instead of ellipses ( . . . ) to indicate truncation at the ends of the string generated by the -t option. Using -l allows display of the longest possible string while still notifying users it has been truncated.</p> <p>-nnum        If -n is specified, <i>num</i> is the maximum length of the string (in characters) generated by the -t option. The argument <i>num</i> can be any integer from 1 to 255.</p> <p>-valias   <i>string</i> If the -v option is used, then <i>alias</i> or <i>string</i> can be specified when <code>pathconv</code> is called. The argument <i>alias</i> must be an alias defined in the <i>alias_file</i> named when <code>fml</code> was invoked. The argument <i>string</i> can only be used with the -t option and must be a pathname.</p> |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> A sample that uses <code>pathconv</code> to construct the menu title. It searches for <code>MYPATH</code> in the <i>alias_file</i> named when <code>fml</code> command.</p> <p>Here is a menu descriptor that uses <code>pathconv</code> to construct the menu title. It searches for <code>MYPATH</code> in the <i>alias_file</i> named when <code>fml</code> was invoked:</p> <pre>menu='pathconv -v MYPATH/ls'<br/>.<br/>.<br/>.</pre> <p>where there is a line in <i>alias_file</i> that defines <code>MYPATH</code>. For example,<br/><code>MYPATH=\$HOME/bin:/usr/bin.</code></p> <p>Here is a menu descriptor that takes <i>alias</i> from the standard input.</p> <pre>menu='echo MYPATH/ls   pathconv'<br/>.<br/>.<br/>.</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>DESCRIPTION</b>         | <p>The pax utility reads, writes, and writes lists of the members of archive files and copies directory hierarchies. A variety of archive formats are supported. See the -x <i>format</i> option.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Modes of Operations</b> | <p>The action to be taken depends on the presence of the -r and -w options. The four combinations of -r and -w are referred to as the four modes of operation: <i>list</i>, <i>read</i>, <i>write</i>, and <i>copy</i> modes, corresponding respectively to the four forms shown in the SYNOPSIS.</p> <p><b>list</b>     In <i>list</i> mode, that is, when neither -r nor -w are specified, pax writes the names of the members of the archive file read from the standard input, with path names matching the specified patterns, to standard output. If a named file has extended attributes, the extended attributes are also listed. If a named file is of type directory, the file hierarchy rooted at that file is listed as well.</p> <p><b>read</b>     In <i>read</i> mode, that is, when -r is specified, but -w is not, pax extracts the members of the archive file read from the standard input, with path names matching the specified patterns. If an extracted file is of type directory, the file hierarchy rooted at that file is extracted as well. The extracted files are created performing path name resolution with the directory in which pax was invoked as the current working directory.</p> <p style="padding-left: 2em;">If an attempt is made to extract a directory when the directory already exists, this is not considered an error. If an attempt is made to extract a FIFO when the FIFO already exists, this is not considered an error.</p> <p style="padding-left: 2em;">The ownership, access and modification times, and file mode of the restored files are discussed under the -p option.</p> <p><b>write</b>     In <i>write</i> mode, that is, when -w is specified, but -r is not, pax writes the contents of the <i>file</i> operands to the standard output in an archive format. If no <i>file</i> operands are specified, a list of files to copy, one per line, are read from the standard input. A file of type directory includes all of the files in the file hierarchy rooted at the file.</p> <p><b>copy</b>     In <i>copy</i> mode, that is, when both -r and -w are specified, pax copies the <i>file</i> operands to the destination directory.</p> |

If no *file* operands are specified, a list of files to copy, one per line, are read from the standard input. A file of type directory includes all of the files in the file hierarchy rooted at the file.

The effect of the `copy` is as if the copied files were written to an archive file and then subsequently extracted, except that there can be hard links between the original and the copied files. If the destination directory is a subdirectory of one of the files to be copied, the results are unspecified. It is an error if *directory* does not exist, is not writable by the user, or is not a directory.

In `read` or `copy` modes, if intermediate directories are necessary to extract an archive member, `pax` performs actions equivalent to the `mkdir(2)` function, called with the following arguments:

- The intermediate directory used as the *path* argument.
- The octal value of `777` or `rxw` (read, write, and execute permissions) as the *mode* argument (see `chmod(1)`).

If any specified *pattern* or *file* operands are not matched by at least one file or archive member, `pax` writes a diagnostic message to standard error for each one that did not match and exits with a non-zero exit status.

The supported archive formats are automatically detected on input. The default output archive format is `tar(1)`.

A single archive can span multiple files. The `pax` utility determines what file to read or write as the next file.

If the selected archive format supports the specification of linked files, it is an error if these files cannot be linked when the archive is extracted, except if the files to be linked are symbolic links and the system is not capable of making hard links to symbolic links. In that case, separate copies of the symbolic link are created instead. Any of the various names in the archive that represent a file can be used to select the file for extraction. For archive formats that do not store file contents with each name that causes a hard link, if the file that contains the data is not extracted during this `pax` session, either the data is restored from the original file, or a diagnostic message is displayed with the name of a file that can be used to extract the data. In traversing directories, `pax` detects infinite loops, that is, entering a previously visited directory that is an ancestor of the last file visited. When it detects an infinite loop, `pax` writes a diagnostic message to standard error and terminates.

**OPTIONS** The following options are supported:

- a Appends files to the end of the archive. This option does not work for some archive devices, such as 1/4-inch streaming tapes and 8mm tapes.

## pax(1)

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -b <i>blocksize</i> | Blocks the output at a positive decimal integer number of bytes per write to the archive file. Devices and archive formats can impose restrictions on blocking. Blocking is automatically determined on input. Portable applications must not specify a <i>blocksize</i> value larger than 32256. Default blocking when creating archives depends on the archive format. See the -x option below.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| -c                  | Matches all file or archive members except those specified by the <i>pattern</i> or <i>file</i> operands.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| -d                  | Causes files of type directory being copied or archived or archive members of type directory being extracted or listed to match only the file or archive member itself and not the file hierarchy rooted at the file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| -f <i>archive</i>   | Specifies the path name of the input or output archive, overriding the default standard input (in <i>list</i> or <i>read</i> modes) or standard output ( <i>write</i> mode).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| -H                  | If a symbolic link referencing a file of type directory is specified on the command line, <i>pax</i> archives the file hierarchy rooted in the file referenced by the link, using the name of the link as the root of the file hierarchy. Otherwise, if a symbolic link referencing a file of any other file type which <i>pax</i> can normally archive is specified on the command line, then <i>pax</i> archives the file referenced by the link, using the name of the link. The default behavior is to archive the symbolic link itself.                                                                                                                                                                                                                                                                                                               |
| -i                  | Interactively renames files or archive members. For each archive member matching a <i>pattern</i> operand or file matching a <i>file</i> operand, a prompt is written to the file <i>/dev/tty</i> . The prompt contains the name of the file or archive member. A line is then read from <i>/dev/tty</i> . If this line is blank, the file or archive member is skipped. If this line consists of a single period, the file or archive member is processed with no modification to its name. Otherwise, its name is replaced with the contents of the line. <i>pax</i> immediately exits with a non-zero exit status if end-of-file is encountered when reading a response or if <i>/dev/tty</i> cannot be opened for reading and writing.<br><br>The results of extracting a hard link to a file that has been renamed during extraction are unspecified. |
| -k                  | Prevents the overwriting of existing files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| -l                  | Links files. In <i>copy</i> mode, hard links are made between the source and destination file hierarchies whenever possible. If specified in conjunction with -H or -L, when a symbolic link is encountered, the hard link created in the destination file hierarchy is to the file referenced by the symbolic link. If specified when neither -H nor                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

The default behavior is to archive the symbolic link itself.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| -n                | <p>Selects the first archive member that matches each <i>pattern</i> operand. No more than one archive member is matched for each pattern, although members of type directory still match the file hierarchy rooted at that file.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| -o <i>options</i> | <p>Provides information to the implementation to modify the algorithm for extracting or writing files. The value of <i>options</i> consists of one or more comma-separated keywords of the form:</p> <p><i>keyword</i> [[:]=<i>value</i>] [, <i>keyword</i> [[:]=<i>value</i>] , . . .]</p> <p>Some keywords apply only to certain file formats, as indicated with each description. Use of keywords that are inapplicable to the file format being processed produces undefined results.</p> <p>Keywords in the <i>options</i> argument must be a string that would be a valid portable filename.</p> <p>Keywords are not expected to be filenames, merely to follow the same character composition rules as portable filenames.</p> <p>Keywords can be preceded with white space. The <i>value</i> field consists of zero or more characters. Within <i>value</i>, the application precedes any literal comma with a backslash, which is ignored, but preserves the comma as part of <i>value</i>. A comma as the final character, or a comma followed solely by white space as the final characters, in <i>options</i> is ignored. Multiple -o options can be specified. If keywords given to these multiple -o options conflict, the keywords and values appearing later in command line sequence take precedence and the earlier ones are silently ignored. The following keyword values of <i>options</i> are supported for the file formats as indicated:</p> |

*delete=pattern*

This keyword is applicable only to the `-x pax` format. When used in `write` or `copy` mode, `pax` omits from extended header records that it produces any keywords matching the string pattern. When used in `read` or `list` mode, `pax` ignores any keywords matching the string pattern in the extended header records. In both cases, matching is performed using the pattern matching notation. For example:

```
-o delete=security.*
```

would suppress security-related information.

When multiple `-o delete=pattern` options are specified, the patterns are additive. All keywords matching the specified string patterns are omitted from extended header records that `pax` produces.

*exthdr.name=string*

This keyword is applicable only to the `-x pax` format. This keyword allows user control over the name that is written into the `ustar` header blocks for the extended header. The name is the contents of *string*, after the following character substitutions have been made:

|                 |                                                                                                                     |
|-----------------|---------------------------------------------------------------------------------------------------------------------|
| <code>%d</code> | The directory name of the file, equivalent to the result of the <i>dirname</i> utility on the translated path name. |
| <code>%f</code> | The filename of the file, equivalent to the result of the <i>basename</i> utility on the translated path name.      |
| <code>%p</code> | The process ID of the <code>pax</code> process.                                                                     |
| <code>%%</code> | A <code>'%'</code> character.                                                                                       |

Any other `'%'` characters in *string* produce undefined results.

If no `-o exthdr.name=string` is specified, `pax` uses the following default value:

```
%d/PaxHeaders.%p/%f
```

*globexthdr.name=string*

This keyword is applicable only to the `-x pax` format. When used in `write` or `copy` mode with the appropriate options, `pax` creates global extended header records with `ustar` header blocks that are treated as regular files by previous versions of `pax`. This keyword allows user control over the name that is written into the `ustar` header blocks for global extended header records. The name is the contents of *string*, after the following character substitutions have been made:

`%n` An integer that represents the sequence number of the global extended header record in the archive, starting at 1.

`%p` The process ID of the pax process.

`%%` A '%' character.

Any other '%' characters in *string* produce undefined results.

If no `-o globexthdr.name=string` is specified, pax uses the following default value:

```
$TMPDIR/GlobalHead.%p.%n
```

where `$TMPDIR` represents the value of the `TMPDIR` environment variable. If `TMPDIR` is not set, pax uses `/tmp`.

#### `invalid=action`

This keyword is applicable only to the `-x` pax format. This keyword allows user control over the action pax takes upon encountering values in an extended header record that, in `read` or `copy` mode, are invalid in the destination hierarchy or, in `list` mode, cannot be written in the codeset and current locale of the implementation. The following are invalid values that are recognized by pax:

- In `read` or `copy` mode, a filename or link name that contains character encodings invalid in the destination hierarchy. For example, the name can contain embedded NULs.
- In `read` or `copy` mode, a filename or link name that is longer than the maximum allowed in the destination hierarchy, for either a path name component or the entire path name.
- In `list` mode, any character string value (filename, link name, user name, and so on) that cannot be written in the codeset and current locale of the implementation.

The following mutually-exclusive values of the *action* argument are supported:

`bypass` In `read` or `copy` mode, pax bypasses the file, causing no change to the destination hierarchy. In `list` mode, pax writes all requested valid values for the file, but its method for writing invalid values is unspecified.

## pax(1)

- rename** In read or copy mode, pax acts as if the `-i` option were in effect for each file with invalid filename or link name values, allowing the user to provide a replacement name interactively. In `list` mode, pax behaves identically to the `bypass` action.
- UTF-8** pax uses the actual UTF-8 encoding for the name when it is used in `read`, `copy`, or `list` mode and a filename, link name, owner name, or any other field in an extended header record cannot be translated from the pax UTF-8 codeset format to the codeset and current locale of the implementation.
- write** In read or copy mode, pax writes the file, translating the name, regardless of whether this can overwrite an existing file with a valid name. In `list` mode, pax behaves identically to the `bypass` action.

If no `-o invalid=` option is specified, pax acts as if `-o invalid=bypass` were specified. Any overwriting of existing files that can be allowed by the `-o invalid=actions` are subject to permission (`-p`) and modification time (`-u`) restrictions, and are suppressed if the `-k` option is also specified.

### linkdata

This keyword is applicable only to the `-x pax` format. In `write` mode, pax writes the contents of a file to the archive even when that file is merely a hard link to a file whose contents have already been written to the archive.

### listopt=format

This keyword specifies the output format of the table of contents produced when the `-v` option is specified in `list` mode. (See `List Mode Format Specifications` below.) To avoid ambiguity, the `listopt=format` is the only or final `keyword=value` pair in an `-o option-argument`. All characters in the remainder of the option-argument are considered to be part of the format string. When multiple `-o listopt=format` options are specified, the format strings are considered to be a single, concatenated string, evaluated in command line order.

### times

This keyword is applicable only to the `-x pax` and `-x xustar` formats. When used in `write` or `copy` mode, pax includes `atime` and `mtime` extended header records for each file.

In addition to these keywords, if the `-x pax` format is specified, any of the keywords and values, including implementation extensions, can be used in `-o option-arguments`, in either of two modes:

`keyword=value` When used in `write` or `copy` mode, these keyword/value pairs are included at the beginning of the archive as `typeflag g` global extended header records. When used in `read` or `list` mode, these keyword/value pairs act as if they had been at the beginning of the archive as `typeflag g` global extended header records.

`keyword:=value` When used in `write` or `copy` mode, these keyword/value pairs are included as records at the beginning of a `typeflag x` extended header for each file. This is equivalent to the equal-sign form except that it creates no `typeflag g` global extended header records. When used in `read` or `list` mode, these keyword/value pairs act as if they were included as records at the end of each extended header. Thus, they override any global or file-specific extended header record keywords of the same names. For example, in the command:

```
pax -r -o "
gname:=mygroup,
" <archive
```

the group name is forced to a new value for all files read from the archive.

`-p string`

Specifies one or more file characteristic options (privileges). The *string* option-argument must be a string specifying file characteristics to be retained or discarded on extraction. The string consists of the specification characters `a`, `e`, `m`, `o`, and `p`. Multiple characteristics can be concatenated within the same string and multiple `-p` options can be specified. The meaning of the specification characters is as follows:

- `a` Does not preserve file access times.
- `e` Preserves the user ID, group ID, file mode bits, access time, and modification time.
- `m` Does not preserve file modification times.
- `o` Preserves the user ID and group ID.
- `p` Preserves the file mode bits.

## pax(1)

In the preceding list, “preserve” indicates that an attribute stored in the archive is given to the extracted file, subject to the permissions of the invoking process. Otherwise, the attribute is determined as part of the normal file creation action. The access and modification times of the file is preserved unless otherwise specified with the `-p` option or not stored in the archive. All attributes that are not preserved are determined as part of the normal file creation action.

If neither the `e` nor the `o` specification character is specified, or the user ID and group ID are not preserved for any reason, `pax` does not set the `setuid` and `setgid` bits of the file mode.

If the preservation of any of these items fails for any reason, `pax` writes a diagnostic message to standard error. Failure to preserve these items affects the final exit status, but does not cause the extracted file to be deleted.

If file-characteristic letters in any of the *string* option-arguments are duplicated or conflict with each other, the ones given last take precedence. For example, if `-p eme` is specified, file modification times are preserved.

`-r`

Reads an archive file from standard input.

`-s replstr`

Modifies file or archive member names named by *pattern* or *file* operands according to the substitution expression *replstr*, which is based on the `ed(1) s` (substitution) utility, using the regular expression syntax on the `regex(5)` manual page. The concepts of “address” and “line” are meaningless in the context of the `pax` command, and must not be supplied. The format is:

```
-s /old/new/ [gp]
```

where, as in `ed`, *old* is a basic regular expression and *new* can contain an ampersand (&), a `\n` backreference, where *n* is a digit, or subexpression matching. The *old* string is also permitted to contain newlines.

Any non-null character can be used as a delimiter (/ shown here). Multiple `-s` expressions can be specified. The expressions are applied in the order specified, terminating with the first successful substitution. The optional trailing `g` is as defined in the `ed` command. The optional trailing `p` causes successful substitutions to be written to standard error. File or archive member names that substitute to the empty string are ignored when reading and writing archives.

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -t               | When reading files from the file system, and if the user has the permissions required by <code>utime()</code> to do so, sets the access time of each file read to the access time that it had before being read by <code>pax</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| -u               | <p>Ignores files that are older (having a less recent file modification time) than a pre-existing file or archive member with the same name.</p> <p><code>read mode</code>      An archive member with the same name as a file in the file system is extracted if the archive member is newer than the file.</p> <p><code>write mode</code>      An archive file member with the same name as a file in the file system is superseded if the file is newer than the archive member. If option <code>-a</code> is also specified, this is accomplished by appending to the archive. Otherwise, it is unspecified whether this is accomplished by actual replacement in the archive or by appending to the archive.</p> <p><code>copy mode</code>      The file in the destination hierarchy is replaced by the file in the source hierarchy or by a link to the file in the source hierarchy if the file in the source hierarchy is newer.</p> |
| -v               | In <code>list</code> mode, produces a verbose table of contents (see <code>Standard Output</code> ). Otherwise, writes archive member path names and extended attributes to standard error (see <code>Standard Error</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| -w               | Writes files to the standard output in the specified archive format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| -x <i>format</i> | <p>Specifies the output archive format. The <code>pax</code> utility recognizes the following formats:</p> <p><code>cpio</code>      The extended <code>cpio(1)</code> interchange format. See IEEE Std 1003.1–2001. The default <i>blocksize</i> for this format for character special archive files is 5120. | xustar | <p>Similar to <code>ustar</code>. Also allows archiving and extracting files whose size is greater than 8GB; whose UID, GID, devmajor, or devminor values are greater than 2097151; whose path (including filename) is greater than 255 characters; or whose linkname is greater than 100 characters. This option should not be used if the archive is to be extracted by an archiver that cannot handle the larger values.</p>                                                                                                                               |
|        | <p>Any attempt to append to an archive file in a format different from the existing archive format causes pax to exit immediately with a non-zero exit status.</p> <p>In copy mode, if no <code>-x</code> format is specified, pax behaves as if <code>-x pax</code> were specified.</p>                                                                                                                                                                                                                                                                      |
| -X     | <p>When traversing the file hierarchy specified by a path name, pax does not descend into directories that have a different device ID (<code>st_dev</code>, see <code>stat(2)</code>).</p>                                                                                                                                                                                                                                                                                                                                                                    |
| -@     | <p>When traversing the file hierarchy specified by a path name, pax descends into the attribute directory for any file with extended attributes. Extended attributes go into the archive as special files. When this flag is used during file extraction, any extended attributes associated with a file being extracted are also extracted. Extended attribute files can only be extracted from an archive as</p>                                                                                                                                            |

part of a normal file extract. Attempts to explicitly extract attribute records are ignored.

Specifying more than one of the mutually-exclusive options `-H` and `-L` is not considered an error. The last option specified determines the behavior of the utility.

The options that operate on the names of files or archive members (`-c`, `-i`, `-n`, `-s`, `-u` and `-v`) interact as follows.

In read mode, the archive members are selected based on the user-specified *pattern* operands as modified by the `-c`, `-n` and `-u` options. Then, any `-s` and `-i` options modify, in that order, the names of the selected files. The `-v` option writes names resulting from these modifications.

In write mode, the files are selected based on the user-specified path names as modified by the `-n` and `-u` options. Then, any `-s` and `-i` options modify, in that order, the names of these selected files. The `-v` option writes names resulting from these modifications.

If both the `-u` and `-n` options are specified, `pax` does not consider a file selected unless it is newer than the file to which it is compared.

#### List Mode Format Specifications

In list mode with the `-o listopt=format` option, the *format* argument is applied for each selected file. The `pax` utility appends a newline to the `listopt` output for each selected file. The *format* argument is used as the format string with the following exceptions. (See `printf(1)` for the first five exceptions.)

1. A SPACE character in the format string, in any context other than a flag of a conversion specification, is treated as an ordinary character that is copied to the output.
2. A ' ' character in the format string is treated as a ' ' character, not as a SPACE.
3. In addition to the escape sequences described in the `formats(5)` manual page (`\\`, `\a`, `\b`, `\f`, `\n`, `\r`, `\t`, `\v`), `\ddd`, where *ddd* is a one-, two-, or three-digit octal number, is written as a byte with the numeric value specified by the octal number.
4. Output from the `d` or `u` conversion specifiers is not preceded or followed with BLANKs not specified by the format operand.
5. Output from the `o` conversion specifier is not preceded with zeros that are not specified by the format operand.
6. The sequence (*keyword*) can occur before a format conversion specifier. The conversion argument is defined by the value of *keyword*. The following keywords are supported (see IEEE Std 1003.1–2001):
  - Any of the Field Name entries in `ustar` Header Block and Octet-Oriented `cpio` Archive Entry. The implementation supports the `cpio` keywords without the leading `c_` in addition to the form required by Values for `cpio c_ mode` Field.
  - Any keyword defined for the extended header in `pax` Extended Header.

pax(1)

- Any keyword provided as an implementation-defined extension within the extended header defined in `pax Extended Header`.

For example, the sequence “%(charset)s” is the string value of the name of the character set in the extended header.

The result of the keyword conversion argument is the value from the applicable header field or extended header, without any trailing NULs.

All keyword values used as conversion arguments are translated from the UTF-8 encoding to the character set appropriate for the local file system, user database, and so on, as applicable.

7. An additional conversion specifier character, `T`, is used to specify time formats. The `T` conversion specifier character can be preceded by the sequence *(keyword=subformat)*, where *subformat* is a date format as defined by *date* operands. The default *keyword* is `mtime` and the default *subformat* is:

```
%b %e %H:%M %Y
```

8. An additional conversion specifier character, `M`, is used to specify the file mode string as defined in `ls Standard Output`. If *(keyword)* is omitted, the `mode` keyword is used. For example, `%.1M` writes the single character corresponding to the *entry type* field of the `ls -l` command.
9. An additional conversion specifier character, `D`, is used to specify the device for block or special files, if applicable, in an implementation-defined format. If not applicable, and *(keyword)* is specified, then this conversion is equivalent to `%(keyword)u`. If not applicable, and *(keyword)* is omitted, then this conversion is equivalent to `SPACE`.
10. An additional conversion specifier character, `F`, is used to specify a path name. The `F` conversion character can be preceded by a sequence of comma-separated keywords:

```
(keyword [, keyword] . . . )
```

The values for all the keywords that are non-null are concatenated, each separated by a `'/'`. The default is `(path)` if the keyword `path` is defined. Otherwise, the default is `(prefix,name)`.

11. An additional conversion specifier character, `L`, is used to specify a symbolic link expansion. If the current file is a symbolic link, then `%L` expands to:

```
"%s -> %s", value of keyword, contents of link
```

Otherwise, the `%L` conversion specification is the equivalent of `%F`.

## OPERANDS

The following operands are supported:

|                  |                                                                 |
|------------------|-----------------------------------------------------------------|
| <i>directory</i> | The destination directory path name for <code>copy</code> mode. |
| <i>file</i>      | A path name of a file to be copied or archived.                 |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | <p><i>pattern</i> A pattern matching one or more path names of archive members. A pattern must conform to the pattern matching notation found on the <code>fnmatch(5)</code> manual page. The default, if no <i>pattern</i> is specified, is to select all members in the archive.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>OUTPUT</b>          | Output formats are discussed below:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Standard Output</b> | <p>In <code>write</code> mode, if <code>-f</code> is not specified, the standard output is the archive formatted according to <code>cpio</code> or <code>ustar</code>. (See <code>-x</code> format.)</p> <p>In <code>list</code> mode, when the <code>-o listopt=format</code> option has been specified, the selected archive members are written to standard output using the format described above under List Mode Format Specifications. In <code>list</code> mode without the <code>-o listopt=format</code> option, the table of contents of the selected archive members are written to standard output using the following format:</p> <pre>%s\n", <i>pathname</i></pre> <p>If the <code>-v</code> option is specified in <code>list</code> mode, the table of contents of the selected archive members are written to standard output using the following formats:</p> <ul style="list-style-type: none"> <li>■ For path names representing hard links to previous members of the archive: <pre>%s == %s\n", &lt;ls -l listing&gt;, <i>linkname</i></pre> </li> <li>■ For all other path names: <pre>%s\n", &lt;ls -l listing&gt;</pre> </li> </ul> <p>where <code>&lt;ls -l listing&gt;</code> is the format specified by the <code>ls</code> command with the <code>-l</code> option. When writing path names in this format, it is unspecified what is written for fields for which the underlying archive format does not have the correct information, although the correct number of blank-character-separated fields is written.</p> <p>In <code>list</code> mode, standard output is not buffered more than a line at a time.</p> |
| <b>Standard Error</b>  | <p>If <code>-v</code> is specified in <code>read</code>, <code>write</code> or <code>copy</code> modes, <code>pax</code> writes the path names it processes to the standard error output using the following format:</p> <pre>%s\n", <i>pathname</i></pre> <p>These path names are written as soon as processing is begun on the file or archive member, and are flushed to standard error. The trailing newline character, which is not buffered, is written when the file has been read or written.</p> <p>If the <code>-s</code> option is specified, and the replacement string has a trailing <code>p</code>, substitutions are written to standard error in the following format:</p> <pre>%s &gt;&gt; %s\n", &lt;original pathname&gt;, &lt;new pathname&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## pax(1)

In all operating modes of `pax`, optional messages of unspecified format concerning the input archive format and volume number, the number of files, blocks, volumes, and media parts as well as other diagnostic messages can be written to standard error.

In all formats, for both standard output and standard error, it is unspecified how non-printable characters in path names or link names are written.

When `pax` is in `read` mode or `list` mode, using the `-x pax` archive format, and a file name, link name, owner name, or any other field in an extended header record cannot be translated from the `pax` UTF-8 codeset format to the codeset and current locale of the implementation, `pax` writes a diagnostic message to standard error, processes the file as described for the `-o invalid=option`, and then processes the next file in the archive.

### Output Files

In `read` mode, the extracted output files are of the archived file type. In `copy` mode, the copied output files are the type of the file being copied. In either mode, existing files in the destination hierarchy are overwritten only when all permission (`-p`), modification time (`-u`), and invalid-value (`-o invalid=`) tests allow it. In `write` mode, the output file named by the `-f` option-argument is a file formatted according to one of the specifications in IEEE Std 1003.1-2001.

### ERRORS

If `pax` cannot create a file or a link when reading an archive, or cannot find a file when writing an archive, or cannot preserve the user ID, group ID, or file mode when the `-p` option is specified, a diagnostic message is written to standard error and a non-zero exit status is returned, but processing continues. In the case where `pax` cannot create a link to a file, `pax` does not, by default, create a second copy of the file.

If the extraction of a file from an archive is prematurely terminated by a signal or error, `pax` can have only partially extracted the file or, if the `-n` option was not specified, can have extracted a file of the same name as that specified by the user, but which is not the file the user wanted. Additionally, the file modes of extracted directories can have additional bits from the read, write, execute mask set as well as incorrect modification and access times.

### USAGE

The `-p` (privileges) option was invented to reconcile differences between historical `tar(1)` and `cpio(1)` implementations. In particular, the two utilities use `-m` in diametrically opposed ways. The `-p` option also provides a consistent means of extending the ways in which future file attributes can be addressed, such as for enhanced security systems or high-performance files. Although it can seem complex, there are really two modes that are most commonly used:

- `-p e`      “Preserve everything”. This would be used by the historical superuser, someone with all the appropriate privileges, to preserve all aspects of the files as they are recorded in the archive. The `e` flag is the sum of `o` and `p`, and other implementation-dependent attributes.
- `-p p`      “Preserve” the file mode bits. This would be used by the user with regular privileges who wished to preserve aspects of the file other than the ownership. The file times are preserved by default, but two other flags are

offered to disable these and use the time of extraction.

The one path name per line format of standard input precludes path names containing newlines. Although such path names violate the portable filename guidelines, they can exist and their presence can inhibit usage of `pax` within shell scripts. This problem is inherited from historical archive programs. The problem can be avoided by listing file name arguments on the command line instead of on standard input.

It is almost certain that appropriate privileges are required for `pax` to accomplish parts of this volume of IEEE Std 1003.1-2001. Specifically, creating files of type block special or character special, restoring file access times unless the files are owned by the user (the `-t` option), or preserving file owner, group, and mode (the `-p` option) all probably require appropriate privileges.

In read mode, implementations are permitted to overwrite files when the archive has multiple members with the same name. This can fail if permissions on the first version of the file do not permit it to be overwritten.

See `largefile(5)` for the description of the behavior of `pax` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

#### Standard Input

In write mode, the standard input is used only if no *file* operands are specified. It is a text file containing a list of path names, one per line, without leading or trailing blanks. In list and read modes, if `-f` is not specified, the standard input is an archive file. Otherwise, the standard input is not used.

#### Input Files

The input file named by the *archive* option-argument, or standard input when the archive is read from there, is a file formatted according to IEEE Std 1003.1-2001, `pax` Shell and Utilities. The file `/dev/tty` is used to write prompts and read responses.

#### EXAMPLES

##### EXAMPLE 1 Copying the Contents of the Current Directory

The following command:

```
example% pax -w -f /dev/rmt/lm .
```

copies the contents of the current directory to tape drive 1, medium density. This assumes historical System V device naming procedures. The historical BSD device name would be `/dev/rmt9`.

##### EXAMPLE 2 Copying the Directory Hierarchy

The following commands:

```
example% mkdir newdir
example% pax -rw olddir newdir
```

copy the `olddir` directory hierarchy to `newdir`.

pax(1)

**EXAMPLE 3** Reading an Archive Extracted Relative to the Current Directory

The following command:

```
example% pax -r -s ',^/*usr/*,,,' -f a.pax
```

reads the archive `a.pax`, with all files rooted in `/usr` in the archive extracted relative to the current directory.

**EXAMPLE 4** Overriding the Default Output Description

Using the option:

```
-o listopt="%M %(atime)T %(size)D %(name)s"
```

overrides the default output description in Standard Output and instead writes:

```
-rw-rw- - - Jan 12 15:53 2003 1492 /usr/foo/bar
```

Using the options:

```
-o listopt='%L\t%(size)D\n%.7' \  
-o listopt='(name)s\n%(atime)T\nT'
```

overrides the default output description in standard output and instead writes:

```
usr/foo/bar -> /tmp          1492  
/usr/foo  
Jan 12 15:53 1991  
Jan 31 15:53 2003
```

**ENVIRONMENT  
VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `pax`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, and `NLSPATH`.

|                         |                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>LC_COLLATE</code> | Determine the locale for the behaviour of ranges, equivalence classes, and multi-character collating elements used in the pattern matching expressions for the <i>pattern</i> operand, the basic regular expression for the <code>-s</code> option, and the extended regular expression defined for the <code>yesexpr</code> locale keyword in the <code>LC_MESSAGES</code> category. |
| <code>TMPDIR</code>     | Determine the path name that provides part of the default global extended header record file, as described for the <code>-o globexthdr=</code> keyword as described in the <code>OPTIONS</code> section.                                                                                                                                                                              |
| <code>TZ</code>         | Determine the timezone used to calculate date and time strings when the <code>-v</code> option is specified. If <code>TZ</code> is unset or null, an unspecified default timezone is used.                                                                                                                                                                                            |

**EXIT STATUS**

The following exit values are returned:

0 All files were processed successfully.

>0 An error occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Standard        |

|--------------------------|------------------------|

#### Platform-Specific

If you're new to Perl, you should start with `perlintro`, which is a general intro for beginners and provides some background to help you navigate the rest of Perl's extensive documentation. For ease of access, the Perl manual has been split up into several sections.

The manpages listed above are installed in the `/usr/perl5/man/` directory.

Extensive additional documentation for Perl modules is available. This additional documentation is in the `/usr/perl5/man` directory. Some of this additional documentation is distributed standard with Perl, but you'll also find documentation for any customer-installed third-party modules there.

You can view Perl's documentation with `man(1)` by including `/usr/perl5/man` in the `MANPATH` environment variable. Notice that running `catman(1M)` on the Perl manual pages is not supported. For other Solaris-specific details, see the `NOTES` section below.

You can also use the supplied `/usr/perl5/bin/perldoc` script to view Perl information.

If something strange has gone wrong with your program and you're not sure where you should look for help, try the `-w` switch first. It will often point out exactly where the trouble is.

Perl is a language optimized for scanning arbitrary text files, extracting information from those text files, and printing reports based on that information. It's also a good language for many system management tasks. The language is intended to be practical (easy to use, efficient, complete) rather than beautiful (tiny, elegant, minimal).

Perl combines (in the author's opinion, anyway) some of the best features of C, sed, awk, and sh, so people familiar with those languages should have little difficulty with it. (Language historians will also note some vestiges of csh, Pascal, and even BASIC-PLUS.) Expression syntax corresponds closely to C expression syntax. Unlike most Unix utilities, Perl does not arbitrarily limit the size of your data -if you've got the memory, Perl can slurp in your whole file as a single string. Recursion is of unlimited depth. And the tables used by hashes (sometimes called "associative arrays") grow as necessary to prevent degraded performance. Perl can use sophisticated pattern matching techniques to scan large amounts of data quickly. Although optimized for scanning text, Perl can also deal with binary data, and can make dbm files look like hashes. Setuid Perl scripts are safer than C programs through a dataflow tracing mechanism that prevents many stupid security holes.

If you have a problem that would ordinarily use sed or awk or sh, but it exceeds their capabilities or must run a little faster, and you don't want to write the silly thing in C, then Perl may be for you. There are also translators to turn your sed and awk scripts into Perl scripts.

But wait, there's more...

Begun in 1993 (see perlhist), Perl version 5 is nearly a complete rewrite that provides the following additional benefits:

- Modularity and reusability using innumerable modules Described in perlmod, perlmodlib, and perlmodinstall.
- Embeddable and extensible Described in perlembed, perlxs, perlcall, perlguits, and xsubpp.
- Roll-your-own magic variables (including multiple simultaneous DBM implementations). Described in perltie and AnyDBM\_File.
- Subroutines can now be overridden, autoloaded, and prototyped. Described in perlsub.
- Arbitrarily nested data structures and anonymous functions. Described in perlreftut, perlref, perldsc, and perllo.
- Object-oriented programming. Described in perlobj, perlboot, perltoot, perltooc, and perlbot.
- Support for light-weight processes (threads). Described in perlthrtut and threads.
- Support for Unicode, internationalization, and localization Described in perluniintro, perllocale and Locale::Maketext.
- Lexical scoping. Described in perlsub.
- Regular expression enhancements. Described in perlre, with additional examples in perlop.

perl(1)

- Enhanced debugger and interactive Perl environment, with integrated editor support. Described in `perldebtut`, `perldebug` and `perldebguts`.
- POSIX 1003.1 compliant library Described in POSIX.

Okay, that's *definitely* enough hype.

**ENVIRONMENT VARIABLES**

The Perl shipped with Solaris is installed under `/usr/perl5` rather than the default `/usr/local` location. This is so that it can coexist with a customer-installed Perl in the default `/usr/local` location.

Any additional modules that you choose to install will be placed in the `/usr/perl5/site_perl/5.8.4` directory. The `/usr/perl5/vendor_perl` directory is reserved for SMI-provided modules.

Notice that the Perl utility scripts such as `perldoc` and `perlbug` are in the `/usr/perl5/bin` directory, so if you wish to use them you need to include `/usr/perl5/bin` in your `PATH` environment variable.

See also the `perlrun` mapage.

**AUTHOR**

Larry Wall, with the help of oodles of other folks.

If your Perl success stories and testimonials may be of help to others who wish to advocate the use of Perl in their applications, or if you wish to simply express your gratitude to Larry and the Perl developers, please write to `perl-thanks@perl.org`.

<http://www.perl.com/CPAN>            The Comprehensive Perl Archive

<http://www.perl.org>                Perl Mongers (Perl user groups)

**DIAGNOSTICS**    The `'use warnings'` pragma (and the `-w` switch) produce some lovely diagnostics.

See `perldiag` for explanations of all Perl's diagnostics. The `'use diagnostics'` pragma automatically turns Perl's normally terse warnings and errors into these longer forms.

Compilation errors will tell you the line number of the error, with an indication of the next token or token type that was to be examined. (In a script passed to Perl via `-e` switches, each `-e` is counted as one line.)

Setuid scripts have additional constraints that can produce error messages such as "Insecure dependency". See `perlsec`.

Did we mention that you should definitely consider using the `-w` switch?

**NOTES**            Perl 5.8.4 has been built to be largefile-aware and to use 64-bit integers, although the interpreter itself is a 32-bit application (LP32). To view detailed configuration information, use `perl -V` and `perlbug -dv`.

If you wish to build and install add-on modules from CPAN using `gcc`, you can do so using the `/usr/perl5/5.8.4/bin/perlgcc` script – see `perlgcc(1)` for details.

If you wish to build and install your own version of Perl, you should NOT remove the 5.8.4 version of `perl` under `/usr/perl5`, as it is required by several system utilities. The Perl package names are as follows:

|                              |                             |
|------------------------------|-----------------------------|
| <code>SUNWperl584core</code> | Perl 5.8.4 (Core files)     |
| <code>SUNWperl584usr</code>  | Perl 5.8.4 (Non-core files) |
| <code>SUNWperl584man</code>  | Perl 5.8.4 (Manual pages)   |

Solaris 10 also ships with the 5.6.1 version of Perl that was included in Solaris 9. If you are upgrading your system and wish to continue to use Perl 5.6.1 as the default Perl version you should refer to the `perlsolaris` manpage for details of how to do this. Note that you should upgrade your installation to use Perl 5.8.4 as soon as is practicable, as Perl 5.6.1 may be removed in a future release.

The Perl motto is "There's more than one way to do it." Divining how many more is left as an exercise to the reader.

The three principal virtues of a programmer are Laziness, Impatience, and Hubris. See the Camel Book for why.

**BUGS**            The `-w` switch is not mandatory.

Perl is at the mercy of your machine's definitions of various operations such as type casting, `atof()`, and floating-point output with `sprintf()`.

perl(1)

If your `stdio` requires a seek or eof between reads and writes on a particular stream, so does Perl. (This doesn't apply to `sysread()` and `syswrite()`.)

While none of the built-in data types have any arbitrary size limits (apart from memory size), there are still a few arbitrary limits: a given variable name may not be longer than 251 characters. Line numbers displayed by diagnostics are internally stored as short integers, so they are limited to a maximum of 65535 (higher numbers usually being affected by wraparound).

You may mail your bug reports (be sure to include full configuration information as output by the `myconfig` program in the perl source tree, or by `'perl -V'`) to `perlbug@perl.org`. If you've succeeded in compiling perl, the `perlbug` script in the `utils/` subdirectory can be used to help mail in a bug report.

Perl actually stands for Pathologically Eclectic Rubbish Lister, but don't tell anyone I said that.

**NAME** pfexec, pfsh, pfcsh, pfksh – execute a command in a profile

**SYNOPSIS** */usr/bin/pfexec command*  
*/usr/bin/pfexec -P privspec command [ arg ...]*  
*/usr/bin/pfsh [ options ] [ argument ...]*  
*/usr/bin/pfcsh [ options ] [ argument ...]*  
*/usr/bin/pfksh [ options ] [ argument ...]*

**DESCRIPTION** The pfexec program is used to execute commands with the attributes specified by the user's profiles in the exec\_attr(4) database. It is invoked by the profile shells, pfsh, pfcsh, and pfksh which are linked to the Bourne shell, C shell, and Korn shell, respectively.

Profiles are searched in the order specified in the user's entry in the user\_attr(4) database. If the same command appears in more than one profile, the profile shell uses the first matching entry.

The second form, pfexec -P privspec, allows a user to obtain the additional privileges awarded to the user's profiles in prof\_attr(4). The privileges specification on the commands line is parsed using priv\_str\_to\_set(3C). The resulting privileges are intersected with the union of the privileges specified using the "privs" keyword in prof\_attr(4) for all the user's profiles and added to the inheritable set before executing the command.

**USAGE** pfexec is used to execute commands with predefined process attributes, such as specific user or group IDs.

Refer to the sh(1), csh(1), and ksh(1) man pages for complete usage descriptions of the profile shells.

**EXAMPLES** **EXAMPLE 1** Obtaining additional user privileges

```
example% pfexec -P all chown user file
```

This command runs chown user file with all privileges assigned to the current user, not necessarily all privileges.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

1 An error occurred.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| <b>NAME</b>        | pg – files perusal filter for CRTs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <b>pg</b> [- <i>number</i> ] [-p <i>string</i> ] [-cefnrs] [ + <i>linenumber</i> ] [ +/ <i>pattern</i> /]<br>[ <i>filename...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>The <b>pg</b> command is a filter that allows the examination of <i>filenames</i> one screenful at a time on a CRT. If the user types a RETURN, another page is displayed; other possibilities are listed below.</p> <p>This command is different from previous paginators in that it allows you to back up and review something that has already passed. The method for doing this is explained below.</p> <p>To determine terminal attributes, <b>pg</b> scans the <code>terminfo(4)</code> data base for the terminal type specified by the environment variable <code>TERM</code>. If <code>TERM</code> is not defined, the terminal type <code>dumb</code> is assumed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>OPTIONS</b>     | <p><i>-number</i>            An integer specifying the size (in lines) of the window that <b>pg</b> is to use instead of the default. (On a terminal containing 24 lines, the default window size is 23).</p> <p><i>-p string</i>           <b>pg</b> uses <i>string</i> as the prompt. If the prompt string contains a <code>%d</code>, the first occurrence of <code>%d</code> in the prompt will be replaced by the current page number when the prompt is issued. The default prompt string is <code>:"</code>.</p> <p><i>-c</i>                    Home the cursor and clear the screen before displaying each page. This option is ignored if <code>clear_screen</code> is not defined for this terminal type in the <code>terminfo(4)</code> data base.</p> <p><i>-e</i>                    <b>pg</b> does <i>not</i> pause at the end of each file.</p> <p><i>-f</i>                    Normally, <b>pg</b> splits lines longer than the screen width, but some sequences of characters in the text being displayed (for instance, escape sequences for underlining) generate undesirable results. The <i>-f</i> option inhibits <b>pg</b> from splitting lines.</p> <p><i>-n</i>                    Normally, commands must be terminated by a <code>&lt;newline&gt;</code> character. This option causes an automatic end of command as soon as a command letter is entered.</p> <p><i>-r</i>                    Restricted mode. The shell escape is disallowed. <b>pg</b> prints an error message but does not exit.</p> <p><i>-s</i>                    <b>pg</b> prints all messages and prompts in the standard output mode (usually inverse video).</p> <p><i>+linenumber</i>         Start up at <i>linenumber</i>.</p> <p><i>+/pattern/</i>           Start up at the first line containing the regular expression pattern.</p> |
| <b>OPERANDS</b>    | The following operands are supported:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

pg(1)

*filename* A path name of a text file to be displayed. If no *filename* is given, or if it is -, the standard input is read.

## USAGE

**Commands** The responses that may be typed when pg pauses can be divided into three categories: those causing further perusal, those that search, and those that modify the perusal environment.

Commands that cause further perusal normally take a preceding *address*, an optionally signed number indicating the point from which further text should be displayed. This *address* is interpreted in either pages or lines depending on the command. A signed *address* specifies a point relative to the current page or line, and an unsigned *address* specifies an address relative to the beginning of the file. Each command has a default address that is used if none is provided.

The perusal commands and their defaults are as follows:

|                                            |                                                                                                                                                                                                                        |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| (+1)< <i>newline</i> > or < <i>blank</i> > | This causes one page to be displayed. The address is specified in pages.                                                                                                                                               |
| (+1) l                                     | With a relative address this causes pg to simulate scrolling the screen, forward or backward, the number of lines specified. With an absolute address this command prints a screenful beginning at the specified line. |
| (+1) d or ^D                               | Simulates scrolling half a screen forward or backward.                                                                                                                                                                 |
| <i>i</i> f                                 | Skip <i>i</i> screens of text.                                                                                                                                                                                         |
| <i>i</i> z                                 | Same as < <i>newline</i> > except that <i>i</i> , if present, becomes the new default number of lines per screenful.                                                                                                   |

The following perusal commands take no *address*.

|         |                                                                                     |
|---------|-------------------------------------------------------------------------------------|
| . or ^L | Typing a single period causes the current page of text to be redisplayed.           |
| \$      | Displays the last windowful in the file. Use with caution when the input is a pipe. |

The following commands are available for searching for text patterns in the text. The regular expressions are described on the `regex(5)` manual page. They must always be terminated by a <*newline*>, even if the -n option is specified.

|                             |                                                                                                                                                                                                                |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>i</i> / <i>pattern</i> / | Search forward for the <i>i</i> th (default <i>i</i> =1) occurrence of <i>pattern</i> . Searching begins immediately after the current page and continues to the end of the current file, without wrap-around. |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

*i*^*pattern*^

*i*?*pattern*? Search backwards for the *i*th (default *i*=1) occurrence of *pattern*. Searching begins immediately before the current page and continues to the beginning of the current file, without wrap-around. The ^ notation is useful for Adds 100 terminals which will not properly handle the ?.

After searching, pg will normally display the line found at the top of the screen. This can be modified by appending m or b to the search command to leave the line found in the middle or at the bottom of the window from now on. The suffix t can be used to restore the original situation.

The user of pg can modify the environment of perusal with the following commands:

|                      |                                                                                                                                                                                                                                                  |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>in</i>            | Begin perusing the <i>i</i> th next file in the command line. The <i>i</i> is an unsigned number, default value is 1.                                                                                                                            |
| <i>ip</i>            | Begin perusing the <i>i</i> th previous file in the command line. <i>i</i> is an unsigned number, default is 1.                                                                                                                                  |
| <i>iw</i>            | Display another window of text. If <i>i</i> is present, set the window size to <i>i</i> .                                                                                                                                                        |
| <i>s filename</i>    | Save the input in the named file. Only the current file being perused is saved. The white space between the <i>s</i> and <i>filename</i> is optional. This command must always be terminated by a <newline>, even if the -n option is specified. |
| <i>h</i>             | Help by displaying an abbreviated summary of available commands.                                                                                                                                                                                 |
| <i>q</i> or <i>Q</i> | Quit pg.                                                                                                                                                                                                                                         |
| ! <i>command</i>     | <i>Command</i> is passed to the shell, whose name is taken from the SHELL environment variable. If this is not available, the default shell is used. This command must always be terminated by a <newline>, even if the -n option is specified.  |

At any time when output is being sent to the terminal, the user can hit the quit key (normally CTRL-\) or the interrupt (break) key. This causes pg to stop sending output, and display the prompt. The user may then enter one of the above commands in the normal manner. Unfortunately, some output is lost when this is done, because any characters waiting in the terminal's output queue are flushed when the quit signal occurs.

If the standard output is not a terminal, then pg acts just like [cat\(1\)](#), except that a header is printed before each file (if there is more than one).

### Large File Behavior

See [largefile\(5\)](#) for the description of the behavior of pg when encountering files greater than or equal to 2 Gbyte (2<sup>31</sup> bytes).

pg(1)

**EXAMPLES**

**EXAMPLE 1** An example of the pg command.

The following command line uses pg to read the system news:

```
example% news | pg -p "(Page %d) :"
```

**ENVIRONMENT VARIABLES**

See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of pg: LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

The following environment variables affect the execution of pg:

- COLUMNS** Determine the horizontal screen size. If unset or NULL, use the value of TERM, the window size, baud rate, or some combination of these, to indicate the terminal type for the screen size calculation.
- LINES** Determine the number of lines to be displayed on the screen. If unset or NULL, use the value of TERM, the window size, baud rate, or some combination of these, to indicate the terminal type for the screen size calculation.
- SHELL** Determine the name of the command interpreter executed for a !command.
- TERM** Determine terminal attributes. Optionally attempt to search a system-dependent database, keyed on the value of the TERM environment variable. If no information is available, a terminal incapable of cursor-addressable movement is assumed.

**EXIT STATUS**

The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**FILES**

- /tmp/pg\* temporary file when input is from a pipe
- /usr/share/lib/terminfo/?/\* terminal information database

**ATTRIBUTES**

See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | enabled         |

**SEE ALSO**

[cat\(1\)](#), [grep\(1\)](#), [more\(1\)](#), [terminfo\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [regex\(5\)](#)

**NOTES** While waiting for terminal input, `pg` responds to `BREAK`, `CTRL-C`, and `CTRL-\` by terminating execution. Between prompts, however, these signals interrupt `pg`'s current task and place the user in prompt mode. These should be used with caution when input is being read from a pipe, since an interrupt is likely to terminate the other commands in the pipeline.

The terminal `/`, `^`, or `?` may be omitted from the searching commands.

If terminal tabs are not set every eight positions, undesirable results may occur.

When using `pg` as a filter with another command that changes the terminal I/O options, terminal settings may not be restored correctly.

## pgrep(1)

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>DESCRIPTION</b> | <p>The <code>pgrep</code> utility examines the active processes on the system and reports the process IDs of the processes whose attributes match the criteria specified on the command line. Each process ID is printed as a decimal value and is separated from the next ID by a delimiter string, which defaults to a newline. For each attribute option, the user can specify a set of possible values separated by commas on the command line. For example,</p> <pre><b>pgrep -G other,daemon</b></pre> <p>matches processes whose real group ID is <code>other</code> OR <code>daemon</code>. If multiple criteria options are specified, <code>pgrep</code> matches processes whose attributes match the logical AND of the criteria options. For example,</p> <pre><b>pgrep -G other,daemon -U root,daemon</b></pre> <p>matches processes whose attributes are:</p> <p>(real group ID is <code>other</code> OR <code>daemon</code>) AND<br/>(real user ID is <code>root</code> OR <code>daemon</code>)</p> <p><code>pkill</code> functions identically to <code>pgrep</code>, except that each matching process is signaled as if by <code>kill(1)</code> instead of having its process ID printed. A signal name or number may be specified as the first command line option to <code>pkill</code>.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li><code>-c <i>ctidlist</i></code> Matches only processes whose process contract ID is in the given list.</li><li><code>-d <i>delim</i></code> Specifies the output delimiter string to be printed between each matching process ID. If no <code>-d</code> option is specified, the default is a newline character. The <code>-d</code> option is only valid when specified as an option to <code>pgrep</code>.</li><li><code>-f</code> The regular expression <i>pattern</i> should be matched against the full process argument string (obtained from the <code>pr_psargs</code> field of the <code>/proc/<i>nnnnn</i>/psinfo</code> file). If no <code>-f</code> option is specified, the expression is matched only against the name of the executable file (obtained from the <code>pr_fname</code> field of the <code>/proc/<i>nnnnn</i>/psinfo</code> file).</li></ul>                                                                                                                                                                                                                                                                                                                                                     |

|                            |                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-g pgrplist</code>   | Matches only processes whose process group ID is in the given list. If group 0 is included in the list, this is interpreted as the process group ID of the <code>pgrep</code> or <code>pkill</code> process.                                                                                                                                                         |
| <code>-G gidlist</code>    | Matches only processes whose real group ID is in the given list. Each group ID may be specified as either a group name or a numerical group ID.                                                                                                                                                                                                                      |
| <code>-J projidlist</code> | Matches only processes whose project ID is in the given list. Each project ID may be specified as either a project name or a numerical project ID.                                                                                                                                                                                                                   |
| <code>-l</code>            | Long output format. Prints the process name along with the process ID of each matching process. The process name is obtained from the <code>pr_psargs</code> or <code>pr_fname</code> field, depending on whether the <code>-f</code> option was specified (see above). The <code>-l</code> option is only valid when specified as an option to <code>pgrep</code> . |
| <code>-n</code>            | Matches only the newest (most recently created) process that meets all other specified matching criteria. Cannot be used with option <code>-o</code> .                                                                                                                                                                                                               |
| <code>-o</code>            | Matches only the oldest (earliest created) process that meets all other specified matching criteria. Cannot be used with option <code>-n</code> .                                                                                                                                                                                                                    |
| <code>-P ppidlist</code>   | Matches only processes whose parent process ID is in the given list.                                                                                                                                                                                                                                                                                                 |
| <code>-s sidlist</code>    | Matches only processes whose process session ID is in the given list. If ID 0 is included in the list, this is interpreted as the session ID of the <code>pgrep</code> or <code>pkill</code> process.                                                                                                                                                                |
| <code>-t termlist</code>   | Matches only processes which are associated with a terminal in the given list. Each terminal is specified as the suffix following <code>"/dev/"</code> of the terminal's device path name in <code>/dev</code> . For example, <code>term/a</code> or <code>pts/0</code> .                                                                                            |
| <code>-T taskidlist</code> | Matches only processes whose task ID is in the given list. If ID 0 is included in the list, this is interpreted as the task ID of the <code>pgrep</code> or <code>pkill</code> process.                                                                                                                                                                              |
| <code>-u euidlist</code>   | Matches only processes whose effective user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID.                                                                                                                                                                                                                    |
| <code>-U uidlist</code>    | Matches only processes whose real user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID.                                                                                                                                                                                                                         |
| <code>-v</code>            | Reverses the sense of the matching. Matches all processes <i>except</i> those which meet the specified matching criteria.                                                                                                                                                                                                                                            |

## pgrep(1)

|                    |                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------|----------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                    | <b>-x</b>                                                | Considers only processes whose argument string or executable file name <i>exactly</i> matches the specified <i>pattern</i> to be matching processes. The pattern match is considered to be exact when all characters in the process argument string or executable file name match the pattern.                                                                                                                                       |
|                    | <b>-z <i>zoneidlist</i></b>                              | Matches only processes whose zone ID is in the given list. Each zone ID may be specified as either a zone name or a numerical zone ID. This option is only useful when executed in the global zone. If the <code>pskill</code> utility is used to send signals to processes in other zones, the process must have asserted the <code>{ PRIV_PROC_ZONE }</code> privilege (see <code>privileges(5)</code> ).                          |
|                    | <b>-<i>signal</i></b>                                    | Specifies the signal to send to each matched process. If no signal is specified, <code>SIGTERM</code> is sent by default. The value of <i>signal</i> can be one of the symbolic names defined in <code>signal.h(3HEAD)</code> without the <code>SIG</code> prefix, or the corresponding signal number as a decimal value. The <b>-<i>signal</i></b> option is only valid when specified as the first option to <code>pskill</code> . |
| <b>OPERANDS</b>    | The following operand is supported:                      |                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                    | <b><i>pattern</i></b>                                    | Specifies an Extended Regular Expression (ERE) pattern to match against either the executable file name or full process argument string. See <code>regex(5)</code> for a complete description of the ERE syntax.                                                                                                                                                                                                                     |
| <b>EXAMPLES</b>    | <b>EXAMPLE 1</b> Obtaining a Process ID                  |                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                    | Obtain the process ID of <code>sendmail</code> :         |                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>FILES</b>       | <code>/proc/<i>nnnnn</i>/psinfo</code>                   | Process information files                                                                                                                                                                                                                                                                                                                                                                                                            |

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `kill(1)`, `proc(1)`, `ps(1)`, `truss(1)`, `kill(2)`, `signal.h(3HEAD)`, `proc(4)`, `attributes(5)`, `privileges(5)`, `regex(5)`, `zones(5)`

**NOTES** Both utilities match the ERE *pattern* argument against either the `pr_fname` or `pr_psargs` fields of the `/proc/nnnnn/psinfo` files. The lengths of these strings are limited according to definitions in `<sys/procfs.h>`. Patterns which can match strings longer than the current limits may fail to match the intended set of processes.

If the *pattern* argument contains ERE meta-characters which are also shell meta-characters, it may be necessary to enclose the pattern with appropriate shell quotes.

Defunct processes are never matched by either `pgrep` or `pkill`.

The current `pgrep` or `pkill` process will never consider itself a potential match.

| <b>NAME</b>        | pkginfo – display software package information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <b>pkginfo</b> [-q   -x   -l] [-p   -i] [-r] [-a <i>arch</i> ] [-v <i>version</i> ]<br>[-c <i>category...</i> ] [ <i>pkginst...</i> ]<br><b>pkginfo</b> [-d <i>device</i> ] [-R <i>root_path</i> ] [-q   -x   -l] [-a <i>arch</i> ] [-v <i>version</i> ]<br>[-c <i>category...</i> ] [ <i>pkginst...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>pkginfo displays information about software packages that are installed on the system (with the first synopsis) or that reside on a particular device or directory (with the second synopsis).</p> <p>Without options, pkginfo lists the primary category, package instance, and the names of all completely installed and partially installed packages. It displays one line for each package selected.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>OPTIONS</b>     | <p>The -p and -i options are meaningless if used in conjunction with the -d option.</p> <p>The options -q, -x, and -l are mutually exclusive.</p> <p>-a <i>arch</i> Specify the architecture of the package as <i>arch</i>.</p> <p>-c <i>category</i> Display packages that match <i>category</i>. Categories are defined with the CATEGORY parameter in the pkginfo(4) file. If more than one category is supplied, the package needs to match only one category in the list. The match is not case specific.</p> <p>-d <i>device</i> Defines a device, <i>device</i>, on which the software resides. <i>device</i> can be an absolute directory pathname or the identifiers for tape, floppy disk, removable disk, and so forth. The special token spool may be used to indicate the default installation spool directory (/var/spool/pkg).</p> <p>-i Display information for fully installed packages only.</p> <p>-l Specify long format, which includes all available information about the designated package(s).</p> <p>-p Display information for partially installed packages only.</p> <p>-q Do not list any information. Used from a program to check whether or not a package has been installed.</p> <p>-r List the installation base for relocatable packages.</p> <p>-R <i>root_path</i> Defines the full path name of a directory to use as the <i>root_path</i>. All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i>.</p> <p>-v <i>version</i> Specify the version of the package as <i>version</i>. The version is defined with the VERSION parameter in the pkginfo(4) file. All compatible versions can be requested by preceding the version name with a tilde (~). Multiple white spaces are replaced with a single white space during version comparison.</p> |

- OPERANDS**
  - x Designate an extracted listing of package information. The listing contains the package abbreviation, package name, package architecture (if available) and package version (if available).
  - pkginst* A package designation by its instance. An instance can be the package abbreviation or a specific instance (for example, *inst . 1* or *inst . 2*). All instances of a package can be requested by *inst . \**. The asterisk character (\*) is a special character to some shells and may need to be escaped. In the C-Shell, "\*" must be surrounded by single quotes (') or preceded by a backslash (\).
- EXIT STATUS**
  - 0 Successful completion.
  - >0 An error occurred.
- FILES**
  - /var/spool/pkg default installation spool directory
- ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

| <b>NAME</b>            | pkgmk – produce an installable package                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                                                                                           |                        |                                                                                                                                                                                                                                                                                                    |                  |                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>        | <b>pkgmk</b> [-o] [-a <i>arch</i> ] [-b <i>base_src_dir</i> ] [-d <i>device</i> ] [-f <i>prototype</i> ] [-l <i>limit</i> ]<br>[-p <i>pstamp</i> ] [-r <i>root_path</i> ] [-v <i>version</i> ] [ <i>variable=value...</i> ] [ <i>pkginst</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                                                                                           |                        |                                                                                                                                                                                                                                                                                                    |                  |                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b>     | <p>The pkgmk utility produces an installable package to be used as input to the pkgadd(1M) command. The package contents will be in directory structure format.</p> <p>The command uses the package prototype(4) file as input and creates a pkgmap(4) file. The contents for each entry in the prototype file is copied to the appropriate output location. Information concerning the contents (checksum, file size, modification date) is computed and stored in the pkgmap file, along with attribute information specified in the prototype file.</p> <p>pkgmk searches for the files listed in the prototype(4) file as described in the following conditions. <i>Note:</i> If a prototype file contains the explicit location of the file to include in the package, then the following search explanations do not apply.</p> <ol style="list-style-type: none"><li>1. If neither -b nor -r options are specified, the file name component of each file path listed in the prototype(4) file is expected to be found in the same directory as the prototype(4) file</li><li>2. If -b is specified as a relative path (without a leading "/"), then <i>base_src_dir</i> is prepended to the relative file paths from the prototype(4) file. The resulting path is searched for in the <i>root_path</i> directories. If a <i>root_path</i> is not specified, it defaults to "/".</li><li>3. If -b is specified as an absolute path (with a leading "/"), then <i>base_src_dir</i> is prepended to the relative paths from the prototype(4) file and the result is the location of the file. <i>root_path</i> is not searched.</li><li>4. If -r is specified, then full file paths are used from the prototype(4) file. Relative paths have <i>base_src_dir</i> prepended. If <i>base_src_dir</i> is not specified, it defaults to "". The resulting path is searched for in each directory of the <i>root_path</i>.</li></ol> <p>If you created your prototype file using "pkgproto a/relative/path" or "pkgproto a/relative/path=install/path", then you should use the -r <i>root_path</i> option to specify the location of a/relative/path so that pkgmk can correctly locate your source files.</p> |                |                                                                                           |                        |                                                                                                                                                                                                                                                                                                    |                  |                                                                                                                                                                                                                                                          |
| <b>OPTIONS</b>         | <p>The following options are supported:</p> <table><tr><td>-a <i>arch</i></td><td>Overrides the architecture information provided in the pkginfo(4) file with <i>arch</i>.</td></tr><tr><td>-b <i>base_src_dir</i></td><td>Prepends the indicated <i>base_src_dir</i> to locate relocatable objects on the source machine. Use this option to search for all objects in the prototype file. pkgmk expects to find the objects in <i>/base_src_dir</i> or to locate the objects by use of the -b and -r options, respectively.</td></tr><tr><td>-d <i>device</i></td><td>Creates the package on <i>device</i>. <i>device</i> can be an absolute directory pathname or the identifiers for a floppy disk or removable disk (for example, /dev/diskette). | -b <i>base_src_dir</i> | Prepends the indicated <i>base_src_dir</i> to locate relocatable objects on the source machine. Use this option to search for all objects in the prototype file. pkgmk expects to find the objects in <i>/base_src_dir</i> or to locate the objects by use of the -b and -r options, respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                                                                                           |                        |                                                                                                                                                                                                                                                                                                    |                  |                                                                                                                                                                                                                                                          |
| -d <i>device</i>       | Creates the package on <i>device</i> . <i>device</i> can be an absolute directory pathname or the identifiers for a floppy disk or removable disk (for example, /dev/diskette). The default device is the installation spool directory (/var/spool/pkg).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                                                                                           |                        |                                                                                                                                                                                                                                                                                                    |                  |                                                                                                                                                                                                                                                          |

- f *prototype* Uses the file *prototype* as input to the command. The default *prototype* filename is [Pp]*prototype*.
- l *limit* Specifies the maximum size in 512 byte blocks of the output device as *limit*. By default, if the output file is a directory or a mountable device, *pkgmk* will employ the *df(1M)* command to dynamically calculate the amount of available space on the output device. This option is useful in conjunction with *pkgtrans(1)* to create a package with a datastream format.
- o Overwrites the same instance; package instance will be overwritten if it already exists.
- p *pstamp* Overrides the production stamp definition in the *pkginfo(4)* file with *pstamp*.
- r *root\_path* Uses the indicated *root\_path* with the source pathname appended to locate objects on the source machine, using a comma (,) as the separator for the path elements. If this option is specified, look for the full destination path in each of the directories specified. If neither -b nor -r is specified, look for the leaf filename in the current directory.
- v *version* Overrides the version information provided in the *pkginfo(4)* file with *version*.
- variable=value* Places the indicated variable in the packaging environment. (See *prototype(4)* for definitions of variable specifications.)

**OPERANDS** The following operand is supported:

- pkginst* A package designation by its instance. An instance can be the package abbreviation or a specific instance (for example, *inst.1* or *inst.2*). All instances of a package can be requested by *inst.\**. The asterisk character (\*) is a special character to some shells and may need to be escaped. In the C-Shell, "\*" must be surrounded by single quotes (') or preceded by a backslash (\).

**EXIT STATUS** The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**ATTRIBUTES** See *attributes(5)* for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** *pkgparam(1)*, *pkgproto(1)*, *pkgtrans(1)*, *uname(1)*, *df(1M)*, *pkgadd(1M)*, *pkginfo(4)*, *pkgmap(4)*, *prototype(4)*, *attributes(5)*

pkgmk(1)

*Application Packaging Developer's Guide*

- NOTES** Architecture information is provided on the command line with the `-a` option or in the `prototype(4)` file. If no architecture information is supplied, `pkgmk` uses the output of `uname -m` (see [uname\(1\)](#)).
- Version information is provided on the command line with the `-v` option or in the `pkginfo(4)` file. If no version information is supplied, a default based on the current date will be provided.
- Command line definitions for both architecture and version override the `prototype(4)` definitions.

| <b>NAME</b>        | pkgparam – display package parameter values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <b>pkgparam</b> [-v] [-d <i>device</i> ] [-R <i>root_path</i> ] <i>pkginst</i> [ <i>param...</i> ]<br><b>pkgparam</b> -f <i>filename</i> [-v] [ <i>param...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | <p>pkgparam displays the value associated with the parameter or parameters requested on the command line. The values are located in either the pkginfo(4) file for <i>pkginst</i> or from the specific file named with the -f option.</p> <p>One parameter value is shown per line. Only the value of a parameter is given unless the -v option is used. With this option, the output of the command is in this format:</p> <pre>parameter1='value1' parameter2='value2' parameter3='value3'</pre> <p>If no parameters are specified on the command line, values for all parameters associated with the package are shown.</p>                                                                                                                                                                                                                             |
| <b>OPTIONS</b>     | <p>Options and arguments for this command are:</p> <p>-d <i>device</i>           Specify the <i>device</i> on which a <i>pkginst</i> is stored. It can be a directory pathname or the identifiers for tape, floppy disk, or removable disk (for example, /var/tmp, /dev/diskette, and /dev/dsk/c1d0s0). The special token <i>spool</i> may be used to represent the default installation spool directory (/var/spool/pkg).</p> <p>-f <i>filename</i>           Read <i>filename</i> for parameter values.</p> <p>-R <i>root_path</i>           Defines the full path name of a subdirectory to use as the <i>root_path</i>. All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i>.</p> <p>-v                      Verbose mode. Display name of parameter and its value.</p> |
| <b>OPERANDS</b>    | <p><i>pkginst</i>                Defines a specific package instance for which parameter values should be displayed.</p> <p><i>param</i>                 Defines a specific parameter whose value should be displayed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>ERRORS</b>      | If parameter information is not available for the indicated package, the command exits with a non-zero status.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>EXIT STATUS</b> | <p>0                      Successful completion.</p> <p>&gt;0                     An error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

pkgparam(1)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `pkgmk(1)`, `pkgproto(1)`, `pkgtrans(1)`, `pkginfo(4)`, `attributes(5)`

*Application Packaging Developer's Guide*

**NOTES** With the `-f` option, you can specify the file from which parameter values should be extracted. This file should be in the same format as a `pkginfo(4)` file. For example, such a file might be created during package development and used while testing software during this stage.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## pkgproto(1)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `pkgmk(1)`, `pkgparam(1)`, `pkgtrans(1)`, `prototype(4)`, `attributes(5)`

*Application Packaging Developer's Guide*

**NOTES** By default, `pkgproto` creates symbolic link entries for any symbolic link encountered (`ftype=s`). When you use the `-i` option, `pkgproto` creates a file entry for symbolic links (`ftype=f`). The `prototype(4)` file would have to be edited to assign such file types as `v` (volatile), `e` (editable), or `x` (exclusive directory). `pkgproto` detects linked files. If multiple files are linked together, the first path encountered is considered the source of the link.

By default, `pkgproto` prints prototype entries on the standard output. However, the output should be saved in a file (named `Prototype` or `prototype`, for convenience) to be used as input to the `pkgmk(1)` command.

| <b>NAME</b>        | pkgtrans – translate package format                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>    | <b>pkgtrans</b> [-inosg] [-k <i>keystore</i> ] [-a <i>alias</i> ] [-P <i>passwd</i> ] <i>device1 device2</i><br>[ <i>pkginst...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p>The pkgtrans utility translates an installable package from one format to another. It translates:</p> <ul style="list-style-type: none"> <li>■ a file system format to a datastream</li> <li>■ a file system format to a signed datastream</li> <li>■ a datastream to a file system format</li> <li>■ one file system format to another file system format</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>OPTIONS</b>     | <p>The options and arguments for this command are:</p> <p>-i<br/>Copies only the pkginfo(4) and pkgmap(4) files.</p> <p>-n<br/>Creates a new instance of the package on the destination device if any instance of this package already exists, up to the number specified by the MAXINST variable in the pkginfo(4) file.</p> <p>-o<br/>Overwrites the same instance on the destination device. Package instance will be overwritten if it already exists.</p> <p>-s<br/>Indicates that the package should be written to <i>device2</i> as a datastream rather than as a file system. The default behavior is to write a file system format on devices that support both formats.</p> <p>-g<br/>Sign resulting datastream.</p> <p>-k <i>keystore</i><br/>Use keystore to retrieve private key used to generate signature. If it not specified, default locations are searched to find the specified private key specified by -a. If no alias is given, and multiple keys exist in the key store, pkgtrans will abort. See KEYSTORE LOCATIONS and KEYSTORE AND CERTIFICATE FORMATS in pkgadd(1M) for more information on search locations and formats.</p> <p>When running as a user other than root, the default base directory for certificate searching is <code>~/.pkg/security</code>, where <code>~</code> is the home directory of the user invoking pkgtrans.</p> <p>-a <i>alias</i><br/>Use public key certificate associated with friendlyName <i>alias</i>, and the corresponding private key. See KEYSTORE LOCATIONS and KEYSTORE AND CERTIFICATE FORMATS in pkgadd(1M) for more information.</p> <p>-P <i>passwd</i><br/>Supply password used to decrypt the keystore. See PASS PHRASE ARGUMENTS in pkgadd(1M) for details on the syntax of the argument to this option.</p> |

## pkgtrans(1)

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OPERANDS</b>          | <p><i>device1</i> Indicates the source device. The package or packages on this device will be translated and placed on <i>device2</i>. See DEVICE SPECIFIERS, below.</p> <p><i>device2</i> Indicates the destination device. Translated packages will be placed on this device. See DEVICE SPECIFIERS, below.</p> <p><i>pkginst</i> Specifies which package instance or instances on <i>device1</i> should be translated. The token <code>all</code> may be used to indicate all packages. <code>pkginst.*</code> can be used to indicate all instances of a package. If no packages are defined, a prompt shows all packages on the device and asks which to translate.</p> <p>The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, "*" must be surrounded by single quotes (') or preceded by a backslash (\).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DEVICE SPECIFIERS</b> | <p>Packaging tools, including <code>pkgtrans</code>, <code>pkgadd(1M)</code>, and <code>pkgchk(1M)</code>, have options for specifying a package location by specifying the device on which it resides. Listed below are the device types that a package can be stored to and retrieved from. Note that source and destination devices cannot be the same.</p> <p><b>directory</b><br/>Packages can be stored onto a directory by specifying an absolute path to a file system directory. The package contents reside in a directory within the specified directory. The package directory name must be identical to its PKG specification in the <code>pkginfo(4)</code> file. An example device specification of this type is <code>/export/packages</code>.</p> <p><b>device</b><br/>Packages can be stored to a character or block device by specifying the device identifier as the device. Common examples of this device type are <code>/dev/rmt/0</code> for a removable magnetic tape and <code>/floppy/floppy0</code> for the first floppy disk on the system. <code>pkgtrans</code> can also produce regular file system files in a stream format, which is suitable for storage on a character device, web server, or as input to <code>pkgadd(1M)</code>.</p> <p><b>device alias</b><br/>Devices that have been specified in <code>/etc/device.tab</code> are eligible for being the recipient or source of a package. Common examples of this type of device specification are <code>spool</code> (the default package device location) and <code>disk1</code>. These names correspond to devices specified in <code>/etc/device.tab</code>.</p> |
| <b>EXAMPLES</b>          | <p><b>EXAMPLE 1</b> Examples of the <code>pkgtrans</code> command</p> <p>The following example translates all packages on the floppy drive <code>/dev/diskette</code> and places the translations on <code>/tmp</code>:</p> <pre>example% pkgtrans /dev/diskette /tmp all</pre> <p>The following example translates packages <code>pkg1</code> and <code>pkg2</code> on <code>/tmp</code> and places their translations (that is, a datastream) on the <code>9track1</code> output device:</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**EXAMPLE 1** Examples of the pkgtrans command (Continued)

```
example% pkgtrans /tmp 9track1 pkg1 pkg2
```

The following example translates pkg1 and pkg2 on /tmp and places them on the diskette in a datastream format:

```
example% pkgtrans -s /tmp /dev/diskette pkg1 pkg2
```

The following example creates a signed package from pkg1 and pkg2, and reads the password from the \$PASS environment variable:

```
example% pkgtrans -sg -k /tmp/keystore.p12 -alias foo \  
-p env:PASS /tmp /tmp/signedpkg pkg1 pkg2
```

**ENVIRONMENT VARIABLES**

The MAXINST variable is set in the pkginfo(4) file and declares the maximum number of package instances.

**EXIT STATUS**

0 Successful completion.  
>0 An error occurred.

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE                  | ATTRIBUTE VALUE |
|---------------------------------|-----------------|
| Availability                    | SUNWpkgcmdsu    |
| Interface Stability             | :               |
| Command line                    | Evolving        |
| Digitally signed stream package | Evolving        |

*Application Packaging Developer's Guide*

**NOTES**

By default, pkgtrans will not translate any instance of a package if any instance of that package already exists on the destination device. Using the -n option creates a new instance if an instance of this package already exists. Using the -o option overwrites an instance of this package if it already exists. Neither of these options are useful if the destination device is a datastream.

pktool(1)

**NAME** pktool – manage softtoken object storage

**SYNOPSIS** **pktool** setpin

**DESCRIPTION** The **pktool** command allows users to manage the softtoken object store.

The **setpin** subcommand changes the passphrase used to authenticate a user to the softtoken object store. **setpin** prompts the user for the old passphrase, if any. If the old passphrase matches, **pktool** prompts for the new passphrase twice. If the two entries of the new passphrase match, it will become the current passphrase for the token.

Passphrases may be any string of characters with lengths between 1 and 256 with no nulls.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**FILES**  $\${HOME}/.sunw/pkcs11_softtoken$   
The user's default token object store.

$\${SOFTTOKEN_DIR}/pkcs11_softtoken$   
The alternate token object store.

**ATTRIBUTES** See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Evolving        |

| <b>NAME</b>        | p-limit – get or set the resource limits of running processes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <p><b>p-limit</b> [-km] <i>pid...</i></p> <p><b>p-limit</b> {-cdfnstv} <i>soft,hard...</i> <i>pid...</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p>If one or more of the <i>cdfnstv</i> options is specified, <b>p-limit</b> sets the soft (current) limit and/or the hard (maximum) limit of the indicated resource(s) in the processes identified by the process-ID list, <i>pid</i>. Otherwise <b>p-limit</b> reports the resource limits of the processes identified by the process-ID list, <i>pid</i>.</p> <p>Only the owner of a process or the super-user is permitted either to get or to set the resource limits of a process. Only the super-user can increase the hard limit.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-k            On output, show file sizes in kilobytes (1024 bytes) rather than in 512-byte blocks.</li> <li>-m            On output, show file and memory sizes in megabytes (1024*1024 bytes).</li> </ul> <p>The remainder of the options are used to change specified resource limits. They each accept an argument of the form:</p> <p><i>soft,hard</i></p> <p>where <i>soft</i> specifies the soft (current) limit and <i>hard</i> specifies the hard (maximum) limit. If the hard limit is not specified, the comma may be omitted. If the soft limit is an empty string, only the hard limit is set. Each limit is either the literal string <i>unlimited</i>, or a number, with an optional scaling factor, as follows:</p> <ul style="list-style-type: none"> <li><i>nk</i>            <i>n</i> kilobytes</li> <li><i>nm</i>            <i>n</i> megabytes (minutes for CPU time)</li> <li><i>nh</i>            <i>n</i> hours (for CPU time only)</li> <li><i>mm:ss</i>        minutes and seconds (for CPU time only)</li> </ul> <p>The soft limit cannot exceed the hard limit.</p> <ul style="list-style-type: none"> <li>-c <i>soft,hard</i>    Set core file size limits (default unit is 512-byte blocks).</li> <li>-d <i>soft,hard</i>    Set data segment (heap) size limits (default unit is kilobytes).</li> <li>-f <i>soft,hard</i>    Set file size limits (default unit is 512-byte blocks).</li> <li>-n <i>soft,hard</i>    Set file descriptor limits (no default unit).</li> <li>-s <i>soft,hard</i>    Set stack segment size limits (default unit is kilobytes).</li> <li>-t <i>soft,hard</i>    Set CPU time limits (default unit is seconds).</li> </ul> |

plimit(1)

*-v soft,hard* Set virtual memory size limits (default unit is kilobytes).

**OPERANDS** The following operands are supported.

*pid* Process ID list.

**EXIT STATUS** *plimit* returns the exit value zero on success, non-zero on failure (such as no such process, permission denied, or invalid option).

**FILES** */proc/pid/\** process information and control files

**ATTRIBUTES** See *attributes(5)* for descriptions of the following attributes:

| <b>NAME</b>            | pmap – display information about the address space of a process                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>        | <pre> /usr/bin/pmap [-rslF] [pid   core...] /usr/bin/pmap -x [-aslF] [pid   core...] /usr/bin/pmap -S [-alF] [pid   core...] </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b>     | The pmap utility prints information about the address space of a process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>OPTIONS</b>         | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a Prints anonymous and swap reservations for shared mappings.</li> <li>-F Force. Grabs the target process even if another process has control.</li> <li>-l Shows unresolved dynamic linker map names.</li> <li>-r Prints the process's reserved addresses.</li> <li>-s Prints HAT page size information.</li> <li>-S Displays swap reservation information per mapping. See USAGE for more information.</li> <li>-x Displays additional information per mapping. See USAGE for more information.</li> </ul>                                                                                                                                                                                                                                                                                                                                          |
| <b>USAGE</b>           | <p>The pmap utility prints information about the address space of a process.</p> <p>Process Mappings</p> <pre> /usr/bin/pmap [ -rslF ] [ pid   core ] ... </pre> <p>By default, pmap displays the mappings in the virtual address order they are mapped into the process. The mapping size, flags, and mapped object name are shown.</p> <p>Process anon/locked mapping details</p> <pre> /usr/bin/pmap -x [ -aslF ] [ pid   core ] ... </pre> <p>The -x option displays additional information per mapping. The size of each mapping, the amount of resident physical memory (RSS), the amount of anonymous memory, and the amount of memory locked is shown with this option. This does not include anonymous memory taken by kernel address space due to this process.</p> <p>Swap Reservations</p> <pre> /usr/bin/pmap -S [ -alF ] [ pid   core ] ... </pre> <p>The -S option displays swap reservation information per mapping.</p> |
| <b>DISPLAY FORMATS</b> | One line of output is printed for each mapping within the process, unless the -s option is specified, where one line is printed for a contiguous mapping of each hardware translation page size. The column headings are shown in parentheses below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## pmap(1)

### Virtual Address (Address)

The first column of output represents the starting virtual address of each mapping. Virtual addresses are displayed in ascending order.

### Virtual Mapping Size (Kbytes)

The virtual size in kilobytes of each mapping.

### Resident Physical Memory (RSS)

The amount of physical memory in kilobytes that is resident for each mapping, including that which is shared with other address spaces.

### Anonymous Memory (Anon)

The number of pages, counted by using the system page size, of anonymous memory associated with the specified mapping. Anonymous memory shared with other address spaces is not included, unless the `-a` option is specified.

Anonymous memory is reported for the process heap, stack, for 'copy on write' pages with mappings mapped with `MAP_PRIVATE` (see `mmap(2)`).

### Locked (Locked)

The number of pages locked within the mapping. Typical examples are memory locked with `mlock()` and System V shared memory created with `SHM_SHARE_MMU`.

### Permissions/Flags (Mode)

The virtual memory permissions are shown for each mapping. Valid permissions are:

- `r`: The mapping may be read by the process.
- `w`: The mapping may be written by the process.
- `x`: Instructions that reside within the mapping may be executed by the process.

Flags showing additional information for each mapping may be displayed:

- `s`: The mapping is shared such that changes made in the observed address space are committed to the mapped file, and are visible from all other processes sharing the mapping.
- `R`: Swap space is not reserved for this mapping. Mappings created with `MAP_NORESERVE` and System V ISM shared memory mappings do not reserve swap space.
- `*`: The data for the mapping is not present in the core file (only applicable when applied to a core file). See `coreadm(1M)` for information on configuring core file content.

### Mapping Name (Mapped File)

A descriptive name for each mapping. The following major types of names are displayed for mappings:

- *A mapped file:* For mappings between a process and a file, the pmap command attempts to resolve the file name for each mapping. If the file name cannot be resolved, pmap displays the major and minor number of the device containing the file, and the file system inode number of the file.
- *Anonymous memory:* Memory not relating to any named object or file within the file system is reported as [ anon ].

The pmap command displays common names for certain known anonymous memory mappings:

|                            |                                                                         |
|----------------------------|-------------------------------------------------------------------------|
| [ heap ]                   | The mapping is the process heap.                                        |
| [ stack ]                  | The mapping is the main stack.                                          |
| [ stack tid= <i>n</i> ]    | The mapping is the stack for thread <i>n</i> .                          |
| [ altstack tid= <i>n</i> ] | The mapping is used as the alternate signal stack for thread <i>n</i> . |

If the common name for the mapping is unknown, pmap displays [ anon ] as the mapping name.

- *System V Shared Memory:* Mappings created using System V shared memory system calls are reported with the names shown below:
 

|                        |                                                                                                                                                                                     |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| shmid= <i>n</i> :      | The mapping is a System V shared memory mapping. The shared memory identifier that the mapping was created with is reported.                                                        |
| ism shmid= <i>n</i> :  | The mapping is an “Intimate Shared Memory” variant of System V shared memory. ISM mappings are created with the SHM_SHARE_MMU flag set, in accordance with shmat(2) (see shmop(2)). |
| dism shmid= <i>n</i> : | The mapping is a pageable variant of ISM. Pageable ISM is created with the SHM_PAGEABLE flag set in accordance with shmat(2) (see shmop(2)).                                        |
- *Other:* Mappings of other objects, including devices such as frame buffers. No mapping name is shown for other mapped objects.

#### Page Size (Pgsz)

The page size in kilobytes that is used for hardware address translation for this mapping. See memcntl(2) for further information.

#### Swap Space (Swap)

The amount of swap space in kilobytes that is reserved for this mapping. That is, swap space that is deducted from the total available pool of reservable swap space that is displayed with the command swap -s. See swap(1M).

## pmap(1)

### EXAMPLES | EXAMPLE 1 Displaying Process Mappings

By default, pmap prints one line for each mapping within the address space of the target process. The following example displays the address space of a typical bourne shell:

```
example$ pmap 102905
102905:  sh
00010000 192K r-x-- /usr/bin/ksh
00040000 8K rwx-- /usr/bin/ksh
00042000 40K rwx-- [ heap ]
FF180000 664K r-x-- /usr/lib/libc.so.1
FF236000 24K rwx-- /usr/lib/libc.so.1
FF23C000 8K rwx-- /usr/lib/libc.so.1
FF250000 8K rwx-- [ anon ]
FF260000 16K r-x-- /usr/lib/en_US.ISO8859-1.so.2
FF272000 16K rwx-- /usr/lib/en_US.ISO8859-1.so.2
FF280000 560K r-x-- /usr/lib/libnsl.so.1
FF31C000 32K rwx-- /usr/lib/libnsl.so.1
FF324000 32K rwx-- /usr/lib/libnsl.so.1
FF340000 16K r-x-- /usr/lib/libc_psr.so.1
FF350000 16K r-x-- /usr/lib/libmp.so.2
FF364000 8K rwx-- /usr/lib/libmp.so.2
FF380000 40K r-x-- /usr/lib/libsocket.so.1
FF39A000 8K rwx-- /usr/lib/libsocket.so.1
FF3A0000 8K r-x-- /usr/lib/libdl.so.1
FF3B0000 8K rwx-- [ anon ]
FF3C0000 152K r-x-- /usr/lib/ld.so.1
FF3F6000 8K rwx-- /usr/lib/ld.so.1
FFBFC000 16K rw--- [ stack ]
total 1880K
```

### EXAMPLE 2 Displaying Memory Allocation and Mapping Types

The `-x` option can be used to provide information about the memory allocation and mapping types per mapping. The amount of resident, non-shared anonymous, and locked memory is shown for each mapping:

```
example$ pmap -x 102908
102908:  sh
Address  Kbytes  RSS    Anon  Locked Mode  Mapped File
00010000 88      88    -     - r-x-- sh
00036000 8       8     8     - rwx-- sh
00038000 16      16    16    - rwx-- [ heap ]
FF260000 16      16    -     - r-x-- en_US.ISO8859-1.so.2
FF272000 16      16    -     - rwx-- en_US.ISO8859-1.so.2
FF280000 664     624   -     - r-x-- libc.so.1
FF336000 32      32    8     - rwx-- libc.so.1
FF360000 16      16    -     - r-x-- libc_psr.so.1
FF380000 24      24    -     - r-x-- libgen.so.1
FF396000 8       8     -     - rwx-- libgen.so.1
FF3A0000 8       8     -     - r-x-- libdl.so.1
FF3B0000 8       8     8     - rwx-- [ anon ]
FF3C0000 152     152   -     - r-x-- ld.so.1
FF3F6000 8       8     8     - rwx-- ld.so.1
FFBFE000 8       8     8     - rw--- [ stack ]
```

**EXAMPLE 2** Displaying Memory Allocation and Mapping Types (Continued)

```

-----
total Kb    1072    1032     56     -

```

The amount of incremental memory used by each additional instance of a process can be estimated by using the resident and anonymous memory counts of each mapping.

In the above example, the bourne shell has a resident memory size of 1032Kbytes. However, a large amount of the physical memory used by the shell is shared with other instances of shell. Another identical instance of the shell will share physical memory with the other shell where possible, and allocate anonymous memory for any non-shared portion. In the above example, each additional bourne shell uses approximately 56Kbytes of additional physical memory.

A more complex example shows the output format for a process containing different mapping types. In this example, the mappings are as follows:

```

0001000: Executable text, mapped from 'maps' program
0002000: Executable data, mapped from 'maps' program
0002200: Program heap

0300000: A mapped file, mapped MAP_SHARED
0400000: A mapped file, mapped MAP_PRIVATE

0500000: A mapped file, mapped MAP_PRIVATE | MAP_NORESERVE
0600000: Anonymous memory, created by mapping /dev/zero
0700000: Anonymous memory, created by mapping /dev/zero
         with MAP_NORESERVE
0800000: A DISM shared memory mapping, created with SHM_PAGEABLE
         with 8MB locked via mlock(2)
0900000: A DISM shared memory mapping, created with SHM_PAGEABLE,
         with 4MB of its pages touched.
0A00000: A DISM shared memory mapping, created with SHM_PAGEABLE,
         with none of its pages touched.
0B00000: An ISM shared memory mapping, created with SHM_SHARE_MMU

```

```
example$ pmap -xs 15492
```

```

**EXAMPLE 3** Displaying Page Size Information

The `-s` option can be used to display the hardware translation page sizes for each portion of the address space. (See `memcntl(2)` for further information on Solaris multiple page size support).

In the example below, we can see that the majority of the mappings are using an 8K-Byte page size, while the heap is using a 4M-Byte page size.

Notice that non-contiguous regions of resident pages of the same page size are reported as separate mappings. In the example below, the `libc.so` library is reported as separate mappings, since only some of the `libc.so` text is resident:

```

example$ pmap -xs 15492
15492: ./maps
Address  Kbytes  RSS    Anon  Locked  Pgsz  Mode  Mapped File

```

**EXAMPLE 4** Displaying swap reservations

The `-S` option can be used to describe the swap reservations for a process. The amount of swap space reserved is displayed for each mapping within the process. Swap reservations are reported as zero for shared mappings, since they are accounted for only once system wide.

```

example$ pmap -S 15492
15492: ./maps
Address  Kbytes  Swap Mode  Mapped File
00010000      8      - r-x-- maps

00022000  20344  20344 rwx-- [ heap ]
03000000     1024      - rw-s- dev:0,2 ino:4628487
04000000     1024     1024 rw--- dev:0,2 ino:4628487
05000000     1024     512 rw--R dev:0,2 ino:4628487
06000000     1024     1024 rw--- [ anon ]
07000000      512     512 rw--R [ anon ]
08000000     8192      - rwxs- [ dism shmid=0x5]
09000000     8192      - rwxs- [ dism shmid=0x4]
0A000000     8192      - rwxs- [ dism shmid=0x2]
0B000000     8192      - rwxsR [ ism shmid=0x3]
FF280000      680      - r-x-- libc.so.1
FF33A000      32      32 rwx-- libc.so.1
FF390000       8      - r-x-- libc_psr.so.1
FF3A0000       8      - r-x-- libdl.so.1
FF3B0000       8       8 rwx-- [ anon ]
FF3C0000     152      - r-x-- ld.so.1
FF3F6000       8       8 rwx-- ld.so.1
FFBFA000      24      24 rwx-- [ stack ]
-----
total Kb    50464   23496

```

The swap reservation information can be used to estimate the amount of virtual swap used by each additional process. Each process consumes virtual swap from a global virtual swap pool. Global swap reservations are reported by the `'avail'` field of the `swap(1M)` command.

**EXAMPLE 5** Labeling stacks in a multi-threaded process

```

example$ pmap 121969
121969: ./stacks
00010000      8K r-x-- /tmp/stacks

```

pmap(1)

| <b>SYNOPSIS</b>    | <b>postdaisy</b> [-c <i>num</i> ] [-f <i>num</i> ] [-h <i>num</i> ] [-m <i>num</i> ] [-n <i>num</i> ] [-o <i>list</i> ]<br>[-p <i>mode</i> ] [-r <i>num</i> ] [-s <i>num</i> ] [-v <i>num</i> ] [-x <i>num</i> ] [-y <i>num</i> ] [ <i>file...</i> ]<br>/usr/lib/lp/postscript/postdaisy                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | The <code>postdaisy</code> filter translates Diablo 630 daisy-wheel <i>files</i> into PostScript and writes the results on the standard output. If no <i>files</i> are specified, or if <code>-</code> is one of the input <i>files</i> , the standard input is read.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>OPTIONS</b>     | <ul style="list-style-type: none"> <li>-c <i>num</i>    Print <i>num</i> copies of each page. By default only one copy is printed.</li> <li>-f <i>name</i>    Print <i>files</i> using font <i>name</i>. Any PostScript font can be used, although the best results will be obtained only with constant-width fonts. The default font is Courier.</li> <li>-h <i>num</i>    Set the initial horizontal motion index to <i>num</i>. Determines the character advance and the default point size, unless the <code>-s</code> option is used. The default is 12.</li> <li>-m <i>num</i>    Magnify each logical page by the factor <i>num</i>. Pages are scaled uniformly about the origin, which is located near the upper left corner of each page. The default magnification is 1.0.</li> <li>-n <i>num</i>    Print <i>num</i> logical pages on each piece of paper, where <i>num</i> can be any positive integer. By default, <i>num</i> is set to 1.</li> <li>-o <i>list</i>    Print pages whose numbers are given in the comma-separated <i>list</i>. The list contains single numbers <i>N</i> and ranges <i>N1</i> – <i>N2</i>. A missing <i>N1</i> means the lowest numbered page, a missing <i>N2</i> means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3-4, when requesting two logical pages to a sheet; then <i>only</i> page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.</li> <li>-p <i>mode</i>    Print <i>files</i> in either portrait or landscape <i>mode</i>. Only the first character of <i>mode</i> is significant. The default <i>mode</i> is portrait.</li> <li>-r <i>num</i>    Selects carriage return and line feed behavior. If <i>num</i> is 1, a line feed generates a carriage return. If <i>num</i> is 2, a carriage return generates a line feed. Setting <i>num</i> to 3 enables both modes.</li> <li>-s <i>num</i>    Use point size <i>num</i> instead of the default value set by the initial horizontal motion index.</li> <li>-v <i>num</i>    Set the initial vertical motion index to <i>num</i>. The default is 8.</li> <li>-x <i>num</i>    Translate the origin <i>num</i> inches along the positive x axis. The default coordinate system has the origin fixed near the upper left corner of the page, with positive x to the right and positive y down the page. Positive <i>num</i> moves everything right. The default offset is 0.25 inches.</li> </ul> |

postdaisy(1)

*-y num* Translate the origin *num* inches along the positive y axis. Positive *num* moves text up the page. The default offset is  $-0.25$  inches.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

| NAME        | postdmd – PostScript translator for DMD bitmap files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| SYNOPSIS    | <pre>postdmd [-b num] [-c num] [-f] [-m num] [-n num] [-o list] [-p mode]         [-x num] [-y num] [file...]</pre> <p><code>/usr/lib/lp/postscript/postdmd</code></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| DESCRIPTION | <p>postdmd translates DMD bitmap <i>files</i>, as produced by <i>dmdps</i>, or <i>files</i> written in the Ninth Edition <code>bitfile(9.5)</code> format into PostScript and writes the results on the standard output. If no <i>files</i> are specified, or if <code>-</code> is one of the input <i>files</i>, the standard input is read.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| OPTIONS     | <p><code>-b num</code> Pack the bitmap in the output file using <i>num</i> byte patterns. A value of 0 turns off all packing of the output file. By default, <i>num</i> is 6.</p> <p><code>-c num</code> Print <i>num</i> copies of each page. By default only one copy is printed.</p> <p><code>-f</code> Flip the sense of the bits in <i>files</i> before printing the bitmaps.</p> <p><code>-m num</code> Magnify each logical page by the factor <i>num</i>. Pages are scaled uniformly about the origin, which by default is located at the center of each page. The default magnification is 1.0.</p> <p><code>-n num</code> Print <i>num</i> logical pages on each piece of paper, where <i>num</i> can be any positive integer. By default <i>num</i> is set to 1.</p> <p><code>-o list</code> Print pages whose numbers are given in the comma-separated <i>list</i>. The list contains single numbers <i>N</i> and ranges <i>N1</i> – <i>N2</i>. A missing <i>N1</i> means the lowest numbered page, a missing <i>N2</i> means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3-4, when requesting two logical pages to a sheet; then <i>only</i> page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.</p> <p><code>-p mode</code> Print <i>files</i> in either portrait or landscape <i>mode</i>. Only the first character of <i>mode</i> is significant. The default <i>mode</i> is portrait.</p> <p><code>-x num</code> Translate the origin <i>num</i> inches along the positive x axis. The default coordinate system has the origin fixed at the center of the page, with positive x to the right and positive y up the page. Positive <i>num</i> moves everything right. The default offset is 0 inches.</p> <p><code>-y num</code> Translate the origin <i>num</i> inches along the positive y axis. Positive <i>num</i> moves everything up the page. The default offset is 0.</p> <p>Only one bitmap is printed on each logical page, and each of the input <i>files</i> must contain complete descriptions of at least one bitmap. Decreasing the pattern size using the <code>-b</code> option may help throughput on printers with fast processors (such as PS-810s), while increasing the pattern size will often be the right move on older models (such as PS-800s).</p> |

| <b>DESCRIPTION</b> | postio sends <i>files</i> to the PostScript printer attached to <i>line</i> . If no <i>files</i> are specified the standard input is sent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>OPTIONS</b>     | <p>The first group of <i>options</i> should be sufficient for most applications:</p> <ul style="list-style-type: none"> <li>-D            Enable debug mode. Guarantees that everything read on <i>line</i> will be added to the log file (standard error by default).</li> <li>-q            Prevents status queries while <i>files</i> are being sent to the printer. When status queries are disabled a dummy message is appended to the log file before each block is transmitted.</li> <li>-b <i>speed</i>    Transmit data over <i>line</i> at baud rate <i>speed</i>. Recognized baud rates are 1200, 2400, 4800, 9600, and 19200. The default <i>speed</i> is 9600 baud.</li> <li>-B <i>num</i>       Set the internal buffer size for reading and writing <i>files</i> to <i>num</i> bytes. By default <i>num</i> is 2048 bytes.</li> <li>-l <i>line</i>       Connect to the printer attached to <i>line</i>. In most cases there is no default and postio must be able to read and write <i>line</i>. If the <i>line</i> does not begin with a / it may be treated as a Datakit destination.</li> <li>-L <i>file</i>       Data received on <i>line</i> gets put in <i>file</i>. The default log file is standard error. Printer or status messages that don't show a change in state are not normally written to <i>file</i> but can be forced out using the -D option.</li> <li>-P <i>string</i>     Send <i>string</i> to the printer before any of the input files. The default <i>string</i> is simple PostScript code that disables timeouts.</li> <li>-R <i>num</i>       Run postio as a single process if <i>num</i> is 1 or as separate read and write processes if <i>num</i> is 2. By default postio runs as a single process.</li> </ul> <p>The next two <i>options</i> are provided for users who expect to run postio on their own. Neither is suitable for use in spooler interface programs:</p> <ul style="list-style-type: none"> <li>-i            Run the program in interactive mode. Any <i>files</i> are sent first and followed by the standard input. Forces separate read and write processes and overrides many other options. To exit interactive mode use your interrupt or quit character. To get a friendly interactive connection with the printer type <code>executive</code> on a line by itself.</li> <li>-t            Data received on <i>line</i> and not recognized as printer or status information is written to the standard output. Forces separate read and write processes.</li> </ul> |

postio(1)

Convenient if you have a PostScript program that will be returning useful data to the host.

The last option is not generally recommended and should only be used if all else fails to provide a reliable connection:

**-S** Slow the transmission of data to the printer. Severely limits throughput, runs as a single process, disables the **-q** option, limits the internal buffer size to 1024 bytes, can use an excessive amount of CPU time, and does nothing in interactive mode.

The best performance will usually be obtained by using a large internal buffer (the **-B** option) and by running the program as separate read and write processes (the **-R 2** option). Inability to fork the additional process causes `postio` to continue as a single read/write process. When one process is used, only data sent to the printer is flow controlled.

The *options* are not all mutually exclusive. The **-i** option always wins, selecting its own settings for whatever is needed to run interactive mode, independent of anything else found on the command line. Interactive mode runs as separate read and write processes and few of the other *options* accomplish anything in the presence of the **-i** option. The **-t** option needs a reliable two way connection to the printer and therefore tries to force separate read and write processes. The **-S** option relies on the status query mechanism, so **-q** is disabled and the program runs as a single process.

In most cases `postio` starts by making a connection to `line` and then attempts to force the printer into the IDLE state by sending an appropriate sequence of **^T** (status query), **^C** (interrupt), and **^D** (end of job) characters. When the printer goes IDLE, *files* are transmitted along with an occasional **^T** (unless the **-q** option was used). After all the *files* are sent the program waits until it's reasonably sure the job is complete. Printer generated error messages received at any time except while establishing the initial connection (or when running interactive mode) cause `postio` to exit with a non-zero status. In addition to being added to the log file, printer error messages are also echoed to standard error.

#### EXAMPLES **EXAMPLE 1** Examples of the `postio` command.

Run as a single process at 9600 baud and send *file1* and *file2* to the printer attached to `/dev/tty01`:

```
example% postio -l /dev/tty01 file1 file2
```

Same as above except two processes are used, the internal buffer is set to 4096 bytes, and data returned by the printer gets put in file *log*:

```
example% postio -R 2 -B 4096 -l/dev/tty01 -L log file1 file2
```

Establish an interactive connection with the printer at Datakit destination *my/printer*:

```
example% postio -i -l my/printer
```

**EXAMPLE 1** Examples of the `postio` command. (Continued)

Send file program to the printer connected to `/dev/tty22`, recover any data in file results, and put log messages in file `log`:

```
example% postio -t -l /dev/tty22 -L log program >results
```

**EXIT STATUS** The following exit values are returned:

0 Successful completion.  
non-zero An error occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWpsf         |

**SEE ALSO** `download(1)`, `dpost(1)`, `postdaisy(1)`, `postdmd(1)`, `postmd(1)`, `postprint(1)`, `postreverse(1)`, `posttek(1)`, `attributes(5)`

**NOTES** The input *files* are handled as a single PostScript job. Sending several different jobs, each with their own internal end of job mark (^D) is not guaranteed to work properly. `postio` may quit before all the jobs have completed and could be restarted before the last one finishes.

All the capabilities described above may not be available on every machine or even across the different versions of the UNIX system that are currently supported by the program.

There may be no default `line`, so using the `-l` option is strongly recommended. If omitted, `postio` may attempt to connect to the printer using the standard output. If Datakit is involved, the `-b` option may be ineffective and attempts by `postio` to impose flow control over data in both directions may not work. The `-q` option can help if the printer is connected to RADIANT. The `-S` option is not generally recommended and should be used only if all other attempts to establish a reliable connection fail.

| <b>DESCRIPTION</b> | The <code>postmd</code> filter reads a series of floating point numbers from <i>files</i> , translates them into a PostScript gray scale image, and writes the results on the standard output. In a typical application, the numbers might be the elements of a large matrix, written in row major order, while the printed image could help locate patterns in the matrix. If no <i>files</i> are specified, or if - is one of the input <i>files</i> , the standard input is read.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OPTIONS</b>     | The following options are supported:<br><br>-b <i>num</i> Packs the bitmap in the output file using <i>num</i> byte patterns. A value of 0 turns off all packing of the output file. By default, <i>num</i> is 6.<br><br>-c <i>num</i> Prints <i>num</i> copies of each page. By default, only one copy is printed.<br><br>-d <i>dimen</i> Sets the default matrix dimensions for all input <i>files</i> to <i>dimen</i> . The <i>dimen</i> string can be given as <i>rows</i> or <i>rowsx columns</i> . If <i>columns</i> is omitted it will be set to <i>rows</i> . By default, <code>postmd</code> assumes each matrix is square and sets the number of rows and columns to the square root of the number of elements in each input file.<br><br>-g <i>list</i> <i>list</i> is a comma- or space-separated string of integers, each lying between 0 and 255 inclusive, that assigns PostScript gray scales to the regions of the real line selected by the -i option. 255 corresponds to white, and 0, to black. The <code>postmd</code> filter assigns a default gray scale that omits white (that is, 255) and gets darker as the regions move from left to right along the real line.<br><br>-i <i>list</i> <i>list</i> is a comma-, space-, or slash(/)-separated string of <i>N</i> floating point numbers that partition the real line into $2N+1$ regions. The <i>list</i> must be given in increasing numerical order. The partitions are used to map floating point numbers read from the input <i>files</i> into gray scale integers that are either assigned automatically by <code>postmd</code> or arbitrarily selected using the -g option. The default interval <i>list</i> is -1, 0, 1, which partitions the real line into seven regions.<br><br>-m <i>num</i> Magnifies each logical page by the factor <i>num</i> . Pages are scaled uniformly about the origin which, by default, is located at the center of each page. The default magnification is 1.0.<br><br>-n <i>num</i> Prints <i>num</i> logical pages on each piece of paper, where <i>num</i> can be any positive integer. By default, <i>num</i> is set to 1.<br><br>-o <i>list</i> Prints pages whose numbers are given in the comma separated <i>list</i> . The list contains single numbers <i>N</i> and ranges <i>N1</i> – <i>N2</i> . A |

missing *N1* means the lowest numbered page, a missing *N2* means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3 - 4, when requesting two logical pages to a sheet; then *only* page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.

- p *mode* Prints *files* in either portrait or landscape *mode*. Only the first character of *mode* is significant. The default *mode* is portrait.
- w *window* *window* is a comma- or space-separated list of four positive integers that select the upper left and lower right corners of a submatrix from each of the input *files*. Row and column indices start at 1 in the upper left corner and the numbers in the input *files* are assumed to be written in row major order. By default, the entire matrix is displayed.
- x *num* Translates the origin *num* inches along the positive x axis. The default coordinate system has the origin fixed at the center of the page, with positive x to the right and positive y up the page. Positive *num* moves everything right. The default offset is 0 inches.
- y *num* Translates the origin *num* inches along the positive y axis. Positive *num* moves everything up the page. The default offset is 0.

Only one matrix is displayed on each logical page, and each of the input *files* must contain complete descriptions of exactly one matrix. Matrix elements are floating point numbers arranged in row major order in each input file. White space, including newlines, is not used to determine matrix dimensions. By default, `postmd` assumes each matrix is square and sets the number of rows and columns to the square root of the number of elements in the input file. Supplying default dimensions on the command line with the `-d` option overrides this default behavior, and in that case the dimensions apply to all input *files*.

An optional header can be supplied with each input file and is used to set the matrix dimensions, the partition of the real line, the gray scale map, and a window into the matrix. The header consists of keyword/value pairs, each on a separate line. It begins on the first line of each input file and ends with the first unrecognized string, which should be the first matrix element. Values set in the header take precedence, but apply only to the current input file. Recognized header keywords are `dimension`, `interval`, `grayscale`, and `window`. The syntax of the value string that follows each keyword parallels what is accepted by the `-d`, `-i`, `-g`, and `-w` options.

#### EXAMPLES **EXAMPLE 1** Generating an interval list

For example, suppose *file* initially contains the 1000 numbers in a 20x50 matrix. Then you can produce exactly the same output by completing three steps.

## postmd(1)

### **EXAMPLE 1** Generating an interval list *(Continued)*

1. First, issue the following command line:

```
example% postmd -d20x50 -i"-100 100" -g0,128,254,128,0 file
```

2. Second, prepend the following header to file:

```
example% postmd -d20x50 -i"-100 100" -g0,128,254,128,0 file
```

3. Third, issue the following command line:

```
example% postmd file
```

The interval list partitions the real line into five regions and the gray scale list maps numbers less than -100 or greater than 100 into 0 (that is, black), numbers equal to -100 or 100 into 128 (that is, 50 percent black), and numbers between -100 and 100 into 254 (that is, almost white).

**FILES** /usr/lib/lp/postscript/forms.ps  
/usr/lib/lp/postscript/ps.requests

**EXIT STATUS** The following exit values are returned:

0 Successful completion.  
non-zero An error occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWpsf         |

**SEE ALSO** `dpost(1)`, `postdaisy(1)`, `postdmd(1)`, `postio(1)`, `postprint(1)`, `postreverse(1)`, `posttek(1)`, `attributes(5)`

**NOTES** The largest matrix that can be adequately displayed is a function of the interval and gray scale lists, the printer resolution, and the paper size. A 600 by 600 matrix is an optimistic upper bound for a two element interval list (that is, five regions) using 8.5 by 11 inch paper on a 300 dpi printer.

Using white (that is, 255) in a gray scale list is not recommended and won't show up in the legend and bar graph that `postmd` displays below each image.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>DESCRIPTION</b> | The <code>postplot</code> filter translates <code>plot(1B)</code> graphics <i>filenames</i> into PostScript and writes the results on the standard output. If no <i>filenames</i> are specified, or if <code>-</code> is one of the input <i>filenames</i> , the standard input is read.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>OPTIONS</b>     | The following options are supported: <ul style="list-style-type: none"> <li>-c <i>num</i>    Print <i>num</i> copies of each page. By default, only one copy is printed.</li> <li>-f <i>name</i>    Print text using font <i>name</i>. Any PostScript font can be used, although the best results will be obtained only with constant width fonts. The default font is Courier.</li> <li>-m <i>num</i>    Magnify each logical page by the factor <i>num</i>. Pages are scaled uniformly about the origin which, by default, is located at the center of each page. The default magnification is 1.0.</li> <li>-n <i>num</i>    Print <i>num</i> logical pages on each piece of paper, where <i>num</i> can be any positive integer. By default, <i>num</i> is set to 1.</li> <li>-o <i>list</i>    Print pages whose numbers are given in the comma-separated <i>list</i>. The list contains single numbers <i>N</i> and ranges <i>N1</i> – <i>N2</i>. A missing <i>N1</i> means the lowest numbered page, a missing <i>N2</i> means the highest.</li> <li>-p <i>mode</i>    Print <i>filenames</i> in either portrait or landscape <i>mode</i>. Only the first character of <i>mode</i> is significant. The default <i>mode</i> is landscape.</li> <li>-w <i>num</i>    Set the line width used for graphics to <i>num</i> points, where a point is approximately 1/72 of an inch. By default, <i>num</i> is set to 0 points, which forces lines to be one pixel wide.</li> <li>-x <i>num</i>    Translate the origin <i>num</i> inches along the positive x axis. The default coordinate system has the origin fixed at the center of the page, with positive x to the right and positive y up the page. Positive <i>num</i> moves everything right. The default offset is 0.0 inches.</li> <li>-y <i>num</i>    Translate the origin <i>num</i> inches along the positive y axis. Positive <i>num</i> moves everything up the page. The default offset is 0.0.</li> </ul> |
| <b>OPERANDS</b>    | The following operand is supported: <ul style="list-style-type: none"> <li><i>filename</i>            The graphics filename to be translated</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| DESCRIPTION | The <code>postprint</code> filter translates text <i>files</i> into PostScript and writes the results on the standard output. If no <i>files</i> are specified, or if <code>-</code> is one of the input <i>files</i> , the standard input is read.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| OPTIONS     | <p><code>-c <i>num</i></code> Print <i>num</i> copies of each page. By default, only one copy is printed.</p> <p><code>-f <i>name</i></code> Print <i>files</i> using font <i>name</i>. Any PostScript font can be used, although the best results will be obtained only with constant width fonts. The default font is Courier.</p> <p><code>-l <i>num</i></code> Set the length of a page to <i>num</i> lines. By default, <i>num</i> is 66. Setting <i>num</i> to 0 is allowed, and will cause <code>postprint</code> to guess a value, based on the point size that's being used.</p> <p><code>-m <i>num</i></code> Magnify each logical page by the factor <i>num</i>. Pages are scaled uniformly about the origin, which is located near the upper left corner of each page. The default magnification is 1.0.</p> <p><code>-n <i>num</i></code> Print <i>num</i> logical pages on each piece of paper, where <i>num</i> can be any positive integer. By default, <i>num</i> is set to 1.</p> <p><code>-o <i>list</i></code> Print pages whose numbers are given in the comma-separated <i>list</i>. The <i>list</i> contains single numbers <i>N</i> and ranges <i>N1</i> – <i>N2</i>. A missing <i>N1</i> means the lowest numbered page, a missing <i>N2</i> means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3-4, when requesting two logical pages to a sheet; then <i>only</i> page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.</p> <p><code>-p <i>mode</i></code> Print <i>files</i> in either portrait or landscape <i>mode</i>. Only the first character of <i>mode</i> is significant. The default <i>mode</i> is portrait.</p> <p><code>-r <i>num</i></code> Selects carriage return behavior. Carriage returns are ignored if <i>num</i> is 0, cause a return to column 1 if <i>num</i> is 1, and generate a newline if <i>num</i> is 2. The default <i>num</i> is 0.</p> <p><code>-s <i>num</i></code> Print <i>files</i> using point size <i>num</i>. When printing in landscape mode <i>num</i> is scaled by a factor that depends on the imaging area of the device. The default size for portrait mode is 10. Note that increasing point size increases virtual image size, so you either need to load larger paper, or use the <code>-l0</code> option to scale the number of lines per page.</p> <p><code>-t <i>num</i></code> Assume tabs are set every <i>num</i> columns, starting with the first column. By default, tabs are set every 8 columns.</p> |

## postprint(1)

- `-x num` Translate the origin *num* inches along the positive x axis. The default coordinate system has the origin fixed near the upper left corner of the page, with positive x to the right and positive y down the page. Positive *num* moves everything to the right. The default offset is 0.25 inches.
- `-y num` Translate the origin *num* inches along the positive y axis. Positive *num* moves text up the page. The default offset is -0.25 inches.

A new logical page is started after 66 lines have been printed on the current page, or whenever an ASCII form feed character is read. The number of lines per page can be changed using the `-l` option. Unprintable ASCII characters are ignored, and lines that are too long are silently truncated by the printer.

**EXAMPLES** **EXAMPLE 1** Examples of `postprint`.

To print *file1* and *file2* in landscape mode, issue the following command:

```
example% postprint -pland file1 file2
```

To print three logical pages on each physical page in portrait mode:

```
example% postprint -n3 file
```

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

**FILES** `/usr/lib/lp/postscript/forms.ps`

| <b>NAME</b>        | postreverse – reverse the page order in a PostScript file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <b>postreverse</b> [-o <i>list</i> ] [-r] [ <i>file</i> ]<br><br><b>/usr/lib/lp/postscript/postreverse</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b> | <p>The <code>postreverse</code> filter reverses the page order in files that conform to Adobe’s Version 1.0 or Version 2.0 file structuring conventions, and writes the results on the standard output. Only one input <code>file</code> is allowed and if no <code>file</code> is specified, the standard input is read.</p> <p>The <code>postreverse</code> filter can handle a limited class of files that violate page independence, provided all global definitions are bracketed by <code>%%BeginGlobal</code> and <code>%%EndGlobal</code> comments. In addition, files that mark the end of each page with <code>%%EndPage: label ordinal</code> comments will also reverse properly, provided the prologue and trailer sections can be located. If <code>postreverse</code> fails to find an <code>%%EndProlog</code> or <code>%%EndSetup</code> comment, the entire <code>file</code> is copied, unmodified, to the standard output.</p> <p>Because global definitions are extracted from individual pages and put in the prologue, the output file can be minimally conforming, even if the input <code>file</code> was not.</p> |
| <b>OPTIONS</b>     | <p><code>-o list</code>     Select pages whose numbers are given in the comma-separated <i>list</i>. The <i>list</i> contains single numbers <i>N</i> and ranges <i>N1</i> – <i>N2</i>. A missing <i>N1</i> means the lowest numbered page, a missing <i>N2</i> means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3-4, when requesting two logical pages to a sheet; then <i>only</i> page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.</p> <p><code>-r</code>            Do not reverse the pages in <i>file</i>.</p>                                                                                                                                                                                                                                                                                                               |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Examples of <code>postreverse</code>.</p> <p>o select pages 1 to 100 from <code>file</code> and reverse the pages:</p> <pre>example% postreverse -o1-100 file</pre> <p>To print four logical pages on each physical page and reverse all the pages:</p> <pre>example% postprint -n4 file   postreverse</pre> <p>To produce a minimally conforming file from output generated by <code>dpost</code> without reversing the pages:</p> <pre>example% dpost file   postreverse -r</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>EXIT STATUS</b> | The following exit values are returned:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                    | 0                    Successful completion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

postreverse(1)

non-zero            An error occurred.

**ATTRIBUTES**    See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWpsf         |

**SEE ALSO**    `download(1)`, `dpost(1)`, `postdaisy(1)`, `postdmd(1)`, `postio(1)`, `postmd(1)`,  
`postprint(1)`, `posttek(1)`, `attributes(5)`

**NOTES**        No attempt has been made to deal with redefinitions of global variables or procedures.  
If standard input is used, the input file will be read three times before being  
reversed.

| <b>DESCRIPTION</b> | The <code>posttek</code> filter translates Tektronix 4014 graphics <i>files</i> into PostScript and writes the results on the standard output. If no <i>files</i> are specified, or if <code>-</code> is one of the input <i>files</i> , the standard input is read.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>OPTIONS</b>     | <p><code>-c <i>num</i></code> Print <i>num</i> copies of each page. By default, only one copy is printed.</p> <p><code>-f <i>name</i></code> Print text using font <i>name</i>. Any PostScript font can be used, although the best results will be obtained only with constant width fonts. The default font is Courier.</p> <p><code>-m <i>num</i></code> Magnify each logical page by the factor <i>num</i>. Pages are scaled uniformly about the origin which, by default, is located at the center of each page. The default magnification is 1.0.</p> <p><code>-n <i>num</i></code> Print <i>num</i> logical pages on each piece of paper, where <i>num</i> can be any positive integer. By default, <i>num</i> is set to 1.</p> <p><code>-o <i>list</i></code> Print pages whose numbers are given in the comma-separated <i>list</i>. The <i>list</i> contains single numbers <i>N</i> and ranges <i>N1</i> – <i>N2</i>. A missing <i>N1</i> means the lowest numbered page, a missing <i>N2</i> means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3-4, when requesting two logical pages to a sheet; then <i>only</i> page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.</p> <p><code>-p <i>mode</i></code> Print <i>files</i> in either portrait or landscape <i>mode</i>. Only the first character of <i>mode</i> is significant. The default <i>mode</i> is landscape.</p> <p><code>-w <i>num</i></code> Set the line width used for graphics to <i>num</i> points, where a point is approximately 1/72 of an inch. By default, <i>num</i> is set to 0 points, which forces lines to be one pixel wide.</p> <p><code>-x <i>num</i></code> Translate the origin <i>num</i> inches along the positive x axis. The default coordinate system has the origin fixed at the center of the page, with positive x to the right and positive y up the page. Positive <i>num</i> moves everything right. The default offset is 0.0 inches.</p> <p><code>-y <i>num</i></code> Translate the origin <i>num</i> inches along the positive y axis. Positive <i>num</i> moves everything up the page. The default offset is 0.0.</p> |
| <b>EXIT STATUS</b> | The following exit values are returned:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>NAME</b>        | ppgsz – set preferred page size for stack, heap, and/or other anonymous segments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <code>/usr/bin/ppgsz [-F] -o option [,option] cmd   -p pid...</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | The <code>ppgsz</code> utility sets the preferred page size for stack, heap, and/or other anonymous segments for the target process(es), that is, the launched <code>cmd</code> or the process(es) in the pid list. <code>ppgsz</code> stops the target process(es) while changing the page size. See <code>memcntl(2)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><b>-F</b> Force. Sets the preferred page size options(s) for target process(es) even if controlled by other process(es). Caution should be exercised when using the <code>-F</code> flag. See <code>proc(1)</code>.</p> <p><b>-o option[,option]</b> The <i>options</i> are:</p> <p><i>heap=size</i><br/>This option specifies the preferred page size for the heap of the target process(es). <code>heap</code> is defined to be the <code>bss</code> (uninitialized data) and the <code>brk</code> area that immediately follows the <code>bss</code> (see <code>brk(2)</code>). The preferred heap page size is set for the existing heap and for any additional heap memory allocated in the future. See <b>NOTES</b>.</p> <p><i>stack=size</i><br/>This option specifies the preferred page size for the stack of the target process(es). The preferred stack page size is set for the existing stack and newly allocated parts of the stack as it expands.</p> <p><i>anon=size</i><br/>This option specifies the preferred page size for all existing <code>MAP_PRIVATE</code> anonymous segments of the target process(es), other than <code>heap</code> and <code>stack</code>, which are large enough to fit at least one aligned page of the specified size. For the segments that are large enough, the preferred page size is set starting at the first size-aligned address in the segment. The <code>anon</code> preferred pagesize is not applied to <code>MAP_PRIVATE</code> anonymous segments created in the future. See <code>MAP_ANON</code> in <code>mmap(2)</code>.</p> <p>Anonymous memory refers to <code>MAP_PRIVATE</code> pages that are not directly associated with a file in some filesystem. The <code>ppgsz</code> command uses <code>memcntl(2)</code> to set the preferred page size for anonymous segments. See <code>MC_HAT_ADVISE</code> in <code>memcntl(2)</code>.</p> <p>At least one of the above options must be specified.</p> |

## ppgsz(1)

*size* must be a supported page size (see [pagesize\(1\)](#)) or 0, in which case the system will select an appropriate page size. See [memcnt1\(2\)](#).

*size* defaults to bytes and can be specified in octal (0), decimal, or hexadecimal (0x). The numeric value can be qualified with K, M, G, or T to specify Kilobytes, Megabytes, Gigabytes, or Terabytes, respectively. 4194304, 0x400000, 4096K, 0x1000K, and 4M are different ways to specify 4 Megabytes.

**-p** *pid*

Sets the preferred page size option(s) for the target process(es) in the process-id (*pid*) list following the **-p** option. The pid list can also consist of names in the `/proc` directory. Only the process owner or the super-user is permitted to set page size.

*cmd* is interpreted if **-p** is not specified. `ppgsz` launches *cmd* and applies page size option(s) to the new process.

The heap and stack preferred page sizes are inherited. Child process(es) created (see [fork\(2\)](#)) from the launched process or the target process(es) in the pid list after `ppgsz` completes will inherit the preferred heap and stack page sizes. The preferred page sizes of all segments are set back to the default system page size on [exec\(2\)](#) (see [getpagesize\(3C\)](#)). The preferred page size for all other anonymous segments is not inherited by children of the launched or target process(es).

### EXAMPLES

#### EXAMPLE 1 Setting the preferred heap and stack page size

The following example sets the preferred heap page size to 4M and the preferred stack page size to 512K for all `ora`—owned processes running commands that begin with `ora`:

```
example% ppgsz -o heap=4M,stack=512K -p `pgrep -u ora '^ora'`
```

#### EXAMPLE 2 Setting the preferred anonymous page size

The following example sets the preferred page size of existing qualifying anonymous segments to 512k for process ID 953:

```
example% ppgsz -o anon=512k -p 953
```

### EXIT STATUS

If *cmd* is specified and successfully invoked (see [exec\(2\)](#)), the exit status of `ppgsz` will be the exit status of *cmd*. Otherwise, `ppgsz` will exit with one of the following values:

ppgsz(1)

- 0 Successfully set preferred page size(s) for processes in the pid list.
- 125 An error occurred in `ppgsz`. Errors include: invalid argument, invalid page size(s) specified, and failure to set preferred page size(s) for one or more processes in the pid list or `cmd`.
- 126 `cmd` was found but could not be invoked.
- 127 `cmd` could not be found.

**FILES** /proc/\* Process files.  
/usr/lib/ld/map.bssalign A template link-editor `mapfile` for aligning bss (see NOTES).

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                       |
|---------------------|---------------------------------------|
| Availability        | SUNWesu (32-bit)<br>SUNWesxu (64-bit) |
| Interface Stability | Evolving                              |

**SEE ALSO** `ld(1)`, `mpss.so.1(1)`, `pagesize(1)`, `pgrep(1)`, `pmap(1)`, `proc(1)`, `brk(2)`, `exec(2)`, `fork(2)`, `memcntl(2)`, `mmap(2)`, `sbrk(2)`, `getpagesize(3C)`, `proc(4)`, `attributes(5)`

*Linker and Libraries Guide*

**NOTES** Due to resource constraints, the setting of the preferred page size does not necessarily guarantee that the target process(es) will get the preferred page size. Use `pmap(1)` to view the *actual* heap and stack page sizes of the target process(es) (see `pmap -s` option).

Large pages are required to be mapped at addresses that are multiples of the size of the large page. Given that the heap is typically not large page aligned, the starting portions of the heap (below the first large page aligned address) are mapped with the system memory page size. See `getpagesize(3C)`.

To provide a heap that will be mapped with a large page size, an application can be built using a link-editor (`ld(1)`) `mapfile` containing the `bss` segment declaration directive. Refer to the section “Mapfile Option” in the *Linker and Libraries Guide* for more details of this directive and the template `mapfile` provided in `/usr/lib/ld/map.bssalign`. Users are cautioned that an alignment specification may be machine-specific and may lose its benefit on different hardware platforms. A more flexible means of requesting the most optimal underlying page size may evolve in future releases.

`mpss.so.1(1)`, a preloadable shared object, can also be used to set the preferred stack and/or heap page sizes.

| <b>NAME</b>        | ppriv – inspect or modify process privilege sets and attributes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <pre>/usr/bin/ppriv -e [-D   -N] [-s spec] command [arg...]<br/>/usr/bin/ppriv [-v] [-S] [-D   -N] [-s spec] [pid   core]...<br/>/usr/bin/ppriv -l [-v] [privilege-specification...]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p>The first invocation of the <code>ppriv</code> command runs the <i>command</i> specified with the privilege sets and flags modified according to the arguments on the command line.</p> <p>The second invocation examines or changes the privilege state of running process and core files.</p> <p>The third invocation lists the privileges defined and information about specified privileges or privileges set specifications.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-D Turns on privilege debugging for the processes or command supplied.</li><li>-e Interprets the remainder of the arguments as a command line and runs the command line with specified privilege attributes and sets.</li><li>-l Lists all currently defined privileges on stdout.</li><li>-N Turns off privilege debugging for the processes or command supplied.</li><li>-s <i>spec</i> Modifies a process's privilege sets according to <i>spec</i>, a specification with the format [AEILP][+ =]<i>privsetspec</i>, containing no spaces, where:<ul style="list-style-type: none"><li>AEILP Indicates one or more letters indicating which privilege sets to change. These are case insensitive, for example, either a or A indicates all privilege sets.</li><li>+ = Indicates a modifier to respectively add (+), remove (-), or assign (=) the listed privileges to the specified set(s) in <i>privsetspec</i>.</li><li><i>privsetspec</i> Indicates a comma-separated privilege set specification (<i>priv1,priv2</i>, and so on), as described in <code>priv_str_to_set(3C)</code>.</li></ul></li></ul> <p>Modifying the same set with multiple <code>-s</code> options is possible as long as there is either precisely one assignment to an individual set or any number of additions and removals. That is, assignment and addition or removal for one set are mutually exclusive.</p> <ul style="list-style-type: none"><li>-S Short. Reports the shortest possible output strings for sets. The default is portable output. See <code>priv_str_to_set(3C)</code>.</li><li>-v Verbose. Reports privilege sets using privilege names.</li></ul> |
| <b>USAGE</b>       | The <code>ppriv</code> utility examines processes and core files and prints or changes their privilege sets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

ppriv can run commands with privilege debugging on or off or with fewer privileges than the invoking process.

When executing a sub process, the only sets that can be modified are L and I. Privileges can only be removed from L and I as ppriv starts with P=E=I.

ppriv can also be used to remove privileges from processes or to convey privileges to other processes. In order to control a process, the effective set of the ppriv utility must be a super set of the controlled process's E, I, and P. The utility's limit set must be a super set of the target's limit set. If the target's process uids do not match, the {PRIV\_PROC\_OWNER} privilege must be asserted in the utility's effective set. If the controlled processes have any uid with the value 0, more restrictions may exist. See privileges(5).

## EXAMPLES

**EXAMPLE 1** Obtaining the process privileges of the current shell

```
example$ ppriv $$
387:  -sh
flags = <none>
      E: basic
      I: basic
      P: basic
      L: all
```

**EXAMPLE 2** Removing a privilege from your shell's Inheritable and Effective set

```
example$ ppriv -s EI-proc_session $$
```

*Note:* The subprocess can still inspect the parent shell but it can no longer influence the parent because the parent has more privileges in its Permitted set than the ppriv child process:

```
example$ truss -p $$
truss: permission denied: 387

example$ ppriv $$
387:  -sh
flags = <none>
      E: basic,!proc_session
      I: basic,!proc_session
      P: basic
      L: all
```

**EXAMPLE 3** Running a process with privilege debugging

```
example$ ppriv -e -D cat /etc/shadow
cat[418]: missing privilege "file_dac_read" (euid = 21782),
         needed at ufs_access+0x3c
cat: cannot open /etc/shadow
```

## ppriv(1)

**EXAMPLE 3** Running a process with privilege debugging (Continued)

*Note:* The privilege debugging error messages are sent to the controlling terminal of the current process. The “needed at” address specification is an artifact of the kernel implementation and it can be changed at any time after a software update.

The system call number can be mapped to a system call using `/etc/name_to_sysnum`.

**EXAMPLE 4** Listing the privileges available in the current zone

This example lists the privileges available in the current zone (see `zones(5)`). When run in the global zone, all defined privileges are listed.

```
example$ ppriv -l zone
... listing of all privileges elided ...
```

**EXIT STATUS** The following exit values are returned:

0 Successful operation.

non-zero An error has occurred.

**FILES** `/proc/*` Process files

`/etc/name_to_sysnum` system call name to number mapping

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWesu         |
| Interface Stability | See below.      |

The invocation is Evolving. The output is Unstable.

| <b>NAME</b>          | pr – print files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                    |                                                                  |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                 |                                                                                                                        |
| <b>SYNOPSIS</b>      | <pre> /usr/bin/pr [ + page] [-column] [-adFmrt] [ -e [char] [gap]]            [-h header] [ -i [char] [gap]] [-l lines] [ -n [char] [width]]            [-o offset] [ -s [char]] [-w width] [-fp] [file...]  /usr/xpg4/bin/pr [ + page] [-column   -c column] [-adFmrt] [ -e            [char] [gap]] [-h header] [ -i [char] [gap]] [-l lines] [ -n [char]            [width]] [-o offset] [ -s [char]] [-w width] [-fp] [file...] </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                    |                                                                  |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                 |                                                                                                                        |
| <b>DESCRIPTION</b>   | <p>The <code>pr</code> utility is a printing and pagination filter. If multiple input files are specified, each is read, formatted, and written to standard output. By default, the input is separated into 66-line pages, each with:</p> <ul style="list-style-type: none"> <li>■ a 5-line header that includes the page number, date, time and the path name of the file</li> <li>■ a 5-line trailer consisting of blank lines</li> </ul> <p>If standard output is associated with a terminal, diagnostic messages will be deferred until the <code>pr</code> utility has completed processing.</p> <p>When options specifying multi-column output are specified, output text columns will be of equal width; input lines that do not fit into a text column will be truncated. By default, text columns are separated with at least one blank character.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                    |                                                                  |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                 |                                                                                                                        |
| <b>OPTIONS</b>       | <p>The following options are supported. In the following option descriptions, <i>column</i>, <i>lines</i>, <i>offset</i>, <i>page</i>, and <i>width</i> are positive decimal integers; <i>gap</i> is a non-negative decimal integer. Some of the option-arguments are optional, and some of the option-arguments cannot be specified as separate arguments from the preceding option letter. In particular, the <code>-s</code> option does not allow the option letter to be separated from its argument, and the options <code>-e</code>, <code>-i</code>, and <code>-n</code> require that both arguments, if present, not be separated from the option letter.</p> <p>The following options are supported for both <code>/usr/bin/pr</code> and <code>/usr/xpg4/bin/pr</code>:</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 20px;"><code>+page</code></td> <td>Begins output at page number <i>page</i> of the formatted input.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;"><code>-column</code></td> <td>Produces multi-column output that is arranged in <i>column</i> columns (default is 1) and is written down each column in the order in which the text is received from the input file. This option should not be used with <code>-m</code>. The <code>-e</code> and <code>-i</code> options will be assumed for multiple text-column output. Whether or not text columns are produced with identical vertical lengths is unspecified, but a text column will never exceed the length of the page (see the <code>-l</code> option). When used with <code>-t</code>, use the minimum number of lines to write the output.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;"><code>-a</code></td> <td>Modifies the effect of the <code>-column</code> option so that the columns are filled across the page in a round-robin</td> </tr> </table> | <code>+page</code> | Begins output at page number <i>page</i> of the formatted input. | <code>-column</code> | Produces multi-column output that is arranged in <i>column</i> columns (default is 1) and is written down each column in the order in which the text is received from the input file. This option should not be used with <code>-m</code> . The <code>-e</code> and <code>-i</code> options will be assumed for multiple text-column output. | <code>-column</code> | Produces multi-column output that is arranged in <i>column</i> columns (default is 1) and is written down each column in the order in which the text is received from the input file. This option should not be used with <code>-m</code> . The <code>-e</code> and <code>-i</code> options will be assumed for multiple text-column output. Whether or not text columns are produced with identical vertical lengths is unspecified, but a text column will never exceed the length of the page (see the <code>-l</code> option). When used with <code>-t</code> , use the minimum number of lines to write the output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                    |                                                                  |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                 |                                                                                                                        |
| <code>-a</code>      | Modifies the effect of the <code>-column</code> option so that the columns are filled across the page in a round-robin                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                    |                                                                  |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                 |                                                                                                                        |

pr(1)

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                     | order (for example, when <i>column</i> is 2, the first input line heads column 1, the second heads column 2, the third is the second line in column 1, and so forth).                                                                                                                                                                                                                                   |
| -d                                  | Produces output that is double-spaced; append an extra NEWLINE character following every NEWLINE character found in the input.                                                                                                                                                                                                                                                                          |
| -e [ <i>char</i> ] [ <i>gap</i> ]   | Expands each input TAB character to the next greater column position specified by the formula $n * gap + 1$ , where $n$ is an integer $> 0$ . If <i>gap</i> is 0 or is omitted, it defaults to 8. All TAB characters in the input will be expanded into the appropriate number of SPACE characters. If any non-digit character, <i>char</i> , is specified, it will be used as the input tab character. |
| -f                                  | Uses a FORMFEED character for new pages, instead of the default behavior that uses a sequence of NEWLINE characters. Pauses before beginning the first page if the standard output is associated with a terminal.                                                                                                                                                                                       |
| -h <i>header</i>                    | Uses the string <i>header</i> to replace the contents of the <i>file</i> operand in the page header.                                                                                                                                                                                                                                                                                                    |
| -l <i>lines</i>                     | Overrides the 66-line default and reset the page length to <i>lines</i> . If <i>lines</i> is not greater than the sum of both the header and trailer depths (in lines), pr will suppress both the header and trailer, as if the -t option were in effect.                                                                                                                                               |
| -m                                  | Merges files. Standard output will be formatted so pr writes one line from each file specified by <i>file</i> , side by side into text columns of equal fixed widths, in terms of the number of column positions. Implementations support merging of at least nine <i>files</i> .                                                                                                                       |
| -n [ <i>char</i> ] [ <i>width</i> ] | Provides <i>width</i> -digit line numbering (default for <i>width</i> is 5). The number will occupy the first <i>width</i> column positions of each text column of default output or each line of -m output. If <i>char</i> (any non-digit character) is given, it will be appended to the line number to separate it from whatever follows (default for <i>char</i> is a TAB character).               |
| -o <i>offset</i>                    | Each line of output will be preceded by offset $\langle space \rangle s$ . If the -o option is not specified, the default offset is 0. The space taken will be in addition to the output line width (see -w option below).                                                                                                                                                                              |

|                                   |                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -p                                | Pauses before beginning each page if the standard output is directed to a terminal (pr will write an ALERT character to standard error and wait for a carriage-return character to be read on /dev/tty).                                                                                                                                                                                |
| -r                                | Writes no diagnostic reports on failure to open files.                                                                                                                                                                                                                                                                                                                                  |
| -s [ <i>char</i> ]                | Separates text columns by the single character <i>char</i> instead of by the appropriate number of SPACE characters (default for <i>char</i> is the TAB character).                                                                                                                                                                                                                     |
| -t                                | Writes neither the five-line identifying header nor the five-line trailer usually supplied for each page. Quits writing after the last line of each file without spacing to the end of the page.                                                                                                                                                                                        |
| -w <i>width</i>                   | Sets the width of the line to <i>width</i> column positions for multiple text-column output only. If the -w option is not specified and the -s option is not specified, the default width is 72. If the -w option is not specified and the -s option is specified, the default width is 512.<br><br>For single column output, input lines will not be truncated.                        |
| <b>/usr/bin/pr</b>                | The following options are supported for /usr/bin/pr only:                                                                                                                                                                                                                                                                                                                               |
| -F                                | Folds the lines of the input file. When used in multi-column mode (with the -a or -m options), lines will be folded to fit the current column's width. Otherwise, they will be folded to fit the current line width (80 columns).                                                                                                                                                       |
| -i [ <i>char</i> ] [ <i>gap</i> ] | In output, replaces SPACE characters with TAB characters wherever one or more adjacent SPACE characters reach column positions $gap+1$ , $2*gap+1$ , $3*gap+1$ , and so forth. If <i>gap</i> is 0 or is omitted, default TAB settings at every eighth column position are assumed. If any non-digit character, <i>char</i> , is specified, it will be used as the output TAB character. |
| <b>/usr/xpg4/bin/pr</b>           | The following options are supported for /usr/xpg4/bin/pr only:                                                                                                                                                                                                                                                                                                                          |
| -F                                | Uses a FORMFEED character for new pages, instead of the default behavior that uses a sequence of NEWLINE characters.                                                                                                                                                                                                                                                                    |
| -i [ <i>char</i> ] [ <i>gap</i> ] | In output, replaces multiple SPACE characters with TAB characters wherever two or more adjacent SPACE characters reach column positions $gap+1$ , $2*gap+1$ , $3*gap+1$ , and so forth. If <i>gap</i> is 0 or is omitted, default                                                                                                                                                       |

pr(1)

TAB settings at every eighth column position are assumed. If any non-digit character, *char*, is specified, it will be used as the output TAB character.

**OPERANDS** The following operand is supported:

*file* A path name of a file to be written. If no *file* operands are specified, or if a *file* operand is -, the standard input will be used.

**EXAMPLES** **EXAMPLE 1** Printing a numbered list of all files in the current directory

```
example% ls -a | pr -n -h "Files in $(pwd) ."
```

**EXAMPLE 2** Printing files in columns

This example prints *file1* and *file2* as a double-spaced, three-column listing headed by *file list*:

```
example% pr -3d -h "file list" file1 file2
```

**EXAMPLE 3** Writing files with expanded column tabs

The following example writes *file1* on *file2*, expanding tabs to columns 10, 19, 28, ...

```
example% pr -e9 -t <file1 >file2
```

**ENVIRONMENT VARIABLES** See `environ(5)` for descriptions of the following environment variables that affect the execution of `pr`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `TZ`, and `NLSPATH`.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

praliases(1)

**NAME** praliases – display system mail aliases

**SYNOPSIS** **praliases** [-C *configfile*] [-f *aliasfile*] [*key*]

**DESCRIPTION** The **praliases** utility displays system mail aliases. When no key is given, **praliases** displays the current system aliases, one per line, in no particular order. The form is *key:value*. If a key is given, only that key is looked up and the appropriate *key:value* is displayed if found.

**OPTIONS** The following options are supported:

- C *configfile* Specifies a **sendmail** configuration file.
- f *aliasfile* Reads the specified file *aliasfile* instead of the default **sendmail** system aliases file.

**OPERANDS** The following operands are supported:

- key* A specific alias key to look up.

**EXIT STATUS** The following exit values are returned:

- 0 Successful operation.
- >0 An error occurred.

**FILES**

| <b>SYNOPSIS</b>             | <b>prctl</b> [-P] [-t [basic   privileged   system]] [ -n <i>name</i> [-srx] [-v <i>value</i> ] [-e   -d <i>action</i> ] [-p <i>pid</i> ]] [-i <i>idtype</i> ] [ <i>id...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |            |                                                                                                                                                   |             |                                                                                                                                                                                                                                                                                                                                                                                               |               |                                                                                         |                             |                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b>          | <p>The <b>prctl</b> utility allows the examination and modification of the resource controls associated with an active process, task, or project on the system. It allows access to the basic and privileged limits on the specified entity.</p> <p>See <b>resource_controls(5)</b> for a description of the resource controls supported in the current release of the Solaris operating system.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |            |                                                                                                                                                   |             |                                                                                                                                                                                                                                                                                                                                                                                               |               |                                                                                         |                             |                                                                                                                                                                                                                                 |
| <b>OPTIONS</b>              | <p>If none of the <b>-s</b>, <b>-r</b>, <b>-x</b>, <b>-v</b>, <b>-d</b>, or <b>-e</b> options are specified, the invocation is considered a get operation. Otherwise, it is considered a modify operation.</p> <p>The following options are supported:</p> <p><b>-d   -e <i>action</i></b><br/> Disables (<b>-d</b>) or enables (<b>-e</b>) the specified <i>action</i> on the resource control value specified by <b>-v</b>, <b>-t</b>, and <b>-p</b>. If any of the <b>-v</b>, <b>-t</b>, or <b>-p</b> options are unspecified, they will match any value, privilege, or recipient pid. For example, specifying only <b>-v</b> will modify the first resource control with matching value, matching any privilege and recipient pid. If no matching resource control value is found, a new value is added as if <b>-s</b> were specified.</p> <p><i>Actions:</i></p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><b>all</b></td> <td>This action is only available with <b>-d</b>. It disables all actions. This will fail on resource control values that have the deny global flag.</td> </tr> <tr> <td><b>deny</b></td> <td>Indicates that the resource control will attempt to deny granting the resource to the process, task, project, or zone on a request for resources in excess of the resource control value. <b>deny</b> actions may not be enabled if the resource control has the <b>no-deny</b> global flag. <b>deny</b> actions may not be disabled if the resource control has the <b>deny</b> global flag.</td> </tr> <tr> <td><b>signal</b></td> <td>This action is only available with <b>-d</b>. It deactivates the <b>signal</b> action.</td> </tr> <tr> <td><b>signal=<i>signum</i></b></td> <td>In the <b>signal=<i>signum</i></b> action, <i>signum</i> is a signal number (or string representation of a signal). Setting a <b>signal</b> action on a resource control with the <b>no-local-action</b> global flag will fail.</td> </tr> </table> <p><b>-i <i>idtype</i></b><br/> Specifies the type of the id operands. Valid <i>idtypes</i> are <b>process</b>, <b>task</b>, <b>project</b>, or <b>zone</b>. Also allowed are <b>pid</b>, <b>taskid</b>, <b>projid</b>, and <b>zoneid</b>. The default id type, if the <b>-i</b> option is omitted, is <b>process</b>.</p> | <b>all</b> | This action is only available with <b>-d</b> . It disables all actions. This will fail on resource control values that have the deny global flag. | <b>deny</b> | Indicates that the resource control will attempt to deny granting the resource to the process, task, project, or zone on a request for resources in excess of the resource control value. <b>deny</b> actions may not be enabled if the resource control has the <b>no-deny</b> global flag. <b>deny</b> actions may not be disabled if the resource control has the <b>deny</b> global flag. | <b>signal</b> | This action is only available with <b>-d</b> . It deactivates the <b>signal</b> action. | <b>signal=<i>signum</i></b> | In the <b>signal=<i>signum</i></b> action, <i>signum</i> is a signal number (or string representation of a signal). Setting a <b>signal</b> action on a resource control with the <b>no-local-action</b> global flag will fail. |
| <b>all</b>                  | This action is only available with <b>-d</b> . It disables all actions. This will fail on resource control values that have the deny global flag.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |            |                                                                                                                                                   |             |                                                                                                                                                                                                                                                                                                                                                                                               |               |                                                                                         |                             |                                                                                                                                                                                                                                 |
| <b>deny</b>                 | Indicates that the resource control will attempt to deny granting the resource to the process, task, project, or zone on a request for resources in excess of the resource control value. <b>deny</b> actions may not be enabled if the resource control has the <b>no-deny</b> global flag. <b>deny</b> actions may not be disabled if the resource control has the <b>deny</b> global flag.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |            |                                                                                                                                                   |             |                                                                                                                                                                                                                                                                                                                                                                                               |               |                                                                                         |                             |                                                                                                                                                                                                                                 |
