| <b>signal</b>               | This action is only available with <b>-d</b> . It deactivates the <b>signal</b> action.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |            |                                                                                                                                                   |             |                                                                                                                                                                                                                                                                                                                                                                                               |               |                                                                                         |                             |                                                                                                                                                                                                                                 |
| <b>signal=<i>signum</i></b> | In the <b>signal=<i>signum</i></b> action, <i>signum</i> is a signal number (or string representation of a signal). Setting a <b>signal</b> action on a resource control with the <b>no-local-action</b> global flag will fail.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |            |                                                                                                                                                   |             |                                                                                                                                                                                                                                                                                                                                                                                               |               |                                                                                         |                             |                                                                                                                                                                                                                                 |

## prctl(1)

For a modify operation, the entity to which id operands are members is the target entity. For instance, setting a project resource control on an `-i process` will set the resource control on the project to which each given process argument is a member.

For a get operation, the resource controls are listed for all entities to which the id operands are members. For example, `-i task taskid` will list the task, project, and zone resource controls for the task, and for the project and zone to which that task is a member.

`-n name`

Specifies the name of the resource control to get or set. If the *name* is unspecified, all resource controls are retrieved.

`-p pid`

When manipulating (using `-s`, `-r`, `-x`, `-d`, or `-e`) a basic task project, or zone resource control values, a recipient *pid* can be specified using `-p`. When setting a new basic resource control or controls on a task, project, or zone, the `-p` option is required if the `-i idtype` option argument is not `process`.

`-P`

Display resource control values in semi-colon delimited format.

`-r`

Replaces the first resource control value (matching with the `-t privilege`) with the new value specified through the `-v` option.

`-s`

Set a new resource control value.

This option requires the `-v` option.

If you do not specify the `-t` option, basic privilege is used. If you want to set a basic task, process, or zone rctl, `-p` is required. If `-e` or `-d` are also specified, the action on the new rctl is set as well.

For compatibility with prior releases, this option is implied if `-v` is specified, without any of `-e`, `-d`, `-r`, or `-x`.

See `resource_controls(5)` for a description of unit modifiers and scaling factors you can use to express large values when setting a resource control value.

`-t [basic | privileged | system]`

Specifies which resource control type to set. Unless the “lowerable” flag is set for a resource control, only invocations by users (or `setuid` programs) who have privileges equivalent to those of root can modify privileged resource controls. See `rctlblk_set_value(3C)` for a description of the `RCTL_GLOBAL_LOWERABLE` flag. If the type is not specified, `basic` is assumed. For a get operation, the values of all resource control types, including `system`, are displayed if no type is specified.

**-v *value***

Specifies the value for the resource control for a set operation. If no *value* is specified, then the modification (deletion, action enabling or disabling) will be carried out on the lowest-valued resource control with the given type.

**-x**

Deletes the specified resource control value. If the delete option is not provided, the default operation of `prctl` is to modify a resource control value of matching value and privilege, or insert a new value with the given privilege. The matching criteria are discussed more fully in `setrctl(2)`.

If none of the `-d`, `-e`, `-v`, or `-x` options is specified, the invocation is considered a get operation.

**OPERANDS** The following operand is supported:

*id* The ID of the entity (`process`, `task`, `project`, or `zone`) to interrogate. If the invoking user's credentials are unprivileged and the entity being interrogated possesses different credentials, the operation will fail. If no *id* is specified, an error message is returned.

**EXAMPLES** **EXAMPLE 1** Displaying Current Resource Control Settings

The following example displays current resource control settings for a task to which the current shell belongs:

```
example$ ps -o taskid -p $$
TASKID
8
example$ prctl -i task 8
136150: /bin/ksh
NAME      PRIVILEGE      VALUE      FLAG      ACTION      RECIPIENT
task.max-cpu-time
  system      18.4Es      inf      deny      -
task.max-lwps
  system      2.15G      max      deny      -
project.max-device-locked-memory
  privileged  30.9MB      -      deny      -
  system      16.0EB      max      deny      -
project.max-port-ids
  privileged  8.19K      -      deny      -
  system      65.5K      max      deny      -
project.max-shm-memory
  privileged  123MB      -      deny      -
  system      16.0EB      max      deny      -
project.max-shm-ids
  privileged  128        -      deny      -
  system      16.8M      max      deny      -
project.max-msg-ids
  privileged  128        -      deny      -
  system      16.8M      max      deny      -
project.max-sem-ids
  privileged  128        -      deny      -
  system      16.8M      max      deny      -
project.cpu-shares
```

prctl(1)

**EXAMPLE 1** Displaying Current Resource Control Settings (Continued)

```
      privileged      1      -      none      -
      system          65.5K    max    deny      -
zone.cpu-shares
      privilege      1      -      none      -
      system          65.5K    max    deny      -
```

**EXAMPLE 2** Displaying, Replacing, and Verifying the Value of a Specific Control

The following examples displays, replaces, and verifies the value of a specific control on an existing project:

```
example# prctl -n project.cpu-shares -i project group.staff
project: 10: group.staff
NAME      PRIVILEGE      VALUE      FLAG      ACTION      RECIPIENT
project.cpu-shares
      privileged      1          -          none      -
      system          65.5K      max        none      -

example# prctl -n project.cpu-shares -v 10 -r -i project group.staff
example# prctl -n project.cpu-shares -i project group.staff
project: 10: group.staff
NAME      PRIVILEGE      VALUE      FLAG      ACTION      RECIPIENT
project.cpu-shares
      privileged      10         -          none      -
      system          65.5K      max        none      -
```

**EXAMPLE 3** Adjusting Resources

This example uses the `project.max-device-locked-memory` resource.

First, use `id -p` to find out the project id:

```
/home/garfield> id -p
uid=77880(garfield) gid=10(staff) projid=10(group.staff)
```

Identify the resource limit value before the change. Find a process id of the processes in that project id:

```
/home/garfield> ps -eaf
      UID  PID  PPID  C   STIME TTY      TIME CMD
      ....
garfield  530  528   0 11:24:18 pts/1      0:00 -ksh

/home/garfield> prctl 530
530:      -ksh
project.max-device-locked-memory      [ no-basic deny ]
      261969408 privileged deny
      18446744073709551615 system      deny      [ max ]
.....
current limit is 261969408 bytes.
```

**EXAMPLE 3** Adjusting Resources (Continued)

Next, adjust the `project.max-device-locked-memory` limit to 300000000 for project id 10:

```
# prctl -n project.max-device-locked-memory -v 300000000 -r -i project 10
```

The resource limit value after the change shows a new value of 300000000 bytes:

```
/home/garfield> prctl 530
530:      -ksh
project.max-device-locked-memory      [ no-basic deny ]
              3  00000000 privileged deny
              18446744073709551615 system      deny          [ max ]
```

**EXIT STATUS** The following exit values are returned:

- 0 Success.
- 1 Fatal error encountered.
- 2 Invalid command line options were specified.

**FILES** `/proc/pid/*` Process information and control files

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWesu         |
| Interface Stability | See below.      |

The command-line syntax is Evolving. The human-readable output is Unstable. The parseable output is Evolving.

| <b>SYNOPSIS</b>    | <b>preap</b> [-F] <i>pid</i> ...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |              |                                       |
| <b>DESCRIPTION</b> | <p>A defunct (or zombie) process is one whose exit status has yet to be reaped by its parent. The exit status is reaped via the <code>wait(3C)</code>, <code>waitid(2)</code>, or <code>waitpid(3C)</code> system call. In the normal course of system operation, zombies may occur, but are typically short-lived. This may happen if a parent exits without having reaped the exit status of some or all of its children. In that case, those children are reparented to <code>PID 1</code>. See <code>init(1M)</code>, which periodically reaps such processes.</p> <p>An irresponsible parent process may not exit for a very long time and thus leave zombies on the system. Since the operating system destroys nearly all components of a process before it becomes defunct, such defunct processes do not normally impact system operation. However, they do consume a small amount of system memory.</p> <p><code>preap</code> forces the parent of the process specified by <i>pid</i> to <code>waitid(3C)</code> for <i>pid</i>, if <i>pid</i> represents a defunct process.</p> <p><code>preap</code> will attempt to prevent the administrator from unwisely reaping a child process which might soon be reaped by the parent, if:</p> <ul style="list-style-type: none"><li>■ The process is a child of <code>init(1M)</code>.</li><li>■ The parent process is stopped and might wait on the child when it is again allowed to run.</li><li>■ The process has been defunct for less than one minute.</li></ul> |                |                 |              |                                       |
| <b>OPTIONS</b>     | The following option is supported:<br><br>-F            Forces the parent to reap the child, overriding safety checks.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |                                       |
| <b>OPERANDS</b>    | The following operand is supported:<br><br><i>pid</i> Process ID list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |                                       |

**WARNINGS**

preap should be applied sparingly and only in situations in which the administrator or developer has confirmed that defunct processes will not be reaped by the parent process. Otherwise, applying preap may damage the parent process in unpredictable ways.

| <b>NAME</b>                                     | prex – control tracing and manipulate probe points in a process or the kernel                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>                                 | <b>prex</b> [-o <i>trace_file_name</i> ] [-l <i>libraries</i> ] [-s <i>kbytes_size</i> ] <i>cmd</i> [ <i>cmd-args...</i> ]<br><b>prex</b> [-o <i>trace_file_name</i> ] [-l <i>libraries</i> ] [-s <i>kbytes_size</i> ] -p <i>pid</i><br><b>prex</b> -k [-s <i>kbytes_size</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b>                              | <p>The <code>prex</code> command is the part of the Solaris tracing architecture that controls probes in a process or the kernel. See <code>tracing(3TNF)</code> for an overview of this tracing architecture, including example source code using it.</p> <p><code>prex</code> is the application used for external control of probes. It automatically preloads the <code>libtnfprobe</code> library. <code>prex</code> locates all the probes in a target executable or the kernel and provides an interface for the user to manipulate them. It allows a probe to be turned on for tracing, debugging, or both. Tracing generates a TNF (Trace Normal Form) trace file that can be converted to ASCII by <code>tnfdump(1)</code> and used for performance analysis. Debugging generates a line to standard error whenever the probe is hit at run time.</p> <p><code>prex</code> does not work on static executables. It only works on dynamic executables.</p>                                                                                                                                                                                                                                                                       |
| <b>Invoking prex</b>                            | <p>There are three ways to invoke <code>prex</code>:</p> <ol style="list-style-type: none"><li>1. Use <code>prex</code> to start the target application <i>cmd</i>. In this case, the target application need not be built with a dependency on <code>libtnfprobe</code>. See <code>TNF_PROBE(3TNF)</code>. <code>prex</code> sets the environment variable <code>LD_PRELOAD</code> to load <code>libtnfprobe</code> into the target process. See <code>ld(1)</code>. <code>prex</code> then uses the environment variable <code>PATH</code> to find the target application.</li><li>2. Attach <code>prex</code> to a running application. In this case, the running target application should have <code>libtnfprobe</code> already linked in. Alternatively, the user may manually set <code>LD_PRELOAD</code> to include <code>libtnfprobe.so.1</code> prior to invoking the target.</li><li>3. Use <code>prex</code> with the <code>-k</code> option to set <code>prex</code> to kernel mode. <code>prex</code> can then be used to control probes in the Solaris kernel. In kernel mode, additional commands are defined, and some commands that are valid in other modes are invalid. See <code>Kernel Mode</code> below.</li></ol> |
| <b>Control File Format and Command Language</b> | <p>In a future release of <code>prex</code>, the command language may be moved to a syntax that is supported by an existing scripting language like <code>ksh(1)</code>. In the meantime, the interface to <code>prex</code> is uncommitted.</p> <ul style="list-style-type: none"><li>■ Commands should be in ASCII.</li><li>■ Each command is terminated with the NEWLINE character.</li><li>■ A command can be continued onto the next line by ending the previous line with the backslash (“\”) character.</li><li>■ Tokens in a command must be separated by whitespace (one or more spaces or tabs).</li><li>■ The “#” character implies that the rest of the line is a comment.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Basic prex  
Commands**

| Command                   | Result                                                        |
|---------------------------|---------------------------------------------------------------|
| % <b>prex a.out</b>       | Attaches <i>prex</i> to your program and starts <i>prex</i> . |
| prex> <b>enable \$all</b> | Enables all the probes.                                       |
| prex> <b>quit resume</b>  | Quits <i>prex</i> and resumes execution of program.           |

**Control File Search  
Path**

There are two different methods of communicating with *prex*:

- By specifications in a control file. During start-up, *prex* searches for a file named *.prexrc* in the directories specified below. *prex* does not stop at the first one it finds. This way a user can override any defaults that are set up. The search order is:

```
$HOME/  
./
```

- By typing commands at the *prex* prompt.

The command language for both methods is the same and is specified in USAGE. The commands that return output will not make sense in a control file. The output will go to standard output.

When using *prex* on a target process, the target will be in one of two states, running or stopped. This can be detected by the presence or absence of the *prex>* prompt. If the prompt is absent, it means that the target process is running. Typing Control-C will stop the target process and return the user to the prompt. There is no guarantee that Control-C will return to a *prex* prompt immediately. For example, if the target process is stopped on a job control stop (SIGSTOP), then Control-C in *prex* will wait until the target has been continued (SIGCONT). See *Signals to Target Program* below for more information on signals and the target process.

**OPTIONS**

The following options are supported:

- k                      kernel mode: *prex* is used to control probes in the Solaris kernel. In kernel mode, additional commands are defined, and some commands valid in other modes are invalid. See *Kernel Mode* below.
- l *libraries*            The *libraries* mentioned are linked in to the target application using LD\_PRELOAD (see *ld(1)*). This option cannot be used when attaching to a running process. The argument to the -l option should be a space-separated string enclosed in double quotes. Each token in the string is a library name. It follows the LD\_PRELOAD rules on how libraries should be specified and where they will be found.

## prex(1)

`-o trace_file_name` File to be used for the trace output. *trace\_file\_name* is assumed to be relative to the current working directory of `prex` (that is, the directory that the user was in when `prex` was started).

If `prex` attaches to a process that is already tracing, the new *trace\_file\_name* (if provided) will not be used. If no *trace\_file\_name* is specified, the default is `/${TMPDIR}/trace-pid` where *pid* is the process id of the target program. If `TMPDIR` is not set, `/tmp` is used.

`-s kbytes_size` Maximum size of the output trace file in Kbytes. The default size of the trace *kbytes\_size* is 4096 (2<sup>10</sup>) bytes or 4 Mbytes for normal usage, and 384 or 384 kbytes in kernel mode. The minimum size that can be specified is 128 Kbytes. The trace file can be thought of as a least recently used circular buffer. Once the file has been filled, newer events will overwrite the older ones.

**USAGE** This section describes the usage of the `prex` utility.

**Grammar** Probes are specified by a list of space-separated selectors. Selectors are of the form:

*attribute=value*

(See `TNF_PROBE(3TNF)`). The “*attribute=*” is optional. If it is not specified, it defaults to “*keys=*”.

The *attribute* or *value* (generically called “*spec*”) can be any of the following:

**IDENT** Any sequence of letters, digits, `_`, `\`, `,`, `.`, `%` not beginning with a digit. **IDENT** implies an exact match.

**QUOTED\_STR** Usually used to escape reserved words (any commands in the command language). **QUOTED\_STR** implies an exact match and has to be enclosed in single quotes (`'`).

**REGEXP** An `ed(1)` regular expression pattern match. **REGEXP** has to be enclosed in slashes (`/ /`), A `/` can be included in a **REGEXP** by escaping it with a backslash `\`.

The following grammar explains the syntax.

```
selector_list ::= | /* empty */
                selector_list selector
selector ::= spec=spec | /* whitespace around '=' opt */
            spec
spec ::= IDENT |
        QUOTED_STR |
        REGEXP
```

The terminals in the above grammar are:

```

IDENT =      [a-zA-Z_\.\%]{[a-zA-Z0-9_\.\%]}+
QUOTED_STR = '[^\n']*' /* any string in single quotes */
REGEXP =     /^[^\\n]*/ /* regexp's have to be in / / */

```

This is a list of the remaining grammar that is needed to understand the syntax of the command language (defined in next subsection):

```

filename ::= QUOTED_STR /* QUOTED_STR defined above */
spec_list ::= /* empty */ |
            spec_list spec /* spec defined above */
fcn_handle ::= &IDENT /* IDENT defined above */
set_name ::= $IDENT /* IDENT defined above */

```

## Command Language

### 1. Set Creation and Set Listing

```

create $set_name selector_list
list sets # list the defined sets

```

`create` can be used to define a set which contains probes that match the `selector_list`. The set `$all` is pre-defined as `./.*` and it matches all the probes.

### 2. Function Listing

```

list fcns # list the available fcn_handle

```

The user can list the different functions that can be connected to probe points. Currently, only the debug function called `&debug` is available.

### 3. Commands to Connect and Disconnect Probe Functions

```

connect &fcn_handle $set_name
connect &fcn_handle selector_list
clear $set_name
clear selector_list

```

The `connect` command is used to connect probe functions (which must be prefixed by `&`) to probes. The probes are specified either as a single set (with a `'$'`), or by explicitly listing the probe selectors in the command. The probe function has to be one that is listed by the `list fcns` command. This command does not enable the probes. The `clear` command is used to disconnect all connected probe functions from the specified probes.

### 4. Commands to Toggle the Tracing Mode

```

trace $set_name
trace selector_list
untrace $set_name
untrace selector_list

```

The `trace` and `untrace` commands are used to toggle the tracing action of a probe point (that is, whether a probe will emit a trace record or not if it is hit). This command does not enable the probes specified. Probes have tracing on by default. The most efficient way to turn off tracing is by using the `disable` command. `untrace` is useful if you want debug output but no tracing. If so, set the state of the probe to enabled, untraced, and the debug function connected.

### 5. Commands to Enable and Disable Probes

prex(1)

```
enable $set_name  
enable selector_list  
disable $set_name  
disable selector_list
```

The `enable` and `disable` commands are used to control whether the probes perform the action that they have been set up for. To trace a probe, it has to be both enabled and traced (using the `trace` command). Probes are disabled by default. The `list history` command is used to list the probe control commands issued: `connect`, `clear`, `trace`, `untrace`, `enable`, and `disable`. These are the commands that are executed whenever a new shared object is brought in to the target program by `dlopen(3C)`. See the subsection, `dlopen'ed Libraries`, below for more information.

The following table shows the actions that result from specific combinations of tracing, enabling, and connecting:

| Enabled or Disabled | Tracing State (On/Off) | Debug State (Connected/Cleared) | Results In            |
|---------------------|------------------------|---------------------------------|-----------------------|
| Enabled             | On                     | Connected                       | Tracing and Debugging |
| Enabled             | On                     | Cleared                         | Tracing only          |
| Enabled             | Off                    | Connected                       | Debugging only        |
| Enabled             | Off                    | Cleared                         | Nothing               |
| Disabled            | On                     | Connected                       | Nothing               |
| Disabled            | On                     | Cleared                         | Nothing               |
| Disabled            | Off                    | Connected                       | Nothing               |
| Disabled            | Off                    | Cleared                         | Nothing               |

## 6. List History

```
list history          # lists probe control command history
```

The `list history` command displays a list of the probe control commands previously issued in the tracing session, for example, `connect`, `clear`, `trace`, `disable`. Commands in the history list are executed wherever a new shared object is brought into the target program by `dlopen(3C)`.

## 7. Commands to List Probes, List Values, or List Trace File Name

```
list spec_list probes $set_name      # list probes $all  
list spec_list probes selector_list  # list name probes file=test.c  
list values spec_list                 # list values keys given in spec_list
```

```
list tracefile          # list tracefile
```

The first two commands list the selected attributes and values of the specified probes. They can be used to check the state of a probe. The third command lists the various values associated with the selected attributes. The fourth command lists the current tracefile.

#### 8. Help Command

```
help topic
```

To get a list of the help topics that are available, invoke the `help` command with no arguments. If a *topic* argument is specified, help is printed for that topic.

#### 9. Source a File

```
source filename
```

The `source` command can be used to source a file of `prex` commands. `source` can be nested (that is, a file can source another file). *filename* is a quoted string.

#### 10. Process Control

```
continue          # resumes the target process
quit kill         # quit prex, kill target
quit resume      # quit prex, continue target
quit suspend     # quit prex, leave target suspended
quit             # quit prex (continue or kill target)
```

The default `quit` will continue the target process if `prex` attached to it. Instead, if `prex` had started the target program, `quit` will kill the target process.

#### dlopen'ed Libraries

Probes in shared objects that are brought in by `dlopen(3C)` are automatically set up according to the command history of `prex`. When a shared object is removed by a `dldclose(3C)`, `prex` again needs to refresh its understanding of the probes in the target program. This implies that there is more work to do for `dlopen(3C)` and `dldclose(3C)`—so they will take slightly longer. If a user is not interested in this feature and doesn't want to interfere with `dlopen(3C)` and `dldclose(3C)`, detach `prex` from the target to inhibit this feature.

#### Signals to Target Program

`prex` does not interfere with signals that are delivered directly to the target program. However, `prex` receives all signals normally generated from the terminal, for example, Control-C (`SIGINT`), and Control-Z (`SIGSTOP`), and does not forward them to the target program. To signal the target program, use the `kill(1)` command from a shell.

#### Interactions with Other Applications

Process managing applications like `dbx`, `truss(1)`, and `prex` cannot operate on the same target program simultaneously. `prex` will not be able to attach to a target which is being controlled by another application. A user can trace and debug a program serially by the following method: first attach `prex` to target (or start target through `prex`), set up the probes using the command language, and then type `quit`

prex(1)

|                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                            | <p>suspend. The user can then attach <code>dbx</code> to the suspended process and debug it. A user can also suspend the target by sending it a <code>SIGSTOP</code> signal, and then by typing <code>quit</code> resume to <code>prex</code>. In this case, the user should also send a <code>SIGCONT</code> signal after invoking <code>dbx</code> on the stopped process (else <code>dbx</code> will be hung).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Failure of Event Writing Operations</b> | <p>There are a few failure points that are possible when writing out events to a trace file, for example, system call failures. These failures result in a failure code being set in the target process. The target process continues normally, but no trace records are written. Whenever a user enters Control-C to <code>prex</code> to get to a <code>prex</code> prompt, <code>prex</code> will check the failure code in the target and inform the user if there was a tracing failure.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Target Executing a Fork or exec</b>     | <p>If the target program does a <code>fork(2)</code>, any probes that the child encounters will cause events to be logged to the same trace file. Events are annotated with a process id, so it will be possible to determine which process a particular event came from. In multi-threaded programs, there is a race condition with a thread doing a <code>fork</code> while the other threads are still running. For the trace file not to get corrupted, the user should either use <code>fork1(2)</code>, or make sure that all other threads are quiescent when doing a <code>fork(2)</code>.</p> <p>If the target program itself (not any children it may <code>fork(2)</code>) does an <code>exec(2)</code>, <code>prex</code> detaches from the target and exits. The user can reconnect <code>prex</code> with <code>prex -p pid</code>.</p> <p>A <code>vfork(2)</code> is generally followed quickly by an <code>exec(2)</code> in the child, and in the interim, the child borrows the parent's process while the parent waits for the <code>exec(2)</code>. Any events logged by the child from the parent process will appear to have been logged by the parent.</p>                                                                                                                                       |
| <b>Kernel Mode</b>                         | <p>Invoking <code>prex</code> with the <code>-k</code> flag causes <code>prex</code> to run in kernel mode. In kernel mode, <code>prex</code> controls probes in the Solaris kernel. See <code>tnf_kernel_probes(4)</code> for a list of available probes in the Solaris kernel. A few <code>prex</code> commands are unavailable in kernel mode; many other commands are valid in kernel mode only.</p> <p>The <code>-l</code>, <code>-o</code>, and <code>-p</code> command-line options are not valid in kernel mode (that is, they may not be combined with the <code>-k</code> flag).</p> <p>The rest of this section describes the differences in the <code>prex</code> command language when running <code>prex</code> in kernel mode.</p> <ol style="list-style-type: none"><li><code>prex</code> will not stop the kernel</li></ol> <p>When <code>prex</code> attaches to a running user program, it stops the user program. Obviously, it cannot do this when attaching to the kernel. Instead, <code>prex</code> provides a "tracing master switch": no probes will have any effect unless the tracing master switch is on. This allows the user to iteratively select probes to enable, then enable them all at once by turning on the master switch.</p> <p>The command</p> <pre>ktrace [ on   off ]</pre> |

is used to inspect and set the value of the master switch. Without an argument, `prex` reports the current state of the master switch.

Since `prex` will not stop or kill the kernel, the

```
quit resume
```

and

```
quit kill
```

commands are not valid in kernel mode.

2. No functions may be attached to probes in the kernel

In particular, the `debug` function is unavailable in kernel mode.

3. Trace output is written to an in-core buffer

In kernel mode, a trace output file is not generated directly, in order to allow probes to be placed in time-critical code. Instead, trace output is written to an in-core buffer, and copied out by a separate program, `tnfextract(1)`.

The in-core buffer is not automatically created. The following `prex` command controls buffer allocation and deallocation:

```
buffer [ alloc [ size ] | dealloc ]
```

Without an argument, the `buffer` command reports the size of the currently allocated buffer, if any. With an argument of `alloc [size]`, `prex` allocates a buffer of the given size. *size* is in bytes, with an optional suffix of 'k' or 'm' specifying a multiplier of 1024 or 1048576, respectively. If no *size* is specified, the *size* specified on the command line with the `-s` option is used as a default. If the `-s` command line option was not used, the "default default" is 384 kilobytes.

With an argument of `dealloc`, `prex` deallocates the trace buffer in the kernel.

`prex` will reject attempts to turn the tracing master switch on when no buffer is allocated, and to deallocate the buffer when the tracing master switch is on. `prex` will refuse to allocate a buffer when one is already allocated; use `buffer dealloc` first.

`prex` will not allocate a buffer larger than one-half of a machine's physical memory.

4. `prex` supports per-process probe enabling in the kernel

In kernel mode, it is possible to select a set of processes for which probes are enabled. No trace output will be written when other processes traverse these probe points. This is called "process filter mode". By default, process filter mode is off, and all processes cause the generation of trace records when they hit an enabled probe.

prex(1)

Some kernel events such as interrupts cannot be associated with a particular user process. By convention, these events are considered to be generated by process id 0.

`prex` provides commands to turn process filter mode on and off, to get the current status of the process filter mode switch, to add and delete processes (by process id) from the process filter set, and to list the current process filter set.

The process filter set is maintained even when process filter mode is off, but has no effect unless process filter mode is on.

When a process in the process filter set exits, its process id is automatically deleted from the process filter set.

The command:

```
pfilter [ on | off | add pidlist | delete pidlist ]
```

controls the process filter switch, and process filter set membership. With no arguments, `pfilter` prints the current process filter set and the state of the process filter mode switch:

`on` or `off`            set the state of the process filter mode switch.

`add pidlist`

`delete pidlist`        add or delete processes from the process filter set. `pidlist` is a comma-separated list of one or more process ids.

**EXAMPLES** See `tracing(3TNF)` for complete examples showing, among other things, the use of `prex` to do simple probe control.

When either the process or kernel is started, all probes are disabled.

#### **EXAMPLE 1** Set creation and set listing

```
create $out name=/out/        # $out = probes with "out" in
                                 # value of "name" attribute
create $foo /page/ name=biodone # $foo = union of
         # probes with "page" in value of keys attribute
         # probes with "biodone" as value of "name" attribute
list sets                      # list the defined sets
list fcns                      # list the defined probe fcns
```

#### **EXAMPLE 2** Commands to trace and connect probe functions

```
trace foobar='on'            # exact match on foobar attribute
trace $all                    # trace all probes (predefined set $all)
connect &debug $foo          # connect debug func to probes in $foo
```

#### **EXAMPLE 3** Commands to enable and disable probes

```
enable $all                   # enable all probes
enable /vm/ name=alloc        # enable the specified probes
disable $foo                  # disable probes in set $foo
```

**EXAMPLE 3** Commands to enable and disable probes *(Continued)*

```
list history          # list probe control commands issued
```

**EXAMPLE 4** Process control

```
continue             # resumes the target process
^C                   # stop target; give control to prex
quit resume          # exit prex, leave process running
                    # and resume execution of program
```

**EXAMPLE 5** Kernel mode

```
buffer alloc 2m     # allocate a 2 Megabyte buffer
enable $all         # enable all probes
trace $all          # trace all probes
ktrace on           # turn tracing on
ktrace off          # turn tracing back off
pfilter on          # turn process filter mode on
pfilter add 1379    # add pid 1379 to process filter
ktrace on           # turn tracing on
                    # (only pid 1379 will be traced)
```

**FILES**

```
.prexrc             local prex initialization file
~/ .prexrc          user's prex initialization file
/proc/nnnnn        process files
```

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWtnfc        |

**SEE ALSO** [ed\(1\)](#), [kill\(1\)](#), [ksh\(1\)](#), [ld\(1\)](#), [tnfdump\(1\)](#), [tnfextract\(1\)](#), [truss\(1\)](#), [exec\(2\)](#), [fork\(2\)](#), [fork1\(2\)](#), [vfork\(2\)](#), [TNF\\_DECLARE\\_RECORD\(3TNF\)](#), [TNF\\_PROBE\(3TNF\)](#), [dlclose\(3C\)](#), [dlopen\(3C\)](#), [gethrtime\(3C\)](#), [libtnfctl\(3TNF\)](#), [tnf\\_process\\_disable\(3TNF\)](#), [tracing\(3TNF\)](#), [tnf\\_kernel\\_probes\(4\)](#), [attributes\(5\)](#)

**NOTES** Currently, the only probe function that is available is the `&debug` function. When this function is executed, it prints out the arguments sent in to the probe as well as the value associated with the `sunw%debug` attribute in the detail field (if any) to `stderr`.

For example, for the following probe point:

```
TNF_PROBE_2(input_values, "testapp main",
            "sunw%debug 'have read input values successfully'",
            tnf_long, int_input, x,
            tnf_string, string_input, input);
```

prex(1)

If *x* was 100 and *input* was the string "success", then the output of the debug probe function would be:

```
probe input_values; sunw%debug "have read input values successfully";
int_input=100; string_input="success";
```

Some non-SPARC hardware lacks a true high-resolution timer, causing `gethrtime()` to return the same value multiple times in succession. This can lead to problems in how some tools interpret the trace file. This situation can be improved by interposing a version of `gethrtime()`, which causes these successive values to be artificially incremented by one nanosecond:

```
hrtime_t
gethrtime()
{
    static mutex_t lock;
    static hrtime_t (*real_gethrtime)(void) = NULL;
    static hrtime_t last_time = 0;

    hrtime_t this_time;

    if (real_gethrtime == NULL) {
        real_gethrtime =
            (hrtime_t (*)(void)) dlsym(RTLD_NEXT, "gethrtime");
    }
    this_time = real_gethrtime();

    mutex_lock(&lock);
    if (this_time <= last_time)
        this_time = ++last_time;
    else
        last_time = this_time;
    mutex_unlock(&lock);

    return (this_time);
}
```

Of course, this does not increase the resolution of the timer, so timestamps for individual events are still relatively inaccurate. But this technique maintains ordering, so that if event A causes event B, B never appears to happen before or at the same time as A.

dbx is available with the Sun Workshop Products.

**BUGS** prex should issue a notification when a process id has been automatically deleted from the filter set.

There is a known bug in prex which can result in this message:

```
Tracing shut down in target program due to an internal
error - Please restart prex and target
```

When prex runs as root, and the target process is not root, and the tracefile is placed in a directory where it cannot be removed and re-created (a directory with the sticky bit on, like /tmp),mm then the target process will not be able to open the tracefile when it needs to. This results in tracing being disabled.

prex(1)

Changing any of the circumstances listed above should fix the problem. Either don't run `prex` as root, or run the target process as root, or specify the tracefile in a directory other than `/tmp`.

## print(1)

| <b>NAME</b>        | print – shell built-in function to output characters to the screen or window                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |              |         |

| <b>ksh</b>         | The shell output mechanism. With no flags or with flag <code>-</code> or <code>-</code> , the arguments are printed on standard output as described by <a href="#">echo(1)</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |         |
| <b>OPTIONS</b>     | The following options are supported:<br><br>-n                    suppresses new-line from being added to the output.<br>-R<br>-r                    (raw mode) ignore the escape conventions of <code>echo</code> . The <code>-R</code> option will print all subsequent arguments and options other than <code>-n</code> .<br>-p                    causes the arguments to be written onto the pipe of the process spawned with <code>  &amp;</code> instead of standard output.<br>-s                    causes the arguments to be written onto the history file instead of standard output.<br>-u [ <i>n</i> ]                flag can be used to specify a one digit file descriptor unit number <i>n</i> on which the output will be placed. The default is 1. |                |                 |              |         |
| <b>EXIT STATUS</b> | The following exit values are returned:<br><br>0                    Successful operation.<br>>0                    Output file is not open for writing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |              |         |

| <b>SYNOPSIS</b>    | <code>/usr/ucb/printenv</code> [ <i>variable</i> ]                                                                                                                           |                |                 |              |          |
| <b>DESCRIPTION</b> | printenv prints out the values of the variables in the environment. If a <i>variable</i> is specified, only its value is printed.                                            |                |                 |              |          |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                 |                |                 |              |          |

| <b>NAME</b>        | printf – write formatted output                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>    | <b>printf</b> <i>format</i> [ <i>argument...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | The <code>printf</code> command writes formatted operands to the standard output. The <i>argument</i> operands are formatted under control of the <i>format</i> operand.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><i>format</i></p> <p>A string describing the format to use to write the remaining operands. The <i>format</i> operand is used as the <i>format</i> string described on the <code>formats(5)</code> manual page, with the following exceptions:</p> <ul style="list-style-type: none"><li>■ A <code>SPACE</code> character in the format string, in any context other than a flag of a conversion specification, is treated as an ordinary character that is copied to the output.</li><li>■ A character in the format string is treated as a <code>SPACE</code> character.</li><li>■ In addition to the escape sequences described on the <code>formats(5)</code> manual page (<code>\\</code>, <code>\a</code>, <code>\b</code>, <code>\f</code>, <code>\n</code>, <code>\r</code>, <code>\t</code>, <code>\v</code>), <code>\ddd</code>, where <i>ddd</i> is a one-, two- or three-digit octal number, is written as a byte with the numeric value specified by the octal number.</li><li>■ The program does not precede or follow output from the <code>d</code> or <code>u</code> conversion specifications with blank characters not specified by the <i>format</i> operand.</li><li>■ The program does not precede output from the <code>o</code> conversion specification with zeros not specified by the <i>format</i> operand.</li><li>■ An additional conversion character, <code>b</code>, is supported as follows. The argument is taken to be a string that may contain backslash-escape sequences. The following backslash-escape sequences are supported:<ul style="list-style-type: none"><li>– the escape sequences listed on the <code>formats(5)</code> manual page (<code>\\</code>, <code>\a</code>, <code>\b</code>, <code>\f</code>, <code>\n</code>, <code>\r</code>, <code>\t</code>, <code>\v</code>), which are converted to the characters they represent</li><li>– <code>\0ddd</code>, where <i>ddd</i> is a zero-, one-, two- or three-digit octal number that is converted to a byte with the numeric value specified by the octal number</li><li>– <code>\c</code>, which is written and causes <code>printf</code> to ignore any remaining characters in the string operand containing it, any remaining string operands and any additional characters in the <i>format</i> operand.</li></ul></li></ul> <p>The interpretation of a backslash followed by any other sequence of characters is unspecified.</p> |

printf(1)

Bytes from the converted string are written until the end of the string or the number of bytes indicated by the precision specification is reached. If the precision is omitted, it is taken to be infinite, so all bytes up to the end of the converted string are written. For each specification that consumes an argument, the next argument operand is evaluated and converted to the appropriate type for the conversion as specified below. The *format* operand is reused as often as necessary to satisfy the argument operands. Any extra *c* or *s* conversion specifications are evaluated as if a null string argument were supplied; other extra conversion specifications are evaluated as if a zero argument were supplied. If the *format* operand contains no conversion specifications and *argument* operands are present, the results are unspecified. If a character sequence in the *format* operand begins with a % character, but does not form a valid conversion specification, the behavior is unspecified.

*argument*

The strings to be written to standard output, under the control of *format*. The *argument* operands are treated as strings if the corresponding conversion character is *b*, *c* or *s*. Otherwise, it is evaluated as a C constant, as described by the ISO C standard, with the following extensions:

- A leading plus or minus sign is allowed.
- If the leading character is a single- or double-quote, the value is the numeric value in the underlying codeset of the character following the single- or double-quote.

If an argument operand cannot be completely converted into an internal value appropriate to the corresponding conversion specification, a diagnostic message is written to standard error and the utility does not exit with a zero exit status, but continues processing any remaining operands and writes the value accumulated at the time the error was detected to standard output.

**USAGE** Notice that this `printf` utility, like the `printf(3C)` function on which it is based, makes no special provision for dealing with multi-byte characters when using the `%c` conversion specification or when a precision is specified in a `%b` or `%s` conversion specification. Applications should be extremely cautious using either of these features when there are multi-byte characters in the character set.

Field widths and precisions cannot be specified as `*`.

For compatibility with previous versions of SunOS 5.x, the `§` format specifier is supported for formats containing *only* `%s` specifiers.

## printf(1)

The `%b` conversion specification is not part of the ISO C standard; it has been added here as a portable way to process backslash escapes expanded in string operands as provided by the `echo` utility. See also the USAGE section of the `echo(1)` manual page for ways to use `printf` as a replacement for all of the traditional versions of the `echo` utility.

If an argument cannot be parsed correctly for the corresponding conversion specification, the `printf` utility reports an error. Thus, overflow and extraneous characters at the end of an argument being used for a numeric conversion are to be reported as errors.

It is not considered an error if an argument operand is not completely used for a `c` or `s` conversion or if a string operand's first or second character is used to get the numeric value of a character.

### EXAMPLES

#### EXAMPLE 1 Printing a series of prompts

To alert the user and then print and read a series of prompts:

```
example% printf "\aPlease fill in the following: \nName: "
read name
printf "Phone number: "
read phone
```

#### EXAMPLE 2 Printing a table of calculations

To read out a list of right and wrong answers from a file, calculate the percentage correctly, and print them out. The numbers are right-justified and separated by a single tab character. The percentage is written to one decimal place of accuracy:

```
example% while read right wrong ; do
    percent=$(echo "scale=1; ($right*100)/($right+$wrong)" | bc)
    printf "%2d right\t%2d wrong\t(%%s%%)\n" \
        $right $wrong $percent
done < database_file
```

#### EXAMPLE 3 Printing number strings

The command:

```
example% printf "%5d%4d\n" 1 21 321 4321 54321
```

produces:

```
      1  21
     321 4321
    54321  0
```

Notice that the *format* operand is used three times to print all of the given strings and that a 0 was supplied by `printf` to satisfy the last `%4d` conversion specification.

**EXAMPLE 4** Tabulating conversion errors

The `printf` utility tells the user when conversion errors are detected while producing numeric output; thus, the following results would be expected on an implementation with 32-bit twos-complement integers when `%d` is specified as the *format* operand:

| Arguments  | Standard    | Diagnostic                            |
|------------|-------------|---------------------------------------|
| 5a         | 5           | printf: 5a not completely converted   |
| 999999999  | 2147483647  | printf: 999999999: Results too large  |
| -999999999 | -2147483648 | printf: -999999999: Results too large |
| ABC        | 0           | printf: ABC expected numeric value    |

Notice that the value shown on standard output is what would be expected as the return value from the function `strtoul(3C)`. A similar correspondence exists between `%u` and `strtoul(3C)`, and `%e`, `%f` and `%g` and `strtod(3C)`.

**EXAMPLE 5** Printing output for a specific locale

In a locale using the ISO/IEC 646:1991 standard as the underlying codeset, the command:

```
example% printf "%d\n" 3 +3 -3 \'3 \'+3 "'-3"
```

produces:

|    |                                                                             |
|----|-----------------------------------------------------------------------------|
| 3  | Numeric value of constant 3                                                 |
| 3  | Numeric value of constant 3                                                 |
| -3 | Numeric value of constant -3                                                |
| 51 | Numeric value of the character '3' in the ISO/IEC 646:1991 standard codeset |
| 43 | Numeric value of the character '+' in the ISO/IEC 646:1991 standard codeset |
| 45 | Numeric value of the character '-' in the SO/IEC 646:1991 standard codeset  |

Notice that in a locale with multi-byte characters, the value of a character is intended to be the value of the equivalent of the `wchar_t` representation of the character.

If an argument operand cannot be completely converted into an internal value appropriate to the corresponding conversion specification, a diagnostic message is written to standard error and the utility does exit with a zero exit status, but continues processing any remaining operands and writes the value accumulated at the time the error was detected to standard output.

printf(1)

**ENVIRONMENT VARIABLES**

See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `printf`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, `LC_NUMERIC`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**ATTRIBUTES**

See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWloc         |
| CSI                 | enabled         |
| Interface Stability | Standard        |

| <b>NAME</b>        | prioctl – display or set scheduling parameters of specified process(es)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>    | <pre>prioctl -l prioctl -d [-i <i>idtype</i>] [<i>idlist</i>] prioctl -s [-c <i>class</i>] [<i>class-specific options</i>] [-i <i>idtype</i>] [<i>idlist</i>] prioctl -e [-c <i>class</i>] [<i>class-specific options</i>] <i>command</i> [<i>argument(s)</i>]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>The <code>prioctl</code> command displays or sets scheduling parameters of the specified process(es). It can also be used to display the current configuration information for the system's process scheduler or execute a command with specified scheduling parameters.</p> <p>Processes fall into distinct classes with a separate scheduling policy applied to each class. The process classes currently supported are the real-time class, time-sharing class, interactive class, fair-share class, and the fixed priority class. The characteristics of these classes and the class-specific options they accept are described below in the USAGE section under the headings Real-Time Class, Time-Sharing Class, Inter-Active Class, Fair-Share Class, and Fixed-Priority Class. With appropriate permissions, the <code>prioctl</code> command can change the class and other scheduling parameters associated with a running process.</p> <p>In the default configuration, a runnable real-time process runs before any other process. Therefore, inappropriate use of real-time processes can have a dramatic negative impact on system performance.</p> <p>If an <i>idlist</i> is present, it must appear last on the command line and the elements of the list must be separated by white space. If no <i>idlist</i> is present, an <i>idtype</i> argument of <code>pid</code>, <code>ppid</code>, <code>pgid</code>, <code>sid</code>, <code>taskid</code>, <code>class</code>, <code>uid</code>, <code>gid</code>, <code>projid</code>, or <code>zoneid</code> specifies the process ID, parent process ID, process group ID, session ID, task ID, class, user ID, group ID, project ID, or zone ID, respectively, of the <code>prioctl</code> command itself.</p> <p>The command</p> <pre>prioctl -d [-i <i>idtype</i>] [<i>idlist</i>]</pre> <p>displays the class and class-specific scheduling parameters of the process(es) specified by <i>idtype</i> and <i>idlist</i>.</p> <p>The command</p> <pre>prioctl -s [-c <i>class</i>] [<i>class-specific options</i>] \       [-i <i>idtype</i>] [<i>idlist</i>]</pre> <p>sets the class and class-specific parameters of the specified processes to the values given on the command line. The <code>-c class</code> option specifies the class to be set. (The valid <i>class</i> arguments are RT for real-time, TS for time-sharing, IA for inter-active, FSS for fair-share, or FX for fixed-priority.)</p> <p>The class-specific parameters to be set are specified by the class-specific options as explained under the appropriate heading below. If the <code>-c class</code> option is omitted, <i>idtype</i> and <i>idlist</i> must specify a set of processes which are all in the same class, otherwise an</p> |

## priocntl(1)

error results. If no class-specific options are specified, the process's class-specific parameters are set to the default values for the class specified by `-c class` (or to the default parameter values for the process's current class if the `-c class` option is also omitted).

In order to change the scheduling parameters of a process using `priocntl` the real or effective user ID (respectively, groupID) of the user invoking `priocntl` must match the real or effective user ID (respectively, groupID) of the receiving process or the effective user ID of the user must be super-user. These are the minimum permission requirements enforced for all classes. An individual class can impose additional permissions requirements when setting processes to that class or when setting class-specific scheduling parameters.

When `idtype` and `idlist` specify a set of processes, `priocntl` acts on the processes in the set in an implementation-specific order. If `priocntl` encounters an error for one or more of the target processes, it can or cannot continue through the set of processes, depending on the nature of the error.

If the error is related to permissions, `priocntl` prints an error message and then continues through the process set, resetting the parameters for all target processes for which the user has appropriate permissions. If `priocntl` encounters an error other than permissions, it does not continue through the process set but prints an error message and exits immediately.

A special `sys` scheduling class exists for the purpose of scheduling the execution of certain special system processes (such as the swapper process). It is not possible to change the class of any process to `sys`. In addition, any processes in the `sys` class that are included in the set of processes specified by `idtype` and `idlist` are disregarded by `priocntl`. For example, if `idtype` were `uid`, an `idlist` consisting of a zero would specify all processes with a UID of 0, except processes in the `sys` class and (if changing the parameters using the `-s` option) the `init` process.

The `init` process (process ID 1) is a special case. In order for the `priocntl` command to change the class or other scheduling parameters of the `init` process, `idtype` must be `pid` and `idlist` must consist of only a 1. The `init` process can be assigned to any class configured on the system, but the time-sharing class is almost always the appropriate choice. Other choices can be highly undesirable; see the *System Administration Guide: Basic Administration* for more information.

The command

```
priocntl -e [-c class] [class-specific options] command \
[argument...]
```

executes the specified command with the class and scheduling parameters specified on the command line (*arguments* are the arguments to the command). If the `-c class` option is omitted the command is run in the user's current class.

**OPTIONS** The following options are supported:

`-c class` Specifies the *class* to be set. (The valid *class* arguments are RT for real-time, TS for time-sharing, IA for inter-active, FSS for

fair-share, or FX for fixed-priority.) If the specified class is not already configured, it is automatically configured.

- d Displays the scheduling parameters associated with a set of processes.
- e Executes a specified command with the class and scheduling parameters associated with a set of processes.
- i *idtype* This option, together with the *idlist* arguments (if any), specifies one or more processes to which the `prioctl` command is to apply. The interpretation of *idlist* depends on the value of *idtype*. If the `-i idtype` option is omitted when using the `-d` or `-s` options the default *idtype* of `pid` is assumed.

The valid *idtype* arguments and corresponding interpretations of *idlist* are as follows:

- i all The `prioctl` command applies to all existing processes. No *idlist* should be specified (if one is specified, it is ignored). The permission restrictions described below still apply.
- i ctid *idlist* is a list of process contract IDs. The `prioctl` command applies to all processes with a process contract ID equal to an ID from the list.
- i class *idlist* consists of a single class name (RT for real-time, TS for time-sharing, IA for inter-active, FSS for fair-share, or FX for fixed-priority). The `prioctl` command applies to all processes in the specified class.
- i gid *idlist* is a list of group IDs. The `prioctl` command applies to all processes with an effective group ID equal to an ID from the list.
- i pgid *idlist* is a list of process group IDs. The `prioctl` command applies to all processes in the specified process groups.
- i pid *idlist* is a list of process IDs. The `prioctl` command applies to the specified processes.
- i ppid *idlist* is a list of parent process IDs. The `prioctl` command applies to all processes whose parent process ID is in the list.

## priocntl(1)

|           |                                                                                                                                                                                                                    |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -i projid | <i>idlist</i> is a list of project IDs. The <code>priocntl</code> command applies to all processes with an effective project ID equal to an ID from the list.                                                      |
| -i sid    | <i>idlist</i> is a list of session IDs. The <code>priocntl</code> command applies to all processes in the specified sessions.                                                                                      |
| -i taskid | <i>idlist</i> is a list of task IDs. The <code>priocntl</code> command applies to all processes in the specified tasks.                                                                                            |
| -i uid    | <i>idlist</i> is a list of user IDs. The <code>priocntl</code> command applies to all processes with an effective user ID equal to an ID from the list.                                                            |
| -i zoneid | <i>idlist</i> is a list of zone IDs. The <code>priocntl</code> command applies to all processes with an effective zone ID equal to an ID from the list.                                                            |
| -l        | Displays a list of the classes currently configured in the system along with class-specific information about each class. The format of the class-specific information displayed is described under <b>USAGE</b> . |
| -s        | Sets the scheduling parameters associated with a set of processes.                                                                                                                                                 |

The valid class-specific options for setting real-time parameters are:

|                                  |                                                                                                                                  |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| -p <i>rtpri</i>                  | Sets the real-time priority of the specified process(es) to <i>rtpri</i> .                                                       |
| -t <i>tqntm</i> [-r <i>res</i> ] | Sets the time quantum of the specified process(es) to <i>tqntm</i> . You can optionally specify a resolution as explained below. |
| -q <i>tqsig</i>                  | Sets the real-time time quantum signal of the specified process(es) to <i>tqsig</i> .                                            |

The valid class-specific options for setting time-sharing parameters are:

|                     |                                                                                 |
|---------------------|---------------------------------------------------------------------------------|
| -m <i>tsuprilim</i> | Sets the user priority limit of the specified process(es) to <i>tsuprilim</i> . |
| -p <i>tsupri</i>    | Sets the user priority of the specified process(es) to <i>tsupri</i> .          |

The valid class-specific options for setting inter-active parameters are:

|                     |                                                                                 |
|---------------------|---------------------------------------------------------------------------------|
| -m <i>iauprilim</i> | Sets the user priority limit of the specified process(es) to <i>iauprilim</i> . |
| -p <i>iaupri</i>    | Sets the user priority of the specified process(es) to <i>iaupri</i> .          |

The valid class-specific options for setting fair-share parameters are:

|                      |                                                                                  |
|----------------------|----------------------------------------------------------------------------------|
| -m <i>fssuprilim</i> | Sets the user priority limit of the specified process(es) to <i>fssuprilim</i> . |
|----------------------|----------------------------------------------------------------------------------|

`-p fssupri` Sets the user priority of the specified process(es) to *fssupri*.

The valid class-specific options for setting fixed-priority parameters are:

`-m fxuprilm` Sets the user priority limit of the specified process(es) to *fxuprilm*.

`-p fxupri` Sets the user priority of the specified process(es) to *fxupri*.

`-t tqntm` [`-r res`] Sets the time quantum of the specified process(es) to *tqntm*. You can optionally specify a resolution as explained below.

## USAGE

### Real-Time Class

The real-time class provides a fixed priority preemptive scheduling policy for those processes requiring fast and deterministic response and absolute user/application control of scheduling priorities. If the real-time class is configured in the system, it should have exclusive control of the highest range of scheduling priorities on the system. This ensures that a runnable real-time process is given CPU service before any process belonging to any other class.

The real-time class has a range of real-time priority (*rtpri*) values that can be assigned to processes within the class. Real-time priorities range from 0 to *x*, where the value of *x* is configurable and can be displayed for a specific installation that has already configured a real-time scheduler, by using the command

```
prioctl -l
```

The real-time scheduling policy is a fixed priority policy. The scheduling priority of a real-time process never changes except as the result of an explicit request by the user/application to change the *rtpri* value of the process.

For processes in the real-time class, the *rtpri* value is, for all practical purposes, equivalent to the scheduling priority of the process. The *rtpri* value completely determines the scheduling priority of a real-time process relative to other processes within its class. Numerically higher *rtpri* values represent higher priorities. Since the real-time class controls the highest range of scheduling priorities in the system, it is guaranteed that the runnable real-time process with the highest *rtpri* value is always selected to run before any other process in the system.

In addition to providing control over priority, `prioctl` provides for control over the length of the time quantum allotted to processes in the real-time class. The time quantum value specifies the maximum amount of time a process can run, assuming that it does not complete or enter a resource or event wait state (`sleep`). Notice that if another process becomes runnable at a higher priority, the currently running process can be preempted before receiving its full time quantum.

The command

```
prioctl -d [-i idtype] [idlist]
```

## priocntl(1)

displays the real-time priority, time quantum (in millisecond resolution), and time quantum signal value for each real-time process in the set specified by *idtype* and *idlist*.

Any combination of the `-p`, `-t [-r]`, and `-q` options can be used with `priocntl -s` or `priocntl -e` for the real-time class. If an option is omitted and the process is currently real-time, the associated parameter is unaffected. If an option is omitted when changing the class of a process to real-time from some other class, the associated parameter is set to a default value. The default value for *rtpri* is 0 and the default for time quantum is dependent on the value of *rtpri* and on the system configuration; see `rt_dptbl(4)`.

When using the `-t tqntm` option, you can optionally specify a resolution using the `-r res` option. (If no resolution is specified, millisecond resolution is assumed.) If *res* is specified, it must be a positive integer between 1 and 1,000,000,000 inclusively and the resolution used is the reciprocal of *res* in seconds. For example, specifying `-t 10 -r 100` would set the resolution to hundredths of a second and the resulting time quantum length would be 10/100 seconds (one tenth of a second). Although very fine (nanosecond) resolution can be specified, the time quantum length is rounded up by the system to the next integral multiple of the system clock's resolution. Requests for time quantum of zero or quantum greater than the (typically very large) implementation-specific maximum quantum result in an error.

The real-time time quantum signal can be used to notify runaway real-time processes about the consumption of their time quantum. Those processes, which are monitored by the real-time time quantum signal, receive the configured signal in the event of time quantum expiration. The default value (0) of the time quantum signal *tqsig* denotes no signal delivery. A positive value denotes the delivery of the signal specified by the value. Like `kill(1)` and other commands operating on signals, the `-q tqsig` option is also able to handle symbolically named signals, like XCPU or KILL.

In order to change the class of a process to real-time (from any other class), the user invoking `priocntl` must have super-user privilege. In order to change the *rtpri* value or time quantum of a real-time process, the user invoking `priocntl` must either be super-user, or must currently be in the real-time class (shell running as a real-time process) with a real or effective user ID matching the real or effective user ID of the target process.

The real-time priority, time quantum, and time quantum signal are inherited across the `fork(2)` and `exec(2)` system calls. When using the time quantum signal with a user defined signal handler across the `exec(2)` system call, the new image must install an appropriate user defined signal handler before the time quantum expires. Otherwise, unpredictable behavior would result.

### Time-Sharing Class

The time-sharing scheduling policy provides for a fair and effective allocation of the CPU resource among processes with varying CPU consumption characteristics. The objectives of the time-sharing policy are to provide good response time to interactive processes and good throughput to CPU-bound jobs, while providing a degree of user/application control over scheduling.

The time-sharing class has a range of time-sharing user priority (*tsupri*) values that can be assigned to processes within the class. User priorities range from  $-x$  to  $+x$ , where the value of  $x$  is configurable. The range for a specific installation can be displayed by using the command

```
prioctl -l
```

The purpose of the user priority is to provide some degree of user/application control over the scheduling of processes in the time-sharing class. Raising or lowering the *tsupri* value of a process in the time-sharing class raises or lowers the scheduling priority of the process. It is not guaranteed, however, that a time-sharing process with a higher *tsupri* value runs before one with a lower *tsupri* value. This is because the *tsupri* value is just one factor used to determine the scheduling priority of a time-sharing process. The system can dynamically adjust the internal scheduling priority of a time-sharing process based on other factors such as recent CPU usage.

In addition to the system-wide limits on user priority (displayed with `prioctl -l`), there is a per process user priority limit (*tsuprilim*), which specifies the maximum *tsupri* value that can be set for a given process.

The command

```
prioctl -d [-i idtype] [idlist]
```

displays the user priority and user priority limit for each time-sharing process in the set specified by *idtype* and *idlist*.

Any time-sharing process can lower its own *tsuprilim* (or that of another process with the same user ID). Only a time-sharing process with super-user privilege can raise a *tsuprilim*. When changing the class of a process to time-sharing from some other class, super-user privilege is required in order to set the initial *tsuprilim* to a value greater than zero.

Any time-sharing process can set its own *tsupri* (or that of another process with the same user ID) to any value less than or equal to the process's *tsuprilim*. Attempts to set the *tsupri* above the *tsuprilim* (and/or set the *tsuprilim* below the *tsupri*) result in the *tsupri* being set equal to the *tsuprilim*.

Any combination of the `-m` and `-p` options can be used with `prioctl -s` or `prioctl -e` for the time-sharing class. If an option is omitted and the process is currently time-sharing, the associated parameter is normally unaffected. The exception is when the `-p` option is omitted and `-m` is used to set a *tsuprilim* below the current *tsupri*. In this case, the *tsupri* is set equal to the *tsuprilim* which is being set. If an option is omitted when changing the class of a process to time-sharing from some other class, the associated parameter is set to a default value. The default value for *tsuprilim* is 0 and the default for *tsupri* is to set it equal to the *tsuprilim* value which is being set.

The time-sharing user priority and user priority limit are inherited across the `fork(2)` and `exec(2)` system calls.

prionctl(1)

**Inter-Active Class**

The inter-active scheduling policy provides for a fair and effective allocation of the CPU resource among processes with varying CPU consumption characteristics while providing good responsiveness for user interaction. The objectives of the inter-active policy are to provide good response time to interactive processes and good throughput to CPU-bound jobs. The priorities of processes in the inter-active class can be changed in the same manner as those in the time-sharing class, though the modified priorities continue to be adjusted to provide good responsiveness for user interaction.

The inter-active user priority limit, *iaupri*, is equivalent to *tsupri*. The inter-active per process user priority, *iauprilim*, is equivalent to *tsuprilim*.

Inter-active class processes that have the *iamode* (“interactive mode”) bit set are given a priority boost value of 10, which is factored into the user mode priority of the process when that calculation is made, that is, every time a process’s priority is adjusted. This feature is used by the X windowing system, which sets this bit for those processes that run inside of the current active window to give them a higher priority.

**Fair-Share Class**

The fair-share scheduling policy provides a fair allocation of system CPU resources among projects, independent of the number of processes they own. Projects are given “shares” to control their entitlement to CPU resources. Resource usage is remembered over time, so that entitlement is reduced for heavy usage, and increased for light usage, with respect to other projects. CPU time is scheduled among processes according to their owner’s entitlements, independent of the number of processes each project owns.

The FSS scheduling class supports the notion of per-process user priority and user priority limit for compatibility with the time-share scheduler. The fair share scheduler attempts to provide an evenly graded effect across the whole range of user priorities. Processes with positive *fssupri* values receive time slices less frequently than normal, while negative nice processes receive time slices more frequently than normal. Notice that user priorities do not interfere with shares. That is, changing a *fssupri* value of a process is not going to affect its project’s overall CPU usage which only relates to the amount of shares it is allocated compared to other projects.

The priorities of processes in the fair-share class can be changed in the same manner as those in the time-share class.

**Fixed-Priority Class**

The fixed-priority class provides a fixed priority preemptive scheduling policy for those processes requiring that the scheduling priorities do not get dynamically adjusted by the system and that the user/application have control of the scheduling priorities.

The fixed-priority class shares the same range of scheduling priorities with the time-sharing class, by default. The fixed-priority class has a range of fixed-priority user priority (*fxupri*) values that can be assigned to processes within the class. User priorities range from 0 to *x*, where the value of *x* is configurable. The range for a specific installation can be displayed by using the command

**prioctl -l**

The purpose of the user priority is to provide user/application control over the scheduling of processes in the fixed-priority class. For processes in the fixed-priority class, the *fxupri* value is, for all practical purposes, equivalent to the scheduling priority of the process. The *fxupri* value completely determines the scheduling priority of a fixed-priority process relative to other processes within its class. Numerically higher *fxupri* values represent higher priorities.

In addition to the system-wide limits on user priority (displayed with `prioctl -l`), there is a per process user priority limit (*fxuprilm*), which specifies the maximum *fxupri* value that can be set for a given process.

Any fixed-priority process can lower its own *fxuprilm* (or that of another process with the same user ID). Only a process with super-user privilege can raise a *fxuprilm*. When changing the class of a process to fixed-priority from some other class, super-user privilege is required in order to set the initial *fxuprilm* to a value greater than zero.

Any fixed-priority process can set its own *fxupri* (or that of another process with the same user ID) to any value less than or equal to the process's *fxuprilm*. Attempts to set the *fxupri* above the *fxuprilm* (or set the *fxuprilm* below the *fxupri*) result in the *fxupri* being set equal to the *fxuprilm*.

In addition to providing control over priority, `prioctl` provides for control over the length of the time quantum allotted to processes in the fixed-priority class. The time quantum value specifies the maximum amount of time a process can run, before surrendering the CPU, assuming that it does not complete or enter a resource or event wait state (sleep). Notice that if another process becomes runnable at a higher priority, the currently running process can be preempted before receiving its full time quantum.

Any combination of the `-m`, `-p`, and `-t` options can be used with `prioctl -s` or `prioctl -e` for the fixed-priority class. If an option is omitted and the process is currently fixed-priority, the associated parameter is normally unaffected. The exception is when the `-p` option is omitted and the `-m` option is used to set a *fxuprilm* below the current *fxupri*. In this case, the *fxupri* is set equal to the *fxuprilm* which is being set. If an option is omitted when changing the class of a process to fixed-priority from some other class, the associated parameter is set to a default value. The default value for *fxuprilm* is 0. The default for *fxupri* is to set it equal to the *fxuprilm* value which is being set. The default for time quantum is dependent on the *fxupri* and on the system configuration. See `fx_dptbl(4)`.

The time quantum of processes in the fixed-priority class can be changed in the same manner as those in the real-time class.

The fixed-priority user priority, user priority limit, and time quantum are inherited across the `fork(2)` and `exec(2)` system calls.

prionctl(1)

**EXAMPLES** | The following are real-time class examples:

**EXAMPLE 1** Setting the Class

The following example sets the class of any non-real-time processes selected by *idtype* and *idlist* to real-time and sets their real-time priority to the default value of 0. The real-time priorities of any processes currently in the real-time class are unaffected. The time quantum of all of the specified processes are set to 1/10 seconds.

```
example% prionctl -s -c RT -t 1 -r 10 -i idtype idlist
```

**EXAMPLE 2** Executing a Command in Real-time

The following example executes *command* in the real-time class with a real-time priority of 15 and a time quantum of 20 milliseconds:

```
example% prionctl -e -c RT -p 15 -t 20 command
```

**EXAMPLE 3** Executing a Command in Real-time with a Specified Quantum Signal

The following example executes *command* in the real-time class with a real-time priority of 11, a time quantum of 250 milliseconds, and where the specified real-time quantum signal is SIGXCPU:

```
example% prionctl -e -c RT -p 11 -t 250 -q XCPU command
```

The following are time-sharing class examples:

**EXAMPLE 4** Setting the Class of non-time-sharing Processes

The following example sets the class of any non-time-sharing processes selected by *idtype* and *idlist* to time-sharing and sets both their user priority limit and user priority to 0. Processes already in the time-sharing class are unaffected.

```
example% prionctl -s -c TS -i idtype idlist
```

**EXAMPLE 5** Executing a Command in the Time-sharing Class

The following example executes *command* with the arguments *arguments* in the time-sharing class with a user priority limit of 0 and a user priority of -15:

```
example% prionctl -e -c TS -m 0 -p -15 command [arguments]
```

**EXAMPLE 6** Executing a Command in Fixed-Priority Class

The following example executes a command in the fixed-priority class with a user priority limit of 20 and user priority of 10 and time quantum of 250 milliseconds:

```
example% prionctl -e -c FX -m 20 -p 10 -t 250 command
```

**EXIT STATUS** The following exit values are returned:

For options `-d`, `-l`, and `-s`:

0 Successful operation.

1 Error condition.

For option `-e`:

Return of the Exit Status of the executed command denotes successful operation. Otherwise,

1 Command could not be executed at the specified priority.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | Enabled         |

**SEE ALSO** `kill(1)`, `nice(1)`, `ps(1)`, `exec(2)`, `fork(2)`, `priocntl(2)`, `fx_dptbl(4)`, `process(4)`, `rt_dptbl(4)`, `attributes(5)`, `zones(5)`, `FSS(7)`

*System Administration Guide: Basic Administration*

**DIAGNOSTICS** `priocntl` prints the following error messages:

Process(es) not found

None of the specified processes exists.

Specified processes from different classes

The `-s` option is being used to set parameters, the `-c class` option is not present, and processes from more than one class are specified.

Invalid option or argument

An unrecognized or invalid option or option argument is used.

## proc(1)

| <b>DESCRIPTION</b> | <p>The proc tools are utilities that exercise features of <code>/proc</code> (see <code>proc(4)</code>). Most of them take a list of process-ids (<code>pid</code>). The tools that do take process-ids also accept <code>/proc/nnn</code> as a process-id, so the shell expansion <code>/proc/*</code> can be used to specify all processes in the system.</p> <p>Some of the proc tools can also be applied to core files (see <code>core(4)</code>). The tools that apply to core files accept a list of either process IDs or names of core files or both.</p> <p>Some of the proc tools can operate on individual threads. Users can examine only selected threads by appending <code>/thread-id</code> to the process-id or core. Multiple threads can be selected using the <code>-</code> and <code>,</code> delimiters. For example <code>/1,2,7-9</code> examines threads 1, 2, 7, 8, and 9.</p> <p>See WARNINGS.</p> <table><tr><td>pflags</td><td>Print the <code>/proc</code> tracing flags, the pending and held signals, and other <code>/proc</code> status information for each lwp in each process.</td></tr><tr><td>pcred</td><td>Print or set the credentials (effective, real, saved UIDs and GIDs) of each process.</td></tr><tr><td>pldd</td><td>List the dynamic libraries linked into each process, including shared objects explicitly attached using <code>dlopen(3C)</code>. See also <a href="#">ldd(1)</a>.</td></tr><tr><td>psig</td><td>List the signal actions and handlers of each process. See <code>signal.h(3HEAD)</code>.</td></tr></table> | pflags | Print the <code>/proc</code> tracing flags, the pending and held signals, and other <code>/proc</code> status information for each lwp in each process. | pcred | Print or set the credentials (effective, real, saved UIDs and GIDs) of each process. | pldd | List the dynamic libraries linked into each process, including shared objects explicitly attached using <code>dlopen(3C)</code> . See also <a href="#">ldd(1)</a> . | psig | List the signal actions and handlers of each process. See <code>signal.h(3HEAD)</code> . |

| psig               | List the signal actions and handlers of each process. See <code>signal.h(3HEAD)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |        |                                                                                                                                                         |       |                                                                                      |      |                                                                                                                                                                     |      |                                                                                          |

|                     |                                                                                                                                                                                                                                                                                                                                   |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pstack</code> | Print a hex+symbolic stack trace for each lwp in each process.                                                                                                                                                                                                                                                                    |
| <code>pfiles</code> | Report <code>fstat(2)</code> and <code>fcntl(2)</code> information for all open files in each process. In addition, a path to the file is reported if the information is available from <code>/proc/pid/path</code> . This is not necessarily the same name used to open the file. See <code>proc(4)</code> for more information. |
| <code>pwdx</code>   | Print the current working directory of each process.                                                                                                                                                                                                                                                                              |
| <code>pstop</code>  | Stop each process ( <code>PR_REQUESTED stop</code> ).                                                                                                                                                                                                                                                                             |
| <code>prun</code>   | Set each process running (inverse of <code>pstop</code> ).                                                                                                                                                                                                                                                                        |
| <code>pwait</code>  | Wait for all of the specified processes to terminate.                                                                                                                                                                                                                                                                             |
| <code>ptree</code>  | Print the process trees containing the specified <i>pids</i> or <i>users</i> , with child processes indented from their respective parent processes. An argument of all digits is taken to be a process-id, otherwise it is assumed to be a user login name. Default is all processes.                                            |
| <code>ptime</code>  | Time the <i>command</i> , like <code>time(1)</code> , but using microstate accounting for reproducible precision. Unlike <code>time(1)</code> , children of the command are not timed.                                                                                                                                            |

**OPTIONS** The following options are supported:

- a (ptree only) All. Includes children of process 0.
- c (ptree only). Contracts. Show process contract memberships in addition to parent-child relationships. See `process(4)`. Implies -a.
- F Force. Grabs the target process even if another process has control.
- n (psig and pfiles only) Sets non-verbose mode. `psig` displays signal handler addresses rather than names. `pfiles` does not display verbose information for each file descriptor. Instead, `pfiles` limits its output to the information that would be retrieved if the process applied `fstat(2)` to each of its file descriptors.
- r (pflags only) If the process is stopped, displays its machine registers.
- v (pwait only) Verbose. Reports terminations to standard output.
- z *zone* (ptree only) Prints only processes in the specified *zone*. Each zone ID can be specified as either a zone name or a numerical zone ID. This option is only useful when executed in the global zone.

Additionally, `pcrred` supports the following options:

- g *group/gid* Sets the real, effective, and saved group ids (GIDs) of the target processes to the specified value.

## proc(1)

- G *grouplist* Sets the supplementary GIDs of the target process to the specified list of groups. The supplementary groups should be specified as a comma-separated list of group names ids. An empty list clears the supplementary group list of the target processes.
- l *login* Sets the real, effective, and saved UIDs of the target processes to the UID of the specified login. Sets the real, effective, and saved GIDs of the target processes to the GID of the specified login. Sets the supplementary group list to the supplementary groups list of the specified login.
- u *user/uid* Sets the real, effective, and saved user ids (UIDs) of the target processes to the specified value.

In order to set the credentials of another process, a process must have sufficient privilege to change its user and group ids to those specified according to the rules laid out in `setuid(2)` and it must have sufficient privilege to control the target process.

### USAGE

These proc tools stop their target processes while inspecting them and reporting the results: `pfiles`, `pldd`, and `pstack`. A process can do nothing while it is stopped. Thus, for example, if the X server is inspected by one of these proc tools running in a window under the X server's control, the whole window system can become deadlocked because the proc tool would be attempting to print its results to a window that cannot be refreshed. Logging in from another system using `rlogin(1)` and killing the offending proc tool would clear up the deadlock in this case.

See WARNINGS.

Caution should be exercised when using the `-F` flag. Imposing two controlling processes on one victim process can lead to chaos. Safety is assured only if the primary controlling process, typically a debugger, has stopped the victim process and the primary controlling process is doing nothing at the moment of application of the proc tool in question.

Some of the proc tools can also be applied to core files, as shown by the synopsis above. A core file is a snapshot of a process's state and is produced by the kernel prior to terminating a process with a signal or by the `gcore(1)` utility. Some of the proc tools can need to derive the name of the executable corresponding to the process which dumped core or the names of shared libraries associated with the process. These files are needed, for example, to provide symbol table information for `pstack(1)`. If the proc tool in question is unable to locate the needed executable or shared library, some symbol information is unavailable for display. Similarly, if a core file from one operating system release is examined on a different operating system release, the run-time link-editor debugging interface (`librtld_db`) cannot be able to initialize. In this case, symbol information for shared libraries is not available.

### EXIT STATUS

The following exit values are returned:

- 0 Successful operation.

**FILES** non-zero An error has occurred.  
 /proc/\* process files

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWesu         |
| Interface Stability | See below.      |

Human Readable Output is Unstable. Options are Evolving.

**SEE ALSO** `gcore(1)`, `ldd(1)`, `pargs(1)`, `pgrep(1)`, `pkill(1)`, `plimit(1)`, `pmap(1)`, `preap(1)`, `ps(1)`, `ppgsz(1)`, `pwd(1)`, `rlogin(1)`, `time(1)`, `truss(1)`, `wait(1)`, `fcntl(2)`, `fstat(2)`, `setuid(2)`, `dlopen(3C)`, `signal.h(3HEAD)`, `core(4)`, `proc(4)`, `process(4)`, `attributes(5)`, `zones(5)`

**WARNINGS** The following `proc` tools stop their target processes while inspecting them and reporting the results: `pfiles`, `pldd`, `pmap`, and `pstack`.

A process can do nothing while it is stopped. Stopping a heavily used process in a production environment, even for a short amount of time, can cause severe bottlenecks and even hangs of these processes, causing them to be unavailable to users. Some databases could also terminate abnormally. Thus, for example, a database server under heavy load could hang when one of the database processes is traced using the above mentioned `proc` tools. Because of this, stopping a UNIX process in a production environment should be avoided.

A process being stopped by these tools can be identified by issuing `/usr/bin/ps -eflL` and looking for "T" in the first column. Notice that certain processes, for example "sched", can show the "T" status by default most of the time.

| <b>DESCRIPTION</b> | The <code>prof</code> command interprets a profile file produced by the <code>monitor</code> function. The symbol table in the object file <i>prog</i> (a <code>.out</code> by default) is read and correlated with a profile file ( <code>mon.out</code> by default). For each external text symbol the percentage of time spent executing between the address of that symbol and the address of the next is printed, together with the number of times that function was called and the average number of milliseconds per call.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OPTIONS</b>     | <p>The mutually exclusive options <code>-a</code>, <code>-c</code>, <code>-n</code>, and <code>-t</code> determine the type of sorting of the output lines:</p> <ul style="list-style-type: none"><li><code>-a</code>        Sort by increasing symbol address.</li><li><code>-c</code>        Sort by decreasing number of calls.</li><li><code>-n</code>        Sort lexically by symbol name.</li><li><code>-t</code>        Sort by decreasing percentage of total time (default).</li></ul> <p>The mutually exclusive options <code>-o</code> and <code>-x</code> specify the printing of the address of each symbol monitored:</p> <ul style="list-style-type: none"><li><code>-o</code>        Print each symbol address (in octal) along with the symbol name.</li><li><code>-x</code>        Print each symbol address (in hexadecimal) along with the symbol name.</li></ul> <p>The mutually exclusive options <code>-g</code> and <code>-l</code> control the type of symbols to be reported. The <code>-l</code> option must be used with care; it applies the time spent in a static function to the preceding (in memory) global function, instead of giving the static function a separate entry in the report. If all static functions are properly located, this feature can be very useful. If not, the resulting report may be misleading.</p> <p>Assume that <code>A</code> and <code>B</code> are global functions and only <code>A</code> calls static function <code>S</code>. If <code>S</code> is located immediately after <code>A</code> in the source code (that is, if <code>S</code> is properly located), then, with the <code>-l</code> option, the amount of time spent in <code>A</code> can easily be determined, including the time spent in <code>S</code>. If, however, both <code>A</code> and <code>B</code> call <code>S</code>, then, if the <code>-l</code> option is used, the report will be misleading; the time spent during <code>B</code>'s call to <code>S</code> will be attributed to <code>A</code>, making it appear as if more time had been spent in <code>A</code> than really had. In this case, function <code>S</code> cannot be properly located.</p> <ul style="list-style-type: none"><li><code>-g</code>        List the time spent in static (non-global) functions separately. The <code>-g</code> option function is the opposite of the <code>-l</code> function.</li><li><code>-l</code>        Suppress printing statically declared functions. If this option is given, time spent executing in a static function is allocated to the closest global function loaded before the static function in the executable. This option is the default. It is the opposite of the <code>-g</code> function and should be used with care.</li></ul> <p>The following options may be used in any combination:</p> |

- C Demangle C++ symbol names before printing them out.
- h Suppress the heading normally printed on the report. This is useful if the report is to be processed further.
- m *mdata* Use file *mdata* instead of *mon.out* as the input profile file.
- s Print a summary of several of the monitoring parameters and statistics on the standard error output.
- V Print *prof* version information on the standard error output.
- z Include all symbols in the profile range, even if associated with zero number of calls and zero time.

A program creates a profile file if it has been link edited with the `-p` option of `cc(1B)`. This option to the `cc(1B)` command arranges for calls to `monitor` at the beginning and end of execution. It is the call to `monitor` at the end of execution that causes the system to write a profile file. The number of calls to a function is tallied if the `-p` option was used when the file containing the function was compiled.

A single function may be split into subfunctions for profiling by means of the `MARK` macro. See `prof(5)`.

**ENVIRONMENT VARIABLES**

**PROFDIR** The name of the file created by a profiled program is controlled by the environment variable `PROFDIR`. If `PROFDIR` is not set, *mon.out* is produced in the directory current when the program terminates. If `PROFDIR=string, string/pid.progname` is produced, where *progname* consists of `argv[0]` with any path prefix removed, and *pid* is the process ID of the program. If `PROFDIR` is set, but null, no profiling output is produced.

**FILES**

*mon.out* default profile file  
*a.out* default namelist (object) file

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWbtool       |

**SEE ALSO**

`cc(1B)`, `gprof(1)`, `exit(2)`, `pcsample(2)`, `profil(2)`, `malloc(3C)`, `malloc(3MALLOC)`, `monitor(3C)`, `attributes(5)`, `prof(5)`

**NOTES**

The times reported in successive identical runs may show variances because of varying cache-hit ratios that result from sharing the cache with other processes. Even if a program seems to be the only one using the machine, hidden background or asynchronous processes may blur the data. In rare cases, the clock ticks initiating recording of the program counter may "beat" with loops in a program, grossly distorting measurements. Call counts are always recorded precisely, however.

prof(1)

Only programs that call `exit` or return from `main` are guaranteed to produce a profile file, unless a final call to `monitor` is explicitly coded.

The times for static functions are attributed to the preceding external text symbol if the `-g` option is not used. However, the call counts for the preceding function are still correct; that is, the static function call counts are not added to the call counts of the external function.

If more than one of the options `-t`, `-c`, `-a`, and `-n` is specified, the last option specified is used and the user is warned.

`LD_LIBRARY_PATH` must not contain `/usr/lib` as a component when compiling a program for profiling. If `LD_LIBRARY_PATH` contains `/usr/lib`, the program will not be linked correctly with the profiling versions of the system libraries in `/usr/lib/libp`. See [gprof\(1\)](#).

Functions such as `mcount()`, `_mcount()`, `moncontrol()`, `_moncontrol()`, `monitor()`, and `_monitor()` may appear in the `prof` report. These functions are part of the profiling implementation and thus account for some amount of the runtime overhead. Since these functions are not present in an unprofiled application, time accumulated and call counts for these functions may be ignored when evaluating the performance of an application.

#### 64-bit profiling

64-bit profiling may be used freely with dynamically linked executables, and profiling information is collected for the shared objects if the objects are compiled for profiling. Care must be applied to interpret the profile output, since it is possible for symbols from different shared objects to have the same name. If duplicate names are seen in the profile output, it is better to use the `-s` (summary) option, which prefixes a module id before each symbol that is duplicated. The symbols can then be mapped to appropriate modules by looking at the modules information in the summary.

If the `-a` option is used with a dynamically linked executable, the sorting occurs on a per-shared-object basis. Since there is a high likelihood of symbols from differed shared objects to have the same value, this results in an output that is more understandable. A blank line separates the symbols from different shared objects, if the `-s` option is given.

#### 32-bit profiling

32-bit profiling may be used with dynamically linked executables, but care must be applied. In 32-bit profiling, shared objects cannot be profiled with `prof`. Thus, when a profiled, dynamically linked program is executed, only the "main" portion of the image is sampled. This means that all time spent outside of the "main" object, that is, time spent in a shared object, will not be included in the profile summary; the total time reported for the program may be less than the total time used by the program.

Because the time spent in a shared object cannot be accounted for, the use of shared objects should be minimized whenever a program is profiled with `prof`. If desired, the program should be linked to the profiled version of a library (or to the standard archive version if no profiling version is available), instead of the shared object to get profile information on the functions of a library. Versions of profiled libraries may be supplied with the system in the `/usr/lib/libp` directory. Refer to compiler driver documentation on profiling.

Consider an extreme case. A profiled program dynamically linked with the shared C library spends 100 units of time in some `libc` routine, say, `malloc()`. Suppose `malloc()` is called only from routine B and B consumes only 1 unit of time. Suppose further that routine A consumes 10 units of time, more than any other routine in the "main" (profiled) portion of the image. In this case, `prof` will conclude that most of the time is being spent in A and almost no time is being spent in B. From this it will be almost impossible to tell that the greatest improvement can be made by looking at routine B and not routine A. The value of the profiler in this case is severely degraded; the solution is to use archives as much as possible for profiling.

| <b>DESCRIPTION</b> | <p>The <code>profiles</code> command prints on standard output the names of the execution profiles that have been assigned to you or to the optionally-specified user or role name. Profiles are a bundling mechanism used to enumerate the commands and authorizations needed to perform a specific function. Along with each listed executable are the process attributes, such as the effective user and group IDs, with which the process runs when started by a privileged command interpreter. The profile shells are <code>pf<sub>c</sub>sh</code>, <code>pf<sub>k</sub>sh</code>, and <code>pf<sub>e</sub>exec</code>. See the <code>pf<sub>e</sub>exec(1)</code> man page. Profiles can contain other profiles defined in <code>prof_attr(4)</code>.</p> <p>Multiple profiles can be combined to construct the appropriate access control. When profiles are assigned, the authorizations are added to the existing set. If the same command appears in multiple profiles, the first occurrence, as determined by the ordering of the profiles, is used for process-attribute settings. For convenience, a wild card can be specified to match all commands.</p> <p>When profiles are interpreted, the profile list is loaded from <code>user_attr(4)</code>. If any default profile is defined in <code>/etc/security/policy.conf</code> (see <code>policy.conf(4)</code>), the list of default profiles will be added to the list loaded from <code>user_attr(4)</code>. Matching entries in <code>prof_attr(4)</code> provide the authorizations list, and matching entries in <code>exec_attr(4)</code> provide the commands list.</p> |
| <b>OPTIONS</b>     | <p>-1           Lists the commands in each profile followed by the special process attributes such as user and group IDs.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Sample output</p> <p>The output of the <code>profiles</code> command has the following form:</p> <pre>example% profiles tester01 tester02 tester01 : Audit Management, All Commands tester02 : Device Management, All Commands example%</pre> <p><b>EXAMPLE 2</b> Using the list option</p> <pre>example% profiles -1 tester01 tester02 tester01 :   Audit Management:     /usr/sbin/audit          euid=root     /usr/sbin/auditconfig   euid=root  egid=sys   All Commands:     * tester02 :   Device Management:     /usr/bin/allocate:      euid=root     /usr/bin/deallocate:   euid=root   All Commands     * example%</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>EXIT STATUS</b> | The following exit values are returned:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

projects(1)

**NAME** projects – print project membership of user

**SYNOPSIS** **projects** [-dv] [ *user*]  
**projects** -l [*projectname* [*projectname...*]]

**DESCRIPTION** The `projects` command prints on standard output the projects to which the invoking user or an optionally specified user belongs. Each user belongs to some set of projects specified in the `project(4)` file and possibly in the associated NIS maps and LDAP databases for project information.

**OPTIONS** The following options are supported:

- d Prints only default project.
- l Prints verbose info on each project *projectname*. If no *projectnames* are given, info on all projects is printed.
- v Prints project descriptions along with project names.

**OPERANDS** The following operand is supported:

- projectname* Display information for the specified project.
- user* Displays project memberships for the specified user.

**EXAMPLES** **EXAMPLE 1** Displaying Membership for a Specified User

```
example$ projects paul
default beatles wings
example$ projects ringo
default beatles
example$ projects -d paul
beatles
```

**EXIT STATUS** The following exit values are returned:

- 0 Successful completion.
- 1 A fatal error occurred during execution.
- 2 Invalid command line options were specified.

**FILES** `/etc/project` Local database containing valid project definitions for this machine.

**ATTRIBUTES** See `attributes(5)` for a description of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| Stability      | See below.      |

The invocation is Evolving. The human-readable output is Unstable.

| <b>NAME</b>        | ps – report process status                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <b>ps</b> [-aAcdefjLLPy] [-g <i>grplist</i> ] [-n <i>namelist</i> ] [-o <i>format</i> ]... [-p <i>proclist</i> ]<br>[-s <i>sidlist</i> ] [-t <i>term</i> ] [-u <i>uidlist</i> ] [-U <i>uidlist</i> ] [-G <i>gidlist</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>The <b>ps</b> command prints information about active processes. Without options, <b>ps</b> prints information about processes that have the same effective user ID and the same controlling terminal as the invoker. The output contains only the process ID, terminal identifier, cumulative execution time, and the command name. Otherwise, the information that is displayed is controlled by the options.</p> <p>Some options accept lists as arguments. Items in a list can be either separated by commas or else enclosed in quotes and separated by commas or spaces. Values for <i>proclist</i> and <i>grplist</i> must be numeric.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-a Lists information about all processes most frequently requested: all those except session leaders and processes not associated with a terminal.</li><li>-A Lists information for all processes. Identical to -e, below.</li><li>-c Prints information in a format that reflects scheduler properties as described in <a href="#">prioctl(1)</a>. The -c option affects the output of the -f and -l options, as described below.</li><li>-d Lists information about all processes except session leaders.</li><li>-e Lists information about every process now running.</li><li>-f Generates a full listing. (See below for significance of columns in a full listing.)</li><li>-g <i>grplist</i> Lists only process data whose group leader's ID number(s) appears in <i>grplist</i>. (A group leader is a process whose process ID number is identical to its process group ID number.)</li><li>-G <i>gidlist</i> Lists information for processes whose real group ID numbers are given in <i>gidlist</i>. The <i>gidlist</i> must be a single argument in the form of a blank- or comma-separated list.</li><li>-j Prints session ID and process group ID.</li><li>-l Generates a long listing. (See below.)</li><li>-L Prints information about each light weight process (<i>lwp</i>) in each selected process. (See below.)</li><li>-n <i>namelist</i> Specifies the name of an alternative system <i>namelist</i> file in place of the default. This option is accepted for compatibility, but is ignored.</li><li>-o <i>format</i> Prints information according to the format specification given in <i>format</i>. This is fully described in <a href="#">DISPLAY FORMATS</a>. Multiple -o</li></ul> |

options can be specified; the format specification will be interpreted as the space-character-separated concatenation of all the *format* option-arguments.

- p *proclist* Lists only process data whose process ID numbers are given in *proclist*.
- P Prints the number of the processor to which the process or lwp is bound, if any, under an additional column header, *PSR*.
- s *sidlist* Lists information on all session leaders whose IDs appear in *sidlist*.
- t *term* Lists only process data associated with *term*. Terminal identifiers are specified as a device file name, and an identifier. For example, *term/a*, or *pts/0*.
- u *uidlist* Lists only process data whose effective user ID number or login name is given in *uidlist*. In the listing, the numerical user ID will be printed unless you give the -f option, which prints the login name.
- U *uidlist* Lists information for processes whose real user ID numbers or login names are given in *uidlist*. The *uidlist* must be a single argument in the form of a blank- or comma-separated list.
- y Under a long listing (-l), omits the obsolete *F* and *ADDR* columns and includes an *RSS* column to report the resident set size of the process. Under the -y option, both *RSS* and *SZ* (see below) will be reported in units of kilobytes instead of pages.
- z Lists only processes in the specified zones. Zones can be specified either by name or ID. This option is only useful when executed in the global zone.
- Z Prints the name of the zone with which the process is associated under an additional column header, *ZONE*.

Many of the options shown are used to select processes to list. If any are specified, the default list will be ignored and *ps* will select the processes represented by the inclusive OR of all the selection-criteria options.

## DISPLAY FORMATS

Under the -f option, *ps* tries to determine the command name and arguments given when the process was created by examining the user block. Failing this, the command name is printed, as it would have appeared without the -f option, in square brackets.

The column headings and the meaning of the columns in a *ps* listing are given below; the letters *f* and *l* indicate the option (*full* or *long*, respectively) that causes the corresponding heading to appear; *a**ll* means that the heading always appears. *Note:* These two options determine only what information is provided for a process; they do not determine which processes will be listed.

ps(1)

|            |                                                                                                                                                                                                                                                                                                                            |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| F (l)      | Flags (hexadecimal and additive) associated with the process. These flags are available for historical purposes; no meaning should be currently ascribed to them.                                                                                                                                                          |
| S (l)      | The state of the process:<br>O Process is running on a processor.<br>S Sleeping: process is waiting for an event to complete.<br>R Runnable: process is on run queue.<br>Z Zombie state: process terminated and parent not waiting.<br>T Process is stopped, either by a job control signal or because it is being traced. |
| UID (f,l)  | The effective user ID number of the process (the login name is printed under the -f option).                                                                                                                                                                                                                               |
| PID (all)  | The process ID of the process (this datum is necessary in order to kill a process).                                                                                                                                                                                                                                        |
| PPID (f,l) | The process ID of the parent process.                                                                                                                                                                                                                                                                                      |
| C (f,l)    | Processor utilization for scheduling (obsolete). Not printed when the -c option is used.                                                                                                                                                                                                                                   |
| CLS (f,l)  | Scheduling class. Printed only when the -c option is used.                                                                                                                                                                                                                                                                 |
| PRI (l)    | The priority of the process. Without the -c option, higher numbers mean lower priority. With the -c option, higher numbers mean higher priority.                                                                                                                                                                           |
| NI (l)     | Nice value, used in priority computation. Not printed when the -c option is used. Only processes in the certain scheduling classes have a nice value.                                                                                                                                                                      |
| ADDR (l)   | The memory address of the process.                                                                                                                                                                                                                                                                                         |
| SZ (l)     | The total size of the process in virtual memory, including all mapped files and devices, in pages. See <a href="#">pagesize(1)</a> .                                                                                                                                                                                       |
| WCHAN (l)  | The address of an event for which the process is sleeping (if blank, the process is running).                                                                                                                                                                                                                              |
| STIME (f)  | The starting time of the process, given in hours, minutes, and seconds. (A process begun more than twenty-four hours before the ps inquiry is executed is given in months and days.)                                                                                                                                       |
| TTY (all)  | The controlling terminal for the process (the message, ?, is printed when there is no controlling terminal).                                                                                                                                                                                                               |
| TIME (all) | The cumulative execution time for the process.                                                                                                                                                                                                                                                                             |

**CMD (all)**            The command name (the full command name and its arguments, up to a limit of 80 characters, are printed under the `-f` option).

The following two additional columns are printed when the `-j` option is specified:

**PGID**            The process ID of the process group leader.

**SID**            The process ID of the session leader.

The following two additional columns are printed when the `-L` option is specified:

**LWP**            The lwp ID of the lwp being reported.

**NLWP**          The number of lwps in the process (if `-f` is also specified).

Under the `-L` option, one line is printed for each lwp in the process and the time-reporting fields `STIME` and `TIME` show the values for the lwp, not the process. A traditional single-threaded process contains only one lwp.

A process that has exited and has a parent, but has not yet been waited for by the parent, is marked `<defunct>`.

**-o format**        The `-o` option allows the output format to be specified under user control.

The format specification must be a list of names presented as a single argument, blank- or comma-separated. Each variable has a default header. The default header can be overridden by appending an equals sign and the new text of the header. The rest of the characters in the argument will be used as the header text. The fields specified will be written in the order specified on the command line, and should be arranged in columns in the output. The field widths will be selected by the system to be at least as wide as the header text (default or overridden value). If the header text is null, such as `-o user=`, the field width will be at least as wide as the default header text. If all header text fields are null, no header line will be written.

The following names are recognized in the POSIX locale:

**user**            The effective user ID of the process. This will be the textual user ID, if it can be obtained and the field width permits, or a decimal representation otherwise.

**ruser**           The real user ID of the process. This will be the textual user ID, if it can be obtained and the field width permits, or a decimal representation otherwise.

**group**           The effective group ID of the process. This will be the textual group ID, if it can be obtained and the field width permits, or a decimal representation otherwise.

**rgroup**          The real group ID of the process. This will be the textual group ID, if it can be obtained and the field width permits, or a decimal representation otherwise.

**pid**            The decimal value of the process ID.

ps(1)

|       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ppid  | The decimal value of the parent process ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| pgid  | The decimal value of the process group ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| pcpu  | The ratio of CPU time used recently to CPU time available in the same period, expressed as a percentage. The meaning of “recently” in this context is unspecified. The CPU time available is determined in an unspecified manner.                                                                                                                                                                                                                                                                                   |
| vsz   | The total size of the process in virtual memory, in kilobytes.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| nice  | The decimal value of the system scheduling priority of the process. See <a href="#">nice(1)</a> .                                                                                                                                                                                                                                                                                                                                                                                                                   |
| etime | <p>In the POSIX locale, the elapsed time since the process was started, in the form:</p> <p>[ <i>dd-</i> <i>hh:</i> ] <i>mm:ss</i></p> <p>where</p> <p><i>dd</i> is the number of days</p> <p><i>hh</i> is the number of hours</p> <p><i>mm</i> is the number of minutes</p> <p><i>ss</i> is the number of seconds</p> <p>The <i>dd</i> field will be a decimal integer. The <i>hh</i>, <i>mm</i> and <i>ss</i> fields will be two-digit decimal integers padded on the left with zeros.</p>                        |
| time  | <p>In the POSIX locale, the cumulative CPU time of the process in the form:</p> <p>[ <i>dd-</i> ] <i>hh:mm:ss</i></p> <p>The <i>dd</i>, <i>hh</i>, <i>mm</i>, and <i>ss</i> fields will be as described in the <code>etime</code> specifier.</p>                                                                                                                                                                                                                                                                    |
| tty   | The name of the controlling terminal of the process (if any) in the same format used by the <a href="#">who(1)</a> command.                                                                                                                                                                                                                                                                                                                                                                                         |
| comm  | The name of the command being executed ( <code>argv[0]</code> value) as a string.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| args  | The command with all its arguments as a string. The implementation may truncate this value to the field width; it is implementation-dependent whether any further truncation occurs. It is unspecified whether the string represented is a version of the argument list as it was passed to the command when it started, or is a version of the arguments as they may have been modified by the application. Applications cannot depend on being able to modify their argument list and having that modification be |

reflected in the output of `ps`. The Solaris implementation limits the string to 80 bytes; the string is the version of the argument list as it was passed to the command when it started.

The following names are recognized in the Solaris implementation:

|                      |                                                                                                                               |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <code>f</code>       | Flags (hexadecimal and additive) associated with the process.                                                                 |
| <code>s</code>       | The state of the process.                                                                                                     |
| <code>c</code>       | Processor utilization for scheduling (obsolete).                                                                              |
| <code>uid</code>     | The effective user ID number of the process as a decimal integer.                                                             |
| <code>ruid</code>    | The real user ID number of the process as a decimal integer.                                                                  |
| <code>gid</code>     | The effective group ID number of the process as a decimal integer.                                                            |
| <code>rgid</code>    | The real group ID number of the process as a decimal integer.                                                                 |
| <code>projid</code>  | The project ID number of the process as a decimal integer.                                                                    |
| <code>project</code> | The project ID of the process as a textual value if that value can be obtained; otherwise, as a decimal integer.              |
| <code>zoneid</code>  | The zone ID number of the process as a decimal integer.                                                                       |
| <code>zone</code>    | The zone ID of the process as a textual value if that value can be obtained; otherwise, as a decimal integer.                 |
| <code>sid</code>     | The process ID of the session leader.                                                                                         |
| <code>taskid</code>  | The task ID of the process.                                                                                                   |
| <code>class</code>   | The scheduling class of the process.                                                                                          |
| <code>pri</code>     | The priority of the process. Higher numbers mean higher priority.                                                             |
| <code>opri</code>    | The obsolete priority of the process. Lower numbers mean higher priority.                                                     |
| <code>lwp</code>     | The decimal value of the lwp ID. Requesting this formatting option causes one line to be printed for each lwp in the process. |
| <code>nlwp</code>    | The number of lwps in the process.                                                                                            |
| <code>psr</code>     | The number of the processor to which the process or lwp is bound.                                                             |
| <code>pset</code>    | The ID of the processor set to which the process or lwp is bound.                                                             |
| <code>addr</code>    | The memory address of the process.                                                                                            |
| <code>osz</code>     | The total size of the process in virtual memory, in pages.                                                                    |
| <code>wchan</code>   | The address of an event for which the process is sleeping (if <code>-</code> , the process is running).                       |
| <code>stime</code>   | The starting time or date of the process, printed with no blanks.                                                             |

ps(1)

|                    |                                                                                                                                                                                                                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>rss</code>   | The resident set size of the process, in kilobytes. The <code>rss</code> value reported by <code>ps</code> is an estimate provided by <code>proc(4)</code> that may underestimate the actual resident set size. Users who wish to get more accurate usage information for capacity planning should use <a href="#">pmap(1)</a> -x instead. |
| <code>pmem</code>  | The ratio of the process's resident set size to the physical memory on the machine, expressed as a percentage.                                                                                                                                                                                                                             |
| <code>fname</code> | The first 8 bytes of the base name of the process's executable file.                                                                                                                                                                                                                                                                       |
| <code>ctid</code>  | The contract ID of the process contract the process is a member of as a decimal integer.                                                                                                                                                                                                                                                   |

Only `comm` and `args` are allowed to contain blank characters; all others, including the Solaris implementation variables, are not.

The following table specifies the default header to be used in the POSIX locale corresponding to each format specifier.

| <b>Format Specifier</b> | <b>Default Header</b> | <b>Format Specifier</b> | <b>Default Header</b> |
|-------------------------|-----------------------|-------------------------|-----------------------|
| <code>args</code>       | COMMAND               | <code>ppid</code>       | PPID                  |
| <code>comm</code>       | COMMAND               | <code>rgroup</code>     | RGROUP                |
| <code>etime</code>      | ELAPSED               | <code>ruser</code>      | RUSER                 |
| <code>group</code>      | GROUP                 | <code>time</code>       | TIME                  |
| <code>nice</code>       | NI                    | <code>tty</code>        | TT                    |
| <code>pcpu</code>       | %CPU                  | <code>user</code>       | USER                  |
| <code>pgid</code>       | PGID                  | <code>vsz</code>        | VSZ                   |
| <code>pid</code>        | PID                   |                         |                       |

The following table lists the Solaris implementation format specifiers and the default header used with each.

| <b>Format Specifier</b> | <b>Default Header</b> | <b>Format Specifier</b> | <b>Default Header</b> |
|-------------------------|-----------------------|-------------------------|-----------------------|
| <code>addr</code>       | ADDR                  | <code>projid</code>     | PROJID                |
| <code>c</code>          | C                     | <code>project</code>    | PROJECT               |
| <code>class</code>      | CLS                   | <code>psr</code>        | PSR                   |

| Format Specifier | Default Header | Format Specifier | Default Header |
|------------------|----------------|------------------|----------------|
| f                | F              | rgid             | RGID           |
| fname            | COMMAND        | rss              | RSS            |
| gid              | GID            | ruid             | RUID           |
| lwp              | LWP            | s                | S              |
| nlwp             | NLWP           | sid              | SID            |
| opri             | PRI            | stime            | STIME          |
| osz              | SZ             | taskid           | TASKID         |
| pmem             | %MEM           | uid              | UID            |
| pri              | PRI            | wchan            | WCHAN          |
| ctid             | CTID           |                  |                |

**EXAMPLES****EXAMPLE 1** Using ps Command

The command:

```
example% ps -o user,pid,ppid=MOM -o args
```

writes the following in the POSIX locale:

```
USER PID  MOM  COMMAND
helene 34   12  ps -o uid,pid,ppid=MOM -o args
```

The contents of the COMMAND field need not be the same due to possible truncation.

**ENVIRONMENT VARIABLES**

See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of ps: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, LC\_TIME, and NLSPATH.

**COLUMNS** Override the system-selected horizontal screen size, used to determine the number of text columns to display.

**EXIT STATUS**

The following exit values are returned:

0 Successful completion.  
>0 An error occurred.

**FILES**

/dev/pts/\*  
/dev/term/\* terminal (“tty”) names searcher files  
/etc/passwd UID information supplier  
/proc/\* process control files

ps(1)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE     |
|---------------------|---------------------|
| Availability        | SUNWcsu             |
| CSI                 | Enabled (see USAGE) |
| Interface Stability | Standard            |

**SEE ALSO** `kill(1)`, `nice(1)`, `pagesize(1)`, `pgrep(1)`, `pmap(1)`, `priocntl(1)`, `who(1)`, `getty(1M)`, `proc(4)`, `ttysrch(4)`, `attributes(5)`, `environ(5)`, `standards(5)`, `zones(5)`

**NOTES** Things can change while `ps` is running. The snapshot it gives is true only for a split-second, and it may not be accurate by the time you see it. Some data printed for defunct processes is irrelevant.

If no options to select processes are specified, `ps` will report all processes associated with the controlling terminal. If there is no controlling terminal, there will be no report other than the header.

`ps -ef` or `ps -o stime` may not report the actual start of a tty login session, but rather an earlier time, when a `getty` was last respawned on the tty line.

`ps` is CSI-enabled except for login names (usernames).

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>NAME</b>        | ps – display the status of current processes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <code>/usr/ucb/ps [-aceglnrSuUvwx] [-t <i>term</i>] [<i>num</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p>The <code>ps</code> command displays information about processes. Normally, only those processes that are running with your effective user ID and are attached to a controlling terminal (see <code>termio(7I)</code>) are shown. Additional categories of processes can be added to the display using various options. In particular, the <code>-a</code> option allows you to include processes that are not owned by you (that do not have your user ID), and the <code>-x</code> option allows you to include processes without controlling terminals. When you specify both <code>-a</code> and <code>-x</code>, you get processes owned by anyone, with or without a controlling terminal. The <code>-r</code> option restricts the list of processes printed to running and runnable processes.</p> <p><code>ps</code> displays in tabular form the process ID, under <code>PID</code>; the controlling terminal (if any), under <code>TT</code>; the cpu time used by the process so far, including both user and system time, under <code>TIME</code>; the state of the process, under <code>S</code>; and finally, an indication of the <code>COMMAND</code> that is running.</p> <p>The state is given by a single letter from the following:</p> <ul style="list-style-type: none"> <li>O        Process is running on a processor.</li> <li>S        Sleeping. Process is waiting for an event to complete.</li> <li>R        Runnable. Process is on run queue.</li> <li>Z        Zombie state. Process terminated and parent not waiting.</li> <li>T        Traced. Process stopped by a signal because parent is tracing it.</li> </ul> |
| <b>OPTIONS</b>     | <p>The following options must all be combined to form the first argument:</p> <ul style="list-style-type: none"> <li>-a        Includes information about processes owned by others.</li> <li>-c        Displays the command name rather than the command arguments.</li> <li>-e        Displays the environment as well as the arguments to the command.</li> <li>-g        Displays all processes. Without this option, <code>ps</code> only prints interesting processes. Processes are deemed to be uninteresting if they are process group leaders. This normally eliminates top-level command interpreters and processes waiting for users to login on free terminals.</li> <li>-l        Displays a long listing, with fields <code>F</code>, <code>PPID</code>, <code>CP</code>, <code>PRI</code>, <code>NI</code>, <code>SZ</code>, <code>RSS</code>, and <code>WCHAN</code> as described below.</li> <li>-n        Produces numerical output for some fields. In a user listing, the <code>USER</code> field is replaced by a <code>UID</code> field.</li> <li>-r        Restricts output to running and runnable processes.</li> <li>-s        Displays accumulated CPU time used by this process and all of its reaped children.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                    |

ps(1B)

- t *term* Lists only process data associated with the terminal, *term*. Terminal identifiers may be specified in one of two forms: the device's file name (for example, `tty04` or `term/14`) or, if the device's file name starts with `tty`, just the digit identifier (for example, `04`).
- u Displays user-oriented output. This includes fields `USER`, `%CPU`, `%MEM`, `SZ`, `RSS`, and `START` as described below.
- U Obsolete. This option no longer has any effect. It causes `ps` to exit without printing the process listing.
- v Displays a version of the output containing virtual memory. This includes fields `SIZE`, `%CPU`, `%MEM`, and `RSS`, described below.
- w Uses a wide output format (132 columns rather than 80). If the option letter is repeated, that is, `-ww`, uses arbitrarily wide output. This information is used to decide how much of long commands to print.
- x Includes processes with no controlling terminal.
- num* A process number may be given, in which case the output is restricted to that process. This option must be supplied last.

#### DISPLAY FORMATS

Fields that are not common to all output formats:

|                    |                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>USER</code>  | Name of the owner of the process.                                                                                                                                                      |
| <code>%CPU</code>  | CPU use of the process. This is a decaying average over up to a minute of previous (real) time.                                                                                        |
| <code>NI</code>    | Process scheduling increment (see <code>getpriority(3C)</code> and <code>nice(3UCB)</code> ).                                                                                          |
| <code>SIZE</code>  | The total size of the process in virtual memory, including all mapped files and devices, in kilobyte units.                                                                            |
| <code>SZ</code>    | Same as <code>SIZE</code> .                                                                                                                                                            |
| <code>RSS</code>   | Real memory (resident set) size of the process, in kilobyte units.                                                                                                                     |
| <code>UID</code>   | Numerical user-ID of process owner.                                                                                                                                                    |
| <code>PPID</code>  | Numerical ID of parent of process.                                                                                                                                                     |
| <code>CP</code>    | Short-term CPU utilization factor (used in scheduling).                                                                                                                                |
| <code>PRI</code>   | The priority of the process (higher numbers mean lower priority).                                                                                                                      |
| <code>START</code> | The starting time of the process, given in hours, minutes, and seconds. A process begun more than 24 hours before the <code>ps</code> inquiry is executed is given in months and days. |
| <code>WCHAN</code> | The address of an event for which the process is sleeping (if blank, the process is running).                                                                                          |

%MEM The ratio of the process's resident set size to the physical memory on the machine, expressed as a percentage.

F Flags (hexadecimal and additive) associated with the process. These flags are available for historical purposes; no meaning should be currently ascribed to them.

A process that has exited and has a parent, but has not yet been waited for by the parent, is marked <defunct> ; otherwise, ps tries to determine the command name and arguments given when the process was created by examining the user block.

**FILES** /dev/tty\*

/etc/passwd UID information supplier

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscpu        |

**SEE ALSO** kill(1), ps(1), whodo(1M), getpriority(3C), nice(3UCB), proc(4), attributes(5), termio(7I)

**NOTES** Things can change while ps is running. The picture ps gives is only a close approximation to the current state. Some data printed for defunct processes is irrelevant.

| <b>NAME</b>        | pvs – display the internal version information of dynamic objects                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SYNOPSIS</b>    | <b>pvs</b> [-Cdlnorsv] [-N <i>name</i> ] <i>file</i> ...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | <p>The <code>pvs</code> utility displays any internal version information contained within an ELF file. Commonly, these files are dynamic executables and shared objects, and possibly relocatable objects. This version information can fall into one of two categories:</p> <ul style="list-style-type: none"><li>■ version definitions</li><li>■ version dependencies</li></ul> <p>Version <i>definitions</i> describe the interfaces that are made available by an ELF file. Each version definition is associated to a set of global symbols provided by the file. Version definitions can be assigned to a file during its creation by the link-editor using the <code>-M</code> option and the associated <i>mapfile</i> directives. See the <i>Linker and Libraries Guide</i> for more details.</p> <p>Version <i>dependencies</i> describe the binding requirements of dynamic objects on the version definitions of any shared object dependencies. When a dynamic object is built with a shared object, the link-editor records information within the dynamic object indicating that the shared object is a dependency. This dependency must be satisfied at runtime. If the shared object also contains version <i>definitions</i>, then those version definitions that satisfy the global symbol requirements of the dynamic object are also recorded in the dynamic object being created. At process initialization, the runtime linker uses any version <i>dependencies</i> as a means of validating the interface requirements of the dynamic objects used to construct the process.</p>           |
| <b>OPTIONS</b>     | <p>The following options are supported. If neither the <code>-d</code> or <code>-r</code> options are specified, both are enabled.</p> <ul style="list-style-type: none"><li><code>-C</code> Demangles C++ symbol names.</li><li><code>-d</code> Prints version definition information.</li><li><code>-l</code> When used with the <code>-s</code> option, prints any symbols that have been reduced from global to local binding due to versioning. By convention, these symbol entries are located in the <i>.symtab</i> section, and fall between the <i>FILE</i> symbol representing the output file, and the <i>FILE</i> symbol representing the first input file used to generate the output file. These reduced symbol entries are assigned the fabricated version definition <code>_REDUCED_</code>. No reduced symbols will be printed if the file has been stripped (see <code>strip(1)</code>), or if the symbol entry convention cannot be determined.</li><li><code>-n</code> Normalizes version definition information. By default, all version definitions within the object are displayed. However, version definitions can inherit other version definitions. Under normalization, only the head of each inheritance list is displayed.</li><li><code>-N name</code> When used with the <code>-d</code> option, <code>-N</code> prints only the information for the given version definition <i>name</i> and any of its inherited version definitions. When used with the <code>-r</code> option, <code>-N</code> prints only the information for the given dependency file <i>name</i>.</li></ul> |

- o Creates one-line version definition output. By default, file, version definitions, and any symbol output is indented to ease human inspection. This option prefixes each output line with the file and version definition name and can be more useful for analysis with automated tools.
- r Prints version dependency (requirements) information.
- s Prints the symbols associated with each version definition. Any data symbols are accompanied with the size, in bytes, of the data item.
- v Verbose output. Indicates any weak version definitions, and any version definition inheritance. When used with the `-N` and `-d` options, the inheritance of the base version definition is also shown. When used with the `-s` option, the version symbol definition is also shown.

**OPERANDS** The following operands are supported.

*file* The ELF file about which internal version information is displayed.

**EXAMPLES** **EXAMPLE 1** Displaying version definitions

The following example displays the version definitions of `libelf.so.1`:

```
% pvs -d /lib/libelf.so.1
libelf.so.1;
SUNW_1.1
```

**EXAMPLE 2** Creating a one-liner display

A normalized, one-liner display, suitable for creating a *mapfile* version control directive, can be created using the `-n` and `-o` options:

```
% pvs -don /lib/libelf.so.1
/lib/libelf.so.1 - SUNW_1.1;
```

**EXAMPLE 3** Displaying version requirements

The following example displays the version requirements of `ldd` and `pvs`:

```
% pvs -r /usr/bin/ldd /usr/bin/pvs
/usr/bin/ldd:
libelf.so.1 (SUNW_1.1);
libc.so.1 (SUNW_1.1);
/usr/bin/pvs:
libelf.so.1 (SUNW_1.1);
libc.so.1 (SUNW_1.1);
```

**EXIT STATUS** If the requested version information is not found, a non-zero value is returned. Otherwise, a 0 value is returned.

Version information is determined not found when any of the following is true:

- the `-d` option is specified and no version definitions are found.

pvs(1)

- the `-r` option is specified and no version requirements are found.
- neither the `-d` nor `-r` option is specified and no version definitions or version requirements are found.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWtoo         |

| Interface Stability          | Standard                                                                                                                                                                                                                                                                                                    |                |                 |              |         |     |         |                     |          |
| <b>SEE ALSO</b>              | <a href="#">cd(1)</a> , <a href="#">ksh(1)</a> , <a href="#">sh(1)</a> , <a href="#">shell_builtins(1)</a> , <a href="#">attributes(5)</a> , <a href="#">environ(5)</a> , <a href="#">standards(5)</a>                                                                                                      |                |                 |              |         |     |         |                     |          |
| <b>DIAGNOSTICS</b>           | “Cannot open . . .” and “Read error in . . .” indicate possible file system trouble and should be referred to a UNIX system administrator.                                                                                                                                                                  |                |                 |              |         |     |         |                     |          |
| <b>NOTES</b>                 | If you move the current directory or one above it, <code>pwd</code> may not give the correct response. Use the <a href="#">cd(1)</a> command with a full path name to correct this situation.                                                                                                               |                |                 |              |         |     |         |                     |          |

ranlib(1)

**NAME** ranlib – convert archives to random libraries

**SYNOPSIS** `/usr/ccs/bin/ranlib archive`

**DESCRIPTION** The `ranlib` utility was used in SunOS 4.x to add a table of contents to archive libraries, which converted each archive to a form that could be linked more rapidly. This is no longer needed, as the `ar(1)` command automatically provides all the functionality `ranlib` used to provide.

This script is provided as a convenience for software developers who need to maintain Makefiles that are portable across a variety of operating systems.

**EXIT STATUS** `ranlib` has exit status 0.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWbtool       |

**SEE ALSO** `ar(1)`, `ar.h(3HEAD)`, `attributes(5)`

| <b>NAME</b>        | rcapstat – report resource cap enforcement daemon statistics                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <b>rcapstat</b> [-g] [ <i>interval</i> [ <i>count</i> ]]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>The <code>rcapstat</code> command reports on the projects capped by <code>rcapd(1M)</code>. Each report contains statistics that pertain to the project and paging statistics. Paging refers to the act of relocating portions of memory, called pages, to or from physical memory. <code>rcapd</code> pages out the most infrequently used pages.</p> <p>The paging statistics in the first report issued show the activity since the daemon was started. Subsequent reports reflect the activity since the last report was issued.</p> <p>Reports are issued every <i>interval</i> seconds up to the quantity specified by <i>count</i>, or forever if <i>count</i> is not specified.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>OPTIONS</b>     | <p>The following command-line option is supported:</p> <p><code>-g</code>      Global statistics. Reports the minimum memory utilization for memory cap enforcement (see <code>rcapadm(1M)</code>) and reports current memory utilization as a percentage of installed physical memory.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>OUTPUT</b>      | <p>The following list defines the column headings in the <code>rcapstat</code> report and provides information about how to interpret the report.</p> <p><code>id</code>            The project ID of the capped project.</p> <p><code>project</code>        The project name.</p> <p><code>nproc</code>         The number of processes in the project since the last report.</p> <p><code>vm</code>            The total virtual memory size of the project's processes, including all mapped files and devices, in kilobytes (K), megabytes (M), or gigabytes (G).</p> <p><code>rss</code>            The total resident set size (RSS) of the project's processes, in kilobytes (K), megabytes (M), or gigabytes (G).</p> <p><code>cap</code>            The RSS cap for the project. See <code>rcapd(1M)</code> for information about how to specify memory caps.</p> <p><code>at</code>            The total amount of memory that <code>rcapd</code> attempted to page out.</p> <p>                Paging refers to the act of relocating portions of memory, called pages, to or from physical memory. <code>rcapd</code> pages out the most infrequently used pages.</p> <p><code>avgat</code>         The average amount of memory that <code>rcapd</code> attempted to page out during each sample cycle. The rate at which <code>rcapd</code> samples RSS can be set with <code>rcapadm(1M)</code>.</p> <p><code>pg</code>            An estimate of the total amount of memory that <code>rcapd</code> successfully paged out.</p> |

## rcapstat(1)

*avgpg* An estimate of the average amount of memory that *rcapd* successfully paged out during each sample cycle. The rate at which *rcapd* samples process RSS sizes can be set with *rcapadm*.

**OPERANDS** The following operands are supported:

*interval* Specifies the reporting interval in seconds. The default interval is 5 seconds.

*count* Specifies the number of reports to produce. By default, *rcapstat* reports statistics until a termination signal is received or until the *rcapd* process exits.

**EXAMPLES** **EXAMPLE 1** Using *rcapstat* to report cap and project information

Caps are defined for two projects associated with two users. *user1* has a cap of 50 megabytes and *user2* has a cap of 10 megabytes.

The following command produces five reports at 5-second sampling intervals.

```
example# rcapstat 5 5
  id project nproc  vm  rss  cap  at avgat  pg avgpg
112270 user1  24  123M  35M  50M  50M  0K 3312K  0K
 78194 user2   1 2368K 1856K 10M   0K   0K   0K   0K
  id project nproc  vm  rss  cap  at avgat  pg avgpg
112270 user1  24  123M  35M  50M  0K   0K   0K   0K
 78194 user2   1 2368K 1856K 10M   0K   0K   0K   0K
  id project nproc  vm  rss  cap  at avgat  pg avgpg
112270 user1  24  123M  35M  50M  0K   0K   0K   0K
 78194 user2   1 2368K 1928K 10M   0K   0K   0K   0K
  id project nproc  vm  rss  cap  at avgat  pg avgpg
112270 user1  24  123M  35M  50M  0K   0K   0K   0K
 78194 user2   1 2368K 1928K 10M   0K   0K   0K   0K
```

The first three lines of output constitute the first report, which contains the cap and project information for the two projects and paging statistics since *rcapd* was started. The *at* and *pg* columns are a number greater than zero for *user1* and zero for *user2*, which indicates that at some time in the daemon's history, *user1* exceeded its cap but *user2* did not.

The subsequent reports show no significant activity.

**EXAMPLE 2** Using *rcapstat* to monitor the RSS of a project

```
example% rcapstat 5 5
  id project nproc  vm  rss  cap  at avgat  pg avgpg
376565 user1  57 209M  46M  10M  440M  220M  5528K  2764K
376565 user1  57 209M  44M  10M  394M  131M  4912K  1637K
376565 user1  56 207M  43M  10M  440M  147M  6048K  2016K
376565 user1  56 207M  42M  10M  522M  174M  4368K  1456K
```

**EXAMPLE 2** Using rcapstat to monitor the RSS of a project (Continued)

```
376565 user1 56 207M 44M 10M 482M 161M 3376K 1125K
```

The project `user1` has an RSS in excess of its physical memory cap. The nonzero values in the `pg` column indicate that `rcapd` is consistently paging out memory as it attempts to meet the cap by lowering the physical memory utilization of the project's processes. However, `rcapd` is unsuccessful, as indicated by the varying `rss` values that do not show a corresponding decrease. This means that the application's resident memory is being actively used, forcing `rcapd` to affect the working set. Under this condition, the system continues to experience high page fault rates, and associated I/O, until the working set size (WSS) is reduced, the cap is raised, or the application changes its memory access pattern. Notice that a page fault occurs when either a new page must be created, or the system must copy in a page from the swap device.

**EXAMPLE 3** Determining the working set size of a project

This example is a continuation of Example 1, and it uses the same project.

```
example% rcapstat 5 5
  id project nproc  vm  rss  cap  at avgat  pg  avgpg
376565 user1 56 207M 44M 10M 381M 191M 15M 7924K
376565 user1 56 207M 46M 10M 479M 160M 2696K 898K
376565 user1 56 207M 46M 10M 424M 141M 7280K 2426K
376565 user1 56 207M 43M 10M 401M 201M 4808K 2404K
376565 user1 56 207M 43M 10M 456M 152M 4800K 1600K
376565 user1 56 207M 44M 10M 486M 162M 4064K 1354K
376565 user1 56 207M 52M 100M 191M 95M 1944K 972K
376565 user1 56 207M 55M 100M 0K 0K 0K 0K
376565 user1 56 207M 56M 100M 0K 0K 0K 0K
376565 user1 56 207M 56M 100M 0K 0K 0K 0K
376565 user1 56 207M 56M 100M 0K 0K 0K 0K
376565 user1 56 207M 56M 100M 0K 0K 0K 0K
```

By inhibiting cap enforcement, either by raising the cap of a project or by changing the minimum physical memory utilization for cap enforcement (see `rcapadm(1M)`), the resident set can become the working set. The `rss` column might stabilize to show the project WSS, as shown in the previous example. The WSS is the minimum cap value that allows the project's processes to operate without perpetually incurring page faults.

**EXIT STATUS** The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.
- 2 Invalid command-line options were specified.

rcapstat(1)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWrcapu       |

**SEE ALSO** `rcapadm(1M)`, `rcapd(1M)`, `attributes(5)`

*Physical Memory Control Using the Resource Capping Daemon in System Administration Guide: Resource Management*

**NOTES** If the interval specified to `rcapstat` is shorter than the reporting interval specified to `rcapd` (with `rcapadm(1M)`), the output for some intervals can be zero. This is because `rcapd` does not update statistics more frequently than the interval specified with `rcapadm`, and this interval is independent of (and less precise than) the sampling interval used by `rcapstat`.

| <b>NAME</b>        | rcp – remote file copy                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <pre><b>rcp</b> [-p] [-a] [-x] [-PN   -PO] [-k <i>realm</i>] <i>filename1 filename2</i> <b>rcp</b> [-pr] [-a] [-x] [-PN   -PO] [-k <i>realm</i>] <i>filename... directory</i></pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p>The <code>rcp</code> command copies files between machines. Each <i>filename</i> or <i>directory</i> argument is either a remote file name of the form:</p> <pre><i>hostname: path</i></pre> <p>or a local file name (containing no ":" (colon) characters, or "/" (backslash) before any ":" (colon) characters).</p> <p>The <i>hostname</i> can be an IPv4 or IPv6 address string. See <code>inet(7P)</code> and <code>inet6(7P)</code>. Since IPv6 addresses already contain colons, the <i>hostname</i> should be enclosed in a pair of square brackets when an IPv6 address is used. Otherwise, the first occurrence of a colon can be interpreted as the separator between <i>hostname</i> and <i>path</i>. For example,</p> <pre>[1080::8:800:200C:417A]:tmp/file</pre> <p>If a <i>filename</i> is not a full path name, it is interpreted relative to your home directory on <i>hostname</i>. A <i>path</i> on a remote host may be quoted using <code>\</code>, <code>"</code>, or <code>'</code>, so that the metacharacters are interpreted remotely. Please notice that the kerberized versions of <code>rcp</code> are not IPv6-enabled.</p> <p><code>rcp</code> does not prompt for passwords. It either uses Kerberos authentication which is enabled through command-line options or your current local user name must exist on <i>hostname</i> and allow remote command execution by <code>rsh(1)</code>.</p> <p>The <code>rcp</code> session can be kerberized using any of the following Kerberos specific options: <code>-a</code>, <code>-PN</code> or <code>-PO</code>, <code>-x</code>, and <code>-k realm</code>. Some of these options (<code>-x</code> and <code>-PN</code> or <code>-PO</code>) can also be specified in the <code>[appdefaults]</code> section of <code>krb5.conf(4)</code>. The usage of these options and the expected behavior is discussed in the <code>OPTIONS</code> section below. If Kerberos authentication is used, authorization to the account is controlled by rules in <code>krb5_auth_rules(5)</code>. If this authorization fails, fallback to normal <code>rcp</code> using <code>rhosts</code> will occur only if the <code>-PO</code> option is used explicitly on the command line or is specified in <code>krb5.conf(4)</code>. If authorization succeeds, remote copy succeeds without any prompting of password. Also notice that the <code>-PN</code> or <code>-PO</code>, <code>-x</code>, and <code>-k realm</code> options are just supersets of the <code>-a</code> option.</p> <p><code>rcp</code> handles third party copies, where neither source nor target files are on the current machine. Hostnames may also take the form</p> <pre><i>username@hostname: filename</i></pre> <p>to use <i>username</i> rather than your current local user name as the user name on the remote host. <code>rcp</code> also supports Internet domain addressing of the remote host, so that:</p> <pre><i>username@host.domain: filename</i></pre> |

## rcp(1)

specifies the username to be used, the hostname, and the domain in which that host resides. File names that are not full path names will be interpreted relative to the home directory of the user named *username*, on the remote host.

### OPTIONS

The following options are supported:

- a This option explicitly enables Kerberos authentication and trusts the `.k5login` file for access-control. If the authorization check by `in.rshd(1M)` on the server-side succeeds and if the `.k5login` file permits access, the user is allowed to carry out the `rcp` transfer.
- k *realm* Causes `rcp` to obtain tickets for the remote host in *realm* instead of the remote host's realm as determined by `krb5.conf(4)`.
- p Attempts to give each copy the same modification times, access times, modes, and ACLs if applicable as the original file.
- PO
- PN Explicitly requests new (-PN) or old (-PO) version of the Kerberos "rcmd" protocol. The new protocol avoids many security problems prevalent in the old one and is regarded much more secure, but is not interoperable with older (MIT/SEAM) servers. The new protocol is used by default, unless explicitly specified using these options or through `krb5.conf(4)`. If Kerberos authorization fails when using the old "rcmd" protocol, there is fallback to regular, non-kerberized `rcp`. This is not the case when the new, more secure "rcmd" protocol is used.
- r Copies each subtree rooted at *filename*; in this case the destination must be a directory.
- x Causes the information transferred between hosts to be encrypted. Notice that the command is sent unencrypted to the remote system. All subsequent transfers are encrypted.

### USAGE

See `largefile(5)` for the description of the behavior of `rcp` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

The `rcp` command is IPv6-enabled. See `ip6(7P)`. IPv6 is not currently supported with Kerberos V5 authentication.

For the kerberized `rcp` session, each user may have a private authorization list in a file `.k5login` in their home directory. Each line in this file should contain a Kerberos principal name of the form *principal/instance@realm*. If there is a `~/k5login` file, then access is granted to the account if and only if the originater user is authenticated to one of the principals named in the `~/k5login` file. Otherwise, the originating user will be granted access to the account if and only if the authenticated principal name of the user can be mapped to the local account name using the *authenticated-principal-name* → *local-user-name* mapping rules. The `.k5login` file (for access control) comes into play only when Kerberos authentication is being done.

**EXIT STATUS** The following exit values are returned:

0 All files were copied successfully.  
 >0 An error occurred.

See the NOTES section for caveats on the exit code.

**FILES** \$HOME/.profile  
 \$HOME/.k5login File containing Kerberos principals that are allowed access  
 /etc/krb5/krb5.conf Kerberos configuration file

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWrcmdc       |
| CSI            | Enabled         |

**SEE ALSO** [cpio\(1\)](#), [ftp\(1\)](#), [rlogin\(1\)](#), [rsh\(1\)](#), [setfacl\(1\)](#), [tar\(1\)](#), [tar\(1\)](#), [in.rshd\(1M\)](#), [hosts.equiv\(4\)](#), [krb5.conf\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#), [krb5\\_auth\\_rules\(5\)](#), [inet\(7P\)](#), [inet6\(7P\)](#), [ip6\(7P\)](#)

**NOTES** `rcp` is meant to copy between different hosts. Attempting to `rcp` a file onto itself, as with:

```
example% rcp tmp/file myhost:/tmp/file
```

results in a severely corrupted file.

`rcp` may not correctly fail when the target of a copy is a file instead of a directory.

`rcp` can become confused by output generated by commands in a `$HOME/.profile` on the remote host.

`rcp` requires that the source host have permission to execute commands on the remote host when doing third-party copies.

`rcp` does not properly handle symbolic links. Use `tar` or `cpio` piped to `rsh` to obtain remote copies of directories containing symbolic links or named pipes. See [tar\(1\)](#) and [cpio\(1\)](#).

If you forget to quote metacharacters intended for the remote host, you will get an incomprehensible error message.

`rcp` will fail if you copy ACLs to a file system that does not support ACLs.

`rcp` is CSI-enabled except for the handling of username, hostname, and domain.

rcp(1)

When `rcp` is used to perform third-party copies where either of the remote machines is not running Solaris, the exit code cannot be relied upon. That is, errors could occur when success is reflected in the exit code, or the copy could be completely successful even though an error is reflected in the exit code.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>DESCRIPTION</b> | <p>The <code>rdist</code> utility maintains copies of files on multiple hosts. It preserves the owner, group, mode, and modification time of the master copies, and can update programs that are executing. (<i>Note:</i> <code>rdist</code> does not propagate ownership or mode changes when the file contents have not changed.) Normally, a copy on a remote host is updated if its size or modification time differs from the original on the local host. With the <code>-y</code> option (younger mode), only the modification times are checked, not the size. See <b>OPTIONS</b> below.</p> <p>There are two forms of the <code>rdist</code> command. In the first form shown in the <b>SYNOPSIS</b> section above, <code>rdist</code> reads the indicated <i>distfile</i> for instructions on updating files and/or directories. If <i>distfile</i> is <code>'-'</code>, the standard input is used. If no <code>-f</code> option is present, <code>rdist</code> first looks in its working directory for <i>distfile</i>, and then for <code>Distfile</code>, for instructions.</p> <p>The second form shown in <b>SYNOPSIS</b> uses the <code>-c</code> option and specifies paths as command line options.</p> <p>The user can opt for a secure session of <code>rdist</code> which uses Kerberos V5 for authentication. Encryption of the data being transferred is also possible. The <code>rdist</code> session can be kerberized using any of the following Kerberos specific options: <code>-a</code>, <code>-PN</code> or <code>-PO</code>, <code>-x</code>, and <code>-k realm</code>. Some of these options (<code>-x</code>, <code>-PN</code> or <code>-PO</code>, and <code>-f</code> or <code>-F</code>) can also be specified in the <code>[appdefaults]</code> section of <code>krb5.conf(4)</code>. The usage of these options and the expected behavior is discussed in the <b>OPTIONS</b> section below. If Kerberos authentication is used, authorization to the account is controlled by rules in <code>krb5_auth_rules(5)</code>. If this authorization fails, fallback to normal <code>rdist</code> using <code>rhosts</code> will occur only if the <code>-PO</code> option is used explicitly on the command line or is specified in <code>krb5.conf(4)</code>. Also notice that the <code>-PN</code> or <code>-PO</code>, <code>-x</code>, and <code>-k realm</code> options are just supersets of the <code>-a</code> option. In order to use the non-secure version of <code>rdist</code> across machines, each host machine must have a <code>/etc/host.equiv</code> file, or the user must have an entry in the <code>.rhosts</code> file in the home directory. See <code>hosts.equiv(4)</code> for more information.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a<br/>This option explicitly enables Kerberos authentication and trusts the <code>.k5login</code> file for access-control. If the authorization check by <code>in.rshd(1M)</code> on the server-side succeeds and if the <code>.k5login</code> file permits access, the user is allowed to carry out the <code>rdist</code> transfer.</li> <li>-b<br/>Binary comparison. Performs a binary comparison and updates files if they differ, rather than merely comparing dates and sizes.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## rdist(1)

- c *pathname* . . . [*login @*]*hostname*[:*destpath* ]  
Copies each *pathname* to the named host; if *destpath* is specified, it will not update any *pathname* on the named host. (Relative filenames are taken as relative to your home directory.) If the '*login @*' prefix is given, the update is performed with the user ID of *login*. If the '*:destpath*' is given, the remote file is installed as that *pathname*.
- d *macro=**value*  
Defines *macro* to have *value*. This option is used to define or override macro definitions in the distfile. *value* can be the empty string, one name, or a list of names surrounded by parentheses and separated by white space.
- D  
Enables debugging.
- f *distfile*  
Uses the description file *distfile*. A '-' as the *distfile* argument denotes the standard input.
- h  
Follows symbolic links. Copies the file that the link points to rather than the link itself.
- i  
Ignores unresolved links. *rdist* will normally try to maintain the link structure of files being transferred and warn the user if all the links cannot be found.
- k *realm*  
Causes *rdist* to obtain tickets for the remote host in *realm* instead of the remote host's realm as determined by *krb5.conf*(4).
- m *host*  
Limits which machines are to be updated. Multiple -m arguments can be given to limit updates to a subset of the hosts listed in the distfile.
- n  
Prints the commands without executing them. This option is useful for debugging a distfile.
- PO  
-PN  
Explicitly requests new (-PN) or old (-PO) version of the Kerberos "rcmd" protocol. The new protocol avoids many security problems prevalent in the old one and is regarded much more secure, but is not interoperable with older (MIT/SEAM) servers. The new protocol is used by default, unless explicitly specified using these options or through *krb5.conf*(4). If Kerberos authorization fails when using the old "rcmd" protocol, there is fallback to regular, non-kerberized *rdist*. This is not the case when the new, more secure "rcmd" protocol is used.
- q  
Quiet mode. Does not display the files being updated on the standard output.

- R  
Removes extraneous files. If a directory is being updated, removes files on the remote host that do not correspond to those in the master (local) directory. This is useful for maintaining truly identical copies of directories.
- v  
Verifies that the files are up to date on all the hosts. Any files that are out of date are displayed, but no files are updated, nor is any mail sent.
- w  
Whole mode. The whole file name is appended to the destination directory name. Normally, only the last component of a name is used when renaming files. This preserves the directory structure of the files being copied, instead of flattening the directory structure. For instance, renaming a list of files such as `dir1/dir2` to `dir3` would create files `dir3/dir1` and `dir3/dir2` instead of `dir3` and `dir3`. When the `-w` option is used with a filename that begins with `~`, everything except the home directory is appended to the destination name.
- x  
Causes the information transferred between hosts to be encrypted. Notice that the command is sent unencrypted to the remote system. All subsequent transfers are encrypted.
- Y  
Younger mode. Does not update remote copies that are younger than the master copy, but issues a warning message instead. Only modification times are checked. No comparison of size is made.

**USAGE****White Space Characters**

NEWLINE, TAB, and SPACE characters are all treated as white space; a mapping continues across input lines until the start of the next mapping: either a single *filename* followed by a `'->'` or the opening parenthesis of a filename list.

**Comments**

Comments begin with `#` and end with a NEWLINE.

**Distfiles**

The distfile contains a sequence of entries that specify the files to be copied, the destination files to be copied, the destination hosts, and what operations to perform to do the updating. Each entry has one of the following formats:

```
variable_name '=' name_list
[ label: ] source_list '->' destination_list command_list
[ label: ] source_list ':' time_stamp_file command_list
```

The first format is used for defining variables. The second format is used for distributing files to other hosts. The third format is used for making lists of files that have been changed since some given date. The source list specifies a list of files and/or directories on the local host that are to be used as the master copy for distribution. The destination list is the list of hosts to which these files are to be copied. Each file in the source list is added to a list of changes if the file is out of date on the host that is being updated (second format) or if the file is newer than the time stamp file (third format). Labels are optional. They are used to identify a command for partial updates. The

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                     | <p>colon (:) is used after an optional label, while the double colon (: :) is used for making lists of files that have been changed since a certain date (specified by the date/time of the <i>time_stamp</i> file). Typically, only <code>notify</code> is used with the <code>'::'</code> format of the command line.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Macros</b>                       | <p><code>rdist</code> has a limited macro facility. Macros are only expanded in filename or hostname lists, and in the argument lists of certain primitives. Macros cannot be used to stand for primitives or their options, or the <code>'-&gt;'</code> or <code>'::'</code> symbols.</p> <p>A macro definition is a line of the form:</p> <pre>macro = value</pre> <p>A macro reference is a string of the form:</p> <pre>#{macro}</pre> <p>although (as with <code>make(1S)</code>) the braces can be omitted if the macro name consists of just one character.</p>                                                                                                                                                                                                                                                                                                   |
| <b>Kerberos Access-Control file</b> | <p>For the kerberized <code>rdist</code> session, each user may have a private authorization list in a file <code>.k5login</code> in their home directory. Each line in this file should contain a Kerberos principal name of the form <i>principal/instance@realm</i>. If there is a <code>~/k5login</code> file, then access is granted to the account if and only if the originator user is authenticated to one of the principals named in the <code>~/k5login</code> file. Otherwise, the originating user will be granted access to the account if and only if the authenticated principal name of the user can be mapped to the local account name using the <i>authenticated-principal-name</i> → <i>local-user-name</i> mapping rules. The <code>.k5login</code> file (for access control) comes into play only when Kerberos authentication is being done.</p> |
| <b>Metacharacters</b>               | <p>The shell meta-characters: <code>[, ], {, }, *,</code> and <code>?</code> are recognized and expanded (on the local host only) just as they are with <code>ssh(1)</code>. Metacharacters can be escaped by prepending a backslash.</p> <p>The <code>~</code> character is also expanded in the same way as with <code>ssh</code>; however, it is expanded separately on the local and destination hosts.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Filenames</b>                    | <p>File names that do not begin with <code>' / '</code> or <code>' ~ '</code> are taken to be relative to user's home directory on each destination host; they are <i>not</i> relative to the current working directory. Multiple file names must be enclosed within parentheses.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Primitives</b>                   | <p>The following primitives can be used to specify actions <code>rdist</code> is to take when updating remote copies of each file.</p> <pre>install [-b] [-h] [-i] [-R] [-v] [-w] [-y] [newname]</pre> <p>Copy out of date files and directories (recursively). If no <i>newname</i> operand is given, the name of the local file is given to the remote host's copy. If absent from the remote host, parent directories in a filename's path are created. To help prevent disasters, a non-empty directory on a target host is not replaced with a regular file or a symbolic link by <code>rdist</code>. However, when using the <code>-R</code> option, a non-empty directory is removed if the corresponding filename is completely absent on the master host.</p>                                                                                                   |

The options for `install` have the same semantics as their command line counterparts, but are limited in scope to a particular map. The login name used on the destination host is the same as the local host unless the destination name is of the format `login@host`. In that case, the update is performed under the username `login`.

`notify address ...`

Send mail to the indicated email `address` of the form:

```
user@host
```

that lists the files updated and any errors that may have occurred. If an address does not contain a '@host' suffix, `rdist` uses the name of the destination host to complete the address.

`except filename ...`

Omit from updates the files named as arguments.

`except_pat pattern ...`

Omit from updates the filenames that match each regular-expression `pattern` (see [ed\(1\)](#) for more information on regular expressions). Note that '\' and '\$' characters must be escaped in the distfile. Shell variables can also be used within a pattern, however shell filename expansion is not supported.

`special [filename] ... "command-line "`

Specify a Bourne shell, [sh\(1\)](#) command line to execute on the remote host after each named file is updated. If no `filename` argument is present, the `command-line` is performed for every updated file, with the shell variable `FILE` set to the file's name on the local host. The quotation marks allow `command-line` to span input lines in the distfile; multiple shell commands must be separated by semicolons (;).

The default working directory for the shell executing each `command-line` is the user's home directory on the remote host.

**IPv6** The `rdist` command is IPv6-enabled. See [ip6\(7P\)](#). IPv6 is not currently supported with Kerberos V5 authentication.

**EXAMPLES** **EXAMPLE 1** A sample distfile

The following sample distfile instructs `rdist` to maintain identical copies of a shared library, a shared-library initialized data file, several include files, and a directory, on hosts named `hermes` and `magus`. On `magus`, commands are executed as `super-user`. `rdist` notifies `merlin@druid` whenever it discovers that a local file has changed relative to a timestamp file. (Parentheses are used when the source or destination list contains zero or more names separated by white-space.)

```
HOSTS = ( hermes root@magus )

FILES = ( /usr/local/lib/libcant.so.1.1
          /usrlocal/lib/libcant.sa.1.1 /usr/local/include/{*.h}
          /usr/local/bin )
```

## rdist(1)

### EXAMPLE 1 A sample distfile *(Continued)*

```
(${FILES}) -> (${HOSTS})
    install -R ;
${FILES} :: /usr/local/lib/timestamp
    notify merlin@druid ;
```

|              |                     |                                                             |
|--------------|---------------------|-------------------------------------------------------------|
| <b>FILES</b> | ~/.rhosts           | User's trusted hosts and users                              |
|              | /etc/host.equiv     | system trusted hosts and users                              |
|              | /tmp/rdist*         | Temporary file for update lists                             |
|              | \$HOME/.k5login     | File containing Kerberos principals that are allowed access |
|              | /etc/krb5/krb5.conf | Kerberos configuration file                                 |

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWrcmdc       |

**SEE ALSO** `ssh(1)`, `ed(1)`, `make(1S)`, `sh(1)`, `in.rshd(1M)`, `stat(2)`, `hosts.equiv(4)`, `krb5.conf(4)`, `attributes(5)`, `krb5_auth_rules(5)`, `ip6(7P)`

**DIAGNOSTICS** A complaint about mismatch of `rdist` version numbers may really stem from some problem with starting your shell, for example, you are in too many groups.

**WARNINGS** The super-user does not have its accustomed access privileges on NFS mounted file systems. Using `rdist` to copy to such a file system may fail, or the copies may be owned by user "nobody".

**BUGS** Source files must reside or be mounted on the local host.

There is no easy way to have a special command executed only once after all files in a directory have been updated.

Variable expansion only works for name lists; there should be a general macro facility.

`rdist` aborts on files that have a negative modification time (before Jan 1, 1970).

There should be a "force" option to allow replacement of non-empty directories by regular files or symlinks. A means of updating file modes and owners of otherwise identical files is also needed.

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>/usr/bin/read</b> | <p>The read utility will read a single line from standard input.</p> <p>By default, unless the <code>-r</code> option is specified, backslash (<code>\</code>) acts as an escape character. If standard input is a terminal device and the invoking shell is interactive, read will prompt for a continuation line when:</p> <ul style="list-style-type: none"> <li>■ The shell reads an input line ending with a backslash, unless the <code>-r</code> option is specified.</li> <li>■ A here-document is not terminated after a NEWLINE character is entered.</li> </ul> <p>The line will be split into fields as in the shell. The first field will be assigned to the first variable <i>var</i>, the second field to the second variable <i>var</i>, and so forth. If there are fewer <i>var</i> operands specified than there are fields, the leftover fields and their intervening separators will be assigned to the last <i>var</i>. If there are fewer fields than <i>vars</i>, the remaining <i>vars</i> will be set to empty strings.</p> <p>The setting of variables specified by the <i>var</i> operands will affect the current shell execution environment. If it is called in a subshell or separate utility execution environment, such as one of the following:</p> <pre>(read foo) nohup read ... find . -exec read ... \;</pre> <p>it will not affect the shell variables in the caller's environment.</p> <p>The standard input must be a text file.</p> <p><b>sh</b> One line is read from the standard input and, using the internal field separator, <code>IFS</code> (normally space or tab), to delimit word boundaries, the first word is assigned to the first <i>name</i>, the second word to the second <i>name</i>, and so on, with leftover words assigned to the last <i>name</i>. Lines can be continued using <code>\newline</code>. Characters other than NEWLINE can be quoted by preceding them with a backslash. These backslashes are removed before words are assigned to <i>names</i>, and no interpretation is done on the character that follows the backslash. The return code is 0, unless an end-of-file is encountered.</p> <p><b>cs</b> The notation:</p> <pre>set variable = \$&lt;</pre> <p>loads one line of standard input as the value for <i>variable</i>. (See <code>cs(1)</code>).</p> |

|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ksh</b>                   | The shell input mechanism. One line is read and is broken up into fields using the characters in IFS as separators. The escape character, (\), is used to remove any special meaning for the next character and for line continuation. In raw mode, -r, the \ character is not treated specially. The first field is assigned to the first <i>name</i> , the second field to the second <i>name</i> , and so on, with leftover fields assigned to the last <i>name</i> . The -p option causes the input line to be taken from the input pipe of a process spawned by the shell using  &. If the -s flag is present, the input will be saved as a command in the history file. The flag -u can be used to specify a one digit file descriptor unit <i>n</i> to read from. The file descriptor can be opened with the exec special command. The default value of <i>n</i> is 0. If <i>name</i> is omitted, REPLY is used as the default <i>name</i> . The exit status is 0 unless the input file is not open for reading or an end-of-file is encountered. An end-of-file with the -p option causes cleanup for this process so that another can be spawned. If the first argument contains a ?, the remainder of this word is used as a <i>prompt</i> on standard error when the shell is interactive. The exit status is 0 unless an end-of-file is encountered. |
| <b>OPTIONS</b>               | The following option is supported:<br><br>-r            Does not treat a backslash character in any special way. Considers each backslash to be part of the input line.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>OPERANDS</b>              | The following operand is supported:<br><br><i>var</i> The name of an existing or non-existing shell variable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>EXAMPLES</b>              | <b>EXAMPLE 1</b> An example of the read command<br><br>The following example for /usr/bin/read prints a file with the first field of each line moved to the end of the line:<br><br><pre>example% while read -r xx yy do     printf "%s %s\n" "\$yy" "\$xx" done &lt; input_file</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>ENVIRONMENT VARIABLES</b> | See environ(5) for descriptions of the following environment variables that affect the execution of read: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.<br><br>IFS            Determines the internal field separators used to delimit fields.<br><br>PS2            Provides the prompt string that an interactive shell will write to standard error when a line ending with a backslash is read and the -r option was not specified, or if a here-document is not terminated after a newline character is entered.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## readfile(1F)

| <b>NAME</b>        | readfile, longline – reads file, gets longest line                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |         |

| <b>SYNOPSIS</b>    | <b>readfile</b> <i>filename</i><br><b>longline</b> [ <i>filename</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>The <code>readfile</code> function reads <i>filename</i> and copies it to <i>stdout</i>. No translation of NEWLINE is done. It keeps track of the longest line it reads and if there is a subsequent call to <code>longline</code>, the length of that line, including the NEWLINE character, is returned.</p> <p>The <code>longline</code> function returns the length, including the NEWLINE character, of the longest line in <i>filename</i>. If <i>filename</i> is not specified, it uses the file named in the last call to <code>readfile</code>.</p> |                |                 |              |         |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Typical use of <code>readfile</code> and <code>longline</code></p> <p>Here is a typical use of <code>readfile</code> and <code>longline</code> in a text frame definition file:</p> <pre>.<br/>. .<br/>text=`readfile myfile`<br/>columns=`longline`<br/>. .<br/>.</pre>                                                                                                                                                                                                                                                                    |                |                 |              |         |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |              |         |

| <b>DIAGNOSTICS</b> | <p>If <i>filename</i> does not exist, <code>readfile</code> will return <code>FALSE</code> (that is, the expression will have an error return).</p> <p><code>longline</code> returns 0 if a <code>readfile</code> has not previously been issued.</p>                                                                                                                                                                                                                                                                                                           |                |                 |              |         |
| <b>NOTES</b>       | More than one descriptor can call <code>readfile</code> in the same frame definition file. In text frames, if one of those calls is made from the <code>text</code> descriptor, then a subsequent use of <code>longline</code> will always get the longest line of the file read by the <code>readfile</code> associated with the <code>text</code> descriptor, even if it was not the most recent use of <code>readfile</code> .                                                                                                                               |                |                 |              |         |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>NAME</b>        | readonly – shell built-in function to protect the value of the given variable from reassignment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <pre>sh  readonly [name...] ksh **readonly [ name [ = value]...]     **readonly -p</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p><b>sh</b> The given <i>names</i> are marked <code>readonly</code> and the values of the these <i>names</i> may not be changed by subsequent assignment. If no arguments are given, a list of all <code>readonly</code> names is printed.</p> <p><b>ksh</b> The given <i>names</i> are marked <code>readonly</code> and these names cannot be changed by subsequent assignment.</p> <p>When <code>-p</code> is specified, <code>readonly</code> writes to the standard output the names and values of all read-only variables, in the following format:</p> <pre>"readonly %s=%s\n", name, value</pre> <p>if <i>name</i> is set, and:</p> <pre>"readonly \$s\n", name</pre> <p>if <i>name</i> is unset.</p> <p>The shell formats the output, including the proper use of quoting, so that it is suitable for reinput to the shell as commands that achieve the same value and <code>readonly</code> attribute-setting results in a shell execution environment in which:</p> <ol style="list-style-type: none"> <li>1. Variables with values set at the time they were output do not have the <code>readonly</code> attribute set.</li> <li>2. Variables that were unset at the time they were output do not have a value at the time at which the saved output is reinput to the shell.</li> </ol> <p>On this man page, <a href="#">ksh(1)</a> commands that are preceded by one or two <code>**</code> (asterisks) are treated specially in the following ways:</p> <ol style="list-style-type: none"> <li>1. Variable assignment lists preceding the command remain in effect when the command completes.</li> <li>2. I/O redirections are processed after variable assignments.</li> <li>3. Errors cause a script that contains them to abort.</li> <li>4. Words, following a command preceded by <code>**</code> that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the <code>=</code> sign and word splitting and file name generation are not performed.</li> </ol> |

readonly(1)

| <b>NAME</b>        | refer – expand and insert references from a bibliographic database                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>    | <b>refer</b> [-ben] [-ar] [-cstring] [-kx] [-lm,n] [-p filename] [-skeys] filename...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b> | <p>refer is a preprocessor for <code>nroff(1)</code>, or <code>troff(1)</code>, that finds and formats references. The input files (standard input by default) are copied to the standard output, except for lines between <code>' . [ ' and ' . ] '</code> command lines. Such lines are assumed to contain keywords as for <code>lookbib(1)</code>, and are replaced by information from a bibliographic data base. The user can avoid the search, override fields from it, or add new fields. The reference data, from whatever source, is assigned to a set of <code>troff</code> strings. Macro packages such as <code>ms(5)</code> print the finished reference text from these strings. A flag is placed in the text at the point of reference. By default, the references are indicated by numbers.</p> <p>When <code>refer</code> is used with <code>eqn(1)</code>, <code>neqn</code>, or <code>tbl(1)</code>, <code>refer</code> should be used first in the sequence, to minimize the volume of data passed through pipes.</p>                                                                                                                                                                                                                                                                                                                                                              |
| <b>OPTIONS</b>     | <p><code>-b</code> Bare mode — do not put any flags in text (neither numbers or labels).</p> <p><code>-e</code> Accumulate references instead of leaving the references where encountered, until a sequence of the form:</p> <pre style="margin-left: 2em;">. [   \$LIST\$ .]</pre> <p>is encountered, and then write out all references collected so far. Collapse references to the same source.</p> <p><code>-n</code> Do not search the default file.</p> <p><code>-ar</code> Reverse the first <i>r</i> author names (Jones, J. A. instead of J. A. Jones). If <i>r</i> is omitted, all author names are reversed.</p> <p><code>-cstring</code> Capitalize (with SMALL CAPS) the fields whose key-letters are in <i>string</i>.</p> <p><code>-kx</code> Instead of numbering references, use labels as specified in a reference data line beginning with the characters <code>%x</code>; By default, <i>x</i> is L.</p> <p><code>-lm,n</code> Instead of numbering references, use labels from the senior author's last name and the year of publication. Only the first <i>m</i> letters of the last name and the last <i>n</i> digits of the date are used. If either of <i>m</i> or <i>n</i> is omitted, the entire name or date, respectively, is used.</p> <p><code>-p filename</code> Take the next argument as a file of references to be searched. The default file is searched last.</p> |

refer(1)

*-skeys* Sort references by fields whose key-letters are in the *keys* string, and permute reference numbers in the text accordingly. Using this option implies the *-e* option. The key-letters in *keys* may be followed by a number indicating how many such fields are used, with a + sign taken as a very large number. The default is *AD*, which sorts on the senior author and date. To sort on all authors and then the date, for instance, use the options '*-sA+T*'.

**FILES** /usr/lib/refer directory of programs  
/usr/lib/refer/papers directory of default publication lists and indexes

**ATTRIBUTES** See *attributes(5)* for descriptions of the following attributes:

| <b>NAME</b>                  | regcmp – regular expression compile                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>              | <b>regcmp</b> [-] <i>filename</i> ...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b>           | The <code>regcmp</code> command performs a function similar to <code>regcomp</code> and, in most cases, precludes the need for calling <code>regcomp</code> from C programs. Bypassing <code>regcmp</code> saves on both execution time and program size. The command <code>regcmp</code> compiles the regular expressions in <i>filename</i> and places the output in <i>filename.i</i> .                                                                                                                                                                                                                                                                                                                                                     |
| <b>OPTIONS</b>               | – If the <code>-</code> option is used, the output is placed in <i>filename.c</i> . The format of entries in <i>filename</i> is a name (C variable) followed by one or more blanks followed by one or more regular expressions enclosed in double quotes. The output of <code>regcmp</code> is C source code. Compiled regular expressions are represented as <code>extern char</code> vectors. <i>filename.i</i> files may thus be <code>#included</code> in C programs, or <i>filename.c</i> files may be compiled and later loaded. In the C program that uses the <code>regcmp</code> output, <code>regex(abc, line)</code> applies the regular expression named <code>abc</code> to <code>line</code> . Diagnostics are self-explanatory. |
| <b>EXAMPLES</b>              | <p><b>EXAMPLE 1</b> Examples of the <code>regcmp</code> command.</p> <pre>name      " ([A-Za-z] [A-Za-z0-9_]*) \$0 "</pre> <pre>telno     " \({0,1} ([2-9] [01] [1-9]) \$0\) {0,1} * "</pre> <pre>          " ([2-9] [0-9] {2}) \$1 [ -] {0,1} "</pre> <pre>          " ([0-9] {4}) \$2 "</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                              | The three arguments to <code>telno</code> shown above must all be entered on one line.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                              | In the C program that uses the <code>regcmp</code> output,                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>NAME</b>        | regex – match patterns against a string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SYNOPSIS</b>    | <b>regex</b> [-e] [ -v "string" ] [ <i>pattern template</i> ] ... <i>pattern</i> [ <i>template</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b> | <p>The <code>regex</code> command takes a string from the standard input, and a list of <i>pattern</i> / <i>template</i> pairs, and runs <code>regex()</code> to compare the string against each <i>pattern</i> until there is a match. When a match occurs, <code>regex</code> writes the corresponding <i>template</i> to the standard output and returns TRUE. The last (or only) <i>pattern</i> does not need a <i>template</i>. If that is the pattern that matches the string, the function simply returns TRUE. If no match is found, <code>regex</code> returns FALSE.</p> <p>The argument <i>pattern</i> is a regular expression of the form described in <code>regex()</code>. In most cases, <i>pattern</i> should be enclosed in single quotes to turn off special meanings of characters. Note that only the final <i>pattern</i> in the list may lack a <i>template</i>.</p> <p>The argument <i>template</i> may contain the strings <code>\$m0</code> through <code>\$m9</code>, which will be expanded to the part of <i>pattern</i> enclosed in <code>( . . . )\$0</code> through <code>( . . . )\$9</code> constructs (see examples below). Note that if you use this feature, you must be sure to enclose <i>template</i> in single quotes so that FMLI does not expand <code>\$m0</code> through <code>\$m9</code> at parse time. This feature gives <code>regex</code> much of the power of <code>cut(1)</code>, <code>paste(1)</code>, and <code>grep(1)</code>, and some of the capabilities of <code>sed(1)</code>. If there is no <i>template</i>, the default is <code>\$m0\$m1\$m2\$m3\$m4\$m5\$m6\$m7\$m8\$m9</code>.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-e                      Evaluates the corresponding template and writes the result to the standard output.</li> <li>-v "string"            Uses <i>string</i> instead of the standard input to match against patterns.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Cutting letters out of a string</p> <p>To cut the 4th through 8th letters out of a string (this example will output <code>strin</code> and return TRUE):</p> <pre>'regex -v "my string is nice" '^.{3}(.{5})\$0' '\$m0'</pre> <p><b>EXAMPLE 2</b> Validating input in a form</p> <p>In a form, to validate input to field 5 as an integer:</p> <pre>valid='regex -v "\$F5" '^ [0-9]+\$'</pre> <p><b>EXAMPLE 3</b> Translating an environment variable in a form</p> <p>In a form, to translate an environment variable which contains one of the numbers 1, 2, 3, 4, 5 to the letters a, b, c, d, e:</p> <pre>value='regex -v "\$VAR1" 1 a 2 b 3 c 4 d 5 e '.*' 'Error'</pre> <p>Note the use of the pattern <code>' .* '</code> to mean "anything else".</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## regex(1F)

### EXAMPLE 4 Using backquoted expressions

In the example below, all three lines constitute a single backquoted expression. This expression, by itself, could be put in a menu definition file. Since backquoted expressions are expanded as they are parsed, and output from a backquoted expression (the `cat` command, in this example) becomes part of the definition file being parsed, this expression would read `/etc/passwd` and make a dynamic menu of all the login ids on the system.

```
`cat /etc/passwd | regex '^([:]*)$0.*$' `
name=$m0
action='message "$m0 is a user"```
```

**DIAGNOSTICS** If none of the patterns match, `regex` returns `FALSE`, otherwise `TRUE`.

**NOTES** Patterns and templates must often be enclosed in single quotes to turn off the special meanings of characters. Especially if you use the `$m0` through `$m9` variables in the template, since FMLI will expand the variables (usually to `""`) before `regex` even sees them.

Single characters in character classes (inside `[ ]`) must be listed before character ranges, otherwise they will not be recognized. For example, `[a-zA-Z_/_]` will not find underscores (`_`) or slashes (`/`), but `[_/_a-zA-Z]` will.

The regular expressions accepted by `regcmp` differ slightly from other utilities (that is, `sed`, `grep`, `awk`, `ed`, and so forth).

`regex` with the `-e` option forces subsequent commands to be ignored. In other words, if a backquoted statement appears as follows:

```
`regex -e ...; command1; command2`
```

`command1` and `command2` would never be executed. However, dividing the expression into two:

```
`regex -e ...``command1; command2`
```

would yield the desired result.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

| <b>SYNOPSIS</b>    | <b>reinit</b> <i>filename</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>The <code>reinit</code> command is used to change the values of descriptors defined in the initialization file that was named when <code>fml</code> was invoked and/or define additional descriptors. FMLI will parse and evaluate the descriptors in <i>filename</i>, and then continue running the current application. The argument <i>filename</i> must be the name of a valid FMLI initialization file.</p> <p>The <code>reinit</code> command does not re-display the introductory frame or change the layout of screen labels for function keys.</p> |                |                 |              |         |

| <b>DESCRIPTION</b>               | The <b>renice</b> command alters the scheduling priority of one or more running processes. By default, the processes to be affected are specified by their process IDs.<br><br>If the first operand is a number within the valid range of priorities (-20 to 20), <b>renice</b> will treat it as a <i>priority</i> (as in all but the first synopsis form). Otherwise, <b>renice</b> will treat it as an <i>ID</i> (as in the first synopsis form).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Altering Process Priority</b> | Users other than the privileged user may only alter the priority of processes they own, and can only monotonically increase their “nice value” within the range 0 to 19. This prevents overriding administrative fiats. The privileged user may alter the priority of any process and set the priority to any value in the range -20 to 19. Useful priorities are: 19 (the affected processes will run only when nothing else in the system wants to); 0 (the “base” scheduling priority); and any negative value (to make things go very fast). 20 is an acceptable nice value, but will be rounded down to 19.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>OPTIONS</b>                   | <b>renice</b> supports the following option features: <ul style="list-style-type: none"><li>■ The first operand, <i>priority</i>, must precede the options and can have the appearance of a multi-digit option.</li><li>■ The -g, -p, and -u options can each take multiple option-arguments.</li><li>■ The <i>pid</i> option-argument can be used without its -p option.</li><li>■ The -i option can be used to specify the <i>ID</i> type for the ID list. This is preferred in specifying <i>ID</i> type over the use of the -g   -p   -u syntax, which is now obsolete. See NOTES.</li></ul> The following options are supported:<br><br>-g                   Interprets all operands or just the <i>gid</i> arguments as unsigned decimal integer process group IDs.<br><br>-i                   This option, together with the <i>ID</i> list arguments, specifies a class of processes to which the <b>renice</b> command is to apply. The interpretation of the ID list depends on the value of <i>idtype</i> . The valid <i>idtype</i> arguments are: <i>pid</i> , <i>pgid</i> , <i>uid</i> , <i>gid</i> , <i>sid</i> , <i>taskid</i> , <i>projid</i> , and <i>zoneid</i> .<br><br>-n <i>increment</i> Specifies how the system scheduling priority of the specified process or processes is to be adjusted. The <i>increment</i> option-argument is a positive or negative decimal integer that will be used to modify the system scheduling priority of the specified |

process or processes. Positive *increment* values cause a lower system scheduling priority. Negative *increment* values may require appropriate privileges and will cause a higher system scheduling priority.

- p** Interprets all operands or just the *pid* arguments as unsigned decimal integer process IDs. The **-p** option is the default if no options are specified.
- u** Interprets all operands or just the *user* argument as users. If a user exists with a user name equal to the operand, then the user ID of that user will be used in further processing. Otherwise, if the operand represents an unsigned decimal integer, it will be used as the numeric user ID of the user.

**OPERANDS** The following operands are supported:

- ID* A process ID, process group ID, or user name/user ID, depending on the option selected.
- priority* The value specified is taken as the actual system scheduling priority, rather than as an increment to the existing system scheduling priority. Specifying a scheduling priority higher than that of the existing process may require appropriate privileges.

**EXAMPLES** **EXAMPLE 1** Adjusting the scheduling priority of process IDs

Adjust the system scheduling priority so that process IDs 987 and 32 would have a lower scheduling priority:

```
example% renice -n 5 -p 987 32
```

**EXAMPLE 2** Adjusting the scheduling priority of group IDs

Adjust the system scheduling priority so that group IDs 324 and 76 would have a higher scheduling priority, if the user has the appropriate privileges to do so:

```
example% renice -n -4 -g 324 76
```

**EXAMPLE 3** Adjusting the scheduling priority of a user ID and user name

Adjust the system scheduling priority so that numeric user ID 8 and user *sas* would have a lower scheduling priority:

```
example% renice -n 4 -u 8 sas
```

**ENVIRONMENT VARIABLES** See *environ(5)* for descriptions of the following environment variables that affect the execution of *renice*: *LANG*, *LC\_ALL*, *LC\_CTYPE*, *LC\_MESSAGES*, and *NLSPATH*.

**EXIT STATUS** The following exit values are returned:

- 0 Successful completion.

## renice(1)

>0           An error occurred.

**FILES**       /etc/passwd     map user names to user IDs

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Standard        |

**SEE ALSO**   [nice\(1\)](#), [passwd\(1\)](#), [priosctl\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**NOTES**       The renice syntax

```
renice [-n increment] [-i idtype] ID ...
```

is preferred over the old syntax

```
renice [-n increment] [-g | -p | -u] ID ...
```

which is now obsolete.

If you make the priority very negative, then the process cannot be interrupted.

To regain control you must make the priority greater than 0.

Users other than the privileged user cannot increase scheduling priorities of their own processes, even if they were the ones that decreased the priorities in the first place.

The `priosctl` command subsumes the function of `renice`.

reset(1F)

**NAME** reset – reset the current form field to its default values

**SYNOPSIS** **reset**

**DESCRIPTION** The `reset` function changes the entry in a field of a form to its default value; that is, the value displayed when the form was opened.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `attributes(5)`

| <b>NAME</b>        | rlogin – remote login                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>    | <b>rlogin</b> [-8EL] [-ec ] [-A] [-x] [-PN   -PO] [-f   -F] [-a]<br>[-l <i>username</i> ] [-k <i>realm</i> ] <i>hostname</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | <p>The <b>rlogin</b> utility establishes a remote login session from your terminal to the remote machine named <i>hostname</i>. The user can choose to kerberize the rlogin session using Kerberos V5 and also protect the data being transferred.</p> <p>Hostnames are listed in the <i>hosts</i> database, which may be contained in the <i>/etc/hosts</i> and <i>/etc/inet/ipnodes</i> files, the Network Information Service (NIS) <i>hosts</i> map, the Internet domain name server, or a combination of these. Each host has one official name (the first name in the database entry), and optionally one or more nicknames. Either official hostnames or nicknames may be specified in <i>hostname</i>.</p> <p>The user can opt for a secure rlogin session which uses Kerberos V5 for authentication. Encryption of the session data is also possible. The rlogin session can be kerberized using any of the following Kerberos specific options: <i>-A</i>, <i>-PN</i> or <i>-PO</i>, <i>-x</i>, <i>-f</i> or <i>-F</i>, and <i>-k realm</i>. Some of these options (<i>-x</i>, <i>-PN</i> or <i>-PO</i>, and <i>-f</i> or <i>-F</i>) can also be specified in the <i>[appdefaults]</i> section of <i>krb5.conf(4)</i>. The usage of these options and the expected behavior is discussed in the <b>OPTIONS</b> section below. If Kerberos authentication is used, authorization to the account is controlled through rules in <i>krb5_auth_rules(5)</i>. If this authorization fails, fallback to normal rlogin using <i>rhosts</i> will occur only if the <i>-PO</i> option is used explicitly on the command line or is specified in <i>krb5.conf(4)</i>. Also notice that the <i>-PN</i> or <i>-PO</i>, <i>-x</i>, <i>-f</i> or <i>-F</i>, and <i>-k realm</i> options are just supersets of the <i>-A</i> option.</p> <p>The remote terminal type is the same as your local terminal type, as given in your environment <i>TERM</i> variable. The terminal or window size is also copied to the remote system if the server supports the option. Changes in size are reflected as well. All echoing takes place at the remote site, so that (except for delays) the remote login is transparent. Flow control using Control-S and Control-Q and flushing of input and output on interrupts are handled properly.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li><i>-8</i> Passes eight-bit data across the net instead of seven-bit data.</li><li><i>-a</i> Forces the remote machine to ask for a password by sending a null local username.</li><li><i>-A</i> Explicitly enables Kerberos authentication and trusts the <i>.k5login</i> file for access-control. If the authorization check by <i>in.rlogind(1M)</i> on the server-side succeeds and if the <i>.k5login</i> file permits access, the user is allowed to login without supplying a password.</li><li><i>-ec</i> Specifies a different escape character, <i>c</i>, for the line used to disconnect from the remote host.</li><li><i>-E</i> Stops any character from being recognized as an escape character.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

- f Forwards a copy of the local credentials (Kerberos Ticket Granting Ticket) to the remote system. This is a non-forwardable ticket granting ticket. You must forward a ticket granting ticket if you need to authenticate yourself to other Kerberized network services on the remote host. An example is if your home directory on the remote host is NFS mounted via Kerberos V5. If your local credentials are not forwarded in this case, you will not be able to access your home directory. This option is mutually exclusive with the -F option.
- F Forwards a forwardable copy of the local credentials (Kerberos Ticket Granting Ticket) to the remote system. The -F option provides a superset of the functionality offered by the -f option. For example, with the -f option, after you connected to the remote host, any attempt to invoke /usr/bin/ftp, /usr/bin/telnet, /usr/bin/rlogin, or /usr/bin/rsh with the -f or -F options would fail. Thus, you would be unable to push your single network sign on trust beyond one system. This option is mutually exclusive with the -f option.
- k *realm* Causes rlogin to obtain tickets for the remote host in *realm* instead of the remote host's realm as determined by `krb5.conf(4)`.
- l *username* Specifies a different *username* for the remote login. If you do not use this option, the remote username used is the same as your local username.
- L Allows the rlogin session to be run in "litout" mode.
- PN
- PO Explicitly requests the new (-PN) or old (-PO) version of the Kerberos 'rcmd' protocol. The new protocol avoids many security problems prevalent in the old one and is considered much more secure, but is not interoperable with older (MIT/SEAM) servers. The new protocol is used by default, unless explicitly specified using these options or by using `krb5.conf(4)`. If Kerberos authorization fails when using the old 'rcmd' protocol, there is fallback to regular, non-kerberized rlogin. This is not the case when the new, more secure 'rcmd' protocol is used.
- x Turns on DES encryption for all data passed through the rlogin session. This reduces response time and increases CPU utilization.

**Escape Sequences**

Lines that you type which start with the tilde character (~) are "escape sequences." The escape character can be changed using the -e option.

- ~ . Disconnects from the remote host. This is not the same as a logout, because the local host breaks the connection with no warning to the remote end.

## rlogin(1)

|                 |                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                 | <code>~susp</code>            | Suspends the login session, but only if you are using a shell with Job Control. <code>susp</code> is your "suspend" character, usually Control-Z. See <code>tty(1)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                 | <code>~dsusp</code>           | Suspends the input half of the login, but output will still be seen (only if you are using a shell with Job Control). <code>dsusp</code> is your "deferred suspend" character, usually Control-Y. See <code>tty(1)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>OPERANDS</b> | <code>hostname</code>         | The remote machine on which <code>rlogin</code> establishes the remote login session.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>USAGE</b>    |                               | <p>For the kerberized <code>rlogin</code> session, each user may have a private authorization list in a file, <code>.k5login</code>, in his home directory. Each line in this file should contain a Kerberos principal name of the form <code>principal/instance@realm</code>. If there is a <code>~/ .k5login</code> file, access is granted to the account if and only if the originating user is authenticated to one of the principals named in the <code>~/ .k5login</code> file. Otherwise, the originating user will be granted access to the account if and only if the authenticated principal name of the user can be mapped to the local account name using the <code>authenticated-principal-name → local-user-name</code> mapping rules. The <code>.k5login</code> file (for access control) comes into play only when Kerberos authentication is being done.</p> <p>For the non-secure <code>rlogin</code> session, each remote machine may have a file named <code>/etc/hosts.equiv</code> containing a list of trusted host names with which it shares user names. Users with the same user name on both the local and remote machine may <code>rlogin</code> from the machines listed in the remote machine's <code>/etc/hosts.equiv</code> file without supplying a password. Individual users may set up a similar private equivalence list with the file <code>.rhosts</code> in their home directories. Each line in this file contains two names, that is, a host name and a user name, separated by a space. An entry in a remote user's <code>.rhosts</code> file permits the user named <code>username</code> who is logged into <code>hostname</code> to log in to the remote machine as the remote user without supplying a password. If the name of the local host is not found in the <code>/etc/hosts.equiv</code> file on the remote machine, and the local user name and host name are not found in the remote user's <code>.rhosts</code> file, then the remote machine will prompt for a password. Host names listed in the <code>/etc/hosts.equiv</code> and <code>.rhosts</code> files must be the official host names listed in the <code>hosts</code> database. Nicknames may not be used in either of these files.</p> <p>For security reasons, the <code>.rhosts</code> file must be owned by either the remote user or by root.</p> |
| <b>FILES</b>    | <code>/etc/passwd</code>      | Contains information about users' accounts.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

rlogin(1)

`$HOME/.k5login` File containing Kerberos principals that are allowed access.

`/etc/krb5/krb5.conf` Kerberos configuration file.

`/etc/hosts` Hosts database.

`/etc/inet/ipnodes` Hosts database.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWrcmdc       |

**SEE ALSO** `rsh(1)`, `stty(1)`, `tty(1)`, `in.rlogind(1M)`, `hosts(4)`, `hosts.equiv(4)`, `ipnodes(4)`, `krb5.conf(4)`, `nologin(4)`, `attributes(5)`, `krb5_auth_rules(5)`

**DIAGNOSTICS** The following message indicates that the machine is in the process of being shutdown and logins have been disabled:

`NO LOGINS: System going down in N minutes`

**NOTES** When a system is listed in `hosts.equiv`, its security must be as good as local security. One insecure system listed in `hosts.equiv` can compromise the security of the entire system.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP.) The functionality of the two remains the same. Only the name has changed.

This implementation can only use the TCP network service.

| <b>DESCRIPTION</b>    | <p><b>/usr/bin/rm</b><br/><b>/usr/xpg4/bin/rm</b></p> <p>The <code>rm</code> utility removes the directory entry specified by each <i>file</i> argument. If a file has no write permission and the standard input is a terminal, the full set of permissions (in octal) for the file are printed followed by a question mark. This is a prompt for confirmation. If the answer begins with <i>y</i> (for yes), the file is deleted, otherwise the file remains.</p> <p>If <i>file</i> is a symbolic link, the link will be removed, but the file or directory to which it refers will not be deleted. Users do not need write permission to remove a symbolic link, provided they have write permissions in the directory.</p> <p>If multiple <i>files</i> are specified and removal of a <i>file</i> fails for any reason, <code>rm</code> will write a diagnostic message to standard error, do nothing more to the current <i>file</i>, and go on to any remaining <i>files</i>.</p> <p>If the standard input is not a terminal, the utility will operate as if the <code>-f</code> option is in effect.</p> |
| <b>/usr/bin/rmdir</b> | <p>The <code>rmdir</code> utility will remove the directory entry specified by each <i>dirname</i> operand, which must refer to an empty directory.</p> <p>Directories will be processed in the order specified. If a directory and a subdirectory of that directory are specified in a single invocation of <code>rmdir</code>, the subdirectory must be specified before the parent directory so that the parent directory will be empty when <code>rmdir</code> tries to remove it.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>OPTIONS</b>        | <p>The following options are supported for <code>/usr/bin/rm</code> and <code>/usr/xpg4/bin/rm</code>:</p> <p><code>-r</code> Recursively removes directories and subdirectories in the argument list. The directory will be emptied of files and removed. The user is normally prompted for removal of any write-protected files which the directory contains. The write-protected files are removed without prompting, however, if the <code>-f</code> option is used, or if the standard input is not a terminal and the <code>-i</code> option is not used.</p> <p>Symbolic links that are encountered with this option will not be traversed.</p> <p>If the removal of a non-empty, write-protected directory is attempted, the utility will always fail (even if the <code>-f</code> option is used), resulting in an error message.</p> <p><code>-R</code> Same as <code>-r</code> option.</p>                                                                                                                                                                                                           |

|                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>/usr/bin/rm</b>                            | <p>The following options are supported for <code>/usr/bin/rm</code> only:</p> <ul style="list-style-type: none"> <li>-f        Removes all files (whether write-protected or not) in a directory without prompting the user. In a write-protected directory, however, files are never removed (whatever their permissions are), but no messages are displayed. If the removal of a write-protected directory is attempted, this option will not suppress an error message.</li> <li>-i        Interactive. With this option, <code>rm</code> prompts for confirmation before removing any files. It overrides the <code>-f</code> option and remains in effect even if the standard input is not a terminal.</li> </ul> |
| <b>/usr/xpg4/bin/rm</b>                       | <p>The following options are supported for <code>/usr/xpg4/bin/rm</code> only:</p> <ul style="list-style-type: none"> <li>-f        Does not prompt for confirmation. Does not write diagnostic messages or modify the exit status in the case of non-existent operands. Any previous occurrences of the <code>-i</code> option will be ignored.</li> <li>-i        Prompts for confirmation. Any occurrences of the <code>-f</code> option will be ignored.</li> </ul>                                                                                                                                                                                                                                                 |
| <b>/usr/bin/rmdir</b>                         | <p>The following options are supported for <code>/usr/bin/rmdir</code> only:</p> <ul style="list-style-type: none"> <li>-p        Allows users to remove the directory <i>dirname</i> and its parent directories which become empty. A message is printed to standard error if all or part of the path could not be removed.</li> <li>-s        Suppresses the message printed on the standard error when <code>-p</code> is in effect.</li> </ul>                                                                                                                                                                                                                                                                      |
| <b>OPERANDS</b>                               | <p>The following operands are supported:</p> <p><i>file</i>            A path name of a directory entry to be removed.</p> <p><i>dirname</i>        A path name of an empty directory to be removed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>USAGE</b>                                  | <p>See <code>largefile(5)</code> for the description of the behavior of <code>rm</code> and <code>rmdir</code> when encountering files greater than or equal to 2 Gbyte (<math>2^{31}</math> bytes).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>EXAMPLES</b>                               | <p>The following examples are valid for the commands shown.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>/usr/bin/rm</b><br><b>/usr/xpg4/bin/rm</b> | <p><b>EXAMPLE 1</b> Removing directories</p> <p>The following command:</p> <pre>example% rm a.out core</pre> <p>removes the directory entries <code>a.out</code> and <code>core</code>.</p> <p><b>EXAMPLE 2</b> Removing a directory without prompting</p> <p>The following command:</p> <pre>example% rm -rf junk</pre>                                                                                                                                                                                                                                                                                                                                                                                                |

rm(1)

**EXAMPLE 2** Removing a directory without prompting (Continued)

removes the directory junk and all its contents, without prompting.

**/usr/bin/rmdir**

**EXAMPLE 3** Removing empty directories

If a directory a in the current directory is empty, except that it contains a directory b, and a/b is empty except that it contains a directory c, the following command will remove all three directories:

```
example% rmdir -p a/b/c
```

**ENVIRONMENT VARIABLES**

See environ(5) for descriptions of the following environment variables that affect the execution of rm and rmdir: LANG, LC\_ALL, LC\_COLLATE, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**EXIT STATUS**

The following exit values are returned:

0 If the -f option was not specified, all the named directory entries were removed; otherwise, all the existing named directory entries were removed.  
>0 An error occurred.

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

**/usr/bin/rm**  
**/usr/bin/rmdir**

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | enabled         |

**/usr/xpg4/bin/rm**

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWxcu4        |
| CSI                 | enabled         |
| Interface Stability | Standard        |

**SEE ALSO**

rmdir(2), unlink(2), attributes(5), environ(5), largefile(5), standards(5)

**DIAGNOSTICS**

All messages are generally self-explanatory.

It is forbidden to remove the files "." and ".." in order to avoid the consequences of inadvertently doing something like the following:

```
example% rm -r .*
```

It is forbidden to remove the file "/" in order to avoid the consequences of inadvertently doing something like:

```
example% rm -rf $x/$y
```

or

```
example% rm -rf /$y
```

when \$x and \$y expand to empty strings.

**NOTES**

A - permits the user to mark explicitly the end of any command line options, allowing `rm` to recognize file arguments that begin with a -. As an aid to BSD migration, `rm` will accept - - as a synonym for -. This migration aid may disappear in a future release. If a - - and a - both appear on the same command line, the second will be interpreted as a file.

## rmformat(1)

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>DESCRIPTION</b> | <p>The <code>rmformat</code> utility is used to format, label, partition, and perform other miscellaneous functions on removable, rewritable media that include floppy drives, IOMEGA Zip/Jaz products, and the PCMCIA memory and ata cards. In addition, the <code>rmformat</code> utility should also be used with all USB mass storage devices, including USB hard drives. This utility can also be used for the verification and surface analysis and for repair of the bad sectors found during verification if the drive or the driver supports bad block management.</p> <p><code>rmformat</code> provides functionality to read/write protect the media with or without a password. The password protection enabling or disabling is possible only with selective rewritable media such as the IOMEGA Zip/Jaz products.</p> <p>After formatting, <code>rmformat</code> writes the label, which covers the full capacity of the media as one slice on floppy and PCMCIA memory cards to maintain compatibility with the behavior of <code>fdformat</code>. On Zip/Jaz devices, the driver exports one slice covering the full capacity of the disk as default. <code>rmformat</code> does not write the label on Zip/Jaz media, unless explicitly requested. The partition information can be changed with the help of other options provided by <code>rmformat</code>.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-b <i>label</i><br/>Labels the media with a SUNOS label. A SUNOS volume label name is restricted to 8 characters. For writing a DOS Volume label, the user should use <code>mkfs_pcfs(1M)</code>.</li><li>-c <i>blockno</i><br/>Corrects and repairs the given block. This correct and repair option may not be applicable to all devices supported by <code>rmformat</code>, as some devices may have a drive with bad block management capability and others may have this option implemented in the driver. If the drive or driver supports bad block management, a best effort is made to rectify the bad block. If the bad block still cannot be rectified, a message is displayed to indicate the failure to repair. The block number can be provided in decimal, octal, or hexadecimal format.<br/><br/>The normal floppy and PCMCIA memory and ata cards do not support bad block management.</li><li>-D<br/>Formats a 720KB (3.5 inch) double density diskette. This is the default for double density type drives. This option is needed if the drive is a high or extended-density type.</li></ul>                                                                                                                                                                                    |

- e  
Ejects the media upon completion. This feature may not be available if the drive does not support motorized eject.
- F quick | long | force  
Formats the media.  
  
The `quick` option starts a format without certification or format with limited certification of certain tracks on the media.  
  
The `long` option starts a complete format. For some devices this might include the certification of the whole media by the drive itself.  
  
The `force` option to format is provided to start a long format without user confirmation before the format is started. For drives which have a password protection mechanism, it clears the password while formatting. This feature is useful when a password is no longer available. On those media which do not have such password protection, `force` starts a long format.  
  
In legacy media such as floppy drives, all options start a long format depending on the mode (Extended Density mode, High Density mode, or Double Density mode) with which the floppy drive operates by default. On PCMCIA memory cards, all options start a long format.
- H  
Formats a 1.44 MB (3.5 inch) high density diskette. This is the default for high density type drives. It is needed if the drive is the Extended Density type.
- l  
Lists all removable devices. By default, without any options, `rmformat` also lists all removable devices. If the `dev_name` is given, `rmformat` lists the device associated with the `dev_name`. The output shows the device pathname, vendor information, and the device type.
- p  
Prints the protection status of the media. This option prints information whether the media is write, read, or password protected.
- R enable | disable  
Enables read/write protection with a password or disables the password read/write protection. This always works in interactive mode, as the password is requested from the user in an interactive manner to maintain security.  
  
A password length of 32 bytes (maximum) is allowed for the IOMEGA products that support this feature. This option is applicable only for IOMEGA products. IOMEGA products do not allow read/write protection without a password. On the devices which do not have such software read/write protect facility, warnings indicating the non-availability of this feature are provided.
- s *filename*  
Enables the user to lay out the partition information in the SUNOS label.

## rmformat(1)

The user should provide a file as input with information about each slice in a format providing byte offset, size required, tags, and flags, as follows:

```
slices: n = offset, size [, flags, tags]
```

where *n* is the slice number, *offset* is the byte offset at which the slice *n* starts, and *size* is the required size for slice *n*. Both *offset* and *size* must be a multiple of 512 bytes. These numbers can be represented as decimal, hexadecimal, or octal numbers. No floating point numbers are accepted. Details about maximum number of slices can be obtained from the *System Administration Guide: Basic Administration*.

To specify the *size* or *offset* in kilobytes, megabytes, or gigabytes, add KB, MB, GB, respectively. A number without a suffix is assumed to be a byte offset. The flags are represented as follows:

```
wm = read-write, mountable  
wu = read-write, unmountable  
ru = read-only, unmountable
```

The tags are represented as follows: unassigned, boot, root, swap, usr, backup, stand, var, home, alternates.

The tags and flags can be omitted from the four tuple when finer control on those values is not required. It is required to omit both or include both. If the tags and flags are omitted from the four tuple for a particular slice, a default value for each is assumed. The default value for flags is `wm` and for tags is `unassigned`.

Either full tag names can be provided or an abbreviation for the tags can be used. The abbreviations can be the first two or more letters from the standard tag names. `rmformat` is case insensitive in handling the defined tags & flags.

Slice specifications are separated by :

For example:

```
slices: 0 = 0, 30MB, "wm", "home" :  
        1 = 30MB, 51MB :  
        2 = 0, 100MB, "wm", "backup" :  
        6 = 81MB, 19MB
```

`rmformat` does the necessary checking to detect any overlapping partitions or illegal requests to addresses beyond the capacity of the media under consideration. There can be only one slice information entry for each slice *n*. If multiple slice information entries for the same slice *n* are provided, an appropriate error message is displayed. The slice 2 is the backup slice covering the whole disk capacity. The pound sign character, #, can be used to describe a line of comments in the input file. If the line starts with #, then `rmformat` ignores all the characters following # until the end of the line.

Partitioning some of the media with very small capacity is permitted, but be cautious in using this option on such devices.

-U

Performs `umount` on any file systems and then formats. See `mount(1M)`. This option unmounts all the mounted slices and issues a long format on the device requested.

-v read | write

Verifies each block of media after format. The write verification is a destructive mechanism. The user is queried for confirmation before the verification is started. The output of this option is a list of block numbers, which are identified as bad.

The read verification only verifies the blocks and report the blocks which are prone to errors.

The list of block numbers displayed can be used with the `-c` option for repairing.

-w enable | disable

Enables or disables the write protection on media. On devices that do not have a software write protect facility, a message indicating non-availability of this feature is displayed.

-W enable | disable

Enables or disables write protection with password. This option always works in interactive mode, as a password is requested from the user to maintain security.

A maximum password length of 32 bytes is allowed for IOMEGA products that support this feature. On devices that do not have the write protection with password, the software displays appropriate messages indicating the non-availability of such features.

**OPERANDS** The following operand is supported:

*devname*            *devname* can be provided as absolute device pathname or relative pathname for the device from the current working directory or the nickname as exported by the System Volume manager. See `vold(1M)`.

For floppy devices, to access the first drive use `/dev/rdiskette0` (for systems without volume management) or `floppy0` (for systems with volume management). Specify `/dev/rdiskette1` (for systems without volume management) or `floppy1` (for systems with volume management) to use the second drive.

For systems without volume management running, the user can also provide the absolute device pathname as `/dev/rdsk/c?t?d?s?` or the appropriate relative device pathname from the current working directory.

**EXAMPLES**    **EXAMPLE 1** Formatting a diskette

```
example$ rmformat -F quick /dev/rdiskette
Formatting will erase all the data on disk.
```

## rmformat(1)

### EXAMPLE 1 Formatting a diskette (Continued)

```
Do you want to continue? (y/n)y
```

### EXAMPLE 2 Formatting a Zip drive

```
example$ rmformat -F quick /vol/dev/aliases/zip0
Formatting will erase all the data on disk.
Do you want to continue? (y/n)y
```

### EXAMPLE 3 Formatting a diskette for a UFS file system

The following example formats a diskette and creates a UFS file system:

```
example$ rmformat -F quick /vol/dev/aliases/floppy0
Formatting will erase all the data on disk.
Do you want to continue? (y/n)y
example$ su
# /usr/sbin/newfs /vol/dev/aliases/floppy0
newfs: construct a new file system /dev/rdiskette: (y/n)? y
/dev/rdiskette: 2880 sectors in 80 cylinders of 2 tracks, 18 sectors
      1.4MB in 5 cyl groups (16 c/g, 0.28MB/g, 128 i/g)
super-block backups (for fsck -F ufs -o b=#) at:
      32, 640, 1184, 1792, 2336,
#
```

### EXAMPLE 4 Formatting removable media for a PCFS file system

The following example shows how to create an alternate fdisk partition:

```
example$ rmformat -F quick /dev/rdisk/c0t4d0s2:c
Formatting will erase all the data on disk.
Do you want to continue? (y/n)y
example$ su
# fdisk /dev/rdisk/c0t4d0s2:c
# mkfs -F pcfs /dev/rdisk/c0t4d0s2:c
Construct a new FAT file system on /dev/rdisk/c0t4d0s2:c: (y/n)? y
#
```

The following example describes how to create a PCFS file system *without* an fdisk partition:

```
example$ rmformat -F quick /dev/rdiskette
Formatting will erase all the data on disk.
Do you want to continue? (y/n)y
example$ su
# mkfs -F pcfs -o nofdisk,size=2 /dev/rdiskette
Construct a new FAT file system on /dev/rdiskette: (y/n)? y
#
```

**EXAMPLE 5** Enabling or disabling read or write protection

The following example shows how to enable write protection and set a password on a Zip drive:

```
example$ rmformat -W enable /vol/dev/aliases/zip0
Please enter password (32 chars maximum): xxx
Please reenter password: xxx
```

The following example shows how to disable write protection and remove the password on a Zip drive:

```
example$ rmformat -W disable /vol/dev/aliases/zip0
Please enter password (32 chars maximum): xxx
```

The following example shows how to enable read protection and set a password on a Zip drive:

```
example$ rmformat -R enable /vol/dev/aliases/zip0
Please enter password (32 chars maximum): xxx
Please reenter password: xxx
```

The following example shows how to disable read protection and remove the password on a Zip drive:

```
example$ rmformat -R disable /vol/dev/aliases/zip0
Please enter password (32 chars maximum): xxx
```

**EXAMPLE 6** Listing all removable devices

The following example shows how to list removable devices. This output shows that vold is on.

```
example$ rmformat -l
Looking for devices...
  1. Volmgt Node: /vol/dev/aliases/rmdisk1
     Logical Node: /dev/rdisk/c5t0d0s2
     Physical Node: /pci@1e,600000/usb@b/hub@2/storage@4/disk@0,0
     Connected Device: TEAC      FD-05PUB      1026
     Device Type: Floppy drive
```

*System Administration Guide: Basic Administration*

**NOTES** A rewritable media or PCMCIA memory card or PCMCIA ata card containing a `ufs` file system created on a SPARC-based system (using `newfs(1M)`) is not identical to a rewritable media or PCMCIA memory card containing a `ufs` file system created on an

rmformat(1)

x86 based system. Do not interchange any removable media containing `ufs` between these platforms; use `cpio(1)` or `tar(1)` to transfer files on diskettes or memory cards between them. For interchangeable filesystems refer to `pcfs(7FS)` and `udfs(7FS)`.

**BUGS** Currently, bad sector mapping is not supported on floppy diskettes or PCMCIA memory cards. Therefore, a diskette or memory card is unusable if `rmformat` finds an error (`bad sector`).

| <b>DESCRIPTION</b> | <p>roffbib prints out all records in a bibliographic database, in bibliography format rather than as footnotes or endnotes. Generally it is used in conjunction with <a href="#">sortbib(1)</a>:</p> <pre>example% sortbib database   roffbib</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>OPTIONS</b>     | <p>roffbib accepts all options understood by <a href="#">nroff(1)</a> except -i and -q.</p> <p>-e                    Produce equally-spaced words in adjusted lines using full terminal resolution.</p> <p>-h                    Use output tabs during horizontal spacing to speed output and reduce output character count. TAB settings are assumed to be every 8 nominal character widths.</p> <p>-m <i>filename</i>        Prepend the macro file /usr/share/lib/tmac/tmac.name to the input files. There should be a space between the -m and the macro filename. This set of macros will replace the ones defined in /usr/share/lib/tmac/tmac.bib.</p> <p>-np                   Number first generated page <i>p</i>.</p> <p>-olist                Print only page numbers that appear in the comma-separated <i>list</i> of numbers and ranges. A range <i>N–M</i> means pages <i>N</i> through <i>M</i>; an initial -<i>N</i> means from the beginning to page <i>N</i>; a final <i>N–</i> means from page <i>N</i> to end.</p> <p>-Q                    Queue output for the phototypesetter. Page offset is set to 1 inch.</p> <p>-raN                  Set register <i>a</i> (one-character) to <i>N</i>. The command-line argument -rN1 will number the references starting at 1.</p> <p>Four command-line registers control formatting style of the bibliography, much like the number registers of <a href="#">ms(5)</a>. The flag -rV2 will double space the bibliography, while -rV1 will double space references but single space annotation paragraphs. The line length can be changed from the default 6.5 inches to 6 inches with the -rL6i argument, and the page offset can be set from the default of 0 to one inch by specifying -rO1i (capital O, not zero).</p> <p>-sN                   Halt prior to every <i>N</i> pages for paper loading or changing (default <i>N</i>=1). To resume, enter NEWLINE or RETURN.</p> <p>-Tterm                Specify <i>term</i> as the terminal type.</p> <p>-V                    Send output to the Versatec. Page offset is set to 1 inch.</p> |

roffbib(1)

-x If abstracts or comments are entered following the %X field key, roffbib will format them into paragraphs for an annotated bibliography. Several %X fields may be given if several annotation paragraphs are desired.

**FILES** /usr/share/lib/tmac/tmac.bib file of macros used by nroff/troff

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWdoc         |

**SEE ALSO** addbib(1), indxbib(1), lookbib(1), nroff(1), refer(1), sortbib(1), troff(1), attributes(5)

**BUGS** Users have to rewrite macros to create customized formats.

| <b>SYNOPSIS</b>    | <b>roles</b> [ <i>user</i> ...]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |   |                        |   |                    |
| <b>DESCRIPTION</b> | <p>The command <code>roles</code> prints on standard output the roles that you or the optionally-specified user have been granted. Roles are special accounts that correspond to a functional responsibility rather than to an actual person (referred to as a normal user).</p> <p>Each user may have zero or more roles. Roles have most of the attributes of normal users and are identified like normal users in <code>passwd(4)</code> and <code>shadow(4)</code>. Each role must have an entry in the <code>user_attr(4)</code> file that identifies it as a role. Roles can have their own authorizations and profiles. See <code>auths(1)</code> and <code>profiles(1)</code>.</p> <p>Roles are not allowed to log into a system as a primary user. Instead, a user must log in as him— or herself and assume the role. The actions of a role are attributable to the normal user. When auditing is enabled, the audited events of the role contain the audit ID of the original user who assumed the role.</p> <p>A role may not assume itself or any other role. Roles are not hierarchical. However, rights profiles (see <code>prof_attr(4)</code>) are hierarchical and can be used to achieve the same effect as hierarchical roles.</p> <p>Roles must have valid passwords and one of the shells that interprets profiles: either <code>pf<sub>c</sub>sh</code>, <code>pf<sub>k</sub>sh</code>, or <code>pf<sub>s</sub>h</code>. See <code>pfexec(1)</code>.</p> <p>Role assumption may be performed using <code>su(1M)</code>, <code>rlogin(1)</code>, or some other service that supports the <code>PAM_RUSER</code> variable. Successful assumption requires knowledge of the role's password and membership in the role. Role assignments are specified in <code>user_attr(4)</code>.</p> |   |                        |   |                    |

| <b>DESCRIPTION</b> | <p>The <code>rpcgen</code> utility is a tool that generates C code to implement an RPC protocol. The input to <code>rpcgen</code> is a language similar to C known as RPC Language (Remote Procedure Call Language).</p> <p>The <code>rpcgen</code> utility is normally used as in the first synopsis where it takes an input file and generates three output files. If the <i>infile</i> is named <code>proto.x</code>, then <code>rpcgen</code> generates a header in <code>proto.h</code>, XDR routines in <code>proto_xdr.c</code>, server-side stubs in <code>proto_svc.c</code>, and client-side stubs in <code>proto_clnt.c</code>. With the <code>-T</code> option, it also generates the RPC dispatch table in <code>proto_tbl.i</code>.</p> <p><code>rpcgen</code> can also generate sample client and server files that can be customized to suit a particular application. The <code>-Sc</code>, <code>-Ss</code>, and <code>-Sm</code> options generate sample client, server and makefile, respectively. The <code>-a</code> option generates all files, including sample files. If the <i>infile</i> is <code>proto.x</code>, then the client side sample file is written to <code>proto_client.c</code>, the server side sample file to <code>proto_server.c</code> and the sample makefile to <code>makefile.proto</code>.</p> <p>The server created can be started both by the port monitors (for example, <code>inetd</code> or <code>listen</code>) or by itself. When it is started by a port monitor, it creates servers only for the transport for which the file descriptor 0 was passed. The name of the transport must be specified by setting up the environment variable <code>PM_TRANSPORT</code>. When the server generated by <code>rpcgen</code> is executed, it creates server handles for all the transports specified in the <code>NETPATH</code> environment variable, or if it is unset, it creates server handles for all the visible transports from the <code>/etc/netconfig</code> file. Note: the transports are chosen at run time and not at compile time. When the server is self-started, it backgrounds itself by default. A special define symbol <code>RPC_SVC_FG</code> can be used to run the server process in foreground.</p> <p>The second synopsis provides special features which allow for the creation of more sophisticated RPC servers. These features include support for user-provided <code>#defines</code> and RPC dispatch tables. The entries in the RPC dispatch table contain:</p> <ul style="list-style-type: none"><li>■ pointers to the service routine corresponding to that procedure</li><li>■ a pointer to the input and output arguments</li><li>■ the size of these routines</li></ul> <p>A server can use the dispatch table to check authorization and then to execute the service routine. A client library may use the dispatch table to deal with the details of storage management and XDR data conversion.</p> |

The other three synopses shown above are used when one does not want to generate all the output files, but only a particular one. See the EXAMPLES section below for examples of `rpcgen` usage. When `rpcgen` is executed with the `-s` option, it creates servers for that particular class of transports. When executed with the `-n` option, it creates a server for the transport specified by *netid*. If *infile* is not specified, `rpcgen` accepts the standard input.

All the options mentioned in the second synopsis can be used with the other three synopses, but the changes will be made only to the specified output file.

The C preprocessor `cc -E` is run on the input file before it is actually interpreted by `rpcgen`. For each type of output file, `rpcgen` defines a special preprocessor symbol for use by the `rpcgen` programmer:

|                       |                                                 |
|-----------------------|-------------------------------------------------|
| <code>RPC_HDR</code>  | defined when compiling into headers             |
| <code>RPC_XDR</code>  | defined when compiling into XDR routines        |
| <code>RPC_SVC</code>  | defined when compiling into server-side stubs   |
| <code>RPC_CLNT</code> | defined when compiling into client-side stubs   |
| <code>RPC_TBL</code>  | defined when compiling into RPC dispatch tables |

Any line beginning with “%” is passed directly into the output file, uninterpreted by `rpcgen`, except that the leading “%” is stripped off. To specify the path name of the C preprocessor, use the `-Y` flag.

For every data type referred to in *infile*, `rpcgen` assumes that there exists a routine with the string `xdr_` prepended to the name of the data type. If this routine does not exist in the RPC/XDR library, it must be provided. Providing an undefined data type allows customization of XDR routines.

## OPTIONS

The following options are supported:

- `-a` Generates all files, including sample files.
- `-A` Enables the Automatic MT mode in the server main program. In this mode, the RPC library automatically creates threads to service client requests. This option generates multithread-safe stubs by implicitly turning on the `-M` option. Server multithreading modes and parameters can be set using the `rpc_control(3NSL)` call. `rpcgen` generated code does not change the default values for the Automatic MT mode.
- `-b` Backward compatibility mode. Generates transport-specific RPC code for older versions of the operating system.
- `-c` Compiles into XDR routines.
- `-C` Generates header and stub files which can be used with ANSI C compilers. Headers generated with this flag can also be used with C++ programs.

## rpcgen(1)

|                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -D <i>name</i> [= <i>value</i> ] | Defines a symbol <i>name</i> . Equivalent to the <code>#define</code> directive in the source. If no <i>value</i> is given, <i>value</i> is defined as 1. This option may be specified more than once.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| -h                               | Compiles into C data-definitions (a header). The <code>-T</code> option can be used in conjunction to produce a header which supports RPC dispatch tables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| -i <i>size</i>                   | Size at which to start generating inline code. This option is useful for optimization. The default <i>size</i> is 5.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| -I                               | Compiles support for <code>inetd(1M)</code> in the server side stubs. Such servers can be self-started or can be started by <code>inetd</code> . When the server is self-started, it backgrounds itself by default. A special define symbol <code>RPC_SVC_FG</code> can be used to run the server process in foreground, or the user may simply compile without the <code>-I</code> option.<br><br>If there are no pending client requests, the <code>inetd</code> servers exit after 120 seconds (default). The default can be changed with the <code>-K</code> option. All of the error messages for <code>inetd</code> servers are always logged with <code>syslog(3C)</code> .<br><br><i>Note:</i> This option is supported for backward compatibility only. It should always be used in conjunction with the <code>-b</code> option which generates backward compatibility code. By default (that is, when <code>-b</code> is not specified), <code>rpcgen</code> generates servers that can be invoked through portmonitors. |
| -K <i>seconds</i>                | By default, services created using <code>rpcgen</code> and invoked through port monitors wait 120 seconds after servicing a request before exiting. That interval can be changed using the <code>-K</code> flag. To create a server that exits immediately upon servicing a request, use <code>-K 0</code> . To create a server that never exits, the appropriate argument is <code>-K -1</code> .<br><br>When monitoring for a server, some portmonitors, like <code>listen(1M)</code> , <i>always</i> spawn a new process in response to a service request. If it is known that a server will be used with such a monitor, the server should exit immediately on completion. For such servers, <code>rpcgen</code> should be used with <code>-K 0</code> .                                                                                                                                                                                                                                                                       |
| -l                               | Compiles into client-side stubs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| -L                               | When the servers are started in foreground, uses <code>syslog(3C)</code> to log the server errors instead of printing them on the standard error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -m                 | Compiles into server-side stubs, but do not generate a “main” routine. This option is useful for doing callback-routines and for users who need to write their own “main” routine to do initialization.                                                                                                                                                                                                                                                                                                                    |
| -M                 | Generates multithread-safe stubs for passing arguments and results between rpcgen-generated code and user written code. This option is useful for users who want to use threads in their code.                                                                                                                                                                                                                                                                                                                             |
| -N                 | This option allows procedures to have multiple arguments. It also uses the style of parameter passing that closely resembles C. So, when passing an argument to a remote procedure, you do not have to pass a pointer to the argument, but can pass the argument itself. This behavior is different from the old style of rpcgen-generated code. To maintain backward compatibility, this option is not the default.                                                                                                       |
| -n <i>netid</i>    | Compiles into server-side stubs for the transport specified by <i>netid</i> . There should be an entry for <i>netid</i> in the <code>netconfig</code> database. This option may be specified more than once, so as to compile a server that serves multiple transports.                                                                                                                                                                                                                                                    |
| -o <i>outfile</i>  | Specifies the name of the output file. If none is specified, standard output is used (-c, -h, -l, -m, -n, -s, -Sc, -Sm, -Ss, and -t modes only).                                                                                                                                                                                                                                                                                                                                                                           |
| -s <i>nettype</i>  | Compiles into server-side stubs for all the transports belonging to the class <i>nettype</i> . The supported classes are <code>netpath</code> , <code>visible</code> , <code>circuit_n</code> , <code>circuit_v</code> , <code>datagram_n</code> , <code>datagram_v</code> , <code>tcp</code> , and <code>udp</code> (see <code>rpc(3NSL)</code> for the meanings associated with these classes). This option may be specified more than once. <i>Note:</i> The transports are chosen at run time and not at compile time. |
| -Sc                | Generates sample client code that uses remote procedure calls.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| -Sm                | Generates a sample Makefile which can be used for compiling the application.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| -Ss                | Generates sample server code that uses remote procedure calls.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| -t                 | Compiles into RPC dispatch table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| -T                 | Generates the code to support RPC dispatch tables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                    | The options -c, -h, -l, -m, -s, -Sc, -Sm, -Ss, and -t are used exclusively to generate a particular type of file, while the options -D and -T are global and can be used with the other options.                                                                                                                                                                                                                                                                                                                           |
| -v                 | Displays the version number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| -Y <i>pathname</i> | Gives the name of the directory where rpcgen will start looking for the C preprocessor.                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## rpcgen(1)

**OPERANDS** The following operand is supported:

*infile*                   input file

**EXAMPLES** **EXAMPLE 1** Generating the output files and dispatch table

The following entry

```
example% rpcgen -T prot.x
```

generates all the five files: *prot.h*, *prot\_clnt.c*, *prot\_svc.c*, *prot\_xdr.c*, and *prot\_ttbl.i*.

**EXAMPLE 2** Sending headers to standard output

The following example sends the C data-definitions (header) to the standard output:

```
example% rpcgen -h prot.x
```

**EXAMPLE 3** Sending a test version

To send the test version of the *-DTEST*, server side stubs for all the transport belonging to the class *datagram\_n* to standard output, use:

```
example% rpcgen -s datagram_n -DTEST prot.x
```

**EXAMPLE 4** Creating server side stubs

To create the server side stubs for the transport indicated by *netid* *tcp*, use:

```
example% rpcgen -n tcp -o prot_svc.c prot.x
```

**EXIT STATUS** 0           Successful operation.

>0          An error occurred.

**ATTRIBUTES** See *attributes(5)* for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWbtool       |

| <b>SYNOPSIS</b>    | <b>rpm2cpio</b> [ <i>file.rpm</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |              |         |
| <b>DESCRIPTION</b> | The rpm2cpio utility converts the .rpm file specified as its sole argument to a cpio archive on standard output. (See NOTES.) If no argument is given, an rpm stream is read from standard input. In both cases, rpm2cpio will fail and print a usage message if the standard output is a terminal. Therefore, the output is usually redirected to a file or piped through the cpio(1) utility.                                                                                                                                                                                                                                                                                                                                |                |                 |              |         |

| <b>DESCRIPTION</b> | <p>The <code>rsh</code> utility connects to the specified <i>hostname</i> and executes the specified <i>command</i>. <code>rsh</code> copies its standard input to the remote command, the standard output of the remote command to its standard output, and the standard error of the remote command to its standard error. Interrupt, quit, and terminate signals are propagated to the remote command. <code>rsh</code> normally terminates when the remote command does.</p> <p>The user can opt for a secure session of <code>rsh</code> which uses Kerberos V5 for authentication. Encryption of the network session traffic is also possible. The <code>rsh</code> session can be kerberized using any of the following Kerberos specific options: <code>-a</code>, <code>-PN</code> or <code>-PO</code>, <code>-x</code>, <code>-f</code> or <code>-F</code>, and <code>-k realm</code>. Some of these options (<code>-x</code>, <code>-PN</code> or <code>-PO</code>, and <code>-f</code> or <code>-F</code>) can also be specified in the <code>[appdefaults]</code> section of <code>krb5.conf(4)</code>. The usage of these options and the expected behavior is discussed in the <b>OPTIONS</b> section below. If Kerberos authentication is used, authorization to the account is controlled by rules in <code>krb5_auth_rules(5)</code>. If this authorization fails, fallback to normal <code>rsh</code> using <code>rhosts</code> occurs only if the <code>-PO</code> option is used explicitly on the command line or is specified in <code>krb5.conf(4)</code>. Also, the <code>-PN</code> or <code>-PO</code>, <code>-x</code>, <code>-f</code> or <code>-F</code>, and <code>-k realm</code> options are just supersets of the <code>-a</code> option.</p> <p>If you omit <i>command</i>, instead of executing a single command, <code>rsh</code> logs you in on the remote host using <code>rlogin(1)</code>.</p> <p><code>rsh</code> does not return the exit status code of <i>command</i>.</p> <p>Shell metacharacters which are not quoted are interpreted on the local machine, while quoted metacharacters are interpreted on the remote machine. See <b>EXAMPLES</b>.</p> <p>If there is no locale setting in the initialization file of the login shell (<code>.cshrc</code>, ...) for a particular user, <code>rsh</code> always executes the command in the "C" locale instead of using the default locale of the remote machine.</p> <p>The command is sent unencrypted to the remote system. All subsequent network session traffic is encrypted. See <code>-x</code>.</p> |
| <b>OPTIONS</b>     | The following options are supported:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

- a Explicitly enable Kerberos authentication and trusts the `.k5login` file for access-control. If the authorization check by `in.rshd(1M)` on the server-side succeeds and if the `.k5login` file permits access, the user is allowed to carry out the command.
- f Forward a copy of the local credentials (Kerberos Ticket Granting Ticket) to the remote system. This is a non-forwardable ticket granting ticket. Forward a ticket granting ticket if you need to authenticate yourself to other Kerberized network services on the remote host. An example would be if your home directory on the remote host is NFS mounted by way of Kerberos V5. If your local credentials are not forwarded in this case, you cannot access your home directory. This option is mutually exclusive with the `-F` option.
- F Forward a forwardable copy of the local credentials (Kerberos Ticket Granting Ticket) to the remote system. The `-F` option provides a superset of the functionality offered by the `-f` option. For example, with the `-f` option, if, after you connected to the remote host, your remote command attempted to invoke `/usr/bin/ftp`, `/usr/bin/telnet`, `/usr/bin/rlogin`, or `/usr/bin/rsh`, with the `-f` or `-F` options, the attempt would fail. Thus, you would be unable to push your single network sign on trust beyond one system. This option is mutually exclusive with the `-f` option.
- k *realm* Causes `rsh` to obtain tickets for the remote host in *realm* instead of the remote host's realm as determined by `krb5.conf(4)`.
- l *username* Uses *username* as the remote username instead of your local username. In the absence of this option, the remote username is the same as your local username.
- n Redirect the input of `rsh` to `/dev/null`. You sometimes need this option to avoid unfortunate interactions between `rsh` and the shell which invokes it. For example, if you are running `rsh` and invoke a `rsh` in the background without redirecting its input away from the terminal, it blocks even if no reads are posted by the remote command. The `-n` option prevents this.
- PO
- PN Explicitly request new (`-PN`) or old (`-PO`) version of the Kerberos "rcmd" protocol. The new protocol avoids many security problems prevalent in the old one and is regarded much more secure, but is not interoperable with older (MIT/SEAM) servers. The new protocol is used by default, unless explicitly specified using these options or through `krb5.conf(4)`. If Kerberos authorization fails when using the old "rcmd" protocol, there is fallback to regular, non-kerberized `rsh`. This is not the case when the new, more secure "rcmd" protocol is used.

## rsh(1)

|                 | <p><code>-x</code> Cause the network session traffic to be encrypted. See DESCRIPTION.</p> <p>The type of remote shell (<code>sh</code>, <code>rsh</code>, or other) is determined by the user's entry in the file <code>/etc/passwd</code> on the remote system.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>OPERANDS</b> | <p>The following operand is supported:</p> <p><i>command</i> The command to be executed on the specified <i>hostname</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>USAGE</b>    | <p>See <code>largefile(5)</code> for the description of the behavior of <code>rsh</code> and <code>remsh</code> when encountering files greater than or equal to 2 Gbyte ( <math>2^{31}</math> bytes).</p> <p>The <code>rsh</code> and <code>remsh</code> commands are IPv6-enabled. See <code>ip6(7P)</code>. IPv6 is not currently supported with Kerberos V5 authentication.</p> <p>Hostnames are given in the <i>hosts</i> database, which can be contained in the <code>/etc/hosts</code> file, the Internet domain name database, or both. Each host has one official name (the first name in the database entry) and optionally one or more nicknames. Official hostnames or nicknames can be given as <i>hostname</i>.</p> <p>If the name of the file from which <code>rsh</code> is executed is anything other than <code>rsh</code>, <code>rsh</code> takes this name as its <i>hostname</i> argument. This allows you to create a symbolic link to <code>rsh</code> in the name of a host which, when executed, invokes a remote shell on that host. By creating a directory and populating it with symbolic links in the names of commonly used hosts, then including the directory in your shell's search path, you can run <code>rsh</code> by typing <i>hostname</i> to your shell.</p> <p>If <code>rsh</code> is invoked with the basename <code>remsh</code>, <code>rsh</code> checks for the existence of the file <code>/usr/bin/remsh</code>. If this file exists, <code>rsh</code> behaves as if <code>remsh</code> is an alias for <code>rsh</code>. If <code>/usr/bin/remsh</code> does not exist, <code>rsh</code> behaves as if <code>remsh</code> is a host name.</p> <p>For the kerberized <code>rsh</code> session, each user can have a private authorization list in a file <code>.k5login</code> in their home directory. Each line in this file should contain a Kerberos principal name of the form <i>principal/instance@realm</i>. If there is a <code>~/k5login</code> file, then access is granted to the account if and only if the originater user is authenticated to one of the principals named in the <code>~/k5login</code> file. Otherwise, the originating user is granted access to the account if and only if the authenticated principal name of the user can be mapped to the local account name using the <i>authenticated-principal-name</i> <math>\rightarrow</math> <i>local-user-name</i> mapping rules. The <code>.k5login</code> file (for access control) comes into play only when Kerberos authentication is being done.</p> <p>For the non-secure <code>rsh</code> session, each remote machine can have a file named <code>/etc/hosts.equiv</code> containing a list of trusted hostnames with which it shares usernames. Users with the same username on both the local and remote machine can run <code>rsh</code> from the machines listed in the remote machine's <code>/etc/hosts.equiv</code> file. Individual users can set up a similar private equivalence list with the file <code>.rhosts</code> in their home directories. Each line in this file contains two names: a hostname and a username separated by a space. The entry permits the user named <i>username</i> who is</p> |

logged into hostname to use rsh to access the remote machine as the remote user. If the name of the local host is not found in the `/etc/hosts.equiv` file on the remote machine, and the local username and hostname are not found in the remote user's `.rhosts` file, then the access is denied. The hostnames listed in the `/etc/hosts.equiv` and `.rhosts` files must be the official hostnames listed in the `hosts` database; nicknames can not be used in either of these files.

You cannot log in using rsh as a trusted user from a trusted hostname if the trusted user account is locked.

rsh does not prompt for a password if access is denied on the remote machine unless the *command* argument is omitted.

#### EXAMPLES **EXAMPLE 1** Using rsh to Append Files

The following command appends the remote file `lizard.file` from the machine called `lizard` to the file called `example.file` on the machine called `example`:

```
example% rsh lizard cat lizard.file >> example.file
```

The following command appends the file `lizard.file` on the machine called `lizard` to the file `lizard.file2` which also resides on the machine called `lizard`:

```
example% rsh lizard cat lizard.file ">>" lizard.file2
```

#### EXIT STATUS The following exit values are returned:

0 Successful completion.  
1 An error occurred.

| FILES |                                  |                                                             |
|-------|----------------------------------|-------------------------------------------------------------|
|       | <code>/etc/hosts</code>          | Internet host table                                         |
|       | <code>/etc/hosts.equiv</code>    | Trusted remote hosts and users                              |
|       | <code>/etc/passwd</code>         | System password file                                        |
|       | <code>\$HOME/.k5login</code>     | File containing Kerberos principals that are allowed access |
|       | <code>/etc/krb5/krb5.conf</code> | Kerberos configuration file                                 |

#### ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWrcmdc       |
| CSI            | enabled         |

rsh(1)

**NOTES** | When a system is listed in `hosts.equiv`, its security must be as good as local security. One insecure system listed in `hosts.equiv` can compromise the security of the entire system.

You cannot run an interactive command (such as `vi(1)`). Use `rlogin` if you wish to do this.

Stop signals stop the local `rsh` process only. This is arguably wrong, but currently hard to fix for reasons too complicated to explain here.

The current local environment is not passed to the remote shell.

Sometimes the `-n` option is needed for reasons that are less than obvious. For example, the command:

```
example% rsh somehost dd if=/dev/nrmt0 bs=20b | tar xvpBf -
```

puts your shell into a strange state. Evidently, the `tar` process terminates before the `rsh` process. The `rsh` command then tries to write into the "broken pipe" and, instead of terminating neatly, proceeds to compete with your shell for its standard input. Invoking `rsh` with the `-n` option avoids such incidents.

This bug occurs only when `rsh` is at the beginning of a pipeline and is not reading standard input. Do not use the `-n` option if `rsh` actually needs to read standard input. For example:

```
example% tar cf - . | rsh sundial dd of=/dev/rmt0 obs=20b
```

does not produce the bug. If you were to use the `-n` option in a case like this, `rsh` would incorrectly read from `/dev/null` instead of from the pipe.

| <b>NAME</b>        | run – run an executable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |         |

| <b>DESCRIPTION</b> | The run command runs <i>program</i> , using the PATH variable to find it. By default, when <i>program</i> has completed, the user is prompted (Press ENTER to continue:), before being returned to FMLI. The argument <i>program</i> is a system executable followed by its options (if any).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |              |         |
| <b>OPTIONS</b>     | The following options are supported: <ul style="list-style-type: none"> <li>-e                      If -e is specified, the user will be prompted before returning to FMLI only if there is an error condition</li> <li>-n                      If -n is specified, the user will never be prompted before returning to FMLI (useful for programs like vi, in which the user must do some specific action to exit in the first place).</li> <li>-s                      The -s option means "silent", implying that the screen will not have to be repainted when <i>program</i> has completed. Note that the -s option should only be used when <i>program</i> does not write to the terminal. In addition, when -s is used, <i>program</i> cannot be interrupted, even if it recognizes interrupts.</li> <li>-t<i>string</i>              If -t is specified, <i>string</i> is the name this process will have in the pop-up menu generated by the frm-list command. This feature requires the executable facesuspend (see face(1)) to suspend the process and return to the FMLI application.</li> </ul> |                |                 |              |         |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Sample output of run command</p> <p>Here is a menu that uses run:</p> <pre>menu="Edit special System files" name="Password file" action='run -e vi /etc/passwd' name="Group file" action='run -e vi /etc/group' name="My .profile" action='run -n vi \$HOME/.profile'</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |              |         |

| <b>DESCRIPTION</b> | <p>The runat utility is used to execute shell commands in a file's hidden attribute directory. Effectively, this utility changes the current working directory to be the hidden attribute directory associated with the file argument and then executes the specified command in the bourne shell (/bin/sh). If no command argument is provided, an interactive shell is spawned. The environment variable \$SHELL defines the shell to be spawned. If this variable is undefined, the default shell, /bin/sh, is used.</p> <p>The file argument can be any file, including a directory, that can support extended attributes. It is not necessary that this file have any attributes, or be prepared in any way, before invoking the runat command.</p>                                                                                                                                                                                                     |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><i>file</i> Any file, including a directory, that can support extended attributes.</p> <p><i>command</i> The command to be executed in an attribute directory.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>ERRORS</b>      | A non-zero exit status will be returned if runat cannot access the <i>file</i> argument, or the <i>file</i> argument does not support extended attributes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>USAGE</b>       | <p>See <code>fsattr(5)</code> for a detailed description of extended file attributes.</p> <p>The process context created by the runat command has its current working directory set to the hidden directory containing the file's extended attributes. The parent of this directory (the "." entry) always refers to the file provided on the command line. As such, it may not be a directory. Therefore, commands (such as <code>pwd</code>) that depend upon the parent entry being well-formed (that is, referring to a directory) may fail.</p> <p>In the absence of the <i>command</i> argument, runat will spawn a new interactive shell with its current working directory set to be the provided file's hidden attribute directory. Notice that some shells (such as <code>zsh</code> and <code>tcsh</code>) are not well behaved when the directory parent is not a directory, as described above. These shells should not be used with runat.</p> |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Using runat to list extended attributes on a file</p> <pre>example% runat file.1 ls -l example% runat file.1 ls</pre> <p><b>EXAMPLE 2</b> Creating extended attributes</p> <pre>example% runat file.2 cp /tmp/attrdata attr.1 example% runat file.2 cat /tmp/attrdata &gt; attr.1</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**EXAMPLE 3** Copying an attribute from one file to another

```
example% runat file.2 cat attr.1 | runat file.1 "cat > attr.1"
```

**EXAMPLE 4** Using runat to spawn an interactive shell

```
example% runat file.3 /bin/sh
```

This spawns a new shell in the attribute directory for `file.3`. Notice that the shell will not be able to determine what your current directory is. To leave the attribute directory, either exit the spawned shell or change directory (`cd`) using an absolute path.

Recommended methods for performing basic attribute operations:

## display

```
runat file ls [options]
```

## read

```
runat file cat attribute
```

## create/modify

```
runat file cp absolute-file-path attribute
```

## delete

```
runat file rm attribute
```

## permission changes

```
runat file chmod mode attribute
```

```
runat file chgrp group attribute
```

```
runat file chown owner attribute
```

## interactive shell

```
runat file /bin/sh
```

or set your `$SHELL` to `/bin/sh` and

```
runat file
```

The above list includes commands that are known to work with `runat`. While many other commands may work, there is no guarantee that any beyond this list will work. Any command that relies on being able to determine its current working directory is likely to fail. Examples of such commands follow:

**EXAMPLE 5** Using `man` in an attribute directory

```
example% runat file.1 man runat
```

```
getcwd: Not a directory
```

**EXAMPLE 6** Spawning a `tcsh` shell in an attribute directory

```
example% runat file.3 /usr/bin/tcsh
```

```
tcsh: Not a directory
```

```
tcsh: Trying to start from "/home/user"
```

## runat(1)

**EXAMPLE 6** Spawning a tcsh shell in an attribute directory (Continued)

A new tcsh shell has been spawned with the current working directory set to the user's home directory.

**EXAMPLE 7** Spawning a zsh shell in an attribute directory

```
example% runat file.3 /usr/bin/zsh
example%
```

While the command appears to have worked, zsh has actually just changed the current working directory to '/'. This can be seen by using /bin/pwd:

```
example% /bin/pwd
/
```

### ENVIRONMENT VARIABLES EXIT STATUS

**SHELL** Specifies the command shell to be invoked by runat.

The following exit values are returned:

125 The attribute directory of the file referenced by the *file* argument cannot be accessed.

126 The exec of the provided *command* argument failed.

Otherwise, the exit status returned is the exit status of the shell invoked to execute the provided command.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| CSI                 | Enabled         |
| Interface Stability | Evolving        |

**SEE ALSO** `open(2)`, `attributes(5)`, `fsattr(5)`

### NOTES

It is not always obvious why a command fails in `runat` when it is unable to determine the current working directory. The errors resulting can be confusing and ambiguous (see the `tcsh` and `zsh` examples above).

| <b>NAME</b>        | rup – show host status of remote machines (RPC version)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |           |

| <b>DESCRIPTION</b> | <p>rup gives a status similar to <code>uptime</code> for remote machines. It broadcasts on the local network, and displays the responses it receives.</p> <p>Normally, the listing is in the order that responses are received, but this order can be changed by specifying one of the options listed below.</p> <p>When <i>host</i> arguments are given, rather than broadcasting rup will only query the list of specified hosts.</p> <p>A remote host will only respond if it is running the <code>rstatd</code> daemon, which is normally started up from <code>inetd(1M)</code>.</p> <p>In the absence of a name service, such as LDAP or NIS, rup displays host names as numeric IP addresses.</p> |                |                 |              |           |
| <b>OPTIONS</b>     | <p>-h        Sort the display alphabetically by host name.</p> <p>-l        Sort the display by load average.</p> <p>-t        Sort the display by up time.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |           |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |              |           |

rup(1C)

**NAME** rup – show host status of remote machines (RPC version)

**SYNOPSIS** **rup** [-hlt]  
**rup** [*host...*]

**DESCRIPTION** rup gives a status similar to uptime for remote machines. It broadcasts on the local network, and displays the responses it receives.

Normally, the listing is in the order that responses are received, but this order can be changed by specifying one of the options listed below.

When *host* arguments are given, rather than broadcasting rup only queries the list of specified hosts.

A remote host will only respond if it is running the rstatd daemon, which is normally started up from inetd(1M).

**OPTIONS** -h Sort the display alphabetically by host name.  
-l Sort the display by load average.  
-t Sort the display by up time.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWesu         |

**SEE ALSO** ruptime(1), inetd(1M), attributes(5)

**BUGS** Broadcasting does not work through gateways.

| <b>SYNOPSIS</b>    | <b>ruptime</b> [-ar] [-l   -t   -u]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |           |
| <b>DESCRIPTION</b> | <p>The <code>ruptime</code> utility gives a status line like <code>uptime</code> (see <a href="#">uptime(1)</a>) for each machine on the local network; these are formed from packets broadcast by each host on the network approximately every three minutes.</p> <p>Machines for which no status report has been received for 11 minutes are shown as being down.</p> <p>Normally, the listing is sorted by host name, but this order can be changed by specifying one of the options listed below.</p>                                                                               |                |                 |              |           |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a                Counts even those users who have been idle for an hour or more.</li> <li>-r                Reverses the sorting order.</li> <li>-l   -t   -u      These options are mutually exclusive. The use of one overrides the previous one(s). <ul style="list-style-type: none"> <li>-l                Sorts the display by load average.</li> <li>-t                Sorts the display by up time.</li> <li>-u                Sorts the display by number of users.</li> </ul> </li> </ul> |                |                 |              |           |
| <b>FILES</b>       | <code>/var/spool/rwho/whod.*</code> data files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |           |

| <b>SYNOPSIS</b>    | <code>/usr/ucb/rusage command</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                                        |  |                   |                   |                       |                |                  |                       |                  |                 |                        |                                    |                 |                        |                                        |                 |                       |       |                 |                         |                        |                 |                         |                         |                  |                       |                            |                  |                        |                              |                 |                        |                           |                 |                       |             |                 |                       |                            |                 |                       |             |
| <b>DESCRIPTION</b> | The <code>rusage</code> command is similar to <code>time(1)</code> . It runs the given <i>command</i> , which must be specified; that is, <i>command</i> is not optional as it is in the C shell's timing facility. When the command is complete, <code>rusage</code> displays the real (wall clock), the system CPU, and the user CPU times which elapsed during execution of the command, plus other fields in the <code>rusage</code> structure, all on one long line. Times are reported in seconds and hundredths of a second.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                        |  |                   |                   |                       |                |                  |                       |                  |                 |                        |                                    |                 |                        |                                        |                 |                       |       |                 |                         |                        |                 |                         |                         |                  |                       |                            |                  |                        |                              |                 |                        |                           |                 |                       |             |                 |                       |                            |                 |                       |             |

**BUGS** When the command being timed is interrupted, the timing values displayed may be inaccurate.

rusers(1)

**NAME** rusers – who is logged in on remote machines

**SYNOPSIS** **rusers** [-ahilu] *host...*

**DESCRIPTION** The **rusers** command produces output similar to **who(1)**, but for remote machines. The listing is in the order that responses are received, but this order can be changed by specifying one of the options listed below.

The default is to print out the names of the users logged in. When the **-l** flag is given, additional information is printed for each user:

```
userid hostname : terminal login_date login_time idle_time login_host
```

If *hostname* and *login host* are the same value, the *login\_host* field is not displayed. Likewise, if *hostname* is not idle, the *idle\_time* is not displayed.

A remote host will only respond if it is running the **rusersd** daemon, which may be started up from **inetd(1M)** or **listen(1M)**.

In the absence of a name service, such as LDAP or NIS, **rusers** displays host names as numeric IP addresses.

**OPTIONS**

- a Give a report for a machine even if no users are logged on.
- h Sort alphabetically by host name.
- i Sort by idle time.
- l Give a longer listing in the style of **who(1)**.
- u Sort by number of users.

**ATTRIBUTES** See **attributes(5)** for descriptions of the following attributes:

| <b>SYNOPSIS</b>    | <b>rwho</b> [-a]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>The rwho command produces output similar to <a href="#">who(1)</a>, but for all machines on your network. If no report has been received from a machine for 5 minutes, rwho assumes the machine is down, and does not report users last known to be logged into that machine.</p> <p>If a user has not typed to the system for a minute or more, rwho reports this idle time. If a user has not typed to the system for an hour or more, the user is omitted from the output of rwho unless the -a flag is given.</p> |
| <b>OPTIONS</b>     | -a        Report all users whether or not they have typed to the system in the past hour.                                                                                                                                                                                                                                                                                                                                                                                                                                |

**NOTES** rwho does not work through gateways.

The directory /var/spool/rwho must exist on the host from which rwho is run.

This service takes up progressively more network bandwidth as the number of hosts on the local net increases. For large networks, the cost becomes prohibitive.

The rwho service daemon, [in.rwhod\(1M\)](#), must be enabled for this command to return useful results.

| <b>NAME</b>        | sag – system activity graph                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <b>sag</b> [-e <i>time</i> ] [-f <i>file</i> ] [-i <i>sec</i> ] [-s <i>time</i> ] [-T <i>term</i> ] [-x <i>spec</i> ] [-y <i>spec</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>The <b>sag</b> utility graphically displays the system activity data stored in a binary data file by a previous <b>sar</b>(1) run. Any of the <b>sar</b> data items may be plotted singly or in combination, as cross plots or versus time. Simple arithmetic combinations of data may be specified. <b>sag</b> invokes <b>sar</b> and finds the desired data by string-matching the data column header (run <b>sar</b> to see what is available). The <b>sag</b> utility requires a graphic terminal to draw the graph, and uses <b>tplot</b>(1) to produce its output. When running Solaris 2.x and OpenWindows, perform the following steps:</p> <ol style="list-style-type: none"><li>1. Run an "xterm" as a Tektronics terminal: prompt# xterm -t</li><li>2. In the "xterm" window, run <b>sag</b> specifying a tek terminal: prompt# sag -T tek options</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OPTIONS</b>     | <p>The following options are supported and passed through to <b>sar</b> (see <b>sar</b>(1)):</p> <p>-e <i>time</i>    Select data up to <i>time</i>. Default is 18:00.</p> <p>-f <i>file</i>    Use <i>file</i> as the data source for <b>sar</b>. Default is the current daily data file /usr/adm/sa/sadd.</p> <p>-i <i>sec</i>    Select data at intervals as close as possible to <i>sec</i> seconds.</p> <p>-s <i>time</i>    Select data later than <i>time</i> in the form <i>hh [:mm]</i>. Default is 08:00.</p> <p>-T <i>term</i>    Produce output suitable for terminal <i>term</i>. See <b>tplot</b>(1) for known terminals. Default for <i>term</i> is \$TERM.</p> <p>-x <i>spec</i>    x axis specification with <i>spec</i> in the form:</p> <p style="padding-left: 40px;"><i>name</i> [<i>op name</i>] . . . [<i>lo hi</i>]</p> <p style="padding-left: 40px;"><i>name</i> is either a string that will match a column header in the <b>sar</b> report, with an optional device name in square brackets, for example, r+w/s [dsk-1], or an integer value. <i>op</i> is + - * or / surrounded by blank spaces. Up to five names may be specified. Parentheses are not recognized. Contrary to custom, + and - have precedence over * and /. Evaluation is left to right. Thus, A/A+B*100 is evaluated as (A/(A+B))*100, and A+B/C+D is (A+B)/(C+D). <i>lo</i> and <i>hi</i> are optional numeric scale limits. If unspecified, they are deduced from the data.</p> <p style="padding-left: 40px;">Enclose <i>spec</i> in double-quotes (" ") if it includes white space.</p> <p style="padding-left: 40px;">A single <i>spec</i> is permitted for the x axis. If unspecified, <i>time</i> is used.</p> <p>-y <i>spec</i>    y axis specification with <i>spec</i> in the same form as for -x. Up to 5 <i>spec</i> arguments separated by a semi-colon (;) may be given for -y. The -y default is:</p> <p style="padding-left: 40px;">-y"%usr0100;%usr+%sys0100;%usr+%sys+%wio0100"</p> |

**EXAMPLES** **EXAMPLE 1** Examples of the sag command.

To see today's CPU utilization:

```
example$ sag
```

To see activity over 15 minutes of all disk drives:

```
example$ TS=`date +%H:%M`
example$ sar -o /tmp/tempfile 60 15
example$ TE=`date +%H:%M`
example$ sag -f /tmp/tempfile -s $TS -e $TE -y "r+w/s[dsk]"
```

**FILES** /usr/adm/sa/sadd           daily data file for day dd

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWaccu        |

| <b>NAME</b>        | sar – system activity reporter                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <b>sar</b> [-aAbcdgkmpqruvwy] [-o <i>filename</i> ] <i>t</i> [ <i>n</i> ]<br><b>sar</b> [-aAbcdgkmpqruvwy] [-e <i>time</i> ] [-f <i>filename</i> ] [-i <i>sec</i> ] [-s <i>time</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p>In the first instance, the <i>sar</i> utility samples cumulative activity counters in the operating system at <i>n</i> intervals of <i>t</i> seconds, where <i>t</i> should be 5 or greater. If <i>t</i> is specified with more than one option, all headers are printed together and the output can be difficult to read. (If the sampling interval is less than 5, the activity of <i>sar</i> itself can affect the sample.) If the -o option is specified, it saves the samples in <i>filename</i> in binary format. The default value of <i>n</i> is 1.</p> <p>In the second instance, no sampling interval is specified. <i>sar</i> extracts data from a previously recorded <i>filename</i>, either the one specified by the -f option or, by default, the standard system activity daily data file <i>/var/adm/sa/sadd</i> for the current day <i>dd</i>. The starting and ending times of the report can be bounded using the -e and -s arguments with <i>time</i> specified in the form <i>hh[:mm[:ss]]</i>. The -i option selects records at <i>sec</i> second intervals. Otherwise, all intervals found in the data file are reported.</p> |
| <b>OPTIONS</b>     | <p>The following options modify the subsets of information reported by <i>sar</i>.</p> <p>-a Reports use of file access system routines: iget/s, namei/s, dirblk/s</p> <p>-A Reports all data. Equivalent to -abcdgkmpqruvwy.</p> <p>-b Reports buffer activity:</p> <p>bread/s, bwrit/s<br/>transfers per second of data between system buffers and disk or other block devices.</p> <p>lread/s, lwrit/s<br/>accesses of system buffers.</p> <p>%rcache, %wcache<br/>cache hit ratios, that is, (1-bread/lread) as a percentage.</p> <p>pread/s, pwrit/s<br/>transfers using raw (physical) device mechanism.</p> <p>If run in a non-global zone and the pools facility is active, these values reflect activity on the processors of the processor set of the pool to which the zone is bound.</p> <p>-c Reports system calls:</p> <p>scall/s<br/>system calls of all types.</p> <p>sread/s, swrit/s, fork/s, exec/s<br/>specific system calls.</p>                                                                                                                                                                                                    |

rchar/s, wchar/s

characters transferred by read and write system calls. No incoming or outgoing `exec(2)` and `fork(2)` calls are reported.

If run in a non-global zone and the pools facility is active, these values reflect activity on the processors of the processor set of the pool to which the zone is bound.

-d

Reports activity for each block device (for example, disk or tape drive) with the exception of XDC disks and tape drives. When data is displayed, the device specification `dsk-` is generally used to represent a disk drive. The device specification used to represent a tape drive is machine dependent. The activity data reported is:

%busy, avque

portion of time device was busy servicing a transfer request, average number of requests outstanding during that time.

read/s, write/s, blks/s

number of read/write transfers from or to device, number of bytes transferred in 512-byte units.

await

average wait time in milliseconds.

avserv

average service time in milliseconds.

For more general system statistics, use `iostat(1M)`, `sar(1M)`, or `vmstat(1M)`.

See *System Administration Guide: Basic Administration* for naming conventions for disks.

-e *time*

Selects data up to `time`. Default is 18:00.

-f *filename*

Uses *filename* as the data source for `sar`. Default is the current daily data file `/var/adm/sa/sadd`.

-g

Reports paging activities:

pgout/s            page-out requests per second.

ppgout/s          pages paged-out per second.

pgfree/s          pages per second placed on the free list by the page stealing daemon.

pgscan/s          pages per second scanned by the page stealing daemon.

%ufs\_ipf          the percentage of UFS inodes taken off the freelist by `iget` which had reusable pages associated with them. These pages are flushed and cannot be reclaimed by processes. Thus,

sar(1)

this is the percentage of igets with page flushes.

If run in a non-global zone and the pools facility is active, these values reflect activity on the processors of the processor set of the pool to which the zone is bound.

- i *sec* Selects data at intervals as close as possible to *sec* seconds.
- k Reports kernel memory allocation (KMA) activities:
  - sml\_mem, alloc, fail information about the memory pool reserving and allocating space for small requests: the amount of memory in bytes KMA has for the small pool, the number of bytes allocated to satisfy requests for small amounts of memory, and the number of requests for small amounts of memory that were not satisfied (failed).
  - lg\_mem, alloc, fail information for the large memory pool (analogous to the information for the small memory pool).
  - ovsz\_alloc, fail the amount of memory allocated for oversize requests and the number of oversize requests which could not be satisfied (because oversized memory is allocated dynamically, there is not a pool).
- m Reports message and semaphore activities:
  - msg/s, sema/s primitives per second.

If run in a non-global zone and the pools facility is active, these values reflect activity on the processors of the processor set of the pool to which the zone is bound.
- o *filename* Saves samples in file, *filename*, in binary format.
- p Reports paging activities:
  - atc/s page faults per second that are satisfied by reclaiming a page currently in memory (attaches per second).
  - pgin/s page-in requests per second.
  - ppgin/s pages paged-in per second.
  - pflt/s page faults from protection errors per second (illegal access to page) or "copy-on-writes".
  - vflt/s address translation page faults per second (valid page not in memory).

|                |                                    |                                                                                                                                                                            |
|----------------|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | slock/s                            | faults per second caused by software lock requests requiring physical I/O.                                                                                                 |
|                |                                    | If run in a non-global zone and the pools facility is active, these values reflect activity on the processors of the processor set of the pool to which the zone is bound. |
| -q             |                                    | Reports average queue length while occupied, and percent of time occupied:                                                                                                 |
|                | runq-sz, %runocc                   | Run queue of kernel threads in memory and runnable                                                                                                                         |
|                | swpq-sz, %swpocc                   | Swap queue of processes                                                                                                                                                    |
| -r             |                                    | Reports unused memory pages and disk blocks:                                                                                                                               |
|                | freemem                            | average pages available to user processes.                                                                                                                                 |
|                | freeswap                           | disk blocks available for page swapping.                                                                                                                                   |
| -s <i>time</i> |                                    | Selects data later than <i>time</i> in the form <i>hh[:mm]</i> . Default is 08:00.                                                                                         |
| -u             |                                    | Reports CPU utilization (the default):                                                                                                                                     |
|                | %usr, %sys, %wio, %idle            | portion of time running in user mode, running in system mode, idle with some process waiting for block I/O, and otherwise idle.                                            |
|                |                                    | If run in a non-global zone and the pools facility is active, these values reflect activity on the processors of the processor set of the pool to which the zone is bound. |
| -v             |                                    | Reports status of process, i-node, file tables:                                                                                                                            |
|                | proc-sz, inod-sz, file-sz, lock-sz | entries/size for each table, evaluated once at sampling point.                                                                                                             |
|                | ov                                 | overflows that occur between sampling points for each table.                                                                                                               |
| -w             |                                    | Reports system swapping and switching activity:                                                                                                                            |
|                | swpin/s, swpot/s, bswin/s, bswot/s | number of transfers and number of 512-byte units transferred for swapins and swapouts (including initial loading of some programs).                                        |
|                | pswch/s                            | process switches.                                                                                                                                                          |

## sar(1)

If run in a non-global zone and the pools facility is active, these values reflect activity on the processors of the processor set of the pool to which the zone is bound.

-y

Reports TTY device activity:

rawch/s, canch/s, outh/s  
input character rate, input character rate processed by canon,  
output character rate.

rcvin/s, xmtin/s, madmin/s  
receive, transmit and modem interrupt rates.

If run in a non-global zone and the pools facility is active, these values reflect activity on the processors of the processor set of the pool to which the zone is bound.

### EXAMPLES **EXAMPLE 1** Viewing System Activity

The following example displays today's CPU activity so far:

```
example% sar
```

### **EXAMPLE 2** Watching System Activity Evolve

To watch CPU activity evolve for 10 minutes and save data:

```
example% sar -o temp 60 10
```

### **EXAMPLE 3** Reviewing Disk and Tape Activity

To later review disk and tape activity from that period:

```
example% sar -d -f temp
```

**FILES** /var/adm/sa/sadd daily data file, where *dd* are digits representing the day of the month

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWaccu        |

**SEE ALSO** [sag\(1\)](#), [iostat\(1M\)](#), [sar\(1M\)](#), [vmstat\(1M\)](#), [exec\(2\)](#), [fork\(2\)](#), [attributes\(5\)](#)

*System Administration Guide: Basic Administration*

**NOTES** The sum of CPU utilization might vary slightly from 100 because of rounding errors in the production of a percentage figure.

| <b>SYNOPSIS</b>                 | <pre> /usr/ccs/bin/sccs [-r] [-drootprefix] [-psubdir] subcommand [option...] [file...]  /usr/xpg4/bin/sccs [-r] [-d rootprefix] [-p subdir] subcommand [option...] [file...] </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b>              | <p>The <code>sccs</code> command is a comprehensive, straightforward front end to the various utility programs of the Source Code Control System (SCCS).</p> <p><code>sccs</code> applies the indicated <i>subcommand</i> to the history file associated with each of the indicated files.</p> <p>The name of an SCCS history file is derived by prepending the <code>'s.'</code> prefix to the filename of a working copy. The <code>sccs</code> command normally expects these <code>'s .files'</code> to reside in an SCCS subdirectory. Thus, when you supply <code>sccs</code> with a <i>file</i> argument, it normally applies the subcommand to a file named <code>s .file</code> in the SCCS subdirectory. If <i>file</i> is a path name, <code>sccs</code> looks for the history file in the SCCS subdirectory of that file's parent directory. If <i>file</i> is a directory, however, <code>sccs</code> applies the subcommand to every <code>s .file</code> file it contains. Thus, the command:</p> <pre>example% sccs get program.c</pre> <p>would apply the <code>get</code> subcommand to a history file named <code>SCCS/s .program.c</code>, while the command:</p> <pre>example% sccs get SCCS</pre> <p>would apply it to every <code>s .file</code> in the SCCS subdirectory.</p> <p>Options for the <code>sccs</code> command itself must appear before the <i>subcommand</i> argument. Options for a given subcommand must appear after the <i>subcommand</i> argument. These options are specific to each subcommand, and are described along with the subcommands themselves (see Subcommands below).</p> |
| <b>Running Setuid</b>           | The <code>sccs</code> command also includes the capability to run <code>"setuid"</code> to provide additional protection. However, this does not apply to subcommands such as <code>sccs-admin(1)</code> , since this would allow anyone to change the authorizations of the history file. Commands that would do so always run as the real user.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <code>/usr/xpg4/bin/sccs</code> | <code>-d rootprefix</code> Defines the root portion of the path name for SCCS history files. The default root portion is the current directory. <i>rootprefix</i> is prepended to the entire <i>file</i> argument, even if <i>file</i> is an absolute path name. <code>-d</code> overrides any directory specified by the <code>PROJECTDIR</code> environment variable (see ENVIRONMENT VARIABLES below).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>USAGE</b>             | The usage for <i>scs</i> is described below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                         |
| <b>Subcommands</b>       | Many of the following <i>scs</i> subcommands invoke programs that reside in <i>/usr/ccs/bin</i> . Many of these subcommands accept additional arguments that are documented in the reference page for the utility program the subcommand invokes.                                                                                                                                                                                                                                                                                                                                             |                                                                                                                                                                                                                                                                                                         |
|                          | admin                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Modify the flags or checksum of an <i>SCCS</i> history file. Refer to <a href="#">scs-admin(1)</a> for more information about the <i>admin</i> utility. While <i>admin</i> can be used to initialize a history file, you may find that the <i>create</i> subcommand is simpler to use for this purpose. |

|------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><code>/usr/ccs/bin/sccs</code></p> <p><code>/usr/xpg4/bin/sccs</code></p> | <p><code>-b</code> Ignore branches.</p> <p><code>-u[username]</code></p> <p><code>-u [username]   -U</code> Check only files being edited by you. When <i>username</i> is specified, check only files being edited by that user. For <code>/usr/xpg4/bin/sccs</code>, the <code>-U</code> option is equivalent to <code>-u &lt;current_user&gt;</code>.</p> <p><code>clean [ -b ]</code><br/>Remove everything in the current directory that can be retrieved from an SCCS history. Does not remove files that are being edited.</p> <p><code>-b</code> Do not check branches to see if they are being edited. 'clean -b' is dangerous when branch versions are kept in the same directory.</p> <p><code>comb</code><br/>Generate scripts to combine deltas. Refer to <code>sccs-comb(1)</code>.</p> <p><code>create</code><br/>Create (initialize) history files. <code>create</code> performs the following steps:</p> <ul style="list-style-type: none"> <li>■ Renames the original source file to <code>,program.c</code> in the current directory.</li> <li>■ Create the history file called <code>s.program.c</code> in the SCCS subdirectory.</li> <li>■ Performs an 'sccs get' on <code>program.c</code> to retrieve a read-only copy of the initial version.</li> </ul> <p><code>deledit [-s] [-y[comment]]</code><br/>Equivalent to an 'sccs delta' and then an 'sccs edit'. <code>deledit</code> checks in a delta, and checks the file back out again, but leaves the current working copy of the file intact.</p> <p><code>-s</code> Silent. Do not report delta numbers or statistics.</p> <p><code>-y [comment]</code> Supply a comment for the delta commentary. If <code>-y</code> is omitted, delta prompts for a comment. A null <i>comment</i> results in an empty comment field for the delta.</p> <p><code>delget [-s] [-y[comment]]</code><br/>Perform an 'sccs delta' and then an 'sccs get' to check in a delta and retrieve read-only copies of the resulting new version. See the <code>deledit</code> subcommand for a description of <code>-s</code> and <code>-y</code>. <code>sccs</code> performs a delta on all the files specified in the argument list, and then a get on all the files. If an error occurs during the delta, the get is not performed.</p> <p><code>delta [-s] [-y[comment]]</code><br/>Check in pending changes. Records the line-by-line changes introduced while the file was checked out. The effective user ID must be the same as the ID of the person who has the file checked out. Refer to <code>sccs-delta(1)</code>. See the <code>deledit</code> subcommand for a description of <code>-s</code> and <code>-y</code>.</p> <p><code>/usr/ccs/bin/sccs</code> <code>diffs [-C] [-I] [-cdate-time] [-rsid] diff-options</code></p> <p><code>/usr/xpg4/bin/sccs</code> <code>diffs [-C] [-I] [-c date-time   -cdate-time ]</code><br/><code>[-r sid   -rsid] diff-options</code></p> |

|                                 | <p><code>edit</code> Retrieve a version of the file for editing. '<code>sccs edit</code>' extracts a version of the file that is writable by you, and creates a <code>p.</code> file in the SCCS subdirectory as <code>lock</code> on the history, so that no one else can check that version in or out. ID keywords are retrieved in unexpanded form. <code>edit</code> accepts the same options as <code>get</code>, below. Refer to <code>sccs-get(1)</code> for a list of ID keywords and their definitions.</p>                                                                                                            |
|                                 | <p><code>enter</code> Similar to <code>create</code>, but omits the final '<code>sccs get</code>'. This may be used if an '<code>sccs edit</code>' is to be performed immediately after the history file is initialized.</p>                                                                                                                                                                                                                                                                                                                                                                                                    |

| <code>/usr/xpg4/bin/sccs</code> | <code>fix -r sid   -rsid</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                                 | <p>Revise a (leaf) delta. Remove the indicated delta from the SCCS history, but leave a working copy of the current version in the directory. This is useful for incorporating trivial updates for which no audit record is needed, or for revising the delta commentary. <code>fix</code> must be followed by a <code>-r</code> option, to specify the SID of the delta to remove. The indicated delta must be the most recent (leaf) delta in its branch. Use <code>fix</code> with caution since it does not leave an audit trail of differences (although the previous commentary is retained within the history file).</p> |
| <code>/usr/ccs/bin/sccs</code>  | <code>get [-ekmps] [-Gnewname] [-cdate-time] [-r[sid] ]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                                 | <code>-b</code> Ignore branches.                                                                                                                                                                                                                                                       |
| <code>/usr/ccs/bin/sccs</code>  | <code>-u[<i>username</i>]</code>                                                                                                                                                                                                                                                       |
| <code>/usr/xpg4/bin/sccs</code> | <code>-u [<i>username</i>]   -U</code> List only files checked out to you. When <code>username</code> is specified, list only files checked out to that user. For <code>/usr/xpg4/bin/sccs</code> , the <code>-U</code> option is equivalent to <code>-u &lt;current_user&gt;</code> . |

|        |                                                                                                                                                                    |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| unedit | “Undo” the last edit or ‘get -e’, and return the working copy to its previous condition. unedit backs out all pending changes made since the file was checked out. |
| unget  | Same as unedit. Refer to <a href="#">sccs-unget(1)</a> .                                                                                                           |
| val    | Validate the history file. Refer to <a href="#">sccs-val(1)</a> .                                                                                                  |
| what   | Display any expanded ID keyword strings contained in a binary (object) or text file. Refer to <a href="#">what(1)</a> for more information.                        |

**EXAMPLES****EXAMPLE 1** Checking out, editing, and checking in a file

To check out a copy of `program.c` for editing, edit it, and then check it back in:

```
example% sccs edit program.c
1.1
new delta 1.2
14 lines

example% vi program.c
your editing session

example% sccs delget program.c
comments? clarified cryptic diagnostic
1.2
3 inserted
2 deleted
12 unchanged
1.2
15 lines
```

**EXAMPLE 2** Defining the root portion of the command pathname

sccs converts the command:

```
example% sccs -d/usr/src/include get stdio.h

to:

/usr/ccs/bin/get /usr/src/include/SCCS/s.stdio.h
```

**EXAMPLE 3** Defining the resident subdirectory

The command:

```
example% sccs -pprivate get include/stdio.h

becomes:

/usr/ccs/bin/get include/private/s.stdio.h
```

scs(1)

**EXAMPLE 4** Initializing a history file

To initialize the history file for a source file named `program.c`, make the SCCS subdirectory, and then use 'scs create':

```
example% mkdir SCCS
example% sccs create program.c
program.c:
1.1
14 lines
```

After verifying the working copy, you can remove the backup file that starts with a comma:

```
example% diff program.c ,program.c
example% rm ,program.c
```

**EXAMPLE 5** Retrieving a file from another directory

To retrieve a file from another directory into the current directory:

```
example% sccs get /usr/src/sccs/cc.c
```

OR:

```
example% sccs -p/usr/src/sccs/ get cc.c
```

**EXAMPLE 6** Checking out all files

To check out all files under SCCS in the current directory:

```
example% sccs edit SCCS
```

**EXAMPLE 7** Checking in all files

To check in all files currently checked out to you:

```
example% sccs delta `sccs tell -u`
```

**EXAMPLE 8** Entering multiple lines of comments

If using `-y` to enter a comment, for most shells, enclose the comment in single or double quotes. In the following example, `Myfile` is checked in with a two-line comment:

```
example% sccs deledit Myfile -y"Entering a
multi-line comment"
No id keywords (cm7)
1.2
2 inserted
0 deleted
14 unchanged
1.2
```

**EXAMPLE 8** Entering multiple lines of comments (Continued)

```
new delta 1.3
```

Displaying the SCCS history of Myfile:

```
example% sccs prt Myfile
```

```
SCCS/s.Myfile:
```

```
D 1.2 01/04/20 16:37:07 me 2 1 00002/00000/00014
```

```
Entering a
multi-line comment
```

```
D 1.1 01/04/15 13:23:32 me 1 0 00014/00000/00000
```

```
date and time created 01/04/15 13:23:32 by me
```

If `-y` is not used and `sccs` prompts for a comment, the newlines must be escaped using the backslash character (`\`):

```
example% sccs deleedit Myfile
```

```
comments? Entering a \
multi-line comment
```

```
No id keywords (cm7)
```

```
1.2
```

```
0 inserted
```

```
0 deleted
```

```
14 unchanged
```

```
1.2
```

```
new delta 1.3
```

**ENVIRONMENT  
VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `sccs`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**PROJECTDIR** If contains an absolute path name (beginning with a slash), `sccs` searches for SCCS history files in the directory given by that variable.

If `PROJECTDIR` does not begin with a slash, it is taken as the name of a user, and `sccs` searches the `src` or `source` subdirectory of that user's home directory for history files. If such a directory is found, it is used. Otherwise, the value is used as a relative path name.

**EXIT STATUS**

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**FILES**

SCCS SCCS subdirectory

SCCS/d.*file* temporary file of differences

SCCS/p.*file* lock (permissions) file for checked-out versions

sccs(1)

SCCS/q .file temporary file  
SCCS/s .file SCCS history file  
SCCS/x .file temporary copy of the s . file  
SCCS/z .file temporary lock file  
/usr/ccs/bin/\* SCCS utility programs

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

*/usr/ccs/bin/sccs*

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWspot        |

*/usr/xpg4/bin/sccs*

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWxcu4t       |
| Interface Stability | Standard        |

| <b>NAME</b>        | sccs-admin, admin – create and administer SCCS history files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <pre> /usr/ccs/bin/admin [-bhnz] [-a username   groupid...] [-d flag] ...   [-e username   groupid...] [ -f flag [value]] ... [ -i [filename ]]   [-m mr-list] [-rrelease] [ -t [description-file]] [ -y [comment]] s.filename... </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DESCRIPTION</b> | <p>The <code>admin</code> command creates or modifies the flags and other parameters of SCCS history files. Filenames of SCCS history files begin with the <code>'s.'</code> prefix, and are referred to as <code>s.</code> files, or “history” files.</p> <p>The named <code>s.</code> file is created if it does not exist already. Its parameters are initialized or modified according to the options you specify. Parameters not specified are given default values when the file is initialized, otherwise they remain unchanged.</p> <p>If a directory name is used in place of the <code>s.filename</code> argument, the <code>admin</code> command applies to all <code>s.</code> files in that directory. Unreadable <code>s.</code> files produce an error. The use of <code>'-'</code> as the <code>s.filename</code> argument indicates that the names of files are to be read from the standard input, one <code>s.</code> file per line.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a <i>username   groupid</i><br/>Adds a user name, or a numerical group ID, to the list of users who may check deltas in or out. If the list is empty, any user is allowed to do so.</li> <li>-b<br/>Forces encoding of binary data. Files that contain ASCII NUL or other control characters, or that do not end with a <code>NEWLINE</code>, are recognized as binary data files. The contents of such files are stored in the history file in encoded form. See <code>uuencode(1C)</code> for details about the encoding. This option is normally used in conjunction with <code>-i</code> to force <code>admin</code> to encode initial versions not recognized as containing binary data.</li> <li>-d <i>flag</i><br/>Deletes the indicated <i>flag</i> from the SCCS file. The <code>-d</code> option may be specified only for existing <code>s.</code> files. See <code>-f</code> for the list of recognized flags.</li> <li>-e <i>username   groupid</i><br/>Erases a user name or group ID from the list of users allowed to make deltas.</li> <li>-f <i>flag [value]</i><br/>Sets the indicated <i>flag</i> to the (optional) <i>value</i> specified. The following flags are recognized: <ul style="list-style-type: none"> <li>b<br/>Enables branch deltas. When <code>b</code> is set, branches can be created using the <code>-b</code> option of the SCCS <code>get</code> command (see <code>sccs-get(1)</code>).</li> <li><i>ceil</i><br/>Sets a ceiling on the releases that can be checked out. <i>ceil</i> is a number less than or equal to 9999. If <code>c</code> is not set, the ceiling is 9999.</li> </ul> </li> </ul> |

|                                                                     |                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>dsid</i>                                                         | Specifies the default delta number, or SID, to be used by an SCCS <code>get</code> command.                                                                                                                                                                                                                                       |
| <i>f</i> <i>floor</i>                                               | Sets a floor on the releases that can be checked out. The floor is a number greater than 0 but less than 9999. If <i>f</i> is not set, the floor is 1.                                                                                                                                                                            |
| <i>i</i>                                                            | Treats the 'No id keywords (ge6)' message issued by an SCCS <code>get</code> or <code>delta</code> command as an error rather than a warning.                                                                                                                                                                                     |
| <i>j</i>                                                            | Allows concurrent updates.                                                                                                                                                                                                                                                                                                        |
| <i>l</i> <i>a</i><br><i>l</i> <i>release</i> [, <i>release</i> ...] | Locks the indicated list of releases against deltas. If <i>a</i> is used, this flag locks out deltas to all releases. An SCCS ' <code>get -e</code> ' command fails when applied against a locked release.                                                                                                                        |
| <i>m</i> <i>module</i>                                              | Supplies a value for the module name to which the <code>%M%</code> keyword is to expand. If the <i>m</i> flag is not specified, the value assigned is the name of the SCCS file with the leading <code>s.</code> removed.                                                                                                         |
| <i>n</i>                                                            | Creates empty releases when releases are skipped. These null (empty) deltas serve as anchor points for branch deltas.                                                                                                                                                                                                             |
| <i>q</i> <i>value</i>                                               | Supplies a <i>value</i> to which the <code>%Q%</code> keyword is to expand when a read-only version is retrieved with the SCCS <code>get</code> command.                                                                                                                                                                          |
| <i>s</i> <i>number</i>                                              | Specifies how many lines of code are scanned for the SCCS keyword.                                                                                                                                                                                                                                                                |
| <i>t</i> <i>type</i>                                                | Supplies a value for the module type to which the <code>%Y%</code> keyword is to expand.                                                                                                                                                                                                                                          |
| <i>v</i> [ <i>program</i> ]                                         | Specifies a validation <i>program</i> for the MR numbers associated with a new delta. The optional <i>program</i> specifies the name of an MR number validity checking <i>program</i> . If this flag is set when creating an SCCS file, the <code>-m</code> option must also be used, in which case the list of MRs may be empty. |
| <i>y</i> [ <i>value</i> , [ <i>value</i> ]]                         | Specifies the SCCS keywords to be expanded. If no <i>value</i> is specified, no keywords will be expanded.                                                                                                                                                                                                                        |
| <code>-h</code>                                                     | Checks the structure of an existing <code>s.</code> file (see <code>sccsfile(4)</code> ), and compares a newly computed check-sum with one stored in the first line of that file. <code>-h</code> inhibits writing on the file and so nullifies the effect of any other options.                                                  |

- i** [*filename*]  
 Initializes the history file with text from the indicated file. This text constitutes the initial delta, or set of checked-in changes. If *filename* is omitted, the initial text is obtained from the standard input. Omitting the **-i** option altogether creates an empty *s*.file. You can only initialize one *s*.file with text using **-i**. This option implies the **-n** option.
- m** *mr-list*  
 Inserts the indicated Modification Request (MR) numbers into the commentary for the initial version. When specifying more than one MR number on the command line, *mr-list* takes the form of a quoted, space-separated list. A warning results if the **v** flag is not set or the MR validation fails.
- n**  
 Creates a new SCCS history file.
- r** *release*  
 Specifies the release for the initial delta. **-r** may be used only in conjunction with **-i**. The initial delta is inserted into release 1 if this option is omitted. The level of the initial delta is always 1. Initial deltas are named 1.1 by default.
- t** [*description-file*]  
 Inserts descriptive text from the file *description-file*. When **-t** is used in conjunction with **-n**, or **-i** to initialize a new *s*.file, the *description-file* must be supplied. When modifying the description for an existing file: a **-t** option without a *description-file* removes the descriptive text, if any; a **-t** option with a *description-file* replaces the existing text.
- y** [*comment*]  
 Inserts the indicated *comment* in the "Comments:" field for the initial delta. Valid only in conjunction with **-i** or **-n**. If **-y** option is omitted, a default comment line is inserted that notes the date and time the history file was created.
- z**  
 Recomputes the file check-sum and stores it in the first line of the *s*.file. *Caution:* It is important to verify the contents of the history file (see [sccs-val\(1\)](#)), and the **print** subcommand in [sccs\(1\)](#)), since using **-z** on a truly corrupted file may prevent detection of the error.

**EXAMPLES**    **EXAMPLE 1** Preventing SCCS keyword expansion

In the following example, 10 lines of *file* will be scanned and only the *W*, *Y*, *X* keywords will be interpreted:

```
example% sccs admin -fs10 file
example% sccs admin -fyW,Y,X file
example% get file
```

**ENVIRONMENT VARIABLES**

See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of **alias** and **unalias**: *LANG*, *LC\_ALL*, *LC\_CTYPE*, *LC\_MESSAGES*, and *NLSPATH*.

**EXIT STATUS**    The following exit values are returned:

## sccs-admin(1)

0 Successful completion.

1 An error occurred.

### FILES

s.\* history file

SCCS/s.\* history file in SCCS subdirectory

z.\* temporary lock file

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWspot        |
| Interface Stability | Standard        |

### SEE ALSO

### DIAGNOSTICS

Use the `SCCS help` command for explanations (see `sccs-help(1)`).

### WARNINGS

The last component of all SCCS filenames must have the 's.' prefix. New SCCS files are given mode 444 (see `chmod(1)`). All writing done by `admin` is to a temporary file with an x. prefix, created with mode 444 for a new SCCS file, or with the same mode as an existing SCCS file. After successful execution of `admin`, the existing s. file is removed and replaced with the x. file. This ensures that changes are made to the SCCS file only when no errors have occurred.

It is recommended that directories containing SCCS files have permission mode 755, and that the s. files themselves have mode 444. The mode for directories allows only the owner to modify the SCCS files contained in the directories, while the mode of the s. files prevents all modifications except those performed using SCCS commands.

If it should be necessary to patch an SCCS file for any reason, the mode may be changed to 644 by the owner to allow use of a text editor. However, extreme care must be taken when doing this. The edited file should *always* be processed by an 'admin -h' command to check for corruption, followed by an 'admin -z' command to generate a proper check-sum. Another 'admin -h' command is recommended to ensure that the resulting s. file is valid.

`admin` also uses a temporary lock s. file, starting with the 'z.' prefix, to prevent simultaneous updates to the s. file. See `sccs-get(1)` for further information about the 'z. file'.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>NAME</b>        | sccs-cdc, cdc – change the delta commentary of an SCCS delta                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <code>/usr/ccs/bin/cdc -rsid [-mmr-list] [-y [comment]] s.filename...</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | <p>cdc annotates the delta commentary for the SCCS delta ID (SID) specified by the <code>-r</code> option in each named <code>s</code> . file.</p> <p>If the <code>v</code> flag is set in the <code>s</code> . file, you can also use <code>cdc</code> to update the Modification Request (MR) list.</p> <p>If you checked in the delta, or, if you own the file and directory and have write permission, you can use <code>cdc</code> to annotate the commentary.</p> <p>Rather than replacing the existing commentary, <code>cdc</code> inserts the new comment you supply, followed by a line of the form:</p> <pre>*** CHANGED *** yy/mm/dd hh/mm/ss username</pre> <p>above the existing commentary.</p> <p>If a directory is named as the <code>s.filename</code> argument, the <code>cdc</code> command applies to all <code>s</code> . files in that directory. Unreadable <code>s</code> . files produce an error; processing continues with the next file (if any). If <code>'-'</code> is given as the <code>s.filename</code> argument, each line of the standard input is taken as the name of an SCCS history file to be processed, and the <code>-m</code> and <code>-y</code> options must be used.</p>                                                                                                                                                                                                                                                                                                           |
| <b>OPTIONS</b>     | <p><code>-rsid</code> Specify the SID of the delta to change.</p> <p><code>-mmr-list</code> Specify one or more MR numbers to add or delete. When specifying more than one MR on the command line, <code>mmr-list</code> takes the form of a quoted, space-separated list. To delete an MR number, precede it with a <code>!</code> character (an empty MR list has no effect). A list of deleted MRs is placed in the comment section of the delta commentary. If <code>-m</code> is not used and the standard input is a terminal, <code>cdc</code> prompts with <code>MRS?</code> for the list (before issuing the <code>comments?</code> prompt). <code>-m</code> is only useful when the <code>v</code> flag is set in the <code>s</code> . file. If that flag has a value, it is taken to be the name of a program to validate the MR numbers. If that validation program returns a non-zero exit status, <code>cdc</code> terminates and the delta commentary remains unchanged.</p> <p><code>-y[comment]</code> Use <code>comment</code> as the annotation in the delta commentary. The previous comments are retained; the <code>comment</code> is added along with a notation that the commentary was changed. A null <code>comment</code> leaves the commentary unaffected. If <code>-y</code> is not specified and the standard input is a terminal, <code>cdc</code> prompts with <code>comments?</code> for the text of the notation to be added. An unescaped NEWLINE character terminates the annotation text.</p> |

sccs-cdc(1)

**EXAMPLES** **EXAMPLE 1** Changing the annotated commentary

The following command:

```
example% cdc -r1.6 -y"corrected commentary" s.program.c
```

produces the following annotated commentary for delta 1.6 in s.program.c:

```
D 1.6 88/07/05 23:21:07 username 9 0 00001/00000/00000
MRs:
COMMENTS:
corrected commentary
*** CHANGED *** 88/07/07 14:09:41 username
performance enhancements in main()
```

**FILES** z.file temporary lock file

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWspot        |

**SEE ALSO** [sccs\(1\)](#), [sccs-admin\(1\)](#), [sccs-comb\(1\)](#), [sccs-delta\(1\)](#), [sccs-help\(1\)](#), [sccs-prs\(1\)](#), [sccs-prt\(1\)](#), [sccs-rmdel\(1\)](#), [what\(1\)](#), [sccsfile\(4\)](#), [attributes\(5\)](#)

**DIAGNOSTICS** Use the SCCS help command for explanations (see [sccs-help\(1\)](#)).

**NAME** sccs-comb, comb – combine SCCS deltas

**SYNOPSIS** `/usr/ccs/bin/comb [-os] [-csid-list] [-psid] s.filename...`

**DESCRIPTION** comb generates a shell script (see [sh\(1\)](#)) that you can use to reconstruct the indicated `s` . files. This script is written to the standard output.

If a directory name is used in place of the `s.filename` argument, the `comb` command applies to all `s` . files in that directory. Unreadable `s` . files produce an error; processing continues with the next file (if any). The use of `'-'` as the `s.filename` argument indicates that the names of files are to be read from the standard input, one `s` . file per line.

If no options are specified, `comb` preserves only the most recent (leaf) delta in a branch, and the minimal number of ancestors needed to preserve the history.

**OPTIONS** The following options are supported:

- `-o` For each `'get -e'` generated, access the reconstructed file at the release of the delta to be created. Otherwise, the reconstructed file is accessed at the most recent ancestor. The use of `-o` may decrease the size of the reconstructed `s` . file. It may also alter the shape of the delta tree of the original file.
- `-s` Generate scripts to gather statistics, rather than combining deltas. When run, the shell scripts report: the file name, size (in blocks) after combining, original size (also in blocks), and the percentage size change, computed by the formula:  
  

$$100 * ( original - combined ) / original$$

This option can be used to calculate the space that will be saved, before actually doing the combining.
- `-csid-list` Include the indicated list of deltas. All other deltas are omitted. `sid-list` is a comma-separated list of SCCS delta IDs (SIDs). To specify a range of deltas, use a `'-'` separator instead of a comma, between two SIDs in the list.
- `-pSID` The SID of the oldest delta to be preserved.

**FILES**

|                        |                         |
|------------------------|-------------------------|
| <code>s</code> . COMB  | reconstructed SCCS file |
| <code>comb?????</code> | temporary file          |

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWspot        |

scs-comb(1)

**SEE ALSO** [scs\(1\)](#), [scs-admin\(1\)](#), [scs-cdc\(1\)](#), [scs-delta\(1\)](#), [scs-help\(1\)](#), [scs-prs\(1\)](#), [scs-prt\(1\)](#), [scs-rmdel\(1\)](#), [scs-scsdiff\(1\)](#), [what\(1\)](#), [scsfile\(4\)](#), [attributes\(5\)](#)

**DIAGNOSTICS** Use the SCCS help command for explanations (see [scs-help\(1\)](#)).

**BUGS** comb may rearrange the shape of the tree of deltas. It may not save any space; in fact, it is possible for the reconstructed file to actually be larger than the original.

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>NAME</b>                | sccs-delta, delta – make a delta to an SCCS file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>            | <pre> /usr/ccs/bin/delta [-dnps] [-g sid-list   -gsid-list] [-m mr-list   -mmr-list] [-r sid   -rsid] [-y [comment]] s.filename...  /usr/xpg4/bin/delta [-dnps] [-g sid-list   -gsid-list] [-m mr-list   -mmr-list] [-r sid   -rsid] [-y [comment]] s.filename... </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b>         | <p>The <code>delta</code> utility checks in a record of the line-by-line differences made to a checked-out version of a file under SCCS control. These changes are taken from the writable working copy that was retrieved using the SCCS <code>get</code> command (see <a href="#">sccs-get(1)</a>). This working copy does not have the <code>'s.'</code> prefix, and is also referred to as a <code>g-file</code>.</p> <p>If a directory name is used in place of the <code>s.filename</code> argument, the <code>delta</code> command applies to all <code>s.</code> files in that directory. Unreadable <code>s.</code> files produce an error; processing continues with the next file (if any). The use of <code>'-'</code> as the <code>s.filename</code> argument indicates that the names of files are to be read from the standard input, one <code>s.</code> file per line (requires <code>-y</code>, and in some cases, <code>-m</code>).</p> <p><code>delta</code> may issue prompts on the standard output depending upon the options specified and the flags that are set in the <code>s.</code> file (see <a href="#">sccs-admin(1)</a>, and the <code>-m</code> and <code>-y</code> options below, for details).</p> |
| <b>/usr/xpg4/bin/delta</b> | The SID of the delta is not echoed to <code>stdout</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OPTIONS</b>             | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-d</code> Use command <a href="#">diff(1)</a> instead of <a href="#">bdiff(1)</a>. Returns exit status 2 if <code>s.filename</code> argument is not specified.</li> <li><code>-n</code> Retain the edited <code>g-file</code>, which is normally removed at the completion of processing.</li> <li><code>-p</code> Display line-by-line differences (in <a href="#">diff(1)</a> format) on the standard output.</li> <li><code>-s</code> Silent. Do not display warning or confirmation messages. Do not suppress error messages (which are written to standard error).</li> <li><code>-g sid-list   -gsid-list</code> Specify a list of deltas to omit when the file is accessed at the SCCS version ID (SID) created by this delta. <code>sid-list</code> is a comma-separated list of SIDs. To specify a range of deltas, use a <code>'-'</code> separator instead of a comma, between two SIDs in the list.</li> <li><code>-m mr-list   -mmr-list</code> If the SCCS file has the <code>v</code> flag set (see <a href="#">sccs-admin(1)</a>), you must supply one or more Modification Request (MR) numbers</li> </ul>                   |

|                              |                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                              |                                                                                                                                                                                                                                         | for the new delta. When specifying more than one MR number on the command line, <i>mr-list</i> takes the form of a quoted, space-separated list. If <i>-m</i> is not used and the standard input is a terminal, <i>delta</i> prompts with <i>MRs?</i> for the list (before issuing the <i>comments?</i> prompt). If the <i>v</i> flag in the <i>s.file</i> has a value, it is taken to be the name of a program to validate the MR numbers. If that validation program returns a non-zero exit status, <i>delta</i> terminates without checking in the changes. |
|                              | <i>-r sid   -rsid</i>                                                                                                                                                                                                                   | When two or more versions are checked out, specify the version to check in. This SID value can be either the SID specified on the <i>get</i> command line, or the SID of the new version to be checked in as reported by <i>get</i> . A diagnostic results if the specified SID is ambiguous, or if one is required but not supplied.                                                                                                                                                                                                                           |
|                              | <i>-y[comment]</i>                                                                                                                                                                                                                      | Supply a comment for the delta table (version log). A null comment is accepted, and produces an empty commentary in the log. If <i>-y</i> is not specified and the standard input is a terminal, <i>delta</i> prompts with ' <i>comments?</i> '. An unescaped NEWLINE terminates the comment.                                                                                                                                                                                                                                                                   |

**DIAGNOSTICS** Use the `SCCS help` command for explanations (see `sccs-help(1)`).

**WARNINGS** Lines beginning with an ASCII SOH character (binary 001) cannot be placed in the SCCS file unless the SOH is escaped. This character has special meaning to SCCS (see `sccsfile(4)`) and produces an error.

| <b>DESCRIPTION</b>                        | <p>The get utility retrieves a working copy from the SCCS history file, according to the specified options.</p> <p>For each <i>s.filename</i> argument, get displays the SCCS delta ID (SID) and number of lines retrieved.</p> <p>If a directory name is used in place of the <i>s.filename</i> argument, the get command applies to all <i>s.</i> files in that directory. Unreadable <i>s.</i> files produce an error; processing continues with the next file (if any). The use of '-' as the <i>s.filename</i> argument indicates that the names of files are to be read from the standard input, one <i>s.</i> file per line.</p> <p>The retrieved file normally has the same filename base as the <i>s.</i> file, less the prefix, and is referred to as the <i>g</i>-file.</p> <p>For each file processed, get responds (on the standard output) with the SID being accessed, and with the number of lines retrieved from the <i>s.</i> file.</p>                                                                                                                                                                                                                                                                                                         |            |                                                                                                                                                                                                                                                                                                                                          |    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                           |                                                                                                                                                                                                       |
| <b>OPTIONS</b>                            | <p>The following options are supported:</p> <table><tr><td>-asequence</td><td>Retrieves the version corresponding to the indicated delta sequence number. This option is used primarily by the SCCS <code>comb</code> command (see <code>sccs-comb(1)</code>). For users, <code>-r</code> is an easier way to specify a version. The <code>-a</code> option supersedes the <code>-r</code> option when both are used.</td></tr><tr><td>-b</td><td>Creates a new branch. Used with the <code>-e</code> option to indicate that the new delta should have a SID in a new branch. Instead of incrementing the level for version to be checked in, get indicates in the <code>p.</code> file that the delta to be checked in should either initialize a new branch and sequence (if there is no existing branch at the current level), or increment the branch component of the SID. If the <code>b</code> flag is not set in the <i>s.</i> file, this option is ignored.</td></tr><tr><td>-c <i>date-time</i>   -c<i>date-time</i></td><td>Retrieves the latest version checked in prior to the date and time indicated by the <i>date-time</i> argument. <i>date-time</i> takes the form:<br/><br/><code>yy[mm[dd[ hh[mm[ss] ] ] ] ] ] ] ]</code></td></tr></table> | -asequence | Retrieves the version corresponding to the indicated delta sequence number. This option is used primarily by the SCCS <code>comb</code> command (see <code>sccs-comb(1)</code> ). For users, <code>-r</code> is an easier way to specify a version. The <code>-a</code> option supersedes the <code>-r</code> option when both are used. | -b | Creates a new branch. Used with the <code>-e</code> option to indicate that the new delta should have a SID in a new branch. Instead of incrementing the level for version to be checked in, get indicates in the <code>p.</code> file that the delta to be checked in should either initialize a new branch and sequence (if there is no existing branch at the current level), or increment the branch component of the SID. If the <code>b</code> flag is not set in the <i>s.</i> file, this option is ignored. | -c <i>date-time</i>   -c <i>date-time</i> | Retrieves the latest version checked in prior to the date and time indicated by the <i>date-time</i> argument. <i>date-time</i> takes the form:<br><br><code>yy[mm[dd[ hh[mm[ss] ] ] ] ] ] ] ]</code> |
| -asequence                                | Retrieves the version corresponding to the indicated delta sequence number. This option is used primarily by the SCCS <code>comb</code> command (see <code>sccs-comb(1)</code> ). For users, <code>-r</code> is an easier way to specify a version. The <code>-a</code> option supersedes the <code>-r</code> option when both are used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |            |                                                                                                                                                                                                                                                                                                                                          |    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                           |                                                                                                                                                                                                       |
| -b                                        | Creates a new branch. Used with the <code>-e</code> option to indicate that the new delta should have a SID in a new branch. Instead of incrementing the level for version to be checked in, get indicates in the <code>p.</code> file that the delta to be checked in should either initialize a new branch and sequence (if there is no existing branch at the current level), or increment the branch component of the SID. If the <code>b</code> flag is not set in the <i>s.</i> file, this option is ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |            |                                                                                                                                                                                                                                                                                                                                          |    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                           |                                                                                                                                                                                                       |
| -c <i>date-time</i>   -c <i>date-time</i> | Retrieves the latest version checked in prior to the date and time indicated by the <i>date-time</i> argument. <i>date-time</i> takes the form:<br><br><code>yy[mm[dd[ hh[mm[ss] ] ] ] ] ] ] ]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |            |                                                                                                                                                                                                                                                                                                                                          |    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                           |                                                                                                                                                                                                       |

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                       | Units omitted from the indicated date and time default to their maximum possible values; that is <code>-c7502</code> is equivalent to <code>-c750228235959</code> . Values of <i>yy</i> in the range 69–99 refer to the twentieth century. Values in the range 00–68 refer to the twenty-first century. Any number of non-numeric characters may separate the various 2 digit components. If white-space characters occur, the <i>date-time</i> specification must be quoted.                                                                                                                                                                                                               |
| <code>-e</code>                       | Retrieves a version for editing. With this option, <code>get</code> places a lock on the <code>s</code> file, so that no one else can check in changes to the version you have checked out. If the <code>j</code> flag is set in the <code>s</code> file, the lock is advisory: <code>get</code> issues a warning message. Concurrent use of <code>'get -e'</code> for different SIDs is allowed. However, <code>get</code> will not check out a version of the file if a writable version is present in the directory. All SCCS file protections stored in the <code>s</code> file, including the release ceiling, floor, and authorized user list, are honored by <code>'get -e'</code> . |
| <code>-g</code>                       | Gets the SCCS version ID, without retrieving the version itself. Used to verify the existence of a particular SID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>-Gnewname</code>                | Uses <i>newname</i> as the name of the retrieved version.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>-i sid-list   -isid-list</code> | Specifies a list of deltas to include in the retrieved version. The included deltas are noted in the standard output message. <i>sid-list</i> is a comma-separated list of SIDs. To specify a range of deltas, use a <code>'-'</code> separator instead of a comma, between two SIDs in the list.                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>-k</code>                       | Suppresses expansion of ID keywords. <code>-k</code> is implied by the <code>-e</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>-l ]&amp; p ]</code>            | Retrieves a summary of the delta table (version log) and write it to a listing file, with the <code>'l.'</code> prefix (called <code>'l</code> file'). When <code>-lp</code> is used, write the summary onto the standard output.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>-m</code>                       | Precedes each retrieved line with the SID of the delta in which it was added to the file. The SID is separated from the line with a TAB.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>-n</code>                       | Precedes each line with the <code>%M%</code> ID keyword and a TAB. When both the <code>-m</code> and <code>-n</code> options are used, the ID keyword precedes the SID, and the line of text.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>-p</code>                       | Writes the text of the retrieved version to the standard output. All messages that normally go to the standard output are written to the standard error instead.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

sccs-get(1)

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -s                       | Suppresses all output normally written on the standard output. However, fatal error messages (which always go to the standard error) remain unaffected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| -t                       | Retrieves the most recently created (top) delta in a given release (for example: -r1).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>/usr/ccs/bin/get</b>  | <p>-r[<i>sid</i>]</p> <p>Retrieves the version corresponding to the indicated SID (delta).</p> <p>The SID for a given delta is a number, in Dewey decimal format, composed of two or four fields: the <i>release</i> and <i>level</i> fields, and for branch deltas, the <i>branch</i> and <i>sequence</i> fields. For instance, if 1.2 is the SID, 1 is the release, and 2 is the level number. If 1.2.3.4 is the SID, 3 is the branch and 4 is the sequence number.</p> <p>You need not specify the entire SID to retrieve a version with <i>get</i>. When you omit -r altogether, or when you omit both release and level, <i>get</i> normally retrieves the highest release and level. If the d flag is set to an SID in the s. file and you omit the SID, <i>get</i> retrieves the default version indicated by that flag.</p> <p>When you specify a release but omit the level, <i>get</i> retrieves the highest level in that release. If that release does not exist, <i>get</i> retrieves highest level from the next-highest existing release.</p> <p>Similarly with branches, if you specify a release, level and branch, <i>get</i> retrieves the highest sequence in that branch.</p> |
| <b>/usr/xpg4/bin/get</b> | <p>-r <i>sid</i>   -r<i>sid</i></p> <p>Same as for <i>/usr/ccs/bin/get</i> except that SID is mandatory.</p> <p>-x <i>sid-list</i>   -x<i>sid-list</i></p> <p>Excludes the indicated deltas from the retrieved version. The excluded deltas are noted in the standard output message. <i>sid-list</i> is a comma-separated list of SIDs. To specify a range of deltas, use a '-' separator instead of a comma, between two SIDs in the list.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**USAGE** Usage guidelines are as follows:

**ID Keywords** In the absence of `-e` or `-k`, `get` expands the following ID keywords by replacing them with the indicated values in the text of the retrieved source.

| <i>Keyword</i> | <i>Value</i>                                                                                                                                                                                                            |

| %Z%            | 4-character string: '@(#)', recognized by <code>what</code>                                                                                                                                                             |

**ID String** The table below explains how the SCCS identification string is determined for retrieving and creating deltas.

scs-get(1)

| Determination of SCCS Identification String |                    |                                             |               |                            |
|---------------------------------------------|--------------------|---------------------------------------------|---------------|----------------------------|
| SID (1) Specified                           | -b Option Used (2) | Other Conditions                            | SID Retrieved | SID of Delta to be Created |
| none (3)                                    | no                 | R defaults to mR                            | mR.mL         | mR.(mL+1)                  |
| none (3)                                    | yes                | R defaults to mR                            | mR.mL         | mR.mL.(mB+1).1             |
| R                                           | no                 | R > mR                                      | mR.mL         | R.1 (4)                    |
| R                                           | no                 | R = mR                                      | mR.mL         | mR.(mL+1)                  |
| R                                           | yes                | R > mR                                      | mR.mL         | mR.mL.(mB+1).1             |
| R                                           | yes                | R = mR                                      | mR.mL         | mR.mL.(mB+1).1             |
| R                                           | -                  | R < mR and R does <i>not</i> exist          | hR.mL (5)     | hR.mL.(mB+1).1             |
| R                                           | -                  | Trunk succ. (6) in release > R and R exists | R.mL          | R.mL.(mB+1).1              |
| R.L                                         | no                 | No trunk succ.                              | R.L           | R.(L+1)                    |
| R.L                                         | yes                | No trunk succ.                              | R.L           | R.L.(mB+1).1               |
| R.L                                         | -                  | Trunk succ. in release $\geq$ R             | R.L           | R.L.(mB+1).1               |
| R.L.B                                       | no                 | No branch succ.                             | R.L.B.mS      | R.L.B.(mS+1)               |
| R.L.B                                       | yes                | No branch succ.                             | R.L.B.mS      | R.L.(mB+1).1               |
| R.L.B.S                                     | no                 | No branch succ.                             | R.L.B.S       | R.L.B.(S+1)                |
| R.L.B.S                                     | yes                | No branch succ.                             | R.L.B.S       | R.L.(mB+1).1               |
| R.L.B.S                                     | -                  | Branch succ.                                | R.L.B.S       | R.L.(mB+1).1               |

- (1) 'R', 'L', 'B', and 'S' are the 'release', 'level', 'branch', and 'sequence' components of the SID, respectively; 'm' means 'maximum'. Thus, for example, 'R.mL' means 'the maximum level number within release R'; 'R.L.(mB+1).1' means 'the first sequence number on the *new* branch (that is, maximum branch number plus one) of level L within release R'. *Note:* If the SID specified is of the form 'R.L', 'R.L.B', or 'R.L.B.S', each of the specified components *must* exist.
- (2) The -b option is effective only if the b flag is present in the file. An entry of '-' means 'irrelevant'.
- (3) This case applies if the d (default SID) flag is *not* present in the file. If the d flag *is* present in the file, the SID obtained from the d flag is interpreted as if it had been specified on the command line. Thus, one of the other cases in this table applies.

- (4) Forces creation of the *first* delta in a *new* release.
- (5) 'hR' is the highest *existing* release that is lower than the specified, *nonexistent*, release R.
- (6) Successor.

**ENVIRONMENT VARIABLES**

See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `get`: LANG, LC\_ALL, LC\_COLLATE, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**FILES**

- "g-file" version retrieved by `get`
- l.*file* file containing extracted delta table info
- p.*file* permissions (lock) file
- z.*file* temporary copy of s.*file*

**ATTRIBUTES**

See [attributes\(5\)](#) for descriptions of the following attributes:

**/usr/ccs/bin/get**

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWspot        |

**/usr/xpg4/bin/get**

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWxcu4t       |
| Interface Stability | Standard        |

**SEE ALSO**

[sccs\(1\)](#), [sccs-admin\(1\)](#), [sccs-delta\(1\)](#), [sccs-help\(1\)](#), [sccs-prs\(1\)](#), [sccs-prt\(1\)](#), [sccs-sact\(1\)](#), [sccs-unget\(1\)](#), [what\(1\)](#), [sccsfile\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**DIAGNOSTICS**

Use the `SCCS help` command for explanations (see [sccs-help\(1\)](#)).

**BUGS**

If the effective user has write permission (either explicitly or implicitly) in the directory containing the SCCS files, but the real user does not, only one file may be named when using `-e`.

sccs-help(1)

**NAME** | sccs-help, help – ask for help regarding SCCS error or warning messages

**SYNOPSIS** | `/usr/ccs/bin/help` [*argument...*]

**DESCRIPTION** | The `help` utility retrieves information to further explain errors messages and warnings from SCCS commands. It also provides some information about SCCS command usage. If no arguments are given, `help` prompts for one.

| An *argument* may be a message number (which normally appears in parentheses following each SCCS error or warning message), or an SCCS command name. `help` responds with an explanation of the message or a usage line for the command.

| When all else fails, try `'/usr/ccs/bin/help stuck'`.

**FILES** | `/usr/lib/help` directory containing files of message text

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWspot        |

| <b>DESCRIPTION</b> | <p>The <code>prs</code> utility displays part or all of the SCCS file (see <code>sccsfile(4)</code>) in a user supplied format.</p> <p>If a directory name is used in place of the <code>s.filename</code> argument, the <code>prs</code> command applies to all <code>s.</code> files in that directory. Unreadable <code>s.</code> files produce an error; processing continues with the next file (if any). The use of <code>'-'</code> as the <code>s.filename</code> argument indicates that the names of files are to be read from the standard input, one <code>s.</code> file per line.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>OPTIONS</b>     | <p>In the absence of options, <code>prs</code> displays the delta table (version log). In the absence of <code>-d</code>, or <code>-l</code>, <code>prs</code> displays the entry for each delta indicated by the other options.</p> <p><code>-a</code> Includes all deltas, including those marked as removed (see <code>sccs-rmdel(1)</code>).</p> <p><code>-e</code> Requests information for all deltas created <i>earlier</i> than, and including, the delta indicated with <code>-r</code> or <code>-c</code>.</p> <p><code>-l</code> Requests information for all deltas created <i>later</i> than, and including, the delta indicated with <code>-r</code> or <code>-c</code>.</p> <p><code>-cdate-time</code> Either options <code>-e</code> or <code>-l</code> must be used with this option. <code>-cdate-time</code> displays information on the deltas checked in either prior to and including the date and time indicated by the <code>date-time</code> argument (option <code>-e</code>); or later than and including the date and time indicated (option <code>-l</code>). <code>date-time</code> takes the form:</p> <pre>yy[mm[dd[hh[mm[ss] ] ] ] ]</pre> <p>Units omitted from the indicated date and time default to their maximum possible values; that is <code>-c7502</code> is equivalent to <code>-c750228235959</code>. Any number of non-numeric characters may separate the various 2 digit components. If white-space characters occur, the <code>date-time</code> specification must be quoted. Values of <code>yy</code> in the range 69–99 refer to the twentieth century. Values in the range of 00–68 refer to the twenty-first century.</p> <p><code>-ddataspec</code> Produce a report according to the indicated data specification. <code>dataspec</code> consists of a (quoted) text string that includes embedded data keywords of the form: <code>' :key: '</code> (see <code>Data Keywords</code>, below). <code>prs</code> expands these keywords in the output it produces. To specify a TAB character in the output, use <code>\t</code>; to specify a NEWLINE in the output, use <code>\n</code>.</p> <p><code>-rsid</code> Specifies the SCCS delta ID (SID) of the delta for which information is desired. If no SID is specified, the most recently created delta is used.</p> |

sccs-prs(1)

**USAGE** Usage of `prs` is described below.

**Data Keywords** Data keywords specify which parts of an SCCS file are to be retrieved. All parts of an SCCS file (see `sccsfile(4)`) have an associated data keyword. A data keyword may appear any number of times in a data specification argument to `-d`. These data keywords are listed in the table below:

| <i>Keyword</i> | <i>Data Item</i>                              | <i>File Section*</i> | <i>Value</i>                      | <i>Format**</i> |
|----------------|-----------------------------------------------|----------------------|-----------------------------------|-----------------|
| :A:            | a format for the what string:                 | N/A                  | :Z::Y: :M: :I::Z:                 | S               |
| :B:            | branch number                                 | D                    | <i>nnnn</i>                       | S               |
| :BD:           | body                                          | B                    | <i>text</i>                       | M               |
| :BF:           | branch flag                                   | F                    | yes or no                         | S               |
| :CB:           | ceiling boundary                              | F                    | :R:                               | S               |
| :C:            | comments for delta                            | D                    | <i>text</i>                       | M               |

\*B = body, D = delta table, F = flags, U = user names

## sccs-prs(1)

\*\*S = simple format, M = multi-line format

### EXAMPLES

**EXAMPLE 1** Displaying delta entries

The following command:

```
example% /usr/ccs/bin/prs -e -d":I:\t:P:" program.c
```

produces:

```
1.6  username
1.5  username...
```

### ENVIRONMENT VARIABLES

See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `prs`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

### FILES

`/tmp/pr?????` temporary file

### ATTRIBUTES

See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWspot        |
| Interface Stability | Standard        |

| <b>DESCRIPTION</b> | <p>prt prints selected portions of an SCCS file. By default, it prints the delta table (version log).</p> <p>If a directory name is used in place of the <i>s.filename</i> argument, the prt command applies to all <i>s</i>.files in that directory. Unreadable <i>s</i>.files produce an error; processing continues with the next file (if any). The use of '-' as the <i>s.filename</i> argument indicates that the names of files are to be read from the standard input, one <i>s</i>.file per line.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>OPTIONS</b>     | <p>If any option other than -y, -c, or -r is supplied, the name of each file being processed (preceded by one NEWLINE and followed by two NEWLINE characters) appears above its contents.</p> <p>If none of the -u, -f, -t, or -b options are used, -d is assumed. -s, -i are mutually exclusive, as are -c and -r.</p> <ul style="list-style-type: none"> <li>-a                    Display log entries for all deltas, including those marked as removed.</li> <li>-b                    Print the body of the <i>s</i>.file.</li> <li>-d                    Print delta table entries. This is the default.</li> <li>-e                    Everything. This option implies -d, -i, -u, -f, and -t.</li> <li>-f                    Print the flags of each named <i>s</i>.file.</li> <li>-i                    Print the serial numbers of included, excluded, and ignored deltas.</li> <li>-s                    Print only the first line of the delta table entries; that is, only up to the statistics.</li> <li>-t                    Print the descriptive text contained in the <i>s</i>.file.</li> <li>-u                    Print the user-names and/or numerical group IDs of users allowed to make deltas.</li> <li>-cdate-time        Exclude delta table entries that are specified cutoff date and time. Each entry is printed as a single line, preceded by the name of the SCCS file. This format (also produced by -r, and -y) makes it easy to sort multiple delta tables in chronological order. When both -y and -c, or -y and -r are supplied, prt stops printing when the first of the two conditions is met.</li> <li>-rdate-time        Exclude delta table entries that are newer than the specified cutoff date and time.</li> <li>-ysid                Exclude delta table entries made prior to the SID specified. If no delta in the table has the specified SID, the entire table is printed. If no SID is specified, the most recent delta is printed.</li> </ul> |

## USAGE

### Output Format

The following format is used to print those portions of the `s` file that are specified by the various options.

- NEWLINE
- Type of delta (D or R)
- SPACE
- SCCS delta ID (SID)
- TAB
- Date and time of creation in the form: *yy/mm/dd hh/mm/ss*
- SPACE
- Username the delta's creator
- TAB
- Serial number of the delta
- SPACE
- Predecessor delta's serial number
- TAB
- Line-by-line change statistics in the form: *inserted/deleted/unchanged*
- NEWLINE
- List of included deltas, followed by a NEWLINE (only if there were any such deltas and the `-i` options was used)
- List of excluded deltas, followed by a NEWLINE (only if there were any such deltas and the `-i` options was used)
- List of ignored deltas, followed by a NEWLINE (only if there were any such deltas and the `-i` options was used)
- List of modification requests (MRs), followed by a NEWLINE (only if any MR numbers were supplied).
- Lines of the delta commentary (if any), followed by a NEWLINE.

### EXAMPLES

**EXAMPLE 1** Examples of `prt`.

The following command:

```
example% /usr/ccs/bin/prt -y program.c
```

produces a one-line display of the delta table entry for the most recent version:

```
s.program.c: D 1.6 88/07/06 21:39:39 username 5 4  
00159/00080/00636...
```

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWspot        |

**SEE ALSO** `scs(1)`, `scs-cdc(1)`, `scs-delta(1)`, `scs-get(1)`, `scs-help(1)`, `scs-prs(1)`, `scs-sact(1)`, `scs-scsdiff(1)`, `what(1)`, `scsfile(4)`, `attributes(5)`

**DIAGNOSTICS** Use the `SCCS help` command for explanations (see `scs-help(1)`).

sccs-rmdel(1)

**NAME** sccs-rmdel, rmdel – remove a delta from an SCCS file

**SYNOPSIS** `/usr/ccs/bin/rmdel -rsid s.filename...`

**DESCRIPTION** The rmdel utility removes the delta specified by the SCCS delta ID (SID) supplied with -r. The delta to be removed must be the most recent (leaf) delta in its branch. In addition, the SID must *not* be that of a version checked out for editing: it must not appear in any entry of the version lock file (p . file).

If you created the delta, or, if you own the file and directory and have write permission, you can remove it with rmdel.

If a directory name is used in place of the *s.filename* argument, the rmdel command applies to all *s . files* in that directory. Unreadable *s . files* produce an error; processing continues with the next file (if any). The use of '-' as the *s.filename* argument indicates that the names of files are to be read from the standard input, one *s . file* per line.

**OPTIONS** The following option is supported:

`-rsid` Remove the version corresponding to the indicated SID (delta).

**ENVIRONMENT VARIABLES** See environ(5) for descriptions of the following environment variables that affect the execution of rmdel: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**FILES**

|          |                                |
|----------|--------------------------------|
| p . file | permissions file               |
| s . file | history file                   |
| z . file | temporary copy of the s . file |

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWspot        |
| Interface Stability | Standard        |

scs-scsdiff(1)

**NAME** | scs-scsdiff, scsdiff – compare two versions of an SCCS file

**SYNOPSIS** | `/usr/ccs/bin/scsdiff [-p] -rsid -rsid [diff-options] s.filename`

**DESCRIPTION** | `scsdiff` compares two versions of an SCCS file and displays the differences between the two versions. Any number of SCCS files may be specified. The options specified apply to all named `s` files.

**OPTIONS** | The following options are supported:

- `-p` | Pipe output for each file through `pr(1)`.
- `-rsid` | Specify a version corresponding to the indicated SCCS delta ID (SID) for comparison. Versions are passed to `diff(1)` in the order given.
- `diff-options` | Pass options to `diff(1)`, including: `-b`, `-c`, `-e`, `-f`, `-h`, `-u`, `-C number`, `-U number`, and `-D string`.

**FILES** | `/tmp/get?????` temporary files

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWsprot       |

**SEE ALSO** | `diff(1)`, `scs(1)`, `scs-delta(1)`, `scs-get(1)`, `scs-help(1)`, `scs-prs(1)`, `scs-prt(1)`, `what(1)`, `scsfile(4)`, `attributes(5)`

**DIAGNOSTICS** | `filename: No differences` | If the two versions are the same.

Use the SCCS `help` command for explanations of other messages. See `scs-help(1)`.

| <b>NAME</b>                  | sccs-unget, unget – undo a previous get of an SCCS file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |              |          |                     |          |

| <b>SYNOPSIS</b>              | <code>/usr/ccs/bin/unget [-ns] [-rsid] s.filename...</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |              |          |                     |          |
| <b>DESCRIPTION</b>           | <p>The unget utility undoes the effect of a <code>get -e</code> command executed before the creation of the pending delta.</p> <p>If a directory name is used in place of the <i>s.filename</i> argument, the unget command applies to all <i>s.</i> files in that directory. Unreadable <i>s.</i> files produce an error; processing continues with the next file (if any). The use of <code>'-'</code> as the <i>s.filename</i> argument indicates that the names of files are to be read from the standard input, one <i>s.</i> file per line.</p> |                |                 |              |          |                     |          |
| <b>OPTIONS</b>               | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-n</code> Retains the retrieved version, which is otherwise removed.</li> <li><code>-s</code> Suppress display of the SCCS delta ID (SID).</li> <li><code>-rsid</code> When multiple versions are checked out, this option specifies which pending delta to abort. A diagnostic results if the specified SID is ambiguous, or if it is necessary but omitted from the command line.</li> </ul>                                                               |                |                 |              |          |                     |          |
| <b>ENVIRONMENT VARIABLES</b> | See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of unget: LANG, LC_ALL, LC_COLLATE, LC_CTYPE, LC_MESSAGES, and NLSPATH.                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |          |                     |          |
| <b>ATTRIBUTES</b>            | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |          |                     |          |

| <b>NAME</b>                  | scs-val, val – validate an SCCS file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>              | <pre>/usr/ccs/bin/val -<br/>/usr/ccs/bin/val [-s] [-m name] [-rsid] [-y type] s.filename...</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b>           | <p>The val utility determines if the specified s . files meet the characteristics specified by the indicated arguments. val can process up to 50 files on a single command line.</p> <p>val has a special argument, '-', which reads the standard input until the end-of-file condition is detected. Each line read is independently processed as if it were a command line argument list.</p> <p>val generates diagnostic messages on the standard output for each command line and file processed and also returns a single 8-bit code upon exit as described below.</p> <p>The 8-bit code returned by val is a disjunction of the possible errors, that is, it can be interpreted as a bit string where (moving from left to right) the bits set are interpreted as follows:</p> <pre>bit 0 = missing file argument<br/>bit 1 = unknown or duplicate option<br/>bit 2 = corrupted s.file<br/>bit 3 = can not open file or file not in s.file format<br/>bit 4 = the SCCS delta ID (SID) is invalid or ambiguous<br/>bit 5 = the SID does not exist<br/>bit 6 = mismatch between %Y% and -y argument<br/>bit 7 = mismatch between %M% and -m argument</pre> <p>val can process two or more files on a given command line, and in turn can process multiple command lines (when reading the standard input). In these cases, an aggregate code is returned which is the logical OR of the codes generated for each command line and file processed.</p> |
| <b>OPTIONS</b>               | <p>The following options are supported:</p> <pre>-s          Silent. Suppresses the normal error or warning messages.<br/>-m name    Compares name with the %M% ID keyword in the s . file.<br/>-rsid      Checks to see if the indicated SID is ambiguous, invalid, or absent from the<br/>           s . file.<br/>-y type    Compares type with the %Y% ID keyword.</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>ENVIRONMENT VARIABLES</b> | See environ(5) for descriptions of the following environment variables that affect the execution of val: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>ATTRIBUTES</b>            | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>DESCRIPTION</b> | <p>The <code>scp</code> utility copies files between hosts on a network. It uses <code>ssh(1)</code> for data transfer, and uses the same authentication and provides the same security as <code>ssh(1)</code>. Unlike <code>rcp(1)</code>, <code>scp</code> will ask for passwords or passphrases if they are needed for authentication.</p> <p>Any file name may contain a host and user specification to indicate that the file is to be copied to/from that host. Copies between two remote hosts are permitted.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-4 Forces <code>scp</code> to use IPv4 addresses only.</li><li>-6 Forces <code>scp</code> to use IPv6 addresses only.</li><li>-B Selects batch mode. (Prevents asking for passwords or passphrases.)</li><li>-c <i>cipher</i> Selects the cipher to use for encrypting the data transfer. This option is directly passed to <code>ssh(1)</code>.</li><li>-C Compression enable. Passes the -C flag to <code>ssh(1)</code> to enable compression.</li><li>-F <i>ssh_config</i> Specifies an alternative per-user configuration file for <code>ssh(1)</code>.</li><li>-i <i>identity_file</i> Selects the file from which the identity (private key) for RSA authentication is read. This option is directly passed to <code>ssh(1)</code>.</li><li>-o <i>ssh_option</i> The given option is directly passed to <code>ssh(1)</code>.</li><li>-p Preserves modification times, access times, and modes from the original file.</li><li>-P <i>port</i> Specifies the port to connect to on the remote host. Notice that this option is written with a capital 'P', because -p is already reserved for preserving the times and modes of the file in <code>rcp(1)</code>.</li><li>-q Disables the progress meter.</li><li>-r Recursively copies entire directories.</li><li>-S <i>program</i> Specifies the name of the program to use for the encrypted connection. The program must understand <code>ssh(1)</code> options.</li></ul> |

`-v` Verbose mode. Causes `scp` and `ssh(1)` to print debugging messages about their progress. This is helpful in debugging connection, authentication, and configuration problems.

**OPERANDS** The following operands are supported:

*host1, host2,...* The name(s) of the host from or to which the file is to be copied.

*file1, file2,...* The file(s) to be copied.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

1 An error occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWsshu        |
| Interface Stability | Evolving        |

**SEE ALSO** `rcp(1)`, `ssh(1)`, `ssh-add(1)`, `ssh-agent(1)`, `ssh-keygen(1)`, `sshd(1M)`, `attributes(5)`

To view license terms, attribution, and copyright for OpenSSH, the default path is `/var/sadm/pkg/SUNWsshdr/install/copyright`. If the Solaris operating environment has been installed anywhere other than the default, modify the given path to access the file at the installed location.

**AUTHORS** `scp` is based on the `rcp(1)` program in the BSD source code from the Regents of the University of California. The authors are Timo Rinne and Tatu Ylonen.

## script(1)

| <b>NAME</b>        | script – make record of a terminal session                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |              |         |     |         |

| <b>SYNOPSIS</b>    | <b>script</b> [-a] [ <i>filename</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |         |     |         |
| <b>DESCRIPTION</b> | <p>The <code>script</code> utility makes a record of everything printed on your screen. The record is written to <i>filename</i>. If no file name is given, the record is saved in the file <code>typescript</code>. See WARNINGS.</p> <p>The <code>script</code> command forks and creates a sub-shell, according to the value of <code>\$SHELL</code>, and records the text from this session. The script ends when the forked shell exits or when Control-d is typed.</p> |                |                 |              |         |     |         |
| <b>OPTIONS</b>     | <p>The following option is supported:</p> <p>-a           Appends the session record to <i>filename</i>, rather than overwriting it.</p>                                                                                                                                                                                                                                                                                                                                     |                |                 |              |         |     |         |
| <b>NOTES</b>       | <code>script</code> places everything that appears on the screen in <i>filename</i> , including prompts.                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |         |     |         |

| <b>NAME</b>        | sdiff – print differences between two files side-by-side                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <b>sdiff</b> [-l] [-s] [-o <i>output</i> ] [-w <i>n</i> ] <i>filename1 filename2</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | sdiff uses the output of the diff command to produce a side-by-side listing of two files indicating lines that are different. Lines of the two files are printed with a blank gutter between them if the lines are identical, a < in the gutter if the line appears only in <i>filename1</i> , a > in the gutter if the line appears only in <i>filename2</i> , and a   for lines that are different. (See the EXAMPLES section below.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OPTIONS</b>     | <p>-l                    Print only the left side of any lines that are identical.to</p> <p>-s                    Do not print identical lines.</p> <p>-o <i>output</i>            Use the argument <i>output</i> as the name of a third file that is created as a user-controlled merge of <i>filename1</i> and <i>filename2</i>. Identical lines of <i>filename1</i> and <i>filename2</i> are copied to <i>output</i>. Sets of differences, as produced by diff, are printed; where a set of differences share a common gutter character. After printing each set of differences, sdiff prompts the user with a % and waits for one of the following user-typed commands:</p> <p>l                    Append the left column to the output file.</p> <p>r                    Append the right column to the output file.</p> <p>s                    Turn on silent mode; do not print identical lines.</p> <p>v                    Turn off silent mode.</p> <p>e l                  Call the editor with the left column.</p> <p>e r                  Call the editor with the right column.</p> <p>e b                  Call the editor with the concatenation of left and right.</p> <p>e                    Call the editor with a zero length file.</p> <p>q                    Exit from the program.</p> <p>On exit from the editor, the resulting file is concatenated to the end of the <i>output</i> file.</p> <p>-w <i>n</i>                Use the argument <i>n</i> as the width of the output line. The default line length is 130 characters.</p> |
| <b>USAGE</b>       | See largefile(5) for the description of the behavior of sdiff when encountering files greater than or equal to 2 Gbyte ( 2 <sup>31</sup> bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

sdiff(1)

**EXAMPLE 1** An example of the `sdiff` command. (Continued)

```
c <
d      d
      > c
```

**ENVIRONMENT VARIABLES**

If any of the `LC_*` variables ( `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY` ) (see `environ(5)`) are not set in the environment, the operational behavior of `sdiff` for each corresponding locale category is determined by the value of the `LANG` environment variable. If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables is set in the environment, the "C" locale determines how `sdiff` behaves.

`LC_CTYPE` Determines how `sdiff` handles characters. When `LC_CTYPE` is set to a valid value, `sdiff` can display and handle text and filenames containing valid characters for that locale.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWesu         |
| CSI            | Enabled         |

[file...] </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>The sed utility is a stream editor that reads one or more text files, makes editing changes according to a script of editing commands, and writes the results to standard output. The script is obtained from either the <i>script</i> operand string, or a combination of the option-arguments from the <i>-e script</i> and <i>-f script_file</i> options.</p> <p>The sed utility is a text editor. It cannot edit binary files or files containing ASCII NUL (\0) characters or very long lines.</p>                                                                                                                                                                                                                |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li><i>-e script</i>            <i>script</i> is an edit command for sed. See USAGE below for more information on the format of <i>script</i>. If there is just one <i>-e</i> option and no <i>-f</i> options, the flag <i>-e</i> may be omitted.</li> <li><i>-f script_file</i>       Takes the script from <i>script_file</i>. <i>script_file</i> consists of editing commands, one per line.</li> <li><i>-n</i>                    Suppresses the default output.</li> </ul> <p>Multiple <i>-e</i> and <i>-f</i> options may be specified. All commands are added to the script in the order specified, regardless of their origin.</p> |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <ul style="list-style-type: none"> <li><i>file</i>                 A path name of a file whose contents will be read and edited. If multiple <i>file</i> operands are specified, the named files will be read in the order specified and the concatenation will be edited. If no <i>file</i> operands are specified, the standard input will be used.</li> <li><i>script</i>               A string to be used as the script of editing commands. The application must not present a <i>script</i> that violates the restrictions of a text file except that the final character need not be a NEWLINE character.</li> </ul>                                                 |
| <b>USAGE</b>       | <p>A script consists of editing commands, one per line, of the following form:</p> <pre>[ address [ , address ] ] command [ arguments ]</pre> <p>Zero or more blank characters are accepted before the first address and before <i>command</i>. Any number of semicolons are accepted before the first address.</p>                                                                                                                                                                                                                                                                                                                                                                                                       |

sed(1)

In normal operation, *sed* cyclically copies a line of input (less its terminating NEWLINE character) into a *pattern space* (unless there is something left after a D command), applies in sequence all commands whose *addresses* select that pattern space, and copies the resulting pattern space to the standard output (except under -n) and deletes the pattern space. Whenever the pattern space is written to standard output or a named file, *sed* will immediately follow it with a NEWLINE character.

Some of the commands use a *hold space* to save all or part of the *pattern space* for subsequent retrieval. The *pattern* and *hold spaces* will each be able to hold at least 8192 bytes.

**sed Addresses**

An *address* is either empty, a decimal number that counts input lines cumulatively across files, a \$ that addresses the last line of input, or a context address, which consists of a */regular expression/* as described on the `regexp(5)` manual page.

A command line with no addresses selects every pattern space.

A command line with one address selects each pattern space that matches the address.

A command line with two addresses selects the inclusive range from the first pattern space that matches the first address through the next pattern space that matches the second address. Thereafter the process is repeated, looking again for the first address. (If the second address is a number less than or equal to the line number selected by the first address, only the line corresponding to the first address is selected.)

Typically, address are separated from each other by a comma (,). They may also be separated by a semicolon (;).

**sed Regular Expressions**

*sed* supports the basic regular expressions described on the `regexp(5)` manual page, with the following additions:

`\cREc` In a context address, the construction `\cREc`, where *c* is any character other than a backslash or NEWLINE character, is identical to `/RE/`. If the character designated by *c* appears following a backslash, then it is considered to be that literal character, which does not terminate the RE. For example, in the context address `\xabc\xdefx`, the second `x` stands for itself, so that the regular expression is `abcxdef`.

`\n` The escape sequence `\n` matches a NEWLINE character embedded in the pattern space. A literal NEWLINE character must not be used in the regular expression of a context address or in the substitute command.

Editing commands can be applied only to non-selected pattern spaces by use of the negation command `!` (described below).

**sed Editing Commands**

In the following list of functions the maximum number of permissible addresses for each function is indicated.

The `r` and `w` commands take an optional *rfile* (or *wfile*) parameter, separated from the command letter by one or more blank characters.

Multiple commands can be specified by separating them with a semicolon (;) on the same command line.

The *text* argument consists of one or more lines, all but the last of which end with \ to hide the NEWLINE. Each embedded NEWLINE character in the text must be preceded by a backslash. Other backslashes in text are removed and the following character is treated literally. Backslashes in text are treated like backslashes in the replacement string of an s command, and may be used to protect initial blanks and tabs against the stripping that is done on every script line. The *rfile* or *wfile* argument must terminate the command line and must be preceded by exactly one blank. The use of the *wfile* parameter causes that file to be initially created, if it does not exist, or will replace the contents of an existing file. There can be at most 10 distinct *wfile* arguments.

Regular expressions match entire strings, not just individual lines, but a NEWLINE character is matched by \n in a sed RE. A NEWLINE character is not allowed in an RE. Also notice that \n cannot be used to match a NEWLINE character at the end of an input line; NEWLINE characters appear in the pattern space as a result of the N editing command.

Two of the commands take a *command-list*, which is a list of sed commands separated by NEWLINE characters, as follows:

```
{ command
  command
}
```

The { can be preceded with blank characters and can be followed with white space. The *commands* can be preceded by white space. The terminating } must be preceded by a NEWLINE character and can be preceded or followed by <blank>s. The braces may be preceded or followed by <blank>s. The command may be preceded by <blank>s, but may not be followed by <blank>s.

The following table lists the functions, with the maximum number of permissible addresses.

| Max Address | Command         | Description                                                                                                                                                        |
|-------------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1           | a \ <i>text</i> | Append by executing N command or beginning a new cycle. Place <i>text</i> on the output before reading the next input line.                                        |
| 2           | b <i>label</i>  | Branch to the : command bearing the <i>label</i> . If <i>label</i> is empty, branch to the end of the script. Labels are recognized unique up to eight characters. |
| 2           | c \ <i>text</i> | Change. Delete the pattern space. Place <i>text</i> on the output. Start the next cycle.                                                                           |
| 2           | d               | Delete the pattern space. Start the next cycle.                                                                                                                    |

sed(1)

| Max Address | Command         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2           | D               | Delete the initial segment of the pattern space through the first new-line. Start the next cycle. (See the N command below.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 2           | g               | Replace the contents of the pattern space by the contents of the hold space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|             |                 | <code>/usr/xpg4/bin/sed</code> : List the pattern space on the standard output in an unambiguous form. Non-printable characters are displayed in octal notation and long lines are folded. The characters ( <code>\\</code> , <code>\a</code> , <code>\b</code> , <code>\f</code> , <code>\r</code> , <code>\t</code> , and <code>\v</code> ) are written as the corresponding escape sequences. Non-printable characters not in that table will be written as one three-digit octal number (with a preceding backslash character) for each byte in the character (most significant byte first). If the size of a byte on the system is greater than nine bits, the format used for non-printable characters is implementation dependent.<br><br>Long lines are folded, with the point of folding indicated by writing a backslash followed by a <code>NEWLINE</code> ; the length at which folding occurs is unspecified, but should be appropriate for the output device. The end of each line is marked with a <code>§</code> . |
| 2           | n               | Copy the pattern space to the standard output if default output is not suppressed. Replace the pattern space with the next line of input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Max Address | Command                 | Description                                                                                                                                                                                                                                                                                                                                                       |
|-------------|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2           | N                       | Append the next line of input to the pattern space with an embedded new-line. (The current line number changes.) If no next line of input is available, the N command verb shall branch to the end of the script and quit without starting a new cycle and without writing the pattern space.                                                                     |
| 2           | p                       | Print. Copy the pattern space to the standard output.                                                                                                                                                                                                                                                                                                             |
| 2           | P                       | Copy the initial segment of the pattern space through the first new-line to the standard output.                                                                                                                                                                                                                                                                  |
| 1           | q                       | Quit. Branch to the end of the script. Do not start a new cycle.                                                                                                                                                                                                                                                                                                  |
| 2           | r <i>rfile</i>          | Read the contents of <i>rfile</i> . Place them on the output before reading the next input line. If <i>rfile</i> does not exist or cannot be read, it is treated as if it were an empty file, causing no error condition.                                                                                                                                         |
| 2           | t <i>label</i>          | Test. Branch to the : command bearing the <i>label</i> if any substitutions have been made since the most recent reading of an input line or execution of a t. If <i>label</i> is empty, branch to the end of the script.                                                                                                                                         |
| 2           | w <i>wfile</i>          | Write. Append the pattern space to <i>wfile</i> . The first occurrence of w will cause <i>wfile</i> to be cleared. Subsequent invocations of w will append. Each time the sed command is used, <i>wfile</i> is overwritten.                                                                                                                                       |
| 2           | x                       | Exchange the contents of the pattern and hold spaces.                                                                                                                                                                                                                                                                                                             |
| 2           | ! <i>command</i>        | Don't. Apply the <i>command</i> (or group, if <i>command</i> is { }) only to lines <i>not</i> selected by the address(es).                                                                                                                                                                                                                                        |
| 0           | : <i>label</i>          | This command does nothing; it bears a <i>label</i> for b and t commands to branch to.                                                                                                                                                                                                                                                                             |
| 1           | =                       | Place the current line number on the standard output as a line.                                                                                                                                                                                                                                                                                                   |
| 2           | { <i>command-list</i> } | Execute <i>command-list</i> only when the pattern space is selected.                                                                                                                                                                                                                                                                                              |
| 0           |                         | An empty command is ignored.                                                                                                                                                                                                                                                                                                                                      |
| 0           | #                       | If a # appears as the first character on a line of a script file, then that entire line is treated as a comment, with one exception: if a # appears on the first line and the character after the # is an n, then the default output will be suppressed. The rest of the line after #n is also ignored. A script file must contain at least one non-comment line. |

sed(1)

| Max Addr | Command (Using <i>strings</i> ) and Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2        | <p><i>s/regular expression/replacement/flags</i></p> <p>Substitute the <i>replacement</i> string for instances of the <i>regular expression</i> in the pattern space. Any character other than backslash or newline can be used instead of a slash to delimit the RE and the replacement. Within the RE and the replacement, the RE delimiter itself can be used as a literal character if it is preceded by a backslash.</p> <p>An ampersand (&amp;) appearing in the <i>replacement</i> will be replaced by the string matching the RE. The special meaning of &amp; in this context can be suppressed by preceding it by backslash. The characters <i>\n</i>, where <i>n</i> is a digit, will be replaced by the text matched by the corresponding backreference expression. For each backslash (\) encountered in scanning <i>replacement</i> from beginning to end, the following character loses its special meaning (if any). It is unspecified what special meaning is given to any character other than &amp;, \ or digits.</p> <p>A line can be split by substituting a NEWLINE character into it. The application must escape the NEWLINE character in the <i>replacement</i> by preceding it with backslash. A substitution is considered to have been performed even if the replacement string is identical to the string that it replaces.</p> <p><i>flags</i> is zero or more of:</p> <p><i>n n= 1 - 512</i>. Substitute for just the <i>n</i>th occurrence of the <i>regular expression</i>.</p> <p><i>g</i> Global. Substitute for all nonoverlapping instances of the <i>regular expression</i> rather than just the first one. If both <i>g</i> and <i>n</i> are specified, the results are unspecified.</p> |
|          | <p><i>p</i> Print the pattern space if a replacement was made.</p> <p><i>P</i> Copy the initial segment of the pattern space through the first new-line to the standard output.</p> <p><i>w wfile</i> Write. Append the pattern space to <i>wfile</i> if a replacement was made. The first occurrence of <i>w</i> will cause <i>wfile</i> to be cleared. Subsequent invocations of <i>w</i> will append. Each time the <i>sed</i> command is used, <i>wfile</i> is overwritten.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 2        | <p><i>y/ string1 / string2 /</i></p> <p>Transform. Replace all occurrences of characters in <i>string1</i> with the corresponding characters in <i>string2</i>. <i>string1</i> and <i>string2</i> must have the same number of characters, or if any of the characters in <i>string1</i> appear more than once, the results are undefined. Any character other than backslash or NEWLINE can be used instead of slash to delimit the strings. Within <i>string1</i> and <i>string2</i>, the delimiter itself can be used as a literal character if it is preceded by a backslash. For example, <i>y/abc/ABC/</i> replaces a with A, b with B, and c with C.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

See `largefile(5)` for the description of the behavior of `sed` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**EXAMPLES** **EXAMPLE 1** An example sed script

This sed script simulates the BSD `cat -s` command, squeezing excess blank lines from standard input.

```
sed -n '
# Write non-empty lines.
./ {
    p
    d
}
# Write a single empty line, then look for more empty lines.
/^$/ p
# Get next line, discard the held <newline> (empty line),
# and look for more empty lines.
:Empty
/^$/ {
    N
    s/./ /
    b Empty
}
# Write the non-empty line before going back to search
# for the first in a set of empty lines.
p
'
```

**ENVIRONMENT VARIABLES** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of sed: LANG, LC\_ALL, LC\_COLLATE, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**EXIT STATUS** The following exit values are returned:

```
0          Successful completion.
>0        An error occurred.
```

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

**/usr/bin/sed**

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | Not enabled     |

**/usr/xpg4/bin/sed**

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWxcu4        |
| CSI                 | Enabled         |
| Interface Stability | Standard        |

| <b>DESCRIPTION</b> | The <i>sed</i> utility copies the <i>filenames</i> (standard input default) to the standard output, edited according to a script of commands.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                    |                                                                                                                                                                                                                                                                                                                                             |                 |                                                  |                |                                                                    |             |                                                             |
| <b>OPTIONS</b>     | The following options are supported:<br><br>-n                   Suppresses the default output.<br><br>-e <i>script</i> <i>script</i> is an edit command for <i>sed</i> . If there is just one -e option and no -f options, the -e flag may be omitted.<br><br>-f <i>sfilename</i> Takes the script from <i>sfilename</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                    |                                                                                                                                                                                                                                                                                                                                             |                 |                                                  |                |                                                                    |             |                                                             |
| <b>USAGE</b>       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                    |                                                                                                                                                                                                                                                                                                                                             |                 |                                                  |                |                                                                    |             |                                                             |
| <b>sed Scripts</b> | <i>sed</i> scripts consist of editing commands, one per line, of the following form:<br><br>[ <i>address</i> [, <i>address</i> ] ] <i>function</i> [ <i>arguments</i> ]<br><br>In normal operation, <i>sed</i> cyclically copies a line of input into a <i>pattern space</i> (unless there is something left after a D command), sequentially applies all commands with <i>addresses</i> matching that pattern space until reaching the end of the script, copies the pattern space to the standard output (except under -n), and finally, deletes the pattern space.<br><br>Some commands use a <i>hold space</i> to save all or part of the pattern space for subsequent retrieval.<br><br>An <i>address</i> is either: <ul style="list-style-type: none"><li>■ a decimal number linecount, which is cumulative across input files;</li><li>■ a \$, which addresses the last input line;</li><li>■ or a context address, which is a <i>/regular expression/</i> as described on the <code>regex(5)</code> manual page, with the following exceptions:<table><tr><td><code>\?RE?</code></td><td>In a context address, the construction <code>\?regular expression?</code>, where <code>?</code> is any character, is identical to <code>/regular expression/</code>. <i>Note:</i> in the context address <code>\xabc\xdefx</code>, the second <code>x</code> stands for itself, so that the regular expression is <code>abcxdef</code>.</td></tr><tr><td><code>\n</code></td><td>Matches a NEWLINE embedded in the pattern space.</td></tr><tr><td><code>.</code></td><td>Matches any character except the NEWLINE ending the pattern space.</td></tr><tr><td><i>null</i></td><td>A command line with no address selects every pattern space.</td></tr></table></li></ul> | <code>\?RE?</code> | In a context address, the construction <code>\?regular expression?</code> , where <code>?</code> is any character, is identical to <code>/regular expression/</code> . <i>Note:</i> in the context address <code>\xabc\xdefx</code> , the second <code>x</code> stands for itself, so that the regular expression is <code>abcxdef</code> . | <code>\n</code> | Matches a NEWLINE embedded in the pattern space. | <code>.</code> | Matches any character except the NEWLINE ending the pattern space. | <i>null</i> | A command line with no address selects every pattern space. |
| <code>\?RE?</code> | In a context address, the construction <code>\?regular expression?</code> , where <code>?</code> is any character, is identical to <code>/regular expression/</code> . <i>Note:</i> in the context address <code>\xabc\xdefx</code> , the second <code>x</code> stands for itself, so that the regular expression is <code>abcxdef</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                    |                                                                                                                                                                                                                                                                                                                                             |                 |                                                  |                |                                                                    |             |                                                             |
| <code>\n</code>    | Matches a NEWLINE embedded in the pattern space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                    |                                                                                                                                                                                                                                                                                                                                             |                 |                                                  |                |                                                                    |             |                                                             |

Selects only one line if <i>address1</i> is greater than or equal to <i>address2</i> . |
| <b>Comments</b>  | <p>If the first nonwhite character in a line is a '#' (pound sign), <i>sed</i> treats that line as a comment, and ignores it. If, however, the first such line is of the form:</p> <pre>#n</pre> <p><i>sed</i> runs as if the <code>-n</code> flag were specified.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                                                                                                                                                                                                                |
| <b>Functions</b> | <p>The maximum number of permissible addresses for each function is indicated in parentheses in the list below.</p> <p>An argument denoted <i>text</i> consists of one or more lines, all but the last of which end with \ to hide the NEWLINE. Backslashes in <i>text</i> are treated like backslashes in the replacement string of an <code>s</code> command, and may be used to protect initial SPACE and TAB characters against the stripping that is done on every script line.</p> <p>An argument denoted <i>rfilename</i> or <i>wfilename</i> must terminate the command line and must be preceded by exactly one SPACE. Each <i>wfilename</i> is created before processing begins. There can be at most 10 distinct <i>wfilename</i> arguments.</p> <p>(1)a \ <i>text</i>            Append: place <i>text</i> on the output before reading the next input line.</p> <p>(2)b <i>label</i>            Branch to the ':' command bearing the <i>label</i>. Branch to the end of the script if <i>label</i> is empty.</p> <p>(2)c \ <i>text</i>            Change: delete the pattern space. With 0 or 1 address or at the end of a 2 address range, place <i>text</i> on the output. Start the next cycle.</p> <p>(2)d                    Delete the pattern space. Start the next cycle.</p> <p>(2)D                    Delete the initial segment of the pattern space through the first NEWLINE. Start the next cycle.</p> <p>(2)g                    Replace the contents of the pattern space by the contents of the hold space.</p> <p>(2)G                    Append the contents of the hold space to the pattern space.</p> <p>(2)h                    Replace the contents of the hold space by the contents of the pattern space.</p> <p>(2)H                    Append the contents of the pattern space to the hold space.</p> <p>(1)i \ <i>text</i>            Insert: place <i>text</i> on the standard output.</p> |                                                                                                                                                                                                                                |

| (0): <i>label</i>                                                   | This command does nothing. It bears a <i>label</i> for b and t commands to branch to. <i>Note</i> : The maximum length of <i>label</i> is seven characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |          |                                                                                                       |          |                                                                                                                      |          |                                                    |                    |                                                                                |

- (1)= Place the current line number on the standard output as a line.
- (2){ Execute the following commands through a matching '}' only when the pattern space is selected. Commands are separated by ';'.
- (0) An empty command is ignored.

**Large Files**

See `largefile(5)` for the description of the behavior of `sed` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**DIAGNOSTICS**

Too many commands

The command list contained more than 200 commands.

Too much command text

The command list was too big for `sed` to handle. Text in the `a`, `c`, and `i` commands, text read in by `r` commands, addresses, regular expressions and replacement strings in `s` commands, and translation tables in `y` commands all require `sed` to store data internally.

Command line too long

A command line was longer than 4000 characters.

Too many line numbers

More than 256 decimal number linecounts were specified as addresses in the command list.

Too many files in `w` commands

More than 10 different files were specified in `w` commands or `w` options for `s` commands in the command list.

Too many labels

More than 50 labels were specified in the command list.

Unrecognized command

A command was not one of the ones recognized by `sed`.

Extra text at end of command

A command had extra text after the end.

Illegal line number

An address was neither a decimal number linecount, a `$`, nor a context address.

Space missing before filename

There was no space between an `r` or `w` command, or the `w` option for a `s` command, and the filename specified for that command.

Too many { 's

There were more { than } in the list of commands to be executed.

Too many } 's

There were more } than { in the list of commands to be executed.

No addresses allowed

A command that takes no addresses had an address specified.

sed(1B)

Only one address allowed  
A command that takes one address had two addresses specified.

"\digit" out of range  
The number in a \n item in a regular expression or a replacement string in an s command was greater than 9.

Bad number  
One of the endpoints in a range item in a regular expression (that is, an item of the form {n} or {n,m}) was not a number.

Range endpoint too large  
One of the endpoints in a range item in a regular expression was greater than 255.

More than 2 numbers given in \{ \}  
More than two endpoints were given in a range expression.

} expected after \  
A \ appeared in a range expression and was not followed by a }.

First number exceeds second in \{ \}  
The first endpoint in a range expression was greater than the second.

Illegal or missing delimiter  
The delimiter at the end of a regular expression was absent.

\( \) imbalance  
There were more \( than \), or more \) than \(, in a regular expression.

[ ] imbalance  
There were more [ than ], or more ] than [, in a regular expression.

First RE may not be null  
The first regular expression in an address or in a s command was null (empty).

Ending delimiter missing on substitution  
The ending delimiter in a s command was absent.

Ending delimiter missing on string  
The ending delimiter in a y command was absent.

Transform strings not the same size  
The two strings in a y command were not the same size.

Suffix too large - 512 max  
The suffix in a s command, specifying which occurrence of the regular expression should be replaced, was greater than 512.

Label too long  
A label in a command was longer than 8 characters.

Duplicate labels  
The same label was specified by more than one : command.

File name too long  
The filename specified in a r or w command, or in the w option for a s command, was longer than 1024 characters.

Output line too long

An output line was longer than 4000 characters long.

Too many appends or reads after line *n*

More than 20 *a* or *r* commands were to be executed for line *n*.

Hold space overflowed.

More than 4000 characters were to be stored in the *hold space*.

**FILES** usr/ucb/sed BSD sed

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscpu        |

**SEE ALSO** awk(1), grep(1), lex(1), attributes(5), largefile(5), regexp(5)

**BUGS** There is a combined limit of 200 *-e* and *-f* arguments. In addition, there are various internal size limits which, in rare cases, may overflow. To overcome these limitations, either combine or break out scripts, or use a pipeline of *sed* commands.

| <b>NAME</b>        | set, unset, setenv, unsetenv, export – shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>sh</b>          | <b>set</b> [--aefhkntuvx <i>argument</i> ]...<br><b>unset</b> [ <i>name</i> ...]<br><b>export</b> [ <i>name</i> ...]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>DESCRIPTION</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>sh</b>          | The set built-in command has the following options:<br>-- Does not change any of the flags. This option is useful in setting \$1 to –.<br>-a Marks variables which are modified or created for export.<br>-e Exits immediately if a command exits with a non-zero exit status.<br>-f Disables file name generation.<br>-h Locates and remembers function commands as functions are defined. Function commands are normally located when the function is executed.<br>-k All keyword arguments are placed in the environment for a command, not just those that precede the command name.<br>-n Reads commands but does not execute them.<br>-t Exits after reading and executing one command.<br>-u Treats unset variables as an error when substituting.<br>-v Prints shell input lines as they are read.<br>-x Prints commands and their arguments as they are executed. |

Using + rather than – causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags can be found in \$-. The remaining *arguments* are positional parameters and are assigned, in order, to \$1, \$2, . . . . If no *arguments* are given the values of all names are printed.

For each *name*, unset removes the corresponding variable or function value. The variables PATH, PS1, PS2, MAILCHECK, and IF cannot be unset.

With the export built-in, the given *names* are marked for automatic export to the *environment* of subsequently executed commands. If no arguments are given, variable names that have been marked for export during the current shell's execution are listed. Function names are *not* exported.

**cs**h With no arguments, set displays the values of all shell variables. Multiword values are displayed as a parenthesized list. With the *var* argument alone, set assigns an empty (null) value to the variable *var*. With arguments of the form *var = value* set assigns *value* to *var*, where *value* is one of:

*word* A single word (or quoted string).

(*wordlist*) A space-separated list of words enclosed in parentheses.

Values are command and filename expanded before being assigned. The form set *var* [*n*] =*word* replaces the *n*'th word in a multiword value with *word*.

unset removes variables whose names match (filename substitution) *pattern*. All variables are removed by 'unset \*'.

With no arguments, setenv displays all environment variables. With the VAR argument, setenv sets the environment variable VAR to an empty (null) value. (By convention, environment variables are normally given upper-case names.) With both VAR and word arguments specified, setenv sets VAR to word, which must be either a single word or a quoted string. The PATH variable can take multiple word arguments, separated by colons (see EXAMPLES). The most commonly used environment variables, USER, TERM, and PATH, are automatically imported to and exported from the csh variables user, term, and path. Use setenv if you need to change these variables. In addition, the shell sets the PWD environment variable from the csh variable cwd whenever the latter changes.

The environment variables LC\_CTYPE, LC\_MESSAGES, LC\_TIME, LC\_COLLATE, LC\_NUMERIC, and LC\_MONETARY take immediate effect when changed within the C shell. See environ(5) for descriptions of these environment variables.

unsetenv removes *variable* from the environment. As with unset, pattern matching is not performed.

**k**sh The flags for the set built-in have meaning as follows:

## set(1)

- A Array assignment. Unsets the variable *name* and assigns values sequentially from the list *arg*. If +A is used, the variable *name* is not unset first.
- a All subsequent variables that are defined are automatically exported.
- b Causes the shell to notify the user asynchronously of background job completions.
- C Prevents existing files from being overwritten by the shell's > redirection operator. The >| redirection operator overrides this noclobber option for an individual file.
- e If a command has a non-zero exit status, executes the ERR trap, if set, and exits. This mode is disabled while reading profiles.
- f Disables file name generation.
- h Each command becomes a tracked alias when first encountered.
- k All variable assignment arguments are placed in the environment for a command, not just those that precede the command name.
- m Background jobs run in a separate process group and a line prints upon completion. The exit status of background jobs is reported in a completion message. On systems with job control, this flag is turned on automatically for interactive shells.
- n Reads commands and checks them for syntax errors, but does not execute them. Ignored for interactive shells.
- +o Writes the current option settings to standard output in a format that is suitable for reinput to the shell as commands that achieve the same option settings.
- o *option* The *option* argument can be one of the following option names:

|           |                                                                                                                                                             |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| allexport | Same as -a.                                                                                                                                                 |
| errexit   | Same as -e.                                                                                                                                                 |
| bgnice    | All background jobs are run at a lower priority. This is the default mode. <i>emacs</i> Puts you in an <i>emacs</i> style in-line editor for command entry. |
| gmacs     | Puts you in a <i>gmacs</i> style in-line editor for command entry.                                                                                          |
| ignoreeof | The shell does not exit on end-of-file. The command <i>exit</i> must be used.                                                                               |
| keyword   | Same as -k.                                                                                                                                                 |
| markdirs  | All directory names resulting from file name generation have a trailing / appended.                                                                         |

|            |                                                                                                                                                  |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| monitor    | Same as -m.                                                                                                                                      |
| noclobber  | Prevents redirection operator > from truncating existing files. Requires the >  operator to truncate a file when turned on. Same as -C.          |
| noexec     | Same as -n.                                                                                                                                      |
| noglob     | Same as -f.                                                                                                                                      |
| nolog      | Does not save function definitions in history file.                                                                                              |
| notify     | Same as -b.                                                                                                                                      |
| nounset    | Same as -u.                                                                                                                                      |
| privileged | Same as -p.                                                                                                                                      |
| verbose    | Same as -v.                                                                                                                                      |
| trackall   | Same as -h.                                                                                                                                      |
| vi         | Puts you in insert mode of a vi style in-line editor until you hit escape character 033. This puts you in control mode. A return sends the line. |
| viraw      | Each character is processed as it is typed in vi mode.                                                                                           |
| xtrace     | Same as -x.                                                                                                                                      |

If no option name is supplied then the current option settings are printed.

- p Disables processing of the \$HOME/.profile file and uses the file /etc/suid\_profile instead of the ENV file. This mode is on whenever the effective uid is not equal to the real uid, or when the effective gid is not equal to the real gid. Turning this off causes the effective uid and gid to be set to the real uid and gid.
- s Sorts the positional parameters lexicographically.
- t Exits after reading and executing one command.
- u Treats unset parameters as an error when substituting.
- v Prints shell input lines as they are read.
- x Prints commands and their arguments as they are executed.
- Turns off -x and -v flags and stops examining arguments for flags.
- Does not change any of the flags. This option is useful in setting \$1 to a value beginning with -. If no arguments follow this flag then the positional parameters are unset.

## set(1)

Using `+` rather than `-` causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags can be found in `set -`. Unless `-A` is specified, the remaining arguments are positional parameters and are assigned, in order, to `$1 $2 . . .`. If no arguments are given then the names and values of all variables are printed on the standard output.

The variables given by the list of *names* are unassigned, that is, their values and attributes are erased. `readonly` variables cannot be unset. If the `-f` flag is set, then the names refer to function names. Unsetting `ERRNO`, `LINENO`, `MAILCHECK`, `OPTARG`, `OPTIND`, `RANDOM`, `SECONDS`, `TMOUT`, and `_` removes their special meaning even if they are subsequently assigned.

When using `unset`, the variables given by the list of *names* are unassigned, i.e., their values and attributes are erased. `readonly` variables cannot be unset. If the `-f` flag is set, then the names refer to function names. Unsetting `ERRNO`, `LINENO`, `MAILCHECK`, `OPTARG`, `OPTIND`, `RANDOM`, `SECONDS`, `TMOUT`, and `_` removes their special meaning even if they are subsequently assigned.

With the `export` built-in, the given *names* are marked for automatic export to the environment of subsequently-executed commands.

When `-p` is specified, `export` writes to the standard output the names and values of all exported variables in the following format:

```
"export %s=%s\n", name, value
```

if *name* is set, and:

```
"export %s\n", name
```

if *name* is unset.

The shell formats the output, including the proper use of quoting, so that it is suitable for reinput to the shell as commands that achieve the same exporting results, except for the following:

1. Read-only variables with values cannot be reset.
2. Variables that were unset at the time they were output are not reset to the unset state if a value is assigned to the variable between the time the state was saved and the time at which the saved output is reinput to the shell.

On this man page, `ksh(1)` commands that are preceded by one or two `*` (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.

set(1)

4. Words, following a command preceded by \*\* that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

#### EXAMPLES

**cs**h The following example sets the PATH variable to search for files in the /bin, /usr/bin, /usr/sbin, and /usr/ucb/bin directories, in that order:

```
setenv PATH "/bin:/usr/bin:/usr/sbin:usr/ucb/bin"
```

| <b>NAME</b>        | set, unset – set and unset local or global environment variables                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <b>set</b> [ -l <i>variable</i> [ = <i>value</i> ] ] ...<br><b>set</b> [ -e <i>variable</i> [ = <i>value</i> ] ] ...<br><b>set</b> [ -f <i>file</i> <i>variable</i> [ = <i>value</i> ]... ] ...<br><b>unset</b> -l <i>variable</i> ...<br><b>unset</b> -f <i>file</i> <i>variable</i> ...                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DESCRIPTION</b> | <p>The <b>set</b> command sets <i>variable</i> in the environment, or adds <i>variable=value</i> to <i>file</i>. If <i>variable</i> is not equated to a value, <b>set</b> expects the value to be on <i>stdin</i>. The <b>unset</b> command removes <i>variable</i>. Note that the FMLI predefined, read-only variables (such as ARG1), may not be set or unset.</p> <p>Note that at least one of the above options must be used for each variable being set or unset. If you set a variable with the -f<i>filename</i> option, you must thereafter include <i>filename</i> in references to that variable. For example, <code>\$(<i>file</i>) VARIABLE</code>.</p> <p>FMLI inherits the UNIX environment when invoked.</p> |
| <b>OPTIONS</b>     | <p>-l        Sets or unsets the specified variable in the local environment. Variables set with -l will not be inherited by processes invoked from FMLI.</p> <p>-e        Sets the specified variable in the UNIX environment. Variables set with -e will be inherited by any processes started from FMLI. Note that these variables cannot be unset .</p> <p>-ffile    Sets or unsets the specified variable in the global environment. The argument <i>file</i> is the name, or pathname, of a file containing lines of the form <i>variable=value</i>. <i>file</i> will be created if it does not already exist. Note that no space intervenes between -f and <i>file</i>.</p>                                           |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> A sample output of <b>set</b> command.</p> <p>Storing a selection made in a menu:</p> <pre>name=Selection 2 action='set -l SELECTION=2'close</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>NOTES</b>       | <p>Variables set to be available to the UNIX environment (those set using the -e option) can only be set for the current fmli process and the processes it calls.</p> <p>When using the -f option, unless <i>file</i> is unique to the process, other users of FMLI on the same machine will be able to expand these variables, depending on the read/write permissions on <i>file</i>.</p> <p>A variable set in one frame may be referenced or unset in any other frame. This includes local variables.</p>                                                                                                                                                                                                                |

setcolor(1F)

**NAME** | setcolor – redefine or create a color

**SYNOPSIS** | **setcolor** *color red\_level green\_level blue\_level*

**DESCRIPTION** | The **setcolor** command takes four arguments: *color*, which must be a string naming the color; and the arguments *red\_level*, *green\_level*, and *blue\_level*, which must be integer values defining, respectively, the intensity of the red, green, and blue components of *color*. Intensities must be in the range of 0 to 1000. If you are redefining an existing color, you must use its current name (default color names are: black, blue, green, cyan, red, magenta, yellow, and white). **setcolor** returns the color's name string.

**EXAMPLES** | **EXAMPLE 1** A sample output of **setcolor** command.  
The following is an example of the arguments that **setcolor** takes:  

```
'setcolor blue 100 24 300'
```

**BUILT-IN FMLI**

| <b>DESCRIPTION</b>               | <p>For each file specified, <code>setfacl</code> will either replace its entire ACL, including the default ACL on a directory, or it will add, modify, or delete one or more ACL entries, including default entries on directories.</p> <p>When the <code>setfacl</code> command is used, it may result in changes to the file permission bits. When the user ACL entry for the file owner is changed, the file owner class permission bits will be modified. When the group ACL entry for the file group class is changed, the file group class permission bits will be modified. When the other ACL entry is changed, the file other class permission bits will be modified.</p> <p>If you use the <code>chmod(1)</code> command to change the file group owner permissions on a file with ACL entries, both the file group owner permissions and the ACL mask are changed to the new permissions. Be aware that the new ACL mask permissions may change the effective permissions for additional users and groups who have ACL entries on the file.</p> <p>A directory may contain default ACL entries. If a file or directory is created in a directory that contains default ACL entries, the newly created file will have permissions generated according to the intersection of the default ACL entries and the permissions requested at creation time. The <code>umask(1)</code> will not be applied if the directory contains default ACL entries. If a default ACL is specified for a specific user (or users), the file will have a regular ACL created. Otherwise, only the mode bits will be initialized according to the intersection described above. The default ACL should be thought of as the maximum discretionary access permissions that may be granted.</p> |                   |                                                                                                                                                                        |                          |                                                                                         |              |                                                                                                                                                                                                                               |
| <i>acl_entries</i> <b>Syntax</b> | <p>For the <code>-m</code> and <code>-s</code> options, <i>acl_entries</i> are one or more comma-separated ACL entries.</p> <p>An ACL entry consists of the following fields separated by colons:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><i>entry_type</i></td> <td>Type of ACL entry on which to set file permissions. For example, <i>entry_type</i> can be <code>user</code> (the owner of a file) or <code>mask</code> (the ACL mask).</td> </tr> <tr> <td><i>uid</i> or <i>gid</i></td> <td>User name or user identification number. Or, group name or group identification number.</td> </tr> <tr> <td><i>perms</i></td> <td>Represents the permissions that are set on <i>entry_type</i>. <i>perms</i> can be indicated by the symbolic characters <code>rwX</code> or a number (the same permissions numbers used with the <code>chmod</code> command).</td> </tr> </table> <p>The following table shows the valid ACL entries (default entries may only be specified for directories):</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | <i>entry_type</i> | Type of ACL entry on which to set file permissions. For example, <i>entry_type</i> can be <code>user</code> (the owner of a file) or <code>mask</code> (the ACL mask). | <i>uid</i> or <i>gid</i> | User name or user identification number. Or, group name or group identification number. | <i>perms</i> | Represents the permissions that are set on <i>entry_type</i> . <i>perms</i> can be indicated by the symbolic characters <code>rwX</code> or a number (the same permissions numbers used with the <code>chmod</code> command). |
| <i>entry_type</i>                | Type of ACL entry on which to set file permissions. For example, <i>entry_type</i> can be <code>user</code> (the owner of a file) or <code>mask</code> (the ACL mask).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                   |                                                                                                                                                                        |                          |                                                                                         |              |                                                                                                                                                                                                                               |
| <i>uid</i> or <i>gid</i>         | User name or user identification number. Or, group name or group identification number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                   |                                                                                                                                                                        |                          |                                                                                         |              |                                                                                                                                                                                                                               |
| <i>perms</i>                     | Represents the permissions that are set on <i>entry_type</i> . <i>perms</i> can be indicated by the symbolic characters <code>rwX</code> or a number (the same permissions numbers used with the <code>chmod</code> command).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                   |                                                                                                                                                                        |                          |                                                                                         |              |                                                                                                                                                                                                                               |

| u[ser]::perms               | File owner permissions.                                                                                                                                                                            |
| g[roup]::perms              | File group owner permissions.                                                                                                                                                                      |
| o[ther]:perms               | Permissions for users other than the file owner or members of file group owner.                                                                                                                    |
| m[ask]:perms                | The ACL mask. The mask entry indicates the maximum permissions allowed for users (other than the owner) and for groups. The mask is a quick way to change permissions on all the users and groups. |
| u[ser]:uid:perms            | Permissions for a specific user. For <i>uid</i> , you can specify either a user name or a numeric UID.                                                                                             |
| g[roup]:gid:perms           | Permissions for a specific group. For <i>gid</i> , you can specify either a group name or a numeric GID.                                                                                           |
| d[efault]:u[ser]::perms     | Default file owner permissions.                                                                                                                                                                    |
| d[efault]:g[roup]::perms    | Default file group owner permissions.                                                                                                                                                              |
| d[efault]:o[ther]:perms     | Default permissions for users other than the file owner or members of the file group owner.                                                                                                        |
| d[efault]:m[ask]:perms      | Default ACL mask.                                                                                                                                                                                  |
| d[efault]:u[ser]:uid:perms  | Default permissions for a specific user. For <i>uid</i> , you can specify either a user name or a numeric UID.                                                                                     |
| d[efault]:g[roup]:gid:perms | Default permissions for a specific group. For <i>gid</i> , you can specify either a group name or a numeric GID.                                                                                   |

For the `-d` option, *acl\_entries* are one or more comma-separated ACL entries without permissions. Notice that the entries for file owner, file group owner, ACL mask, and others may not be deleted.

### OPTIONS

The options have the following meaning:

- `-d acl_entries` Deletes one or more entries from the file. The entries for the file owner, the file group owner, and others may not be deleted from the ACL. Notice that deleting an entry does not necessarily have the same effect as removing all permissions from the entry.
- `-f acl_file` Sets a file's ACL with the ACL entries contained in the file named *acl\_file*. The same constraints on specified entries hold as with the `-s` option. The entries are not required to be in any specific order in the file. Also, if you specify a dash '-' for *acl\_file*, standard input is used to set the file's ACL.

The character "#" in *acl\_file* may be used to indicate a comment. All characters, starting with the "#" until the end of the line, will be ignored. Notice that if the *acl\_file* has been created as the output of the `getfacl(1)` command, any effective permissions, which will follow a "#", will be ignored.

- m *acl\_entries* Adds one or more new ACL entries to the file, and/or modifies one or more existing ACL entries on the file. If an entry already exists for a specified *uid* or *gid*, the specified permissions will replace the current permissions. If an entry does not exist for the specified *uid* or *gid*, an entry will be created. When using the -m option to modify a default ACL, you must specify a complete default ACL (user, group, other, mask, and any additional entries) the first time.
- r Recalculates the permissions for the ACL mask entry. The permissions specified in the ACL mask entry are ignored and replaced by the maximum permissions necessary to grant the access to all additional user, file group owner, and additional group entries in the ACL. The permissions in the additional user, file group owner, and additional group entries are left unchanged.
- s *acl\_entries* Sets a file's ACL. All old ACL entries are removed and replaced with the newly specified ACL. The entries need not be in any specific order. They will be sorted by the command before being applied to the file.

Required entries:

- Exactly one `user` entry specified for the file owner.
- Exactly one `group` entry for the file group owner.
- Exactly one `other` entry specified.

If there are additional user and group entries:

- Exactly one `mask` entry specified for the ACL mask that indicates the maximum permissions allowed for users (other than the owner) and groups.
- Must not be duplicate `user` entries with the same *uid*.
- Must not be duplicate `group` entries with the same *gid*.

If *file* is a directory, the following default ACL entries may be specified:

- Exactly one `default user` entry for the file owner.
- Exactly one `default group` entry for the file group owner.
- Exactly one `default mask` entry for the ACL mask.
- Exactly one `default other` entry.

## setfacl(1)

There may be additional default user entries and additional default group entries specified, but there may not be duplicate additional default user entries with the same *uid*, or duplicate default group entries with the same *gid*.

### EXAMPLES **EXAMPLE 1** Adding read permission only

The following example adds one ACL entry to file *abc*, which gives user *shea* read permission only.

```
setfacl -m user:shea:r-- abc
```

### **EXAMPLE 2** Replacing a file's entire ACL

The following example replaces the entire ACL for the file *abc*, which gives *shea* read access, the file owner all access, the file group owner read access only, the ACL mask read access only, and others no access.

```
setfacl -s user:shea:rw-,user::rw-,group::rw-,mask:r--,other:--- abc
```

Notice that after this command, the file permission bits are *rwxr-----*. Even though the file group owner was set with read/write permissions, the ACL mask entry limits it to have only read permission. The mask entry also specifies the maximum permissions available to all additional user and group ACL entries. Once again, even though the user *shea* was set with all access, the mask limits it to have only read permission. The ACL mask entry is a quick way to limit or open access to all the user and group entries in an ACL. For example, by changing the mask entry to read/write, both the file group owner and user *shea* would be given read/write access.

### **EXAMPLE 3** Setting the same ACL on two files

The following example sets the same ACL on file *abc* as the file *xyz*.

```
getfacl xyz | setfacl -f - abc
```

**FILES** /etc/passwd password file

/etc/group group file

| <b>NAME</b>        | sftp – secure file transfer program                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <b>sftp</b> [ <i>options</i> ] [ <i>user@</i> ]host[: <i>dir</i> [/]]<br><b>sftp</b> [ <i>options</i> ] [ <i>user@</i> ]host[: <i>file1</i> [ <i>file1</i> [ <i>file</i>   <i>dir2</i> ]]]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DESCRIPTION</b> | <p>The <b>sftp</b> utility is an interactive file transfer program with a user interface similar to <b>ftp(1)</b> that uses the <b>ssh(1)</b> command to create a secure connection to the server.</p> <p><b>sftp</b> implements the SSH File Transfer Protocol as defined in IETF draft-ietf-secsh-filexfer. There is no relationship between the protocol used by <b>sftp</b> and the FTP protocol (RFC959) provided by <b>ftp(1)</b>.</p> <p>The first usage format causes <b>sftp</b> to connect to the given host and enter an interactive mode. If a username was provided then <b>sftp</b> tries to log in as the given user. If a directory is provided then <b>sftp</b> tries to change the current directory on the server to the given directory before entering the interactive mode.</p> <p>The second usage format retrieves the given file from the server and copies it to the given target file or directory on the client. If a username is given <b>sftp</b> tries to log in as the given user.</p>                                                                                                                                                                                                                                                                                                                                        |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-1<br/>Specifies the use of protocol version 1.</li><li>-b <i>batchfile</i><br/>Batch mode reads a series of commands from an input <i>batchfile</i> instead of stdin. Since it lacks user interaction, it should be used in conjunction with non-interactive authentication. <b>sftp</b> aborts if any of the following commands fail: <b>get</b>, <b>rm</b>, and <b>mkdir</b>.</li><li>-B <i>buffer_size</i><br/>Specifies the size of the buffer that <b>sftp</b> uses when transferring files. Larger buffers require fewer round trips at the cost of higher memory consumption. The default is 32768 bytes.</li><li>-C<br/>Enables compression, using the <b>-C</b> flag in <b>ssh(1)</b>.</li><li>-F <i>ssh_config</i><br/>Specifies an alternative per-user configuration file for <b>ssh</b>. This option is directly passed to <b>ssh(1)</b>.</li><li>-o <i>ssh_option</i><br/>Specifies an option to be directly passed to <b>ssh(1)</b>.</li><li>-P <i>sftp_server_path</i><br/>Executes the given path as an <i>sftp-server</i> and uses a pipe, rather than an <b>ssh</b> connection, to communicate with it. This option can be useful in debugging the <b>sftp</b> client and server. The <b>-P</b> and <b>-S</b> options are mutually exclusive.</li></ul> |

- R *num\_requests*  
Specifies how many requests can be outstanding at any one time. Increasing this can slightly improve file transfer speed but increases memory usage. The default is 16 outstanding requests.
- S *ssh program path*  
Uses the given program instead of `ssh(1)` to connect to the `sftp` server. The `-P` and `-S` options are mutually exclusive.
- s *subsystem | sftp\_server*  
Specifies the SSH2 subsystem or the path for an `sftp` server on the remote host. A path is useful for using `sftp` over protocol version 1, or when the remote `sshd` does not have an `sftp` subsystem configured.
- v  
Raises logging level. This option is also passed to `ssh(1)`.

**OPERANDS** The following operands are supported:

*hostname | user@hostname*  
The name of the host to which `sftp` connects and logs into.

**INTERACTIVE COMMANDS** Once in interactive mode, `sftp` understands a set of commands similar to those of `ftp(1)`. Commands are case insensitive and pathnames can be enclosed in quotes if they contain spaces.

`bye`  
Quits `sftp`.

`cd path`  
Changes remote directory to *path*.

`lcd path`  
Changes local directory to *path*.

`chgrp grp path`  
Changes group of file *path* to *grp*. *grp* must be a numeric GID.

`chmod mode path`  
Changes permissions of file *path* to *mode*.

`chown own path`  
Changes owner of file *path* to *own*. *own* must be a numeric UID.

`help`  
Displays help text.

`get [flags] remote-path [local-path]`  
Retrieves the *remote-path* and stores it on the local machine. If the local path name is not specified, it is given the same name it has on the remote machine. If the `-P` flag is specified, then the file's full permission and access time are copied too.

`lls [ls-options [path]]`  
Displays local directory listing of either *path* or current directory if *path* is not specified.

## sftp(1)

**mkdir** *path*  
Creates local directory specified by *path*.

**ln** *oldpath newpath*  
Creates a link from *oldpath* to *newpath*.

**lpwd**  
Prints local working directory.

**ls** [*flags*] [*path*]  
Displays remote directory listing of either *path* or current directory if *path* is not specified.

**lumask** *umask*  
Sets local umask to *umask*.

**mkdir** *path*  
Creates remote directory specified by *path*.

**put** [*flags*] *local-path* [*local-path*]  
Uploads *local-path* and stores it on the remote machine. If the remote path name is not specified, it is given the same name it has on the local machine. If the **-P** flag is specified, then the file's full permission and access time are copied too.

**pwd**  
Displays remote working directory.

**exit**  
Quits **sftp**.

**quit**  
Quits **sftp**.

**rename** *oldpath newpath*  
Renames remote file from *oldpath* to *newpath*.

**rmdir** *path*  
Removes remote directory specified by *path*.

**rm** *path*  
Deletes remote file specified by *path*.

**symlink** *oldpath newpath*  
Creates a symbolic link from *oldpath* to *newpath*.

**!** *command*  
Executes *command* in local shell.

**!**  
Escapes to local shell.

**?**  
Synonym for **help**.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

1 An error occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWsshu        |
| Interface Stability | Evolving        |

**SEE ALSO** `ftp(1)`, `scp(1)`, `ssh(1)`, `ssh-add(1)`, `ssh-keygen(1)`, `sshd(1M)`, `attributes(5)`

To view license terms, attribution, and copyright for OpenSSH, the default path is `/var/sadm/pkg/SUNWsshdr/install/copyright`. If the Solaris operating environment has been installed anywhere other than the default, modify the given path to access the file at the installed location.

| <b>DESCRIPTION</b> | <p>The /usr/bin/sh utility is a command programming language that executes commands read from a terminal or a file.</p> <p>The /usr/xpg4/bin/sh utility is a standards compliant shell. This utility provides all the functionality of <b>ksh(1)</b>, except in cases discussed in <b>ksh(1)</b> where differences in behavior exist.</p> <p>The <b>jsh</b> utility is an interface to the shell that provides all of the functionality of <b>sh</b> and enables job control (see <b>Job Control</b> section below).</p> <p>Arguments to the shell are listed in the <b>Invocation</b> section below.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Definitions</b> | <p>A <i>blank</i> is a tab or a space. A <i>name</i> is a sequence of ASCII letters, digits, or underscores, beginning with a letter or an underscore. A <i>parameter</i> is a name, a digit, or any of the characters *, @, #, ?, -, \$, and !.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>USAGE</b>       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Commands</b>    | <p>A <i>simple-command</i> is a sequence of non-blank <i>words</i> separated by <i>blanks</i>. The first <i>word</i> specifies the name of the command to be executed. Except as specified below, the remaining <i>words</i> are passed as arguments to the invoked command. The command name is passed as argument 0 (see <b>exec(2)</b>). The <i>value</i> of a <i>simple-command</i> is its exit status if it terminates normally, or (octal) 200+<i>status</i> if it terminates abnormally. See <b>signal.h(3HEAD)</b> for a list of status values.</p> <p>A <i>pipeline</i> is a sequence of one or more <i>commands</i> separated by  . The standard output of each <i>command</i> but the last is connected by a <b>pipe(2)</b> to the standard input of the next <i>command</i>. Each <i>command</i> is run as a separate process. The shell waits for the last <i>command</i> to terminate. The exit status of a <i>pipeline</i> is the exit status of the last command in the <i>pipeline</i>.</p> <p>A <i>list</i> is a sequence of one or more <i>pipelines</i> separated by ;, &amp;, &amp;&amp;, or    , and optionally terminated by ; or &amp;. Of these four symbols, ; and &amp; have equal precedence, which is lower than that of &amp;&amp; and    . The symbols &amp;&amp; and     also have equal precedence. A semicolon (;) causes sequential execution of the preceding <i>pipeline</i>, that is, the shell waits for the <i>pipeline</i> to finish before executing any commands following the semicolon. An ampersand (&amp;) causes asynchronous execution of the preceding pipeline, that is, the shell does <i>not</i> wait for that pipeline to finish. The symbol &amp;&amp; (    ) causes the <i>list</i> following it to be executed only if the preceding pipeline returns a zero (non-zero) exit status. An arbitrary number of newlines may appear in a <i>list</i>, instead of semicolons, to delimit commands.</p> |

A *command* is either a *simple-command* or one of the following. Unless otherwise stated, the value returned by a command is that of the last *simple-command* executed in the command.

`for name [ in word ... ] do list done`

Each time a `for` command is executed, *name* is set to the next *word* taken from the `in word` list. If `in word ...` is omitted, then the `for` command executes the `do list` once for each positional parameter that is set (see `Parameter Substitution` section below). Execution ends when there are no more words in the list.

`case word in [ pattern [ | pattern ] ) list ; ; ] ... esac`

A `case` command executes the *list* associated with the first *pattern* that matches *word*. The form of the patterns is the same as that used for file-name generation (see `File Name Generation` section), except that a slash, a leading dot, or a dot immediately following a slash need not be matched explicitly.

`if list ; then list ; [ elif list ; then list ; ] ... [ else list ; ] fi`

The *list* following `if` is executed and, if it returns a zero exit status, the *list* following the first `then` is executed. Otherwise, the *list* following `elif` is executed and, if its value is zero, the *list* following the next `then` is executed. Failing that, the `else list` is executed. If no `else list` or `then list` is executed, then the `if` command returns a zero exit status.

`while list do list done`

A `while` command repeatedly executes the `while list` and, if the exit status of the last command in the list is zero, executes the `do list`; otherwise the loop terminates. If no commands in the `do list` are executed, then the `while` command returns a zero exit status; `until` may be used in place of `while` to negate the loop termination test.

`(list)`

Execute *list* in a sub-shell.

`{ list ; }`

*list* is executed in the current (that is, parent) shell. The `{` must be followed by a space.

`name ( ) { list ; }`

Define a function which is referenced by *name*. The body of the function is the *list* of commands between `{` and `}`. The `{` must be followed by a space. Execution of functions is described below (see `Execution` section). The `{` and `}` are unnecessary if the body of the function is a *command* as defined above, under `Commands`.

The following words are only recognized as the first word of a command and when not quoted:

sh(1)

```
if then else elif fi case esac for while until do done { }
```

**Comments Lines**

A word beginning with # causes that word and all the following characters up to a newline to be ignored.

**Command Substitution**

The shell reads commands from the string between two grave accents (``) and the standard output from these commands may be used as all or part of a word. Trailing newlines from the standard output are removed.

No interpretation is done on the string before the string is read, except to remove backslashes (\) used to escape other characters. Backslashes may be used to escape a grave accent (`) or another backslash (\) and are removed before the command string is read. Escaping grave accents allows nested command substitution. If the command substitution lies within a pair of double quotes (" . . . ` . . . " ), a backslash used to escape a double quote (\") will be removed; otherwise, it will be left intact.

If a backslash is used to escape a newline character (\newline), both the backslash and the newline are removed (see the later section on Quoting). In addition, backslashes used to escape dollar signs (\\$) are removed. Since no parameter substitution is done on the command string before it is read, inserting a backslash to escape a dollar sign has no effect. Backslashes that precede characters other than \, `, ", newline, and \$ are left intact when the command string is read.

**Parameter Substitution**

The character \$ is used to introduce substitutable *parameters*. There are two types of parameters, positional and keyword. If *parameter* is a digit, it is a positional parameter. Positional parameters may be assigned values by *set*. Keyword parameters (also known as variables) may be assigned values by writing:

```
name=value [ name=value ] . . .
```

Pattern-matching is not performed on *value*. There cannot be a function and a variable with the same *name*.

`${parameter}`

The value, if any, of the parameter is substituted. The braces are required only when *parameter* is followed by a letter, digit, or underscore that is not to be interpreted as part of its name. If *parameter* is \* or @, all the positional parameters, starting with \$1, are substituted (separated by spaces). Parameter \$0 is set from argument zero when the shell is invoked.

`${parameter:-word}`

If *parameter* is set and is non-null, substitute its value; otherwise substitute *word*.

`${parameter:=word}`

If *parameter* is not set or is null set it to *word*; the value of the parameter is substituted. Positional parameters may not be assigned in this way.

|                                  |                                                                                                                                                                                                        |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>\${parameter:?word}</code> | If <i>parameter</i> is set and is non-null, substitute its value; otherwise, print <i>word</i> and exit from the shell. If <i>word</i> is omitted, the message “parameter null or not set” is printed. |
| <code>\${parameter:+word}</code> | If <i>parameter</i> is set and is non-null, substitute <i>word</i> ; otherwise substitute nothing.                                                                                                     |

In the above, *word* is not evaluated unless it is to be used as the substituted string, so that, in the following example, `pwd` is executed only if `d` is not set or is null:

```
echo ${d:-`pwd`}
```

If the colon (`:`) is omitted from the above expressions, the shell only checks whether *parameter* is set or not.

The following parameters are automatically set by the shell.

|                 |                                                                               |
|-----------------|-------------------------------------------------------------------------------|
| <code>#</code>  | The number of positional parameters in decimal.                               |
| <code>-</code>  | Flags supplied to the shell on invocation or by the <code>set</code> command. |
| <code>?</code>  | The decimal value returned by the last synchronously executed command.        |
| <code>\$</code> | The process number of this shell.                                             |
| <code>!</code>  | The process number of the last background command invoked.                    |

The following parameters are used by the shell. The parameters in this section are also referred to as environment variables.

|                        |                                                                                                                                                                                                                                                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>HOME</code>      | The default argument (home directory) for the <code>cd</code> command, set to the user’s login directory by <code>login(1)</code> from the password file (see <code>passwd(4)</code> ).                                                                                                                         |
| <code>PATH</code>      | The search path for commands (see <code>Execution</code> section below).                                                                                                                                                                                                                                        |
| <code>CDPATH</code>    | The search path for the <code>cd</code> command.                                                                                                                                                                                                                                                                |
| <code>MAIL</code>      | If this parameter is set to the name of a mail file <i>and</i> the <code>MAILPATH</code> parameter is not set, the shell informs the user of the arrival of mail in the specified file.                                                                                                                         |
| <code>MAILCHECK</code> | This parameter specifies how often (in seconds) the shell will check for the arrival of mail in the files specified by the <code>MAILPATH</code> or <code>MAIL</code> parameters. The default value is 600 seconds (10 minutes). If set to 0, the shell will check before each prompt.                          |
| <code>MAILPATH</code>  | A colon-separated list of file names. If this parameter is set, the shell informs the user of the arrival of mail in any of the specified files. Each file name can be followed by <code>%</code> and a message that will be printed when the modification time changes. The default message is, you have mail. |

sh(1)

|        |                                                                                                                                                               |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PS1    | Primary prompt string, by default "\$ ".                                                                                                                      |
| PS2    | Secondary prompt string, by default "> ".                                                                                                                     |
| IFS    | Internal field separators, normally space, tab, and newline (see Blank Interpretation section).                                                               |
| SHACCT | If this parameter is set to the name of a file writable by the user, the shell will write an accounting record in the file for each shell procedure executed. |
| SHELL  | When the shell is invoked, it scans the environment (see Environment section below) for this name.                                                            |

See `environ(5)` for descriptions of the following environment variables that affect the execution of `sh`: `LC_CTYPE` and `LC_MESSAGES`.

The shell gives default values to `PATH`, `PS1`, `PS2`, `MAILCHECK`, and `IFS`. Default values for `HOME` and `MAIL` are set by `login(1)`.

#### Blank Interpretation

After parameter and command substitution, the results of substitution are scanned for internal field separator characters (those found in `IFS`) and split into distinct arguments where such characters are found. Explicit null arguments (" " or ' ') are retained. Implicit null arguments (those resulting from *parameters* that have no values) are removed.

#### Input/Output Redirection

A command's input and output may be redirected using a special notation interpreted by the shell. The following may appear anywhere in a *simple-command* or may precede or follow a *command* and are *not* passed on as arguments to the invoked command. *Note*: Parameter and command substitution occurs before *word* or *digit* is used.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| < <i>word</i>     | Use file <i>word</i> as standard input (file descriptor 0).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| > <i>word</i>     | Use file <i>word</i> as standard output (file descriptor 1). If the file does not exist, it is created; otherwise, it is truncated to zero length.                                                                                                                                                                                                                                                                                                                                                                                                                |
| >> <i>word</i>    | Use file <i>word</i> as standard output. If the file exists, output is appended to it by first seeking to the EOF. Otherwise, the file is created.                                                                                                                                                                                                                                                                                                                                                                                                                |
| < > <i>word</i>   | Open file <i>word</i> for reading and writing as standard input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <<[-] <i>word</i> | After parameter and command substitution is done on <i>word</i> , the shell input is read up to the first line that literally matches the resulting <i>word</i> , or to an EOF. If, however, the hyphen (-) is appended to <<: <ol style="list-style-type: none"><li>1. leading tabs are stripped from <i>word</i> before the shell input is read (but after parameter and command substitution is done on <i>word</i>);</li><li>2. leading tabs are stripped from the shell input as it is read and before each line is compared with <i>word</i>; and</li></ol> |

3. shell input is read up to the first line that literally matches the resulting *word*, or to an EOF.

If any character of *word* is quoted (see `Quoting` section later), no additional processing is done to the shell input. If no characters of *word* are quoted:

1. parameter and command substitution occurs;
2. (escaped) `\newlines` are removed; and
3. `\` must be used to quote the characters `\`, `$`, and ```.

The resulting document becomes the standard input.

`<&digit` Use the file associated with file descriptor *digit* as standard input. Similarly for the standard output using `>&digit`.

`<&-` The standard input is closed. Similarly for the standard output using `>&-`.

If any of the above is preceded by a digit, the file descriptor which will be associated with the file is that specified by the digit (instead of the default 0 or 1). For example:

```
... 2>&1
```

associates file descriptor 2 with the file currently associated with file descriptor 1.

The order in which redirections are specified is significant. The shell evaluates redirections left-to-right. For example:

```
... 1>xxx 2>&1
```

first associates file descriptor 1 with file *xxx*. It associates file descriptor 2 with the file associated with file descriptor 1 (that is, *xxx*). If the order of redirections were reversed, file descriptor 2 would be associated with the terminal (assuming file descriptor 1 had been) and file descriptor 1 would be associated with file *xxx*.

Using the terminology introduced on the first page, under `Commands`, if a *command* is composed of several *simple commands*, redirection will be evaluated for the entire *command* before it is evaluated for each *simple command*. That is, the shell evaluates redirection for the entire *list*, then each *pipeline* within the *list*, then each *command* within each *pipeline*, then each *list* within each *command*.

If a command is followed by `&`, the default standard input for the command is the empty file, `/dev/null`. Otherwise, the environment for the execution of a command contains the file descriptors of the invoking shell as modified by input/output specifications.

sh(1)

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>File Name Generation</b> | <p>Before a command is executed, each command <i>word</i> is scanned for the characters <code>*</code>, <code>?</code>, and <code>[</code>. If one of these characters appears the word is regarded as a <i>pattern</i>. The word is replaced with alphabetically sorted file names that match the pattern. If no file name is found that matches the pattern, the word is left unchanged. The character <code>.</code> at the start of a file name or immediately following a <code>/</code>, as well as the character <code>/</code> itself, must be matched explicitly.</p> <p><code>*</code> Matches any string, including the null string.</p> <p><code>?</code> Matches any single character.</p> <p><code>[. . .]</code> Matches any one of the enclosed characters. A pair of characters separated by <code>-</code> matches any character lexically between the pair, inclusive. If the first character following the opening <code>[</code> is a <code>!</code>, any character not enclosed is matched.</p> <p>Notice that all quoted characters (see below) must be matched explicitly in a filename.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Quoting</b>              | <p>The following characters have a special meaning to the shell and cause termination of a word unless quoted:</p> <pre>; &amp; ( )   ^ &lt; &gt; newline space tab</pre> <p>A character may be <i>quoted</i> (that is, made to stand for itself) by preceding it with a backslash (<code>\</code>) or inserting it between a pair of quote marks (<code>' '</code> or <code>" "</code>). During processing, the shell may quote certain characters to prevent them from taking on a special meaning. Backslashes used to quote a single character are removed from the word before the command is executed. The pair <code>\newline</code> is removed from a word before command and parameter substitution.</p> <p>All characters enclosed between a pair of single quote marks (<code>' '</code>), except a single quote, are quoted by the shell. Backslash has no special meaning inside a pair of single quotes. A single quote may be quoted inside a pair of double quote marks (for example, <code>" ' "</code>), but a single quote can not be quoted inside a pair of single quotes.</p> <p>Inside a pair of double quote marks (<code>" "</code>), parameter and command substitution occurs and the shell quotes the results to avoid blank interpretation and file name generation. If <code>\$*</code> is within a pair of double quotes, the positional parameters are substituted and quoted, separated by quoted spaces (<code>"\$1 \$2 . . ."</code>). However, if <code>\$@</code> is within a pair of double quotes, the positional parameters are substituted and quoted, separated by unquoted spaces (<code>"\$1" "\$2" . . ."</code>). <code>\</code> quotes the characters <code>\</code>, <code>'</code>, <code>,</code> (comma), and <code>\$</code>. The pair <code>\newline</code> is removed before parameter and command substitution. If a backslash precedes characters other than <code>\</code>, <code>'</code>, <code>,</code> (comma), <code>\$</code>, and <code>newline</code>, then the backslash itself is quoted by the shell.</p> |
| <b>Prompting</b>            | <p>When used interactively, the shell prompts with the value of <code>PS1</code> before reading a command. If at any time a newline is typed and further input is needed to complete a command, the secondary prompt (that is, the value of <code>PS2</code>) is issued.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Environment** | The *environment* (see `environ(5)`) is a list of name-value pairs that is passed to an executed program in the same way as a normal argument list. The shell interacts with the environment in several ways. On invocation, the shell scans the environment and creates a parameter for each name found, giving it the corresponding value. If the user modifies the value of any of these parameters or creates new parameters, none of these affects the environment unless the `export` command is used to bind the shell's parameter to the environment (see also `set -a`). A parameter may be removed from the environment with the `unset` command. The environment seen by any executed command is thus composed of any unmodified name-value pairs originally inherited by the shell, minus any pairs removed by `unset`, plus any modifications or additions, all of which must be noted in `export` commands.

The environment for any *simple-command* may be augmented by prefixing it with one or more assignments to parameters. Thus:

```
TERM=450 command
```

and

```
(export TERM; TERM=450; command
```

are equivalent as far as the execution of *command* is concerned if *command* is not a Special Command. If *command* is a Special Command, then

```
TERM=450 command
```

will modify the `TERM` variable in the current shell.

If the `-k` flag is set, *all* keyword arguments are placed in the environment, even if they occur after the command name. The following example first prints `a=b c` and `c`:

```
echo a=b c
```

```
a=b c
```

```
set -k
```

```
echo a=b c
```

```
c
```

**Signals** | The `INTERRUPT` and `QUIT` signals for an invoked command are ignored if the command is followed by `&`. Otherwise, signals have the values inherited by the shell from its parent, with the exception of signal 11 (but see also the `trap` command below).

sh(1)

**Execution** Each time a command is executed, the command substitution, parameter substitution, blank interpretation, input/output redirection, and filename generation listed above are carried out. If the command name matches the name of a defined function, the function is executed in the shell process (note how this differs from the execution of shell script files, which require a sub-shell for invocation). If the command name does not match the name of a defined function, but matches one of the `Special Commands` listed below, it is executed in the shell process.

The positional parameters `$1, $2, . . .` are set to the arguments of the function. If the command name matches neither a `Special Command` nor the name of a defined function, a new process is created and an attempt is made to execute the command via `exec(2)`.

The shell parameter `PATH` defines the search path for the directory containing the command. Alternative directory names are separated by a colon (:). The default path is `/usr/bin`. The current directory is specified by a null path name, which can appear immediately after the equal sign, between two colon delimiters anywhere in the path list, or at the end of the path list. If the command name contains a / the search path is not used. Otherwise, each directory in the path is searched for an executable file. If the file has execute permission but is not an `.out` file, it is assumed to be a file containing shell commands. A sub-shell is spawned to read it. A parenthesized command is also executed in a sub-shell.

The location in the search path where a command was found is remembered by the shell (to help avoid unnecessary `execs` later). If the command was found in a relative directory, its location must be re-determined whenever the current directory changes. The shell forgets all remembered locations whenever the `PATH` variable is changed or the `hash -r` command is executed (see below).

**Special Commands** Input/output redirection is now permitted for these commands. File descriptor 1 is the default output location. When Job Control is enabled, additional `Special Commands` are added to the shell's environment (see `Job Control` section below).

`:`  
No effect; the command does nothing. A zero exit code is returned.

`. filename`  
Read and execute commands from `filename` and return. The search path specified by `PATH` is used to find the directory containing `filename`.

`bg [%jobid . . .]`  
When Job Control is enabled, the `bg` command is added to the user's environment to manipulate jobs. Resumes the execution of a stopped job in the background. If `%jobid` is omitted the current job is assumed. (See `Job Control` section below for more detail.)

`break [ n ]`  
Exit from the enclosing `for` or `while` loop, if any. If `n` is specified, break `n` levels.

**cd** [ *argument* ]

Change the current directory to *argument*. The shell parameter HOME is the default *argument*. The shell parameter CDPATH defines the search path for the directory containing *argument*. Alternative directory names are separated by a colon (:). The default path is <null> (specifying the current directory). *Note*: The current directory is specified by a null path name, which can appear immediately after the equal sign or between the colon delimiters anywhere else in the path list. If *argument* begins with a / the search path is not used. Otherwise, each directory in the path is searched for *argument*.

**chdir** [ *dir* ]

**chdir** changes the shell's working directory to directory *dir*. If no argument is given, change to the home directory of the user. If *dir* is a relative pathname not found in the current directory, check for it in those directories listed in the CDPATH variable. If *dir* is the name of a shell variable whose value starts with a /, change to the directory named by that value.

**continue** [ *n* ]

Resume the next iteration of the enclosing **for** or **while** loop. If *n* is specified, resume at the *n*-th enclosing loop.

**echo** [ *arguments* ... ]

The words in *arguments* are written to the shell's standard output, separated by space characters. See **echo(1)** for fuller usage and description.

**eval** [ *argument* ... ]

The arguments are read as input to the shell and the resulting command(s) executed.

**exec** [ *argument* ... ]

The command specified by the arguments is executed in place of this shell without creating a new process. Input/output arguments may appear and, if no other arguments are given, cause the shell input/output to be modified.

**exit** [ *n* ]

Causes the calling shell or shell script to exit with the exit status specified by *n*. If *n* is omitted the exit status is that of the last command executed (an EOF will also cause the shell to exit.)

**export** [ *name* ... ]

The given *names* are marked for automatic export to the *environment* of subsequently executed commands. If no arguments are given, variable names that have been marked for export during the current shell's execution are listed. (Variable names exported from a parent shell are listed only if they have been exported again during the current shell's execution.) Function names are *not* exported.

**fg** [%*jobid* ... ]

When Job Control is enabled, the **fg** command is added to the user's environment to manipulate jobs. This command resumes the execution of a stopped job in the foreground and also moves an executing background job into the foreground. If %*jobid* is omitted, the current job is assumed. (See Job Control section below for more detail.)

sh(1)

getopts

Use in shell scripts to support command syntax standards (see [intro\(1\)](#)). This command parses positional parameters and checks for legal options. See [getoptcvt\(1\)](#) for usage and description.

hash [ -r ] [ *name* . . . ]

For each *name*, the location in the search path of the command specified by *name* is determined and remembered by the shell. The -r option causes the shell to forget all remembered locations. If no arguments are given, information about remembered commands is presented. *Hits* is the number of times a command has been invoked by the shell process. *Cost* is a measure of the work required to locate a command in the search path. If a command is found in a "relative" directory in the search path, after changing to that directory, the stored location of that command is recalculated. Commands for which this will be done are indicated by an asterisk (\*) adjacent to the *hits* information. *Cost* will be incremented when the recalculation is done.

jobs [-p | -l] [%*jobid* ...]

jobs -x *command* [*arguments*]

Reports all jobs that are stopped or executing in the background. If %*jobid* is omitted, all jobs that are stopped or running in the background will be reported. (See Job Control section below for more detail.)

kill [ -sig ] %*job* . . .

kill -l

Sends either the TERM (terminate) signal or the specified signal to the specified jobs or processes. Signals are either given by number or by names (as given in `signal.h(3HEAD)` stripped of the prefix "SIG" with the exception that SIGCHD is named CHLD). If the signal being sent is TERM (terminate) or HUP (hangup), then the job or process will be sent a CONT (continue) signal if it is stopped. The argument *job* can be the process id of a process that is not a member of one of the active jobs. See Job Control section below for a description of the format of *job*. In the second form, kill -l, the signal numbers and names are listed. (See [kill\(1\)](#)).

login [ *argument* . . . ]

Equivalent to 'exec login *argument*. . .'. See [login\(1\)](#) for usage and description.

newgrp [ *argument* ]

Equivalent to exec newgrp *argument*. See [newgrp\(1\)](#) for usage and description.

pwd

Print the current working directory. See [pwd\(1\)](#) for usage and description.

read *name* . . .

One line is read from the standard input and, using the internal field separator, IFS (normally space or tab), to delimit word boundaries, the first word is assigned to the first *name*, the second word to the second *name*, and so forth, with leftover words assigned to the last *name*. Lines can be continued using `\newline`. Characters other than `newline` can be quoted by preceding them with a backslash. These backslashes are removed before words are assigned to *names*, and no interpretation is done on the character that follows the backslash. The return code is 0, unless an EOF is encountered.

`readonly [ name ... ]`

The given *names* are marked `readonly` and the values of these *names* may not be changed by subsequent assignment. If no arguments are given, a list of all `readonly` names is printed.

`return [ n ]`

Causes a function to exit with the return value specified by *n*. If *n* is omitted, the return status is that of the last command executed.

`set [ -aefhkntuvx [ argument ... ] ]`

- a        Mark variables which are modified or created for export.
- e        Exit immediately if a command exits with a non-zero exit status.
- f        Disable file name generation.
- h        Locate and remember function commands as functions are defined (function commands are normally located when the function is executed).
- k        All keyword arguments are placed in the environment for a command, not just those that precede the command name.
- n        Read commands but do not execute them.
- t        Exit after reading and executing one command.
- u        Treat unset variables as an error when substituting.
- v        Print shell input lines as they are read.
- x        Print commands and their arguments as they are executed.
- Do not change any of the flags; useful in setting `$1` to `-`.

Using `+` rather than `-` causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags may be found in `$-`. The remaining arguments are positional parameters and are assigned, in order, to `$1`, `$2`, ... If no arguments are given, the values of all names are printed.

`shift [ n ]`

The positional parameters from `$n+1` ... are renamed `$1` ... . If *n* is not given, it is assumed to be 1.

`stop pid ...`

Halt execution of the process number *pid*. (see [ps\(1\)](#)).

`suspend`

Stops the execution of the current shell (but not if it is the login shell).

`test`

Evaluate conditional expressions. See [test\(1\)](#) for usage and description.

`times`

Print the accumulated user and system times for processes run from the shell.

sh(1)

`trap [ argument n [ n2 ... ]`

The command *argument* is to be read and executed when the shell receives numeric or symbolic signal(s) (*n*). (*Note: argument* is scanned once when the trap is set and once when the trap is taken.) Trap commands are executed in order of signal number or corresponding symbolic names. Any attempt to set a trap on a signal that was ignored on entry to the current shell is ineffective. An attempt to trap on signal 11 (memory fault) produces an error. If *argument* is absent, all trap(s) *n* are reset to their original values. If *argument* is the null string, this signal is ignored by the shell and by the commands it invokes. If *n* is 0, the command *argument* is executed on exit from the shell. The `trap` command with no arguments prints a list of commands associated with each signal number.

`type [ name ... ]`

For each *name*, indicate how it would be interpreted if used as a command name.

`ulimit [ [-HS] [-a | -cdfnstv] ]`

`ulimit [ [-HS] [-c | -d | -f | -n | -s | -t | -v] ] limit`

`ulimit` prints or sets hard or soft resource limits. These limits are described in `getrlimit(2)`.

If `limit` is not present, `ulimit` prints the specified limits. Any number of limits may be printed at one time. The `-a` option prints all limits.

If `limit` is present, `ulimit` sets the specified limit to `limit`. The string `unlimited` requests the largest valid limit. Limits may be set for only one resource at a time. Any user may set a soft limit to any value below the hard limit. Any user may lower a hard limit. Only a super-user may raise a hard limit. (See `su(1M)`.)

The `-H` option specifies a hard limit. The `-S` option specifies a soft limit. If neither option is specified, `ulimit` will set both limits and print the soft limit.

The following options specify the resource whose limits are to be printed or set. If no option is specified, the file size limit is printed or set.

- `-c` maximum core file size (in 512-byte blocks)
- `-d` maximum size of data segment or heap (in kbytes)
- `-f` maximum file size (in 512-byte blocks)
- `-n` maximum file descriptor plus 1
- `-s` maximum size of stack segment (in kbytes)
- `-t` maximum CPU time (in seconds)
- `-v` maximum size of virtual memory (in kbytes)

Run the `sysdef(1M)` command to obtain the maximum possible limits for your system. The values reported are in hexadecimal, but can be translated into decimal numbers using the `bc(1)` utility. See `swap(1M)`.)

As an example of `ulimit`, to limit the size of a core file dump to 0 Megabytes, type the following:

```
ulimit -c 0
```

```
umask [ nnn ]
```

The user file-creation mask is set to *nnn* (see [umask\(1\)](#)). If *nnn* is omitted, the current value of the mask is printed.

```
unset [ name . . . ]
```

For each *name*, remove the corresponding variable or function value. The variables PATH, PS1, PS2, MAILCHECK, and IFS cannot be unset.

```
wait [ n ]
```

Wait for your background process whose process id is *n* and report its termination status. If *n* is omitted, all your shell's currently active background processes are waited for and the return code will be zero.

### Invocation

If the shell is invoked through [exec\(2\)](#) and the first character of argument zero is -, commands are initially read from `/etc/profile` and from `$HOME/.profile`, if such files exist. Thereafter, commands are read as described below, which is also the case when the shell is invoked as `/usr/bin/sh`. The flags below are interpreted by the shell on invocation only. *Note:* Unless the `-c` or `-s` flag is specified, the first argument is assumed to be the name of a file containing commands, and the remaining arguments are passed as positional parameters to that command file:

|                               |                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-c</code> <i>string</i> | If the <code>-c</code> flag is present commands are read from <i>string</i> .                                                                                                                                                                                                                                                                                            |
| <code>-i</code>               | If the <code>-i</code> flag is present or if the shell input and output are attached to a terminal, this shell is <i>interactive</i> . In this case, TERMINATE is ignored (so that <code>kill 0</code> does not kill an interactive shell) and INTERRUPT is caught and ignored (so that <code>wait</code> is interruptible). In all cases, QUIT is ignored by the shell. |
| <code>-p</code>               | If the <code>-p</code> flag is present, the shell will not set the effective user and group IDs to the real user and group IDs.                                                                                                                                                                                                                                          |
| <code>-r</code>               | If the <code>-r</code> flag is present the shell is a restricted shell (see <a href="#">rsh(1M)</a> ).                                                                                                                                                                                                                                                                   |
| <code>-s</code>               | If the <code>-s</code> flag is present or if no arguments remain, commands are read from the standard input. Any remaining arguments specify the positional parameters. Shell output (except for Special Commands) is written to file descriptor 2.                                                                                                                      |

The remaining flags and arguments are described under the `set` command above.

### Job Control (jsh)

When the shell is invoked as `jsh`, Job Control is enabled in addition to all of the functionality described previously for `sh`. Typically, Job Control is enabled for the interactive shell only. Non-interactive shells typically do not benefit from the added functionality of Job Control.

With Job Control enabled, every command or pipeline the user enters at the terminal is called a *job*. All jobs exist in one of the following states: foreground, background, or stopped. These terms are defined as follows:

1. A job in the foreground has read and write access to the controlling terminal.

sh(1)

2. A job in the background is denied read access and has conditional write access to the controlling terminal (see `stty(1)`).
3. A stopped job is a job that has been placed in a suspended state, usually as a result of a SIGTSTP signal (see `signal.h(3HEAD)`).

Every job that the shell starts is assigned a positive integer, called a *job number* which is tracked by the shell and will be used as an identifier to indicate a specific job. Additionally, the shell keeps track of the *current* and *previous* jobs. The *current job* is the most recent job to be started or restarted. The *previous job* is the first non-current job.

The acceptable syntax for a Job Identifier is of the form:

`%jobid`

where *jobid* may be specified in any of the following formats:

|                                  |                                                                                                                                                                                                                                                         |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>%</code> or <code>+</code> | For the current job.                                                                                                                                                                                                                                    |
| <code>-</code>                   | For the previous job.                                                                                                                                                                                                                                   |
| <code>?&lt;string&gt;</code>     | Specify the job for which the command line uniquely contains <i>string</i> .                                                                                                                                                                            |
| <i>n</i>                         | For job number <i>n</i> .                                                                                                                                                                                                                               |
| <i>pref</i>                      | Where <i>pref</i> is a unique prefix of the command name. For example, if the command <code>ls -l name</code> were running in the background, it could be referred to as <code>%ls.pref</code> . <i>pref</i> cannot contain blanks unless it is quoted. |

When Job Control is enabled, the following commands are added to the user's environment to manipulate jobs:

`bg [%jobid ...]`

Resumes the execution of a stopped job in the background. If *%jobid* is omitted the current job is assumed.

`fg [%jobid ...]`

Resumes the execution of a stopped job in the foreground, also moves an executing background job into the foreground. If *%jobid* is omitted the current job is assumed.

`jobs [-p | -l] [%jobid ...]`

`jobs -x command [arguments]`

Reports all jobs that are stopped or executing in the background. If *%jobid* is omitted, all jobs that are stopped or running in the background will be reported.

The following options will modify/enhance the output of `jobs`:

- `-l` Report the process group ID and working directory of the jobs.
- `-p` Report only the process group ID of the jobs.
- `-x` Replace any *jobid* found in *command* or *arguments* with the corresponding process group ID, and then execute *command* passing it *arguments*.

`kill [ -signal ] %jobid`

Builtin version of `kill` to provide the functionality of the `kill` command for processes identified with a `jobid`.

`stop %jobid ...`

Stops the execution of a background job(s).

`suspend`

Stops the execution of the current shell (but not if it is the login shell).

`wait [%jobid ...]`

`wait` builtin accepts a job identifier. If `%jobid` is omitted `wait` behaves as described above under `Special Commands`.

### Large File Behavior

See `largefile(5)` for the description of the behavior of `sh` and `jsh` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

### EXIT STATUS

Errors detected by the shell, such as syntax errors, cause the shell to return a non-zero exit status. If the shell is being used non-interactively execution of the shell file is abandoned. Otherwise, the shell returns the exit status of the last command executed (see also the `exit` command above).

### jsh Only

If the shell is invoked as `jsh` and an attempt is made to exit the shell while there are stopped jobs, the shell issues one warning:

There are stopped jobs.

This is the only message. If another exit attempt is made, and there are still stopped jobs they will be sent a `SIGHUP` signal from the kernel and the shell is exited.

### FILES

`$HOME/.profile`

`/dev/null`

`/etc/profile`

`/tmp/sh*`

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

`/usr/bin/sh`,  
`/usr/bin/jsh`

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | Enabled         |

`/usr/xpg4/bin/sh`

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWxcu4        |

sh(1)

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| CSI            | Enabled         |

**SEE ALSO** [intro\(1\)](#), [bc\(1\)](#), [echo\(1\)](#), [getoptcvt\(1\)](#), [kill\(1\)](#), [ksh\(1\)](#), [login\(1\)](#), [newgrp\(1\)](#), [pfsh\(1\)](#), [pfexec\(1\)](#), [ps\(1\)](#), [pwd\(1\)](#), [set\(1\)](#), [shell\\_builtins\(1\)](#), [stty\(1\)](#), [test\(1\)](#), [umask\(1\)](#), [wait\(1\)](#), [rsh\(1M\)](#), [su\(1M\)](#), [swap\(1M\)](#), [sysdef\(1M\)](#), [dup\(2\)](#), [exec\(2\)](#), [fork\(2\)](#), [getrlimit\(2\)](#), [pipe\(2\)](#), [ulimit\(2\)](#), [setlocale\(3C\)](#), [signal.h\(3HEAD\)](#), [passwd\(4\)](#), [profile\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [XPG4\(5\)](#)

**WARNINGS** The use of `setuid` shell scripts is *strongly* discouraged.

**NOTES** Words used for filenames in input/output redirection are not interpreted for filename generation (see [File Name Generation](#) section above). For example, `cat file1 >a*` will create a file named `a*`.

Because commands in pipelines are run as separate processes, variables set in a pipeline have no effect on the parent shell.

If the input or the output of a `while` or `until` loop is redirected, the commands in the loop are run in a sub-shell, and variables set or changed there have no effect on the parent process:

```
lastline=
while read line
do

    lastline=$line
done < /etc/passwd
echo "lastline=$lastline"      # lastline is empty!
```

In these cases, the input or output can be redirected by using `exec`, as in the following example:

```
# Save standard input (file descriptor 0) as file
# descriptor 3, and redirect standard input from the file
/etc/passwd:

exec 3<&0                # save standard input as fd 3
exec </etc/passwd       # redirect input from file

lastline=
while read line
do

    lastline=$line
done

exec 0<&3                # restore standard input
exec 3<&-                # close file descriptor 3
echo "$lastline"        # lastline
```

If you get the error message, “cannot fork, too many processes”, try using the `wait(1)` command to clean up your background processes. If this doesn't help, the system process table is probably full or you have too many active foreground processes. There is a limit to the number of process ids associated with your login, and to the number the system can keep track of.

Only the last process in a pipeline can be waited for.

If a command is executed, and a command with the same name is installed in a directory in the search path before the directory where the original command was found, the shell will continue to `exec` the original command. Use the `hash` command to correct this situation.

The Bourne shell has a limitation on the effective UID for a process. If this UID is less than 100 (and not equal to the real UID of the process), then the UID is reset to the real UID of the process.

Because the shell implements both foreground and background jobs in the same process group, they all receive the same signals, which can lead to unexpected behavior. It is, therefore, recommended that other job control shells be used, especially in an interactive environment.

When the shell executes a shell script that attempts to execute a non-existent command interpreter, the shell returns an erroneous diagnostic message that the shell script file does not exist.

shell(1F)

**NAME** shell – run a command using shell

**SYNOPSIS** `shell command [command] ...`

**DESCRIPTION** The `shell` function concatenate its arguments, separating each by a space, and passes this string to the shell (`$SHELL` if set, otherwise `/usr/bin/sh`).

**EXAMPLES** **EXAMPLE 1** A sample output of `shell` command.

Since the Form and Menu Language does not directly support background processing, the `shell` function can be used instead.

```
`shell "build prog > /dev/null &"`
```

If you want the user to continue to be able to interact with the application while the background job is running, the output of an executable run by `shell` in the background must be redirected: to a file if you want to save the output, or to `/dev/null` if you don't want to save it (or if there is no output), otherwise your application may appear to be hung until the background job finishes processing.

`shell` can also be used to execute a command that has the same name as an FMLI built-in function.

**NOTES** The arguments to `shell` will be concatenate using spaces, which may or may not do what is expected. The variables set in local environments will not be expanded by the shell because "local" means "local to the current process."

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `sh(1)`, `attributes(5)`

**NAME** shell\_builtins, case, for, foreach, function, if, repeat, select, switch, until, while – shell command interpreter built-in commands

**DESCRIPTION** The shell command interpreters `cs(1)`, `ksh(1)`, and `sh(1)` have special built-in commands. The commands `case`, `for`, `foreach`, `function`, `if`, `repeat`, `select`, `switch`, `until`, and `while` are commands in the syntax recognized by the shells. They are described in the Commands section of the manual pages of the respective shells. The remaining commands listed in the table below are built into the shells for reasons such as efficiency or data sharing between command invocations. They are described on their respective manual pages.

| Command  | Shell       |
|----------|-------------|
| alias    | cs, ksh     |
| bg       | cs, ksh, sh |
| break    | cs, ksh, sh |
| case     | cs, ksh, sh |
| cd       | cs, ksh, sh |
| chdir    | cs, sh      |
| continue | cs, ksh, sh |
| dirs     | cs          |
| echo     | cs, ksh, sh |
| eval     | cs, ksh, sh |
| exec     | cs, ksh, sh |
| exit     | cs, ksh, sh |
| export   | ksh, sh     |
| fc       | ksh         |
| fg       | cs, ksh, sh |
| for      | ksh, sh     |
| foreach  | cs          |
| function | ksh         |
| getopts  | ksh, sh     |
| glob     | cs          |
| goto     | cs          |
| hash     | ksh, sh     |

shell\_builtins(1)

| Command  | Shell        |

| unalias  | cs, ksh     |
| unhash   | cs          |
| unlimit  | cs          |
| unset    | cs, ksh, sh |
| unsetenv | cs          |
| until    | ksh, sh     |
| wait     | cs, ksh, sh |
| whence   | ksh         |
| while    | cs, ksh, sh |

### Bourne Shell, sh, Special Commands

Input/output redirection is now permitted for these commands. File descriptor 1 is the default output location. When Job Control is enabled, additional *Special Commands* are added to the shell's environment.

In addition to these built-in reserved command words, sh also uses:

:                   No effect; the command does nothing. A zero exit code is returned.

.*filename*        Read and execute commands from *filename* and return. The search path specified by PATH is used to find the directory containing *filename*.

### C shell, csh

Built-in commands are executed within the C shell. If a built-in command occurs as any component of a pipeline except the last, it is executed in a subshell. In addition to these built-in reserved command words, csh also uses:

:                   Null command. This command is interpreted, but performs no action.

shell\_builtins(1)

**Korn Shell, ksh,  
Special Commands**

Input/Output redirection is permitted. Unless otherwise indicated, the output is written on file descriptor 1 and the exit status, when there is no syntax error, is zero.

Commands that are preceded by one or two \* (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by \*\* that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

In addition to these built-in reserved command words, ksh also uses:

- \* : [ *arg* ... ]      The command only expands parameters.
- \* .*file* [ *arg* ... ]      Read the complete *file* then execute the commands. The commands are executed in the current shell environment. The search path specified by `PATH` is used to find the directory containing *file*. If any arguments *arg* are given, they become the positional parameters. Otherwise, the positional parameters are unchanged. The exit status is the exit status of the last command executed. the loop termination test.

| <b>SYNOPSIS</b>    | <pre>sh  shift [n] csh  shift [variable] ksh  * shift [n]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |              |         |
| <b>DESCRIPTION</b> | <p><b>sh</b> The positional parameters from <math>\\$n+1 \dots</math> are renamed <math>\\$1 \dots</math>. If <math>n</math> is not given, it is assumed to be 1.</p> <p><b>csh</b> The components of <i>argv</i>, or <i>variable</i>, if supplied, are shifted to the left, discarding the first component. It is an error for the variable not to be set or to have a null value.</p> <p><b>ksh</b> The positional parameters from <math>\\$n+1 \dots</math> are renamed <math>\\$1 \dots</math>, default <math>n</math> is 1. The parameter <math>n</math> can be any arithmetic expression that evaluates to a non-negative number less than or equal to <math>\\$#</math>.</p> <p>On this man page, <a href="#">ksh(1)</a> commands that are preceded by one or two * (asterisks) are treated specially in the following ways:</p> <ol style="list-style-type: none"> <li>1. Variable assignment lists preceding the command remain in effect when the command completes.</li> <li>2. I/O redirections are processed after variable assignments.</li> <li>3. Errors cause a script that contains them to abort.</li> <li>4. Words, following a command preceded by ** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.</li> </ol> |                |                 |              |         |
| <b>ATTRIBUTES</b>  | See <a href="#">attributes(5)</a> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |              |         |

| <b>SYNOPSIS</b>    | <code>/usr/ucb/shutdown [-fhknr] time [warning-message...]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |          |
| <b>DESCRIPTION</b> | <p>shutdown provides an automated procedure to notify users when the system is to be shut down. <code>time</code> specifies when shutdown will bring the system down; it may be the word <code>now</code> (indicating an immediate shutdown), or it may specify a future time in one of two formats: <code>+number</code> and <code>hour:minute</code>. The first form brings the system down in <code>number</code> minutes, and the second brings the system down at the time of day indicated in 24-hour notation.</p> <p>At intervals that get closer as the apocalypse approaches, warning messages are displayed at terminals of all logged-in users, and of users who have remote mounts on that machine.</p> <p>At shutdown time a message is written to the system log daemon, <code>syslogd(1M)</code>, containing the time of shutdown, the instigator of the shutdown, and the reason. Then a terminate signal is sent to <code>init</code>, which brings the system down to single-user mode.</p> |                |                 |              |          |
| <b>OPTIONS</b>     | <p>As an alternative to the above procedure, these options can be specified:</p> <ul style="list-style-type: none"><li>-f Arrange, in the manner of <code>fastboot(1B)</code>, that when the system is rebooted, the file systems will not be checked.</li><li>-h Execute <code>halt(1M)</code>.</li><li>-k Simulate shutdown of the system. Do not actually shut down the system.</li><li>-n Prevent the normal <code>sync(2)</code> before stopping.</li><li>-r Execute <code>reboot(1M)</code>.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |              |          |

| <b>NAME</b>        | size – print section sizes in bytes of object files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <b>size</b> [-f] [-F] [-n] [-o] [-V] [-x] <i>filename...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>The <code>size</code> command produces segment or section size information in bytes for each loaded section in ELF object files. <code>size</code> prints out the size of the text, data, and bss (uninitialized data) segments (or sections) and their total.</p> <p><code>size</code> processes ELF object files entered on the command line. If an archive file is input to the <code>size</code> command, the information for each object file in the archive is displayed.</p> <p>When calculating segment information, the <code>size</code> command prints out the total file size of the non-writable segments, the total file size of the writable segments, and the total memory size of the writable segments minus the total file size of the writable segments.</p> <p>If it cannot calculate segment information, <code>size</code> calculates section information. When calculating section information, it prints out the total size of sections that are allocatable, non-writable, and not NOBITS, the total size of the sections that are allocatable, writable, and not NOBITS, and the total size of the writable sections of type NOBITS. NOBITS sections do not actually take up space in the <i>filename</i>.</p> <p>If <code>size</code> cannot calculate either segment or section information, it prints an error message and stops processing the file.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-f Prints out the size of each allocatable section, the name of the section, and the total of the section sizes. If there is no section data, <code>size</code> prints out an error message and stops processing the file.</li> <li>-F Prints out the size of each loadable segment, the permission flags of the segment, then the total of the loadable segment sizes. If there is no segment data, <code>size</code> prints an error message and stops processing the file.</li> <li>-n Prints out non-loadable segment or non-allocatable section sizes. If segment data exists, <code>size</code> prints out the memory size of each loadable segment or file size of each non-loadable segment, the permission flags, and the total size of the segments. If there is no segment data, <code>size</code> prints out, for each allocatable and non-allocatable section, the memory size, the section name, and the total size of the sections. If there is no segment or section data, <code>size</code> prints an error message and stops processing.</li> <li>-o Prints numbers in octal, not decimal.</li> <li>-V Prints the version information for the <code>size</code> command on the standard error output.</li> <li>-x Prints numbers in hexadecimal, not decimal.</li> </ul>              |
| <b>EXAMPLES</b>    | The examples below are typical <code>size</code> output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

size(1)

**EXAMPLE 1** Producing size information

```
example% size filename
2724 + 88 + 0 = 2812
```

**EXAMPLE 2** Producing allocatable section size information

```
example% size -f filename
26(.text) + 5(.init) + 5(.fini) = 36
```

**EXAMPLE 3** Producing loadable segment size information

```
example% size -F filename
2724(r-x) + 88(rwx) + 0(rwx) = 2812 ... (If statically linked)
```

| <b>SYNOPSIS</b>              | <b>sleep</b> <i>time</i>                                                                                                                                                                                                                                                                                                           |                |                 |              |         |                     |          |
| <b>DESCRIPTION</b>           | The <code>sleep</code> utility will suspend execution for at least the integral number of seconds specified by the <i>time</i> operand.                                                                                                                                                                                            |                |                 |              |         |                     |          |
| <b>OPERANDS</b>              | The following operands are supported:<br><br><i>time</i> A non-negative decimal integer specifying the number of seconds for which to suspend execution.                                                                                                                                                                           |                |                 |              |         |                     |          |
| <b>EXAMPLES</b>              | <b>EXAMPLE 1</b> Suspending command execution for a time<br><br>To execute a command after a certain amount of time:<br><br>example% ( <b>sleep 105; command</b> ) &<br><br><b>EXAMPLE 2</b> Executing a command every so often<br><br>example% <b>while true</b><br><b>do</b><br><i>command</i><br><b>sleep 37</b><br><b>done</b> |                |                 |              |         |                     |          |
| <b>ENVIRONMENT VARIABLES</b> | See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>sleep</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .                                                                      |                |                 |              |         |                     |          |
| <b>EXIT STATUS</b>           | The following exit values are returned:<br><br>0            The execution was successfully suspended for at least <i>time</i> seconds, or a <code>SIGALRM</code> signal was received (see <b>NOTES</b> ).<br><br>>0          An error has occurred.                                                                                |                |                 |              |         |                     |          |
| <b>ATTRIBUTES</b>            | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                       |                |                 |              |         |                     |          |

| <b>NOTES</b>                 | If the <code>sleep</code> utility receives a <code>SIGALRM</code> signal, one of the following actions will be taken: <ul style="list-style-type: none"> <li>■ Terminate normally with a zero exit status.</li> <li>■ Effectively ignore the signal.</li> </ul>                                                                    |                |                 |              |         |                     |          |

sleep(1)

The `sleep` utility will take the standard action for all other signals.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>NAME</b>        | snmpstatus – retrieve important information from a network entity                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>    | <code>/usr/sfw/bin/snmpstatus</code> [ <i>common options</i> ] [-Cf] <i>agent</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | <p>The <code>snmpstatus</code> command is an SNMP application that retrieves several important statistics from a network entity.</p> <p>The <i>agent</i> operand identifies a target SNMP agent, which is instrumented to monitor specified objects. At its simplest, the <i>agent</i> specification consists of a host name or an IPv4 address. In this situation, the command attempts communication with the agent using UDP/IPv4 to port 161 of the target host.</p> <p>See the <code>snmpcmd(1M)</code> manual page for a full list of the possible formats for <i>agent</i>.</p> <p><code>snmpstatus</code> returns the following information:</p> <ul style="list-style-type: none"> <li>■ the IP address of the entity</li> <li>■ a textual description of the entity (<code>sysDescr.0</code>)</li> <li>■ the uptime of the entity's SNMP agent (<code>sysUpTime.0</code>)</li> <li>■ the sum of received packets on all interfaces (<code>ifInUCastPkts.* + ifInNUCastPkts.*</code>)</li> <li>■ the sum of transmitted packets on all interfaces (<code>ifOutUCastPkts.* + ifOutNUCastPkts.*</code>)</li> <li>■ the number of IP input packets (<code>ipInReceives.0</code>)</li> <li>■ the number of IP output packets (<code>ipOutRequests.0</code>)</li> </ul> <p>For example, the command:</p> <pre>% snmpstatus -c public -v 1 netdev-kbox.cc.cmu.edu</pre> <p>produces output similar to the following:</p> <pre>[128.2.56.220]=&gt;[Kinetics FastPath2] Up: 1 day, 4:43:31 Interfaces: 1, Recv/Trans packets: 262874/39867   IP: 31603/15805</pre> <p><code>snmpstatus</code> also checks the operational status of all interfaces (<code>ifOperStatus.*</code>). If it finds any that are not running, it reports them in a manner similar to this:</p> <pre>2 interfaces are down!</pre> <p>If the network entity has an error processing the request packet, an error packet is returned and a message is displayed, helping to pinpoint the way in which the request was malformed. <code>snmpstatus</code> will attempt to reform its request to eliminate the malformed variable (unless the <code>-Cf</code> option is given, see below), but this variable will then be missing from the displayed data.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><i>common options</i></p> <p>See <code>snmpcmd(1M)</code> for a list of possible values for <i>common options</i>, as well as their descriptions.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## snmpstatus(1)

-Cf

By default, `snmpstatus` will try to fix errors returned by the agent and retry a request. With this option, the command will display the data that it can. `snmpstatus` will not try to fix errors and an error will cause the command to terminate.

### EXIT STATUS

0

Successful completion.

1

A usage syntax error. A usage message is displayed. Also used for timeout errors.

2

An error occurred while executing the command. An error message is displayed.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |

| <b>SYNOPSIS</b>    | <b>soelim</b> [ <i>filename...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>soelim reads the specified files or the standard input and performs the textual inclusion implied by the <a href="#">nroff(1)</a> directives of the form</p> <pre>.so <i>somefile</i></pre> <p>when they appear at the beginning of input lines. This is useful since programs such as <a href="#">tbl(1)</a> do not normally do this; it allows the placement of individual tables in separate files to be run as a part of a large document.</p> <p>An argument consisting of '-' is taken to be a file name corresponding to the standard input.</p> <p>Note: Inclusion can be suppressed by using ' ' instead of ' . ', that is,</p> <pre>' so /usr/share/lib/tmac/tmac.s</pre> |                |                 |              |         |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> A sample of the soelim command.</p> <p>A sample usage of soelim would be</p> <pre>example% soelim exum?.n   tbl   nroff -ms   col   lpr</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |         |

| <b>DESCRIPTION</b>        | <p>The <code>sort</code> command sorts lines of all the named files together and writes the result on the standard output.</p> <p>Comparisons are based on one or more sort keys extracted from each line of input. By default, there is one sort key, the entire input line. Lines are ordered according to the collating sequence of the current locale.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>OPTIONS</b>            | The following options alter the default behavior:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>/usr/bin/sort</b>      | <p><b>-c</b> Checks that the single input file is ordered as specified by the arguments and the collating sequence of the current locale. The exit code is set and no output is produced unless the file is out of sort.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>/usr/xpg4/bin/sort</b> | <p><b>-c</b> Same as <code>/usr/bin/sort</code> except no output is produced under any circumstances.</p> <p><b>-m</b> Merges only. The input files are assumed to be already sorted.</p> <p><b>-o <i>output</i></b> Specifies the name of an output file to be used instead of the standard output. This file can be the same as one of the input files.</p> <p><b>-S <i>kmem</i></b> Specifies the maximum amount of swap-based memory used for sorting, in kilobytes (the default unit). <i>kmem</i> can also be specified directly as a number of bytes (b), kilobytes (k), megabytes (m), gigabytes (g), or terabytes (t); or as a percentage (%) of the installed physical memory.</p> <p><b>-T <i>directory</i></b> Specifies the <i>directory</i> in which to place temporary files.</p> <p><b>-u</b> Unique: suppresses all but one in each set of lines having equal keys. If used with the <code>-c</code> option, checks that there are no lines with duplicate keys in addition to checking that the input file is sorted.</p> <p><b>-y <i>kmem</i></b> (obsolete). This option was used to specify the amount of main memory initially used by <code>sort</code>. Its functionality is not appropriate for a virtual memory system; memory usage for <code>sort</code> is now specified using the <code>-S</code> option.</p> <p><b>-z <i>recsz</i></b> (obsolete). This option was used to prevent abnormal termination when lines longer than the system-dependent default buffer size are encountered. Because <code>sort</code> automatically allocates buffers large enough to hold the longest line, this option has no effect.</p> |

**Ordering Options**

The default sort order depends on the value of `LC_COLLATE`. If `LC_COLLATE` is set to `C`, sorting will be in ASCII order. If `LC_COLLATE` is set to `en_US`, sorting is case insensitive except when the two strings are otherwise equal and one has an uppercase letter earlier than the other. Other locales will have other sort orders.

The following options override the default ordering rules. When ordering options appear independent of any key field specifications, the requested field ordering rules are applied globally to all sort keys. When attached to a specific key (see *Sort Key Options*), the specified ordering options override all global ordering options for that key. In the obsolescent forms, if one or more of these options follows a *+pos1* option, it will affect only the key field specified by that preceding option.

- d           “Dictionary” order: only letters, digits, and blanks (spaces and tabs) are significant in comparisons.
- f           Folds lower-case letters into upper case.
- i           Ignores non-printable characters.
- M           Compares as months. The first three non-blank characters of the field are folded to upper case and compared. For example, in English the sorting order is "JAN" < "FEB" < . . . < "DEC". Invalid fields compare low to "JAN". The `-M` option implies the `-b` option (see below).
- n           Restricts the sort key to an initial numeric string, consisting of optional blank characters, optional minus sign, and zero or more digits with an optional radix character and thousands separators (as defined in the current locale), which will be sorted by arithmetic value. An empty digit string is treated as zero. Leading zeros and signs on zeros do not affect ordering.
- r           Reverses the sense of comparisons.

**Field Separator Options**

The treatment of field separators can be altered using the following options:

- b           Ignores leading blank characters when determining the starting and ending positions of a restricted sort key. If the `-b` option is specified before the first sort key option, it is applied to all sort key options. Otherwise, the `-b` option can be attached independently to each `-k field_start, field_end`, or *+pos1* or *-pos2* option-argument (see below).
- t *char*    Use *char* as the field separator character. *char* is not considered to be part of a field (although it can be included in a sort key). Each occurrence of *char* is significant (for example, `<char><char>` delimits an empty field). If `-t` is not specified, blank characters are used as default field separators; each maximal non-empty sequence of blank characters that follows a non-blank character is a field separator.

sort(1)

### Sort Key Options

Sort keys can be specified using the options:

`-k keydef`      The *keydef* argument is a restricted sort key field definition. The format of this definition is:

`-k field_start [type] [,field_end [type] ]`

where:

*field\_start* and *field\_end*

define a key field restricted to a portion of the line.

*type*

is a modifier from the list of characters `bdfiMnr`. The `b` modifier behaves like the `-b` option, but applies only to the *field\_start* or *field\_end* to which it is attached and characters within a field are counted from the first non-blank character in the field. (This applies separately to *first\_character* and *last\_character*.) The other modifiers behave like the corresponding options, but apply only to the key field to which they are attached. They have this effect if specified with *field\_start*, *field\_end* or both. If any modifier is attached to a *field\_start* or to a *field\_end*, no option applies to either.

When there are multiple key fields, later keys are compared only after all earlier keys compare equal. Except when the `-u` option is specified, lines that otherwise compare equal are ordered as if none of the options `-d`, `-f`, `-i`, `-n` or `-k` were present (but with `-r` still in effect, if it was specified) and with all bytes in the lines significant to the comparison.

The notation:

`-k field_start [type] [,field_end [type] ]`

defines a key field that begins at *field\_start* and ends at *field\_end* inclusive, unless *field\_start* falls beyond the end of the line or after *field\_end*, in which case the key field is empty. A missing *field\_end* means the last character of the line.

A field comprises a maximal sequence of non-separating characters and, in the absence of option `-t`, any preceding field separator.

The *field\_start* portion of the *keydef* option-argument has the form:

`field_number [.first_character]`

Fields and characters within fields are numbered starting with 1. *field\_number* and *first\_character*, interpreted as positive decimal integers, specify the first character to be used as part of a sort key. If *first\_character* is omitted, it refers to the first character of the field.

The *field\_end* portion of the *keydef* option-argument has the form:

```
field_number [. last_character]
```

The *field\_number* is as described above for *field\_start*. *last\_character*, interpreted as a non-negative decimal integer, specifies the last character to be used as part of the sort key. If *last\_character* evaluates to zero or *last\_character* is omitted, it refers to the last character of the field specified by *field\_number*.

If the *-b* option or *b* type modifier is in effect, characters within a field are counted from the first non-blank character in the field. (This applies separately to *first\_character* and *last\_character*.)

[*+pos1* [*-pos2*]] (obsolete). Provide functionality equivalent to the *-kkeydef* option.

*pos1* and *pos2* each have the form *m.n* optionally followed by one or more of the flags *bdfiMnr*. A starting position specified by *+m.n* is interpreted to mean the *n*+1st character in the *m*+1st field. A missing *.n* means *.0*, indicating the first character of the *m*+1st field. If the *b* flag is in effect *n* is counted from the first non-blank in the *m*+1st field; *+m.0b* refers to the first non-blank character in the *m*+1st field.

A last position specified by *-m.n* is interpreted to mean the *n*th character (including separators) after the last character of the *m*th field. A missing *.n* means *.0*, indicating the last character of the *m*th field. If the *b* flag is in effect *n* is counted from the last leading blank in the *m*+1st field; *-m.1b* refers to the first non-blank in the *m*+1st field.

The fully specified *+pos1 -pos2* form with type modifiers *T* and *U*:

```
+w.xT -y.zU
```

is equivalent to:

```
undefined          (z==0 & U contains b & -t is present)
-k w+1.x+1T,y.0U   (z==0 otherwise)
-k w+1.x+1T,y+1.zU (z > 0)
```

Implementations support at least nine occurrences of the sort keys (the *-k* option and obsolescent *+pos1* and *-pos2*) which are significant in command line order. If no sort key is specified, a default sort key of the entire line is used.

**OPERANDS** The following operand is supported:

*file* A path name of a file to be sorted, merged or checked. If no *file* operands are specified, or if a *file* operand is *-*, the standard input will be used.

sort(1)

**USAGE** See `largefile(5)` for the description of the behavior of `sort` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**EXAMPLES** In the following examples, first the preferred and then the obsolete way of specifying `sort` keys are given as an aid to understanding the relationship between the two forms.

**EXAMPLE 1** Sorting with the second field as a sort key

Either of the following commands sorts the contents of `infile` with the second field as the sort key:

```
example% sort -k 2,2 infile
example% sort +1 -2 infile
```

**EXAMPLE 2** Sorting in reverse order

Either of the following commands sorts, in reverse order, the contents of `infile1` and `infile2`, placing the output in `outfile` and using the second character of the second field as the sort key (assuming that the first character of the second field is the field separator):

```
example% sort -r -o outfile -k 2.2,2.2 infile1 infile2
example% sort -r -o outfile +1.1 -1.2 infile1 infile2
```

**EXAMPLE 3** Sorting using a specified character in one of the files

Either of the following commands sorts the contents of `infile1` and `infile2` using the second non-blank character of the second field as the sort key:

```
example% sort -k 2.2b,2.2b infile1 infile2
example% sort +1.1b -1.2b infile1 infile2
```

**EXAMPLE 4** Sorting by numeric user ID

Either of the following commands prints the `passwd(4)` file (user database) sorted by the numeric user ID (the third colon-separated field):

```
example% sort -t : -k 3,3n /etc/passwd
example% sort -t : +2 -3n /etc/passwd
```

**EXAMPLE 5** Printing sorted lines excluding lines that duplicate a field

Either of the following commands prints the lines of the already sorted file `infile`, suppressing all but one occurrence of lines having the same third field:

```
example% sort -um -k 3.1,3.0 infile
example% sort -um +2.0 -3.0 infile
```

**EXAMPLE 6** Sorting by host IP address

Either of the following commands prints the `hosts(4)` file (IPv4 hosts database), sorted by the numeric IP address (the first four numeric fields):

```
example$ sort -t . -k 1,1n -k 2,2n -k 3,3n -k 4,4n /etc/hosts
example$ sort -t . +0 -1n +1 -2n +2 -3n +3 -4n /etc/hosts
```

Since `'.'` is both the field delimiter and, in many locales, the decimal separator, failure to specify both ends of the field will lead to results where the second field is interpreted as a fractional portion of the first, and so forth.

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `sort`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_MESSAGES`, and `NLSPATH`.

- `LC_CTYPE` Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single- versus multi-byte characters in arguments and input files) and the behavior of character classification for the `-b`, `-d`, `-f`, `-i` and `-n` options.
- `LC_NUMERIC` Determine the locale for the definition of the radix character and thousands separator for the `-n` option.

**EXIT STATUS**

The following exit values are returned:

- 0 All input files were output successfully, or `-c` was specified and the input file was correctly sorted.
- 1 Under the `-c` option, the file was not ordered as specified, or if the `-c` and `-u` options were both specified, two input lines were found with equal keys.
- >1 An error occurred.

**FILES**

`/var/tmp/stm???` temporary files

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

**/usr/bin/sort**

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWesu         |
| CSI            | Enabled         |

**/usr/xpg4/bin/sort**

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWxcu4        |
| CSI                 | Enabled         |
| Interface Stability | Standard        |

sort(1)

**SEE ALSO** [comm\(1\)](#), [join\(1\)](#), [uniq\(1\)](#), [nl\\_langinfo\(3C\)](#), [strftime\(3C\)](#), [hosts\(4\)](#), [passwd\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

**DIAGNOSTICS** Comments and exits with non-zero status for various trouble conditions (for example, when input lines are too long), and for disorders discovered under the `-c` option.

**NOTES** When the last line of an input file is missing a new-line character, `sort` appends one, prints a warning message, and continues.

`sort` does not guarantee preservation of relative line ordering on equal keys.

One can tune `sort` performance for a specific scenario using the `-S` option. However, one should note in particular that `sort` has greater knowledge of how to use a finite amount of memory for sorting than the virtual memory system. Thus, a `sort` invoked to request an extremely large amount of memory via the `-S` option could perform extremely poorly.

As noted, certain of the field modifiers (such as `-M` and `-d`) cause the interpretation of input data to be done with reference to locale-specific settings. The results of this interpretation can be unexpected if one's expectations are not aligned with the conventions established by the locale. In the case of the month keys, `sort` does not attempt to compensate for "approximate" month abbreviations. The precise month abbreviations from [nl\\_langinfo\(3C\)](#) or [strftime\(3C\)](#) are the only ones recognized. For printable or dictionary order, if these concepts are not well-defined by the locale, an empty sort key may be the result, leading to the next key being the significant one for determining the appropriate ordering.

| <b>DESCRIPTION</b> | <p>sortbib sorts files of records containing <i>refer</i> key-letters by user-specified keys. Records may be separated by blank lines, or by ‘. [‘ and ‘.]’ delimiters, but the two styles may not be mixed together. This program reads through each <i>database</i> and pulls out key fields, which are sorted separately. The sorted key fields contain the file pointer, byte offset, and length of corresponding records. These records are delivered using disk seeks and reads, so <i>sortbib</i> may not be used in a pipeline to read standard input.</p> <p>The most common key-letters and their meanings are given below.</p> <table> <tr><td>%A</td><td>Author’s name</td></tr> <tr><td>%B</td><td>Book containing article referenced</td></tr> <tr><td>%C</td><td>City (place of publication)</td></tr> <tr><td>%D</td><td>Date of publication</td></tr> <tr><td>%E</td><td>Editor of book containing article referenced</td></tr> <tr><td>%F</td><td>Footnote number or label (supplied by <i>refer</i>)</td></tr> <tr><td>%G</td><td>Government order number</td></tr> <tr><td>%H</td><td>Header commentary, printed before reference</td></tr> <tr><td>%I</td><td>Issuer (publisher)</td></tr> <tr><td>%J</td><td>Journal containing article</td></tr> <tr><td>%K</td><td>Keywords to use in locating reference</td></tr> <tr><td>%L</td><td>Label field used by -k option of <i>refer</i></td></tr> <tr><td>%M</td><td>Bell Labs Memorandum (undefined)</td></tr> <tr><td>%N</td><td>Number within volume</td></tr> <tr><td>%O</td><td>Other commentary, printed at end of reference</td></tr> <tr><td>%P</td><td>Page number(s)</td></tr> <tr><td>%Q</td><td>Corporate or Foreign Author (unreversed)</td></tr> <tr><td>%R</td><td>Report, paper, or thesis (unpublished)</td></tr> <tr><td>%S</td><td>Series title</td></tr> <tr><td>%T</td><td>Title of article or book</td></tr> <tr><td>%V</td><td>Volume number</td></tr> <tr><td>%X</td><td>Abstract — used by <i>roffbib</i>, not by <i>refer</i></td></tr> <tr><td>%Y, Z</td><td>Ignored by <i>refer</i></td></tr> </table> | %A | Author’s name | %B | Book containing article referenced | %C | City (place of publication) | %D | Date of publication | %E | Editor of book containing article referenced | %F | Footnote number or label (supplied by <i>refer</i> ) | %G | Government order number | %H | Header commentary, printed before reference | %I | Issuer (publisher) | %J | Journal containing article | %K | Keywords to use in locating reference | %L | Label field used by -k option of <i>refer</i> | %M | Bell Labs Memorandum (undefined) | %N | Number within volume | %O | Other commentary, printed at end of reference | %P | Page number(s) | %Q | Corporate or Foreign Author (unreversed) | %R | Report, paper, or thesis (unpublished) | %S | Series title | %T | Title of article or book | %V | Volume number | %X | Abstract — used by <i>roffbib</i> , not by <i>refer</i> | %Y, Z | Ignored by <i>refer</i> |

## sortbib(1)

By default, `sortbib` alphabetizes by the first `%A` and the `%D` fields, which contain the senior author and date.

`sortbib` sorts on the last word on the `%A` line, which is assumed to be the author's last name. A word in the final position, such as 'jr.' or 'ed.', will be ignored if the name beforehand ends with a comma. Authors with two-word last names or unusual constructions can be sorted correctly by using the `nroff` convention '\0' in place of a blank. A `%Q` field is considered to be the same as `%A`, except sorting begins with the first, not the last, word. `sortbib` sorts on the last word of the `%D` line, usually the year. It also ignores leading articles (like 'A' or 'The') when sorting by titles in the `%T` or `%J` fields; it will ignore articles of any modern European language. If a sort-significant field is absent from a record, `sortbib` places that record before other records containing that field.

No more than 16 databases may be sorted together at one time. Records longer than 4096 characters will be truncated.

**OPTIONS** `-sKEYS` Specify new *KEYS*. For instance, `-sATD` will sort by author, title, and date, while `-sA+D` will sort by all authors, and date. Sort keys past the fourth are not meaningful.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWdoc         |

**SEE ALSO** `addbib(1)`, `indxbib(1)`, `lookbib(1)`, `refer(1)`, `roffbib(1)`, `attributes(5)`

**BUGS** Records with missing author fields should probably be sorted by title.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>NAME</b>        | sotruss – trace shared library procedure calls                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <code>/usr/bin/sotruss [-f] [-F <i>bindfromlist</i>] [-T <i>bindtolist</i>] [-o <i>outputfile</i>]<br/>executable [ executable arguments...]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | sotruss executes the specified command and produces a trace of the library calls that it performs. Each line of the trace output reports what bindings are occurring between dynamic objects as each procedure call is executed. sotruss traces all of the procedure calls that occur between dynamic objects via the <i>Procedure Linkage Table</i> , so only those procedure calls which are bound via the <i>Procedure Linkage Table</i> will be traced. See <i>Linker and Libraries Guide</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>OPTIONS</b>     | <p><code>-F <i>bindfromlist</i></code>            A colon-separated list of libraries that are to be traced. Only calls from these libraries will be traced. The default is to trace calls from the main executable only.</p> <p><code>-T <i>bindtolist</i></code>            A colon-separated list of libraries that are to be traced. Only calls to these libraries will be traced. The default is to trace all calls.</p> <p><code>-o <i>outputfile</i></code>            sotruss output will be directed to the <i>outputfile</i>. If this option is combined with the <code>-f</code> option then the <i>pid</i> of the executing program will be placed at the end of the filename. By default sotruss output is placed on <code>stderr</code>.</p> <p><code>-f</code>                            Follow all children created by <code>fork()</code> and print <code>truss</code> output on each child process. This option will also cause a <i>pid</i> to be output on each <code>truss</code> output line.</p> |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> An example of sotruss.</p> <p>A simple example shows the tracing of a simple <code>ls</code> command:</p> <pre>% sotruss ls   more ls      -&gt;      libc.so.1:*atexit(0xef7d7d1c, 0x23c00, 0x0) ls      -&gt;      libc.so.1:*atexit(0x1392c, 0xef7d7d1c, 0xef621bb0) ls      -&gt;      libc.so.1:*setlocale(0x6, 0x1396c, 0xef621ba8) ls      -&gt;      libc.so.1:*textdomain(0x13970, 0x1396c, 0xef621ba8) ls      -&gt;      libc.so.1:*time(0x0, 0xef61f6fc, 0xef621ba8) ls      -&gt;      libc.so.1:*isatty(0x1, 0xef61f6fc, 0x0) ls      -&gt;      libc.so.1:*getopt(0x1, 0xfffff8fc, 0x13980) ls      -&gt;      libc.so.1:*malloc(0x100, 0x0, 0x0) ls      -&gt;      libc.so.1:*malloc(0x9000, 0x0, 0x0) ls      -&gt;      libc.so.1:*lstat64(0x23ee8, 0xfffff7a0, 0x0) . . . ls      -&gt;      libc.so.1:*printf(0x13a64, 0x26208, 0x23ef0) ls      -&gt;      libc.so.1:*printf(0x13a64, 0x26448, 0x23ef0) ls      -&gt;      libc.so.1:*exit(0x0, 0x24220, 0x2421c)</pre>        |

| <b>DESCRIPTION</b>     | <p>The <code>spell</code> command collects words from the named <code>files</code> and looks them up in a spelling list. Words that neither occur among nor are derivable (by applying certain inflections, prefixes, or suffixes) from words in the spelling list are written to the standard output.</p> <p>If there are no <code>file</code> arguments, words to check are collected from the standard input. <code>spell</code> ignores most <code>troff(1)</code>, <code>tbl(1)</code>, and <code>eqn(1)</code> constructs. Copies of all output words are accumulated in the history file (<code>spellhist</code>), and a stop list filters out misspellings (for example, <code>their=thy-y+ier</code>) that would otherwise pass.</p> <p>By default, <code>spell</code> (like <code>deroff(1)</code>) follows chains of included files (<code>.so</code> and <code>.nx troff(1)</code> requests), unless the names of such included files begin with <code>/usr/lib</code>.</p> <p>The standard spelling list is based on many sources, and while more haphazard than an ordinary dictionary, is also more effective in respect to proper names and popular technical words. Coverage of the specialized vocabularies of biology, medicine and chemistry is light.</p> <p>Three programs help maintain and check the hash lists used by <code>spell</code>:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><code>hashmake</code></td> <td>Reads a list of words from the standard input and writes the corresponding nine-digit hash code on the standard output.</td> </tr> <tr> <td><code>spellin</code></td> <td>Reads <i>n</i> hash codes from the standard input and writes a compressed spelling list on the standard output.</td> </tr> <tr> <td><code>hashcheck</code></td> <td>Reads a compressed <i>spelling_list</i> and recreates the nine-digit hash codes for all the words in it. It writes these codes on the standard output.</td> </tr> </table> | <code>hashmake</code> | Reads a list of words from the standard input and writes the corresponding nine-digit hash code on the standard output.                                                                | <code>spellin</code> | Reads <i>n</i> hash codes from the standard input and writes a compressed spelling list on the standard output.                                                             | <code>hashcheck</code> | Reads a compressed <i>spelling_list</i> and recreates the nine-digit hash codes for all the words in it. It writes these codes on the standard output. |    |                                                                                                                           |
| <code>hashmake</code>  | Reads a list of words from the standard input and writes the corresponding nine-digit hash code on the standard output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                       |                                                                                                                                                                                        |                      |                                                                                                                                                                             |                        |                                                                                                                                                        |    |                                                                                                                           |
| <code>spellin</code>   | Reads <i>n</i> hash codes from the standard input and writes a compressed spelling list on the standard output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                       |                                                                                                                                                                                        |                      |                                                                                                                                                                             |                        |                                                                                                                                                        |    |                                                                                                                           |
| <code>hashcheck</code> | Reads a compressed <i>spelling_list</i> and recreates the nine-digit hash codes for all the words in it. It writes these codes on the standard output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                       |                                                                                                                                                                                        |                      |                                                                                                                                                                             |                        |                                                                                                                                                        |    |                                                                                                                           |

## spell(1)

**-x** Print every plausible stem, one per line, with = preceding each word.

**+local\_file** Specify a set of words that are correct spellings (in addition to spell's own spelling list) for each job. *local\_file* is the name of a user-provided file that contains a sorted list of words, one per line. Words found in *local\_file* are removed from spell's output. Use [sort\(1\)](#) to order *local\_file* in ASCII collating sequence. If this ordering is not followed, some entries in *local\_file* may be ignored.

**OPERANDS** The following operands are supported:

**file** A path name of a text file to check for spelling errors. If no files are named, words are collected from the standard input.

**ENVIRONMENT VARIABLES** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of spell: LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**SEE ALSO** [deroff\(1\)](#), [eqn\(1\)](#), [sort\(1\)](#), [tbl\(1\)](#), [troff\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**NOTES** Misspelled words can be monitored by default by setting the H\_SPELL variable in /usr/bin/spell to the name of a file that has permission mode 666.

spell works only on English words defined in the U.S. ASCII codeset.

Because copies of all output are accumulated in the spellhist file, spellhist may grow quite large and require purging.

**BUGS** The spelling list's coverage is uneven; new installations may wish to monitor the output for several months to gather local additions.

British spelling was done by an American.

| <b>DESCRIPTION</b> | spline takes pairs of numbers from the standard input as abscissas and ordinates of a function. It produces a similar set, which is approximately equally spaced and includes the input set, on the standard output. The cubic spline output (R. W. Hamming, <i>Numerical Methods for Scientists and Engineers</i> , 2nd ed., 349ff) has two continuous derivatives, and sufficiently many points to look smooth when plotted, for example by <a href="#">graph(1)</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |         |
| <b>OPTIONS</b>     | <p>-a        Supply abscissas automatically (they are missing from the input); spacing is given by the next argument, or is assumed to be 1 if next argument is not a number.</p> <p>-k        The constant <math>k</math> used in the boundary value computation<br/><i>(2nd deriv. at end) = k*(2nd deriv. next to end)</i><br/>is set by the next argument. By default <math>k = 0</math>.</p> <p>-n        Space output points so that approximately <math>n</math> intervals occur between the lower and upper <math>x</math> limits. (Default <math>n = 100</math>.)</p> <p>-p        Make output periodic, that is, match derivatives at ends. First and last input values should normally agree.</p> <p>-x        Next 1 (or 2) arguments are lower (and upper) <math>x</math> limits. Normally these limits are calculated from the data. Automatic abscissas start at lower limit (default 0).</p> |                |                 |              |         |
| <b>ATTRIBUTES</b>  | See <a href="#">attributes(5)</a> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |         |

| <b>DIAGNOSTICS</b> | When data is not strictly monotonic in $x$ , spline reproduces the input without interpolating extra points.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |         |
| <b>BUGS</b>        | A limit of 1000 input points is enforced silently.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |              |         |

## split(1)

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>NAME</b>                  | split – split a file into pieces                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>              | <b>split</b> [-linecount   -l <i>linecount</i> ] [-a <i>suffixlength</i> ] [ <i>file</i> [ <i>name</i> ]]<br><b>split</b> [-b <i>n</i>   <i>nk</i>   <i>nm</i> ] [-a <i>suffixlength</i> ] [ <i>file</i> [ <i>name</i> ]]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b>           | The <code>split</code> utility reads <i>file</i> and writes it in <i>linecount</i> -line pieces into a set of output-files. The name of the first output-file is <i>name</i> with <i>aa</i> appended, and so on lexicographically, up to <i>zz</i> (a maximum of 676 files). The maximum length of <i>name</i> is 2 characters less than the maximum filename length allowed by the filesystem. See <code>statvfs(2)</code> . If no output name is given, <i>x</i> is used as the default (output-files will be called <i>xaa</i> , <i>xab</i> , and so forth).                                                                                                                                                                                                                                                 |
| <b>OPTIONS</b>               | The following options are supported:<br><br>- <i>linecount</i>   -l <i>linecount</i> Number of lines in each piece. Defaults to 1000 lines.<br>-a <i>suffixlength</i> Uses <i>suffixlength</i> letters to form the suffix portion of the filenames of the split file. If -a is not specified, the default suffix length is 2. If the sum of the <i>name</i> operand and the <i>suffixlength</i> option-argument would create a filename exceeding <code>NAME_MAX</code> bytes, an error will result; <code>split</code> will exit with a diagnostic message and no files will be created.<br>-b <i>n</i> Splits a file into pieces <i>n</i> bytes in size.<br>-b <i>nk</i> Splits a file into pieces <i>n</i> *1024 bytes in size.<br>-b <i>nm</i> Splits a file into pieces <i>n</i> *1 048 576 bytes in size. |
| <b>OPERANDS</b>              | The following operands are supported:<br><br><i>file</i> The path name of the ordinary file to be split. If no input file is given or <i>file</i> is -, the standard input will be used.<br><br><i>name</i> The prefix to be used for each of the files resulting from the <code>split</code> operation. If no <i>name</i> argument is given, <i>x</i> will be used as the prefix of the output files. The combined length of the basename of <i>prefix</i> and <i>suffixlength</i> cannot exceed <code>NAME_MAX</code> bytes. See <b>OPTIONS</b> .                                                                                                                                                                                                                                                             |
| <b>USAGE</b>                 | See <code>largefile(5)</code> for the description of the behavior of <code>split</code> when encountering files greater than or equal to 2 Gbyte (2 <sup>31</sup> bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>ENVIRONMENT VARIABLES</b> | See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>split</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>EXIT STATUS</b>           | The following exit values are returned:<br><br>0                                    Successful completion.<br>>0                                  An error occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>NAME</b>        | srchtxt – display contents of, or search for a text string in, message data bases                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <b>srchtxt</b> [-s] [-l <i>locale</i> ] [ -m <i>msgfile</i> ,...] [ <i>text</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>The <code>srchtxt</code> utility is used to display all the text strings in message data bases, or to search for a text string in message data bases (see <code>mkmsgs(1)</code>). These data bases are files in the directory <code>/usr/lib/locale/locale/LC_MESSAGES</code> (see <code>setlocale(3C)</code>), unless a file name given with the <code>-m</code> option contains a <code>/</code>. The directory <code>locale</code> can be viewed as the name of the language in which the text strings are written. If the <code>-l</code> option is not specified, the files accessed will be determined by the value of the environment variable <code>LC_MESSAGES</code>. If <code>LC_MESSAGES</code> is not set, the files accessed will be determined by the value of the environment variable <code>LANG</code>. If <code>LANG</code> is not set, the files accessed will be in the directory <code>/usr/lib/locale//C/LC_MESSAGES</code>, which contains default strings.</p> <p>If no <i>text</i> argument is present, then all the text strings in the files accessed will be displayed.</p> <p>If the <code>-s</code> option is not specified, the displayed text is prefixed by message sequence numbers. The message sequence numbers are enclosed in angle brackets:<br/><code>&lt;msgfile:msgnum&gt;</code>.</p> <p><i>msgfile</i>            name of the file where the displayed text occurred</p> <p><i>msgnum</i>            sequence number in <i>msgfile</i> where the displayed text occurred</p> <p>This display is in the format used by <code>gettext(1)</code> and <code>gettext(3C)</code>.</p> |
| <b>OPTIONS</b>     | <p><code>-s</code>                Suppress printing of the message sequence numbers of the messages being displayed.</p> <p><code>-l locale</code>        Access files in the directory <code>/usr/lib/locale/locale/LC_MESSAGES</code>. If <code>-m msgfile</code> is also supplied, <code>LOCALE</code> is ignored for <i>msgfiles</i> containing a <code>/</code>.</p> <p><code>-m msgfile</code>       Access files specified by one or more <i>msgfiles</i>. If <i>msgfile</i> contains a <code>/</code> character, then <i>msgfile</i> is interpreted as a pathname; otherwise, it will be assumed to be in the directory determined as described above. To specify more than one <i>msgfile</i>, separate the file names using commas.</p> <p><i>text</i>             Search for the text string specified by <i>text</i> and display each one that matches. <i>text</i> can take the form of a regular expression; see <code>regexp(5)</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Using <code>srchtxt</code></p> <p>If message files have been installed in a locale named <code>french</code> by using <code>mkmsgs(1)</code>, then you could display the entire set of text strings in the <code>french</code> locale (<code>/usr/lib/locale/french/LC_MESSAGES/*</code>) by typing:</p> <pre>example% srchtxt -l french</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**EXAMPLE 1** Using srchtxt (Continued)**EXAMPLE 2** Using srchtxt

If a set of error messages associated with the operating system have been installed in the file UX in the french locale (`/usr/lib/locale/french/LC_MESSAGES/UX`), then, using the value of the LANG environment variable to determine the locale to be searched, you could search that file in that locale for all error messages dealing with files by typing:

```
example% setenv LANG=french; export LANG
example% srchtxt -m UX "[Ff]ichier"
```

If `/usr/lib/locale/french/LC_MESSAGES/UX` contained the following strings:

```
Erreur E/S\n
Liste d'arguments trop longue\n
Fichier inexistant\n
Argument invalide\n
Trop de fichiers ouverts\n
Fichier trop long\n
Trop de liens\n
Argument hors du domaine\n
Identificateur supprim\n
Etreinte fatale\n
.\n
.\n
.
```

then the following strings would be displayed:

```
<UX:3>Fichier inexistant\n
<UX:5>Trop de fichiers ouverts\n
<UX:6>Fichier trop long\n
```

**EXAMPLE 3** Using srchtxt

If a set of error messages associated with the operating system have been installed in the file UX and a set of error messages associated with the INGRESS data base product have been installed in the file `ingress`, both in the german locale, then you could search for the pattern `[Dd]atei` in both the files UX and `ingress` in the german locale by typing:

```
example% srchtxt -l german -m UX,ingress "[Dd]atei"
```

**ENVIRONMENT  
VARIABLES**

See `environ(5)` for a description of the LC\_CTYPE environment variable that affects the execution of `srchtxt`.

**FILES**

`/usr/lib/locale/C/LC_MESSAGES/*`  
default files created by `mkmsgs(1)`

`/usr/lib/locale/locale/LC_MESSAGES/*`  
message files created by `mkmsgs(1)`

srchtxt(1)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWloc         |

**SEE ALSO** `exstr(1)`, `gettext(1)`, `locale(1)`, `mkmsgs(1)`, `gettext(3C)`, `setlocale(3C)`, `attributes(5)`, `environ(5)`, `locale(5)`, `regex(5)`

**DIAGNOSTICS** The error messages produced by `srchtxt` are intended to be self-explanatory. They indicate an error in the command line or errors encountered while searching for a particular locale and/or message file.

| <b>DESCRIPTION</b>            | <p>ssh (Secure Shell) is a program for logging into a remote machine and for executing commands on a remote machine. It is intended to replace rlogin and rsh, and to provide secure encrypted communications between two untrusted hosts over an insecure network. X11 connections and arbitrary TCP/IP ports can also be forwarded over the secure channel.</p> <p>ssh connects and logs into the specified hostname. The user must prove his or her identity to the remote machine using one of several methods depending on the protocol version used:</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SSH protocol version 1</b> | <p>First, if the machine the user logs in from is listed in <code>/etc/hosts.equiv</code> or <code>/etc/shosts.equiv</code> on the remote machine, and the user names are the same on both sides, the user is immediately permitted to log in. Second, if <code>.rhosts</code> or <code>.shosts</code> exists in the user's home directory on the remote machine and contains a line containing the name of the client machine and the name of the user on that machine, the user is permitted to log in. This form of authentication alone is normally not allowed by the server because it is not secure.</p> <p>The second (and primary) authentication method is the <code>rhosts</code> or <code>hosts.equiv</code> method combined with RSA-based host authentication. It means that if the login would be permitted by <code>\$HOME/.rhosts</code>, <code>\$HOME/.shosts</code>, <code>/etc/hosts.equiv</code>, or <code>/etc/shosts.equiv</code>, and if additionally the server can verify the client's host key (see <code>/etc/ssh_known_hosts</code> in the FILES section), only then is login permitted. This authentication method closes security holes due to IP spoofing, DNS spoofing, and routing spoofing.</p> <p><i>Note to the administrator:</i> <code>/etc/hosts.equiv</code>, <code>\$HOME/.rhosts</code>, and the <code>rlogin/rsh</code> protocol in general, are inherently insecure and should be disabled if security is desired.</p> <p>As a third authentication method, <code>ssh</code> supports RSA-based authentication. The scheme is based on public-key cryptography. There are cryptosystems where encryption and decryption are done using separate keys, and it is not possible to derive the decryption key from the encryption key. RSA is one such system. The idea is that each user creates a public/private key pair for authentication purposes. The server knows the public key, and only the user knows the private key. The file <code>\$HOME/.ssh/authorized_keys</code> lists the public keys that are permitted for logging in. When the user logs in, the <code>ssh</code> program tells the server which key pair it would like to use for authentication. The server checks if this key is permitted, and if so,</p> |

ssh(1)

sends the user (actually the `ssh` program running on behalf of the user) a challenge in the form of a random number, encrypted by the user's public key. The challenge can only be decrypted using the proper private key. The user's client then decrypts the challenge using the private key, proving that he or she knows the private key but without disclosing it to the server.

`ssh` implements the RSA authentication protocol automatically. The user creates his or her RSA key pair by running `ssh-keygen(1)`. This stores the private key in `HOME/.ssh/identity` and the public key in `HOME/.ssh/identity.pub` in the user's home directory. The user should then copy the `identity.pub` to `HOME/.ssh/authorized_keys` in his or her home directory on the remote machine (the `authorized_keys` file corresponds to the conventional `HOME/.rhosts` file, and has one key per line, though the lines can be very long). After this, the user can log in without giving the password. RSA authentication is much more secure than `rhosts` authentication.

The most convenient way to use RSA authentication can be with an authentication agent. See `ssh-agent(1)` for more information.

If other authentication methods fail, `ssh` prompts the user for a password. The password is sent to the remote host for checking. However, since all communications are encrypted, the password cannot be seen by someone listening on the network.

## SSH protocol version 2

The SSH version 2 protocol supports multiple user authentication methods, some of which are similar to those available with the SSH protocol version 1. These authentication mechanisms are negotiated by the client and server, with the client trying methods in the order specified in the `PreferredAuthentications` client configuration option. The server decides when enough authentication methods have passed successfully so as to complete the authentication phase of the protocol.

When a user connects by using protocol version 2, similar authentication methods are available. Using the default values for `PreferredAuthentications`, the client tries to authenticate first by using the `hostbased` method. If this method fails, public key authentication is attempted. Finally, if this method fails, keyboard-interactive and password authentication are tried.

The public key method is similar to RSA authentication described in the previous section and allows the RSA or DSA algorithm to be used: The client uses his or her private key, `HOME/.ssh/id_dsa` or `HOME/.ssh/id_rsa`, to sign the session identifier and sends the result to the server. The server checks whether the matching public key is listed in `HOME/.ssh/authorized_keys` and grants access if both the key is found and the signature is correct. The session identifier is derived from a shared Diffie-Hellman value and is only known to the client and the server.

If public key authentication fails or is not available, a password can be sent encrypted to the remote host for proving the user's identity, or an extended prompt/reply protocol can be engaged.

Additionally, `ssh` supports `hostbased` or challenge response authentication.

**Login session and remote execution**

Protocol 2 provides additional mechanisms for confidentiality (the traffic is encrypted using 3DES, Blowfish, CAST128 or Arcfour) and integrity (`hmac-sha1`, `hmac-md5`). Protocol 1 lacks a strong mechanism for ensuring the integrity of the connection.

When the user's identity has been accepted by the server, the server either executes the given command, or logs into the machine and gives the user a normal shell on the remote machine. All communication with the remote command or shell is automatically encrypted.

If a pseudo-terminal has been allocated (normal login session), the user can use the escape characters noted below. If a pseudo-terminal has been allocated (normal login session), the user can disconnect with `~.`, and suspend `ssh` with `~^Z`. All forwarded connections can be listed with `~#`. If the session blocks waiting for forwarded X11 or TCP/IP connections to terminate, `ssh` can be backgrounded with `~&`, although this should not be used while the user shell is active, as it can cause the shell to hang. All available escapes can be listed with `~?`.

A single tilde character can be sent as `~~`, or by following the tilde with a character other than those described above. The escape character must always follow a newline to be interpreted as special. The escape character can be changed in configuration files or on the command line.

If no pseudo tty has been allocated, the session is transparent and can be used to reliably transfer binary data. On most systems, setting the escape character to "none" also makes the session transparent even if a tty is used.

The session terminates when the command or shell on the remote machine exits and all X11 and TCP/IP connections have been closed. The exit status of the remote program is returned as the exit status of `ssh`.

**Escape Characters**

When a pseudo-terminal has been requested, `ssh` supports a number of functions through the use of an escape character.

A single tilde character can be sent as `~~` or by following the tilde with a character other than those described below. The escape character must always follow a newline to be interpreted as special. The escape character can be changed in configuration files using the `EscapeChar` configuration directive or on the command line by the `-e` option.

The supported escapes, assuming the default `~`, are:

- `~.` Disconnect.
- `~^Z` Background `ssh`.
- `~#` List forwarded connections.
- `~&` Background `ssh` at logout when waiting for forwarded connection / X11 sessions to terminate.
- `~?` Display a list of escape characters.

ssh(1)

- ~B Send a break to the remote system. Only useful for SSH protocol version 2 and if the peer supports it.
- ~C Open command line. Only useful for adding port forwardings using the `-L` and `-R` options).
- ~R Request rekeying of the connection. Only useful for SSH protocol version 2 and if the peer supports it.

### **X11 and TCP forwarding**

If the `ForwardX11` variable is set to “yes” (or, see the description of the `-X` and `-x` options described later) and the user is using X11 (the `DISPLAY` environment variable is set), the connection to the X11 display is automatically forwarded to the remote side in such a way that any X11 programs started from the shell (or command) goes through the encrypted channel, and the connection to the real X server is made from the local machine. The user should not manually set `DISPLAY`. Forwarding of X11 connections can be configured on the command line or in configuration files.

The `DISPLAY` value set by `ssh` points to the server machine, but with a display number greater than zero. This is normal behavior, because `ssh` creates a “proxy” X11 server on the server machine for forwarding the connections over the encrypted channel.

`ssh` also automatically sets up Xauthority data on the server machine. For this purpose, it generates a random authorization cookie, store it in Xauthority on the server, and verify that any forwarded connections carry this cookie and replace it by the real cookie when the connection is opened. The real authentication cookie is never sent to the server machine (and no cookies are sent in the plain).

If the `ForwardAgent` variable is set to “yes” (or, see the description of the `-A` and `-a` options described later) and the user is using an authentication agent, the connection to the agent is automatically forwarded to the remote side.

Forwarding of arbitrary TCP/IP connections over the secure channel can be specified either on the command line or in a configuration file. One possible application of TCP/IP forwarding is a secure connection to an electronic purse. Another possible application is firewall traversal.

### **Server authentication**

`ssh` automatically maintains and checks a database containing identifications for all hosts it has ever been used with. Host keys are stored in `$HOME/.ssh/known_hosts` in the user’s home directory. Additionally, the file `/etc/ssh_known_hosts` is automatically checked for known hosts. The behavior of `ssh` with respect to unknown host keys is controlled by the `StrictHostKeyChecking` parameter. If a host’s identification ever changes, `ssh` warns about this and disables password authentication to prevent a trojan horse from getting the user’s password. Another purpose of this mechanism is to prevent attacks by intermediaries which could otherwise be used to circumvent the encryption. The `StrictHostKeyChecking` option can be used to prevent logins to machines whose host key is not known or has changed.

**GSS-API user and server authentication**

However, when using key exchange protected by GSS-API, the server can advertise a host key. The client automatically adds this host key to its known hosts file, `$HOME/.ssh/known_hosts`, regardless of the setting of the `StrictHostKeyCheckingKey` option, unless the advertised host key collides with an existing known hosts entry.

When the user's GSS-API credentials expire, the client continues to be able to rekey the session using the server's public host key to protect the key exchanges.

`ssh` uses the user's GSS-API credentials to authenticate the client to the server wherever possible, if `GssKeyEx` and/or `GssAuthentication` are set.

With `GssKeyEx`, one can have an SSHv2 server that has no host public keys, so that only `GssKeyEx` can be used. With such servers, rekeying fails if the client's credentials are expired.

GSS-API user authentication has the disadvantage that it does not obviate the need for SSH host keys, but its failure does not impact rekeying. `ssh` can try other authentication methods (such as public key, password, and so on) if GSS-API authentication fails.

Delegation of GSS-API credentials can be quite useful, but is not without danger. As with passwords, users should not delegate GSS credentials to untrusted servers, since a compromised server can use a user's delegated GSS credentials to impersonate the user.

GSS-API user authorization is covered in `gss_auth_rules(5)`.

Rekeying can be used to redelegate credentials when `GssKeyEx` is "yes". (See `~R` under `Escape Characters` above.)

**OPTIONS**

The following options are supported:

- 1 Forces `ssh` to try protocol version 1 only.
- 2 Forces `ssh` to try protocol version 2 only.
- 4 Forces `ssh` to use IPv4 addresses only.
- 6 Forces `ssh` to use IPv6 addresses only.
- a Disables forwarding of the authentication agent connection.
- A Enables forwarding of the authentication agent connection. This can also be specified on a per-host basis in a configuration file.

Agent forwarding should be enabled with caution. Users with the ability to bypass file permissions on the remote host (for the agent's UNIX-domain socket) can access the local agent through the forwarded

## ssh(1)

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <code>-c blowfish   3des   des</code> | <p>Selects the cipher to use for encrypting the session. <code>3des</code> is used by default. It is believed to be secure. <code>3des</code> (triple-des) is an encrypt-decrypt-encrypt triple with three different keys. It is presumably more secure than the <code>des</code> cipher, which is no longer fully supported in <code>ssh</code>. <code>blowfish</code> is a fast block cipher, it appears very secure and is much faster than <code>3des</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>-c cipher_spec</code>           | <p>Additionally, for protocol version 2 a comma-separated list of ciphers can be specified in order of preference. Protocol version 2 supports 3DES, Blowfish, and AES 128 in CBC mode. See <code>Ciphers</code> in <code>ssh_config(4)</code> for more information.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>-C</code>                       | <p>Additionally, for protocol version 2 a comma-separated list of ciphers can be specified in order of preference. Protocol version 2 supports AES with 128-bit keys in counter and CBC modes, RC4, and 3DES and Blowfish in CBC mode. See <code>ssh_config(4)</code>.</p> <p>Requests compression of all data (including <code>stdin</code>, <code>stdout</code>, <code>stderr</code>, and data for forwarded X11 and TCP/IP connections). The compression algorithm is the same used by <code>gzip(1)</code>. The <code>gzip</code> man page is available in the <code>SUNWSfman</code> package. The “level” can be controlled by the <code>CompressionLevel</code> option (see <code>ssh_config(4)</code>). Compression is desirable on modem lines and other slow connections, but only slows down things on fast networks. The default value can be set on a host-by-host basis in the configuration files. See the <code>Compression</code> option in <code>ssh_config(4)</code>.</p> |
| <code>-D port</code>                  | <p>Specifies a local “dynamic” application-level port forwarding. This works by allocating a socket to listen to <code>port</code> on the local side, and whenever a connection is made to this port, the connection is forwarded over the secure channel. The application protocol is then used to determine where to connect to from the remote machine. Currently, the SOCKS4 protocol is supported and <code>ssh</code> acts as a SOCKS4 server. Only root can forward privileged ports. Dynamic port forwardings can also be specified in the configuration file.</p>                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -e <i>ch</i>   ^ <i>ch</i>   none | Sets the escape character for sessions with a pty (default: '~'). The escape character is only recognized at the beginning of a line. The escape character followed by a dot (".") closes the connection. If followed by Control-z, the escape character suspends the connection. If followed by itself, the escape character sends itself once. Setting the character to "none" disables any escapes and makes the session fully transparent.                                                                                                                                                           |
| -f                                | Requests ssh to go to background just before command execution. This is useful if ssh is going to ask for passwords or passphrases, but the user wants it in the background. This implies the -n option. The recommended way to start X11 programs at a remote site is with something like <code>ssh -f host xterm</code> .                                                                                                                                                                                                                                                                              |
| -F <i>configfile</i>              | Specifies an alternative per-user configuration file. If a configuration file is given on the command line, the system-wide configuration file, <code>/etc/ssh_config</code> , is ignored. The default for the per-user configuration file is <code>\$HOME/.ssh/config</code> .                                                                                                                                                                                                                                                                                                                          |
| -g                                | Allows remote hosts to connect to local forwarded ports.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| -i <i>identity_file</i>           | Selects a file from which the identity (private key) for RSA or DSA authentication is read. The default is <code>\$HOME/.ssh/identity</code> for protocol version 1, and <code>\$HOME/.ssh/id_rsa</code> and <code>\$HOME/.ssh/id_dsa</code> for protocol version 2. Identity files can also be specified on a per-host basis in the configuration file. It is possible to have multiple -i options (and multiple identities specified in configuration files).                                                                                                                                          |
| -l <i>login_name</i>              | Specifies the user to log in as on the remote machine. This also can be specified on a per-host basis in the configuration file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| -L <i>port:host:hostport</i>      | Specifies that the given port on the local (client) host is to be forwarded to the given host and port on the remote side. This works by allocating a socket to listen to the port on the local side. Then, whenever a connection is made to this port, the connection is forwarded over the secure channel and a connection is made to <code>host port hostport</code> from the remote machine. Port forwardings can also be specified in the configuration file. Only root can forward privileged ports. IPv6 addresses can be specified with an alternative syntax: <code>port/host/hostport</code> . |

## ssh(1)

|                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-m <i>mac_spec</i></code>           | Additionally, for protocol version 2 a comma-separated list of MAC (message authentication code) algorithms can be specified in order of preference. See the MACs keyword for more information.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>-n</code>                           | Redirects stdin from <code>/dev/null</code> (actually, prevents reading from stdin). This must be used when <code>ssh</code> is run in the background. A common trick is to use this to run X11 programs on a remote machine. For example,<br><br><pre>ssh -n shadows.cs.hut.fi emacs &amp;</pre><br>starts an emacs on <code>shadows.cs.hut.fi</code> , and the X11 connection is automatically forwarded over an encrypted channel. The <code>ssh</code> program is put in the background. This does not work if <code>ssh</code> needs to ask for a password or passphrase. See also the <code>-f</code> option. |
| <code>-N</code>                           | Does not execute a remote command. This is useful if you just want to forward ports (protocol version 2 only).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>-o <i>option</i></code>             | Can be used to give options in the format used in the configuration file. This is useful for specifying options for which there is no separate command-line flag. The option has the same format as a line in the configuration file.                                                                                                                                                                                                                                                                                                                                                                               |
| <code>-p <i>port</i></code>               | Specifies the port to connect to on the remote host. This can be specified on a per-host basis in the configuration file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>-P</code>                           | Obsoleted option. SSHv1 connections from privileged ports are not supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>-q</code>                           | Quiet mode. Causes all warning and diagnostic messages to be suppressed. Only fatal errors are displayed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>-R <i>port:host:hostport</i></code> | Specifies that the given port on the remote (server) host is to be forwarded to the given host and port on the local side. This works by allocating a socket to listen to the port on the remote side. Then, whenever a connection is made to this port, the connection is forwarded over the secure channel and a connection is made to <code>host port hostport</code> from the local machine. Port forwardings can also be specified in the configuration file. Privileged ports can be forwarded only when logging in as root on the remote machine.                                                            |

- s Can be used to request invocation of a subsystem on the remote system. Subsystems are a feature of the SSH2 protocol which facilitate the use of SSH as a secure transport for other applications, for example, sftp. The subsystem is specified as the remote command.
  - t Forces pseudo-tty allocation. This can be used to execute arbitrary screen-based programs on a remote machine, which can be very useful, for example, when implementing menu services. Multiple -t options force allocation, even if ssh has no local tty.
  - T Disables pseudo-tty allocation (protocol version 2 only).
  - v Verbose mode. Causes ssh to print debugging messages about its progress. This is helpful in debugging connection, authentication, and configuration problems. Multiple -v options increase the verbosity. Maximum is 3.
  - x Disables X11 forwarding.
  - X Enables X11 forwarding. This can also be specified on a per-host basis in a configuration file.
- X11 forwarding should be enabled with caution. Users with the ability to bypass file permissions on the remote host (for the user's X authorization database) can access the local X11 display through the forwarded connection. An attacker can then be able to perform activities such as keystroke monitoring.

## ENVIRONMENT VARIABLES

ssh normally sets the following environment variables:

### DISPLAY

The DISPLAY variable must be set for X11 display forwarding to work.

### SSH\_ASKPASS

If ssh needs a passphrase, it reads the passphrase from the current terminal if it was run from a terminal. If ssh does not have a terminal associated with it but DISPLAY and SSH\_ASKPASS are set, it executes the program specified by SSH\_ASKPASS and opens an X11 window to read the passphrase. This is particularly useful when calling ssh from a .Xsession or related script. On some machines it might be necessary to redirect the input from /dev/null to make this work.

### SSH\_AUTH\_SOCK

Indicates the path of a unix-domain socket used to communicate with the agent.

## ssh(1)

### SSH\_LANGS

A comma-separated list of IETF language tags (see RFC3066) indicating the languages that the user can read and write. Used for negotiation of the locale on the server.

### LANG, LC\_ALL, LC\_CTYPE, LC\_COLLATE, LC\_TIME, LC\_NUMERIC, LC\_MONETARY, LC\_MESSAGES

The values of these environment variables can be set in remote sessions according to the locale settings on the client side and availability of support for those locales on the server side.

Additionally, `ssh` reads `$HOME/.ssh/environment` and adds lines of the format `VARIABLE=value` to the environment

**EXIT STATUS** The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

### FILES

`$HOME/.ssh/known_hosts`

Records host keys for all hosts the user has logged into that are not in `/etc/ssh/ssh_known_hosts`. See `sshd(1M)`.

`$HOME/.ssh/identity`

`$HOME/.ssh/id_dsa`

`$HOME/.ssh/id_ssa`

Contains the authentication identity of the user. These files are for protocol 1 RSA, protocol 2 DSA, and protocol 2 RSA, respectively. These files contain sensitive data and should be readable by the user but not accessible by others (read/write/execute). `ssh` ignores a private key file if it is accessible by others. It is possible to specify a passphrase when generating the key. The passphrase is used to encrypt the sensitive part of this file using 3DES.

`/etc/ssh/sshrd`

Commands in this file are executed by `ssh` when the user logs in just before the user's shell or command is started. See `sshd(1M)` for more information.

`$HOME/.ssh/rc`

Commands in this file are executed by `ssh` when the user logs in just before the user's shell or command is started. See `sshd(1M)` for more information.

`$HOME/.ssh/environment`

Contains additional definitions for environment variables. See `ENVIRONMENT VARIABLES`.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWssh         |

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | See below.      |

The command line syntax is Evolving. The remote locale selection through passing LC\_\* environment variables is Unstable.

To view license terms, attribution, and copyright for OpenSSH, the default path is `/var/sadm/pkg/SUNWsshdr/install/copyright`. If the Solaris operating environment has been installed anywhere other than the default, modify the given path to access the file at the installed location.

**AUTHORS** OpenSSH is a derivative of the original and free ssh 1.2.12 release by Tatu Ylonen. Aaron Campbell, Bob Beck, Markus Friedl, Niels Provos, Theo de Raadt and Dug Song removed many bugs, added newer features and created Open SSH. Markus Friedl contributed the support for SSH protocol versions 1.4 and 2.0.

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>                  | ssh-add – add RSA or DSA identities to the authentication agent                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>              | <b>ssh-add</b> [-lLdDxX] [-t <i>life</i> ] [ <i>file</i> ...]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b>           | <p>The <code>ssh-add</code> utility adds RSA or DSA identities to the authentication agent, <code>ssh-agent(1)</code>. When run without arguments, it attempts to add all of the files <code>\$HOME/.ssh/identity</code> (RSA v1), <code>\$HOME/.ssh/id_rsa</code> (RSA v2), and <code>\$HOME/.ssh/id_dsa</code> (DSA v2) that exist. If more than one of the private keys exists, an attempt to decrypt each with the same passphrase will be made before reprompting for a different passphrase. The passphrase is read from the user's tty or by running the program defined in <code>SSH_ASKPASS</code> (see below).</p> <p>The authentication agent must be running.</p>                                                       |
| <b>OPTIONS</b>               | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-d        Instead of adding the identity, this option <i>removes</i> the identity from the agent.</li><li>-D        Deletes all identities from the agent.</li><li>-l        Lists fingerprints of all identities currently represented by the agent.</li><li>-L        Lists public key parameters of all identities currently represented by the agent.</li><li>-t <i>life</i>   Sets a maximum lifetime when adding identities to an agent. The lifetime may be specified in seconds or in a time format specified in <code>sshd(1M)</code>.</li><li>-x        Locks the agent with a password.</li><li>-X        Unlocks the agent.</li></ul> |
| <b>ENVIRONMENT VARIABLES</b> | <p><code>DISPLAY</code><br/><code>SSH_ASKPASS</code>    If <code>ssh-add</code> needs a passphrase, it will read the passphrase from the current terminal if it was run from a terminal. If <code>ssh-add</code> does not have a terminal associated with it but <code>DISPLAY</code> and <code>SSH_ASKPASS</code> are set, it will execute the program specified by <code>SSH_ASKPASS</code> and open an X11 window to read the passphrase. This is particularly useful when calling <code>ssh-add</code> from a <code>.Xsession</code> or related script.</p> <p><code>SSH_AUTH_SOCKET</code> Identifies the path of a unix-domain socket used to communicate with the agent.</p>                                                 |
| <b>EXIT STATUS</b>           | <p>The following exit values are returned:</p> <ul style="list-style-type: none"><li>0        Successful completion.</li><li>1        An error occurred.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>FILES</b>                 | <p>These files should not be readable by anyone but the user. Notice that <code>ssh-add</code> ignores a file if it is accessible by others. It is possible to specify a passphrase when generating the key; that passphrase will be used to encrypt the private part of this file.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                             |

If these files are stored on a network file system it is assumed that either the protection provided in the file themselves or the transport layer of the network file system provides sufficient protection for the site policy. If this is not the case, then it is recommended the key files are stored on removable media or locally on the relevant hosts.

Recommended names for the DSA and RSA key files:

|                                       |                                                                                                 |
|---------------------------------------|-------------------------------------------------------------------------------------------------|
| <code>\$HOME/.ssh/identity</code>     | Contains the RSA authentication identity of the user for protocol version 1.                    |
| <code>\$HOME/.ssh/identity.pub</code> | Contains the public part of the RSA authentication identity of the user for protocol version 1. |
| <code>\$HOME/.ssh/id_dsa</code>       | Contains the private DSA authentication identity of the user.                                   |
| <code>\$HOME/.ssh/id_dsa.pub</code>   | Contains the public part of the DSA authentication identity of the user.                        |
| <code>\$HOME/.ssh/id_rsa</code>       | Contains the private RSA authentication identity of the user.                                   |
| <code>\$HOME/.ssh/id_rsa.pub</code>   | Contains the public part of the RSA authentication identity of the user.                        |

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWssh         |
| Interface Stability | Evolving        |

**SEE ALSO** `ssh(1)`, `ssh-agent(1)`, `ssh-keygen(1)`, `sshd(1M)`, `attributes(5)`

To view license terms, attribution, and copyright for OpenSSH, the default path is `/var/sadm/pkg/SUNWsshdr/install/copyright`. If the Solaris operating environment has been installed anywhere other than the default, modify the given path to access the file at the installed location.

**AUTHORS** OpenSSH is a derivative of the original and free `ssh 1.2.12` release by Tatu Ylonen. Aaron Campbell, Bob Beck, Markus Friedl, Niels Provos, Theo de Raadt and Dug Song removed many bugs, added newer features and created Open SSH. Markus Friedl contributed the support for SSH protocol versions 1.5 and 2.0.

## ssh-agent(1)

| <b>NAME</b>            | ssh-agent – authentication agent                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                        |                                                                                                                           |    |                                                                                                                            |    |                                                                     |
| <b>SYNOPSIS</b>        | <b>ssh-agent</b> [-a <i>bind_address</i> ] [-c   -s ] [-d] [ <i>command</i> [ <i>args...</i> ] ]<br><b>ssh-agent</b> [-c   -s] -k                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                        |                                                                                                                           |    |                                                                                                                            |    |                                                                     |
| <b>DESCRIPTION</b>     | <p>ssh-agent is a program to hold private keys used for public key authentication (RSA, DSA). ssh-agent is often started at the beginning of a login session. All other windows or programs are started as clients to the ssh-agent program. Through use of environment variables, the agent can be located and automatically used for authentication when logging in to other machines using <a href="#">ssh(1)</a>. (See <i>System Administration Guide: Security Services</i>.)</p> <p>If a command line is given, this is executed as a subprocess of the agent. When the command dies, so does the agent.</p> <p>The agent initially does not have any private keys. Keys are added using <a href="#">ssh-add(1)</a>, which sends the identity to the agent. Several identities can be stored in the agent; the agent can automatically use any of these identities. Use the -l option in <a href="#">ssh-add(1)</a> to display the identities currently held by the agent.</p> <p>The agent is run in the user's local host. Authentication data need not be stored on any other machine, and authentication passphrases never go over the network. However, if the connection to the agent is forwarded over SSH remote logins, the user can use the privileges given by the identities anywhere in the network in a secure way.</p> <p>There are two main ways to get an agent setup. Either you let the agent start a new subcommand into which some environment variables are exported, or you let the agent print the needed shell commands (either <a href="#">sh(1)</a> or <a href="#">csh(1)</a> syntax can be generated) which can be eval'd in the calling shell. Later, use <a href="#">ssh(1)</a> to look at these variables and use them to establish a connection to the agent.</p> <p>A unix-domain socket is created (<code>/tmp/ssh-XXXXXXXX/agent.pid</code>) and the name of this socket is stored in the <code>SSH_AUTH_SOCK</code> environment variable. The socket is made accessible only to the current user. This method is easily abused by root or another instance of the same user.</p> <p>The <code>SSH_AGENT_PID</code> environment variable holds the agent's PID.</p> <p>The agent exits automatically when the command given on the command line terminates.</p> |                        |                                                                                                                           |    |                                                                                                                            |    |                                                                     |
| <b>OPTIONS</b>         | <p>The following options are supported:</p> <table><tr><td>-a <i>bind_address</i></td><td>Binds the agent to the unix-domain socket <i>bind_address</i>. The default is <code>/tmp/ssh-XXXXXXXX/agent.pid</code>.</td></tr><tr><td>-c</td><td>Generates C-shell commands on stdout. This is the default if <code>SHELL</code> indicates that it is a csh style of shell.</td></tr><tr><td>-d</td><td>Debug mode. When this option is specified, ssh-agent will not fork.</td></tr></table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | -a <i>bind_address</i> | Binds the agent to the unix-domain socket <i>bind_address</i> . The default is <code>/tmp/ssh-XXXXXXXX/agent.pid</code> . | -c | Generates C-shell commands on stdout. This is the default if <code>SHELL</code> indicates that it is a csh style of shell. | -d | Debug mode. When this option is specified, ssh-agent will not fork. |
| -a <i>bind_address</i> | Binds the agent to the unix-domain socket <i>bind_address</i> . The default is <code>/tmp/ssh-XXXXXXXX/agent.pid</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                        |                                                                                                                           |    |                                                                                                                            |    |                                                                     |
| -c                     | Generates C-shell commands on stdout. This is the default if <code>SHELL</code> indicates that it is a csh style of shell.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                        |                                                                                                                           |    |                                                                                                                            |    |                                                                     |
| -d                     | Debug mode. ## ssh-agent(1)

- k Kills the current agent (given by the `SSH_AGENT_PID` environment variable).
- s Generates Bourne shell commands on stdout. This is the default if `SHELL` does not indicate that it is a csh style of shell.

**EXIT STATUS** The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

**FILES** `/tmp/ssh-XXXXXXXX/agent.pid`  
Unix-domain sockets used to contain the connection to the authentication agent. These sockets should only be readable by the owner. The sockets are removed when the agent exits.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWssh         |
| Interface Stability | Evolving        |

**SEE ALSO** `ssh(1)`, `ssh-add(1)`, `ssh-keygen(1)`, `sshd(1M)`, `attributes(5)`

*System Administration Guide: Security Services*

To view license terms, attribution, and copyright for OpenSSH, the default path is `/var/sadm/pkg/SUNWsshdr/install/copyright`. If the Solaris operating environment has been installed anywhere other than the default, modify the given path to access the file at the installed location.

**AUTHORS** OpenSSH is a derivative of the original and free `ssh 1.2.12` release by Tatu Ylonen. Aaron Campbell, Bob Beck, Markus Friedl, Niels Provos, Theo de Raadt and Dug Song removed many bugs, added newer features and created Open SSH. Markus Friedl contributed the support for SSH protocol versions 1.5 and 2.0.

## ssh-http-proxy-connect(1)

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>NAME</b>        | ssh-http-proxy-connect – Secure Shell proxy for HTTP                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <code>/usr/lib/ssh/ssh-http-proxy-connect [-h <i>http_proxy_host</i>]<br/>[-p <i>http_proxy_port</i>] <i>connect_host connect_port</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | A proxy command for <code>ssh(1)</code> that uses HTTP CONNECT. Typical use is where connections external to a network are only allowed via a proxy web server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OPTIONS</b>     | The following options are supported:<br><br><code>-h <i>http_proxy_host</i></code> Specifies the proxy web server through which to connect. Overrides the <code>HTTPPROXY</code> and <code>http_proxy</code> environment variables if they are set.<br><br><code>-p <i>http_proxy_port</i></code> Specifies the port on which the proxy web server runs. If not specified, port 80 is assumed. Overrides the <code>HTTPPROXYPORT</code> and <code>http_proxy</code> environment variables if they are set.                                                                                                                                                                                                                                                                                                                                 |
| <b>OPERANDS</b>    | The following operands are supported:<br><br><code><i>http_proxy_host</i></code> The host name or IP address (IPv4 or IPv6) of the proxy.<br><br><code><i>http_proxy_port</i></code> The numeric port number to connect to on <code><i>http_proxy_host</i></code> .<br><br><code><i>connect_host</i></code> The name of the remote host to which the proxy web server is to connect you.<br><br><code><i>connect_port</i></code> The numeric port number of the proxy web server to connect you to on <code><i>http_proxy_host</i></code> .                                                                                                                                                                                                                                                                                                |
| <b>EXAMPLES</b>    | The recommended way to use a proxy connection command is to configure the <code>ProxyCommand</code> in <code>ssh_config(4)</code> (see Example 1 and Example 2). Example 3 shows how the proxy command can be specified on the command line when running <code>ssh(1)</code> .<br><br><b>EXAMPLE 1</b> Setting the proxy from the environment<br><br>The following example uses <code>ssh-http-proxy-connect</code> in <code>ssh_config(4)</code> when the proxy is set from the environment:<br><br><pre>Host playtime.foo.com   ProxyCommand /usr/lib/ssh/ssh-http-proxy-connect \     playtime.foo.com 22</pre><br><b>EXAMPLE 2</b> Overriding proxy environment variables<br><br>The following example uses <code>ssh-http-proxy-connect</code> in <code>ssh_config(4)</code> to override (or if not set) proxy environment variables: |

**EXAMPLE 2** Overriding proxy environment variables (Continued)

```
Host playtime.foo.com
ProxyCommand /usr/lib/ssh/ssh-http-proxy-connect -h webcache \
-p 8080 playtime.foo.com 22
```

**EXAMPLE 3** Using the command line

The following example uses `ssh-http-proxy-connect` from the `ssh(1)` command line:

```
example$ ssh -o'ProxyCommand="/usr/lib/ssh/ssh-http-proxy-connect \
-h webcache -p 8080 playtime.foo.com 22"' playtime.foo.com
```

**ENVIRONMENT VARIABLES**

**HTTPPROXY** Takes the *http\_proxy\_host* operand to specify the default proxy host. Overrides *http\_proxy* if both are set.

**HTTPPROXYPORT** Takes the *http\_proxy\_port* operand to specify the default proxy port. Ignored if **HTTPPROXY** is not set.

**http\_proxy** URL format for specifying proxy host and port.

**EXIT STATUS**

The following exit values are returned:

0 Successful completion.

1 An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWsshu        |
| Interface Stability | Stable          |

| <b>DESCRIPTION</b>          | <p>The <code>ssh-keygen</code> utility generates, manages, and converts authentication keys for <code>ssh(1)</code>. <code>ssh-keygen</code> can create RSA keys for use by SSH protocol version 1 and RSA or DSA keys for use by SSH protocol version 2. The type of key to be generated is specified with the <code>-t</code> option.</p> <p>Normally, each user wishing to use SSH with RSA or DSA authentication runs this once to create the authentication key in <code>\$HOME/.ssh/identity</code>, <code>\$HOME/.ssh/id_dsa</code>, or <code>\$HOME/.ssh/id_rsa</code>. The system administrator can also use this to generate host keys..</p> <p>Ordinarily, this program generates the key and asks for a file in which to store the private key. The public key is stored in a file with the same name but with the “.pub” extension appended. The program also asks for a passphrase. The passphrase can be empty to indicate no passphrase (host keys must have empty passphrases), or it can be a string of arbitrary length. Good passphrases are 10-30 characters long, are not simple sentences or otherwise easy to guess, and contain a mix of uppercase and lowercase letters, numbers, and non-alphanumeric characters. (English prose has only 1-2 bits of entropy per word and provides very poor passphrases.)</p> <p>The passphrase can be changed later by using the <code>-p</code> option.</p> <p>There is no way to recover a lost passphrase. If the passphrase is lost or forgotten, you have to generate a new key and copy the corresponding public key to other machines.</p> <p>For RSA, there is also a comment field in the key file that is only for convenience to the user to help identify the key. The <i>comment</i> can tell what the key is for, or whatever is useful. The comment is initialized to “<code>user@host</code>” when the key is created, but can be changed using the <code>-c</code> option.</p> <p>After a key is generated, instructions below detail where to place the keys to activate them.</p> |                             |                                                                                                            |
| <b>OPTIONS</b>              | <p>The following options are supported:</p> <table><tr><td><code>-b <i>bits</i></code></td><td>Specifies the number of bits in the key to create. The minimum number is 512 bits. Generally, 1024 bits is</td></tr></table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | <code>-b <i>bits</i></code> | Specifies the number of bits in the key to create. | <code>-b <i>bits</i></code> | Specifies the number of bits in the key to create. The minimum number is 512 bits. Generally, 1024 bits is                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                             |                                                                                                            |

|                          |                                                                                                                                                                                                                                                                                                              |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | considered sufficient. Key sizes above that no longer improve security but make things slower. The default is 1024 bits.                                                                                                                                                                                     |
| -B                       | Shows the bubblebabble digest of the specified private or public key file.                                                                                                                                                                                                                                   |
| -c                       | Requests changing the comment in the private and public key files. The program prompts for the file containing the private keys, for the passphrase if the key has one, and for the new comment.                                                                                                             |
|                          | This option only applies to <code>rsa1</code> (SSHv1) keys.                                                                                                                                                                                                                                                  |
| -C <i>comment</i>        | Provides the new comment.                                                                                                                                                                                                                                                                                    |
| -e                       | This option reads a private or public OpenSSH key file and prints the key in a "SECSH" Public Key File Format to stdout. This option allows exporting keys for use by several other SSH implementations.                                                                                                     |
| -f                       | Specifies the filename of the key file.                                                                                                                                                                                                                                                                      |
| -i                       | This option reads an unencrypted private (or public) key file in SSH2-compatible format and prints an OpenSSH compatible private (or public) key to stdout. <code>ssh-keygen</code> also reads the "SECSH" Public Key File Format. This option allows importing keys from several other SSH implementations. |
| -l                       | Shows the fingerprint of the specified private or public key file.                                                                                                                                                                                                                                           |
| -N <i>new_passphrase</i> | Provides the new passphrase.                                                                                                                                                                                                                                                                                 |
| -p                       | Requests changing the passphrase of a private key file instead of creating a new private key. The program prompts for the file containing the private key, for the old passphrase, and prompts twice for the new passphrase.                                                                                 |
| -P <i>passphrase</i>     | Provides the (old) passphrase.                                                                                                                                                                                                                                                                               |
| -q                       | Silences <code>ssh-keygen</code> .                                                                                                                                                                                                                                                                           |
| -t <i>type</i>           | Specifies the algorithm used for the key, where <i>type</i> is one of <code>rsa</code> , <code>dsa</code> , and <code>rsa1</code> . Type <code>rsa1</code> is used only for the SSHv1 protocol.                                                                                                              |
| -x                       | Obsolete. Replaced by the <code>-e</code> option.                                                                                                                                                                                                                                                            |
| -X                       | Obsolete. Replaced by the <code>-i</code> option.                                                                                                                                                                                                                                                            |

## ssh-keygen(1)

-y This option reads a private OpenSSH format file and prints an OpenSSH public key to stdout.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

1 An error occurred.

### FILES

`$HOME/.ssh/identity`

This file contains the RSA private key for the SSHv1 protocol. This file should not be readable by anyone but the user. It is possible to specify a passphrase when generating the key; that passphrase is used to encrypt the private part of this file using 3DES. This file is not automatically accessed by `ssh-keygen`, but it is offered as the default file for the private key. `sshd(1M)` reads this file when a login attempt is made.

`$HOME/.ssh/identity.pub`

This file contains the RSA public key for the SSHv1 protocol. The contents of this file should be added to `$HOME/.ssh/authorized_keys` on all machines where you wish to log in using RSA authentication. There is no need to keep the contents of this file secret.

`$HOME/.ssh/id_dsa`

`$HOME/.ssh/id_rsa`

These files contain, respectively, the DSA or RSA private key for the SSHv2 protocol. These files should not be readable by anyone but the user. It is possible to specify a passphrase when generating the key; that passphrase is used to encrypt the private part of the file using 3DES. Neither of these files is automatically accessed by `ssh-keygen` but is offered as the default file for the private key. `sshd(1M)` reads this file when a login attempt is made.

`$HOME/.ssh/id_dsa.pub`

`$HOME/.ssh/id_rsa.pub`

These files contain, respectively, the DSA or RSA public key for the SSHv2 protocol. The contents of these files should be added, respectively, to `$HOME/.ssh/authorized_keys` on all machines where you wish to log in using DSA or RSA authentication. There is no need to keep the contents of these files secret.

| <b>NAME</b>        | ssh-keyscan – gather public ssh host keys of a number of hosts                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <b>ssh-keyscan</b> [-v46] [-p <i>port</i> ] [-T <i>timeout</i> ] [-t <i>type</i> ] [-f <i>file</i> ] [-] [ <i>host...</i>   <i>addrlist namelist</i> ] [...]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p>ssh-keyscan is a utility for gathering the public ssh host keys of a number of hosts. It was designed to aid in building and verifying <code>ssh_known_hosts</code> files. ssh-keyscan provides a minimal interface suitable for use by shell and perl scripts. The output of ssh-keyscan is directed to standard output.</p> <p>ssh-keyscan uses non-blocking socket I/O to contact as many hosts as possible in parallel, so it is very efficient. The keys from a domain of 1,000 hosts can be collected in tens of seconds, even when some of those hosts are down or do not run ssh. For scanning, one does not need login access to the machines that are being scanned, nor does the scanning process involve any encryption.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>File Format</b> | <p>Input format:</p> <p>1.2.3.4,1.2.4.4<br/><i>name.my.domain,name,n.my.domain,n,1.2.3.4,1.2.4.4</i></p> <p>Output format for rsa1 keys:</p> <p><i>host-or-namelist bits exponent modulus</i></p> <p>Output format for rsa and dsa keys, where <i>keytype</i> is either <code>ssh-rsa</code> or <code>'ssh-dsa</code>:</p> <p><i>host-or-namelist keytype base64-encoded-key</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>-f <i>filename</i>                      Read hosts or addrlist namelist pairs from this file, one per line. If you specify - instead of a filename, ssh-keyscan reads hosts or addrlist namelist pairs from the standard input.</p> <p>-p <i>port</i>                              Port to connect to on the remote host.</p> <p>-T <i>timeout</i>                          Set the timeout for connection attempts. If <i>timeout</i> seconds have elapsed since a connection was initiated to a host or since the last time anything was read from that host, the connection is closed and the host in question is considered unavailable. The default is for <i>timeout</i> is 5 seconds.</p> <p>-t <i>type</i>                              Specify the type of the key to fetch from the scanned hosts. The possible values for <i>type</i> are <code>rsa1</code> for protocol version 1 and <code>rsa</code> or <code>dsa</code> for protocol version 2. Specify multiple values by separating them with commas. The default is <code>rsa1</code>.</p> <p>-v                                      Specify verbose mode. Print debugging messages about progress.</p> |

- 4 Force to use IPv4 addresses only.
- 6 Forces to use IPv6 addresses only.

**SECURITY** If a `ssh_known_hosts` file is constructed using `ssh-keyscan` without verifying the keys, users are vulnerable to man-in-the-middle attacks. If the security model allows such a risk, `ssh-keyscan` can help in the detection of tampered keyfiles or man-in-the-middle attacks which have begun after the `ssh_known_hosts` file was created.

**EXAMPLES** **EXAMPLE 1** Printing the `rsa1` Host Key

The following example prints the `rsa1` host key for machine hostname:

```
$ ssh-keyscan hostname
```

**EXAMPLE 2** Finding All Hosts

The following commands finds all hosts from the file `ssh_hosts` which have new or different keys from those in the sorted file `ssh_known_hosts`:

```
$ ssh-keyscan -t rsa,dsa -f ssh_hosts | \
    sort -u - ssh_known_hosts | diff ssh_known_hosts -
```

**FILES** `/etc/ssh_known_hosts`

**EXIT STATUS** The following exit values are returned:

- 0 No usage errors. `ssh-keyscan` might or might not have succeeded or failed to scan one, more or all of the given hosts.
- 1 Usage error.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWssh         |
| Interface Stability | Evolving        |

**SEE ALSO** `ssh(1)`, `sshd(1M)`, `attributes(5)`

**AUTHORS** David Mazieres wrote the initial version, and Wayne Davison added support for protocol version 2.

**BUGS** `ssh-keyscan` generates

Connection closed by remote host messages on the consoles of all machines it scans if the server is older than version 2.9. This is because `ssh-keyscan` opens a connection to the `ssh` port, reads the public key, and drops the connection as soon as it gets the key.

| <b>NAME</b>        | ssh-socks5-proxy-connect – Secure Shell proxy for SOCKS5                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SYNOPSIS</b>    | <code>/usr/lib/ssh/ssh-socks5-proxy-connect</code> [-h <i>socks5_proxy_host</i> ]<br>[-p <i>socks5_proxy_port</i> ] <i>connect_host connect_port</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>A proxy command for <code>ssh(1)</code> that uses SOCKS5 (RFC 1928). Typical use is where connections external to a network are only allowed via a socks gateway server.</p> <p>This proxy command does not provide any of the SOCKS5 authentication mechanisms defined in RFC 1928. Only anonymous connections are possible.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-h <i>socks5_proxy_host</i> Specifies the proxy web server through which to connect. Overrides the <code>SOCKS5_SERVER</code> environment variable.</li><li>-p <i>socks5_proxy_port</i> Specifies the port on which the proxy web server runs. If not specified, port 80 is assumed. Overrides the <code>SOCKS5_PORT</code> environment variable.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <ul style="list-style-type: none"><li><i>socks5_proxy_host</i> The host name or IP address (IPv4 or IPv6) of the proxy.</li><li><i>socks5_proxy_port</i> The numeric port number to connect to on <i>socks5_proxy_host</i>.</li><li><i>connect_host</i> The name of the remote host to which the socks gateway is to connect you.</li><li><i>connect_port</i> The numeric port number of the socks gateway to connect you to on <i>connect_host</i>.</li></ul>                                                                                                                                                                                                                                                                                                                                         |
| <b>EXAMPLES</b>    | <p>The recommended way to use a proxy connection command is to configure the <code>ProxyCommand</code> in <code>ssh_config(4)</code> (see Example 1 and Example 2). Example 3 shows how the proxy command can be specified on the command line when running <code>ssh(1)</code>.</p> <p><b>EXAMPLE 1</b> Setting the proxy from the environment</p> <p>The following example uses <code>ssh-socks5-proxy-connect</code> in <code>ssh_config(4)</code> when the proxy is set from the environment:</p> <pre>Host playtime.foo.com   ProxyCommand /usr/lib/ssh/ssh-socks5-proxy-connect \     playtime.foo.com 22</pre> <p><b>EXAMPLE 2</b> Overriding proxy environment variables</p> <p>The following example uses <code>ssh-socks5-proxy-connect</code> in <code>ssh_config(4)</code> to override (or if not set) proxy environment variables:</p> |

**EXAMPLE 2** Overriding proxy environment variables *(Continued)*

```
Host playtime.foo.com
  ProxyCommand /usr/lib/ssh/ssh-socks5-proxy-connect -h socks-gw \
    -p 1080 playtime.foo.com 22
```

**EXAMPLE 3** Using the command line

The following example uses `ssh-socks5-proxy-connect` from the [ssh\(1\)](#) command line:

```
example$ ssh -o'ProxyCommand=/usr/lib/ssh/ssh-socks5-proxy-connect \
  -h socks-gw -p 1080 playtime.foo.com 22' playtime.foo.com
```

**ENVIRONMENT VARIABLES**

**SOCKS5\_SERVER** Takes `socks5_proxy_host` operand to specify the default proxy host.

**SOCKS5\_PORT** Takes `socks5_proxy_port` operand to specify the default proxy port.

**EXIT STATUS**

The following exit values are returned:

0 Successful completion.

1 An error occurred.

**ATTRIBUTES**

See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWsshu        |
| Interface Stability | Stable          |

| <b>DESCRIPTION</b> | <p>These commands are used to alter or query the configuration of the stream associated with the user's standard input. The <code>strchg</code> command pushes modules on and/or pops modules off the stream. The <code>strconf</code> command queries the configuration of the stream. Only the super-user or owner of a STREAMS device may alter the configuration of that stream.</p> <p>Invoked without any arguments, <code>strconf</code> prints a list of all the modules in the stream as well as the topmost driver. The list is printed with one name per line where the first name printed is the topmost module on the stream (if one exists) and the last item printed is the name of the driver.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>OPTIONS</b>     | <p>The following options apply to <code>strchg</code> and, <code>-h</code>, <code>-f</code>, and <code>-p</code> are mutually exclusive.</p> <p><code>-h <i>module1</i> [ , <i>module2</i>. . . ]</code><br/>Mnemonic for <i>push</i>, pushes modules onto a stream. It takes as arguments the names of one or more pushable streams modules. These modules are pushed in order; that is, <i>module1</i> is pushed first, <i>module2</i> is pushed second, etc.</p> <p><code>-p</code><br/>Mnemonic for <i>pop</i>, pops modules off the stream. With the <code>-p</code> option alone, <code>strchg</code> pops the topmost module from the stream.</p> <p><code>-a <i>module</i></code><br/>Pop all the modules above the topmost driver off the stream. This option requires the <code>-p</code> option.</p> <p><code>-u <i>module</i></code><br/>All modules above, but not including <i>module</i> are popped off the stream. This option requires the <code>-p</code> option.</p> <p><code>-f <i>filename</i></code><br/>Specify a <i>filename</i> that contains a list of modules representing the desired configuration of the stream. Each module name must appear on a separate line where the first name represents the topmost module and the last name represents the module that should be closest to the driver. <code>strchg</code> will determine the current configuration of the stream and pop and push the necessary modules in order to end up with the desired configuration.</p> <p>The following options apply to <code>strconf</code> and, <code>-m</code> and <code>-t</code> are mutually exclusive.</p> <p><code>-m <i>module</i></code> Determine if the named <i>module</i> is present on a stream. If it is, <code>strconf</code> prints the message <code>yes</code> and returns zero. If not, <code>strconf</code> prints the message <code>no</code> and returns a non-zero value. The <code>-t</code> and <code>-m</code> options are mutually exclusive.</p> |

`-t module` Print only the topmost module (if one exists). The `-t` and `-m` options are mutually exclusive.

### EXAMPLES **EXAMPLE 1** Using the `strchg` Command

The following command pushes the module `ldterm` on the stream associated with the user's standard input:

```
example% strchg -h ldterm
```

The following command pops the topmost module from the stream associated with `/dev/term/24`. The user must be the owner of this device or the super user.

```
example% strchg -p < /dev/term/24
```

If the file `fileconf` contains the following:

```
ttcompat
ldterm
ptem
```

then the command

```
example% strchg -f fileconf
```

will configure the user's standard input stream so that the module `ptem` is pushed over the driver, followed by `ldterm` and `ttcompat` closest to the stream head.

The `strconf` command with no arguments lists the modules and topmost driver on the stream; for a stream that has only the module `ldterm` pushed above the `zs` driver, it would produce the following output:

```
ldterm
zs
```

The following command asks if `ldterm` is on the stream:

```
example% strconf -m ldterm
```

and produces the following output while returning an exit status of 0:

```
yes
```

**DIAGNOSTICS** `strchg` returns zero on success. It prints an error message and returns non-zero status for various error conditions, including usage error, bad module name, too many modules to push, failure of an `ioctl` on the stream, or failure to open `filename` from the `-f` option.

## strchg(1)

`strconf` returns zero on success (for the `-m` or `-t` option, "success" means the named or topmost module is present). It returns a non-zero status if invoked with the `-m` or `-t` option and the module is not present. It prints an error message and returns non-zero status for various error conditions, including usage error or failure of an `ioctl` on the stream.

**NOTES** If the user is neither the owner of the stream nor the super-user, the `strchg` command will fail. If the user does not have read permissions on the stream and is not the super user, the `strconf` command will fail.

If modules are pushed in the wrong order, one could end up with a stream that does not function as expected. For ttys, if the line discipline module is not pushed in the correct place, one could have a terminal that does not respond to any commands.

| <b>NAME</b>                  | strings – find printable strings in an object or binary file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |              |         |     |         |                     |          |

| <b>SYNOPSIS</b>              | <b>strings</b> [-a   -] [-t <i>format</i>   -o] [-n <i>number</i>   -number] [ <i>file...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |         |     |         |                     |          |
| <b>DESCRIPTION</b>           | <p>The <code>strings</code> utility looks for ASCII strings in a binary file. A string is any sequence of 4 or more printing characters ending with a newline or a null character.</p> <p><code>strings</code> is useful for identifying random object files and many other things.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |              |         |     |         |                     |          |
| <b>OPTIONS</b>               | <p>The following options are supported:</p> <p>-a   -                    Look everywhere in the file for strings. If this flag is omitted, <code>strings</code> only looks in the initialized data space of object files.</p> <p>-n <i>number</i>   -<i>number</i>    Use a <i>number</i> as the minimum string length rather than the default, which is 4.</p> <p>-o                        Equivalent to -t d option.</p> <p>-t <i>format</i>                Write each string preceded by its byte offset from the start of the file. The format is dependent on the single character used as the <i>format</i> option-argument:</p> <p style="margin-left: 40px;">d                    The offset will be written in decimal.</p> <p style="margin-left: 40px;">o                    The offset will be written in octal.</p> <p style="margin-left: 40px;">x                    The offset will be written in hexadecimal.</p> |                |                 |              |         |     |         |                     |          |
| <b>OPERANDS</b>              | <p>The following operand is supported:</p> <p><i>file</i>                    A path name of a regular file to be used as input. If no <i>file</i> operand is specified, the <code>strings</code> utility will read from the standard input.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |         |     |         |                     |          |
| <b>ENVIRONMENT VARIABLES</b> | See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>strings</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |         |     |         |                     |          |
| <b>EXIT STATUS</b>           | <p>The following exit values are returned:</p> <p>0                        Successful completion.</p> <p>&gt;0                      An error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |     |         |                     |          |
| <b>ATTRIBUTES</b>            | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |              |         |     |         |                     |          |

strings(1)

**NOTES** | The algorithm for identifying strings is extremely primitive.  
For backwards compatibility, the options -a and - are interchangeable.

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>NAME</b>                  | strip – strip symbol table, debugging and line number information from an object file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>              | <code>/usr/ccs/bin/strip [-lVx] file...</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b>           | <p>The <code>strip</code> command removes the symbol table <code>SHT_SYMTAB</code> and its associated string table, debugging information, and line number information from ELF object files. That is, besides the symbol table and associated string table, the following sections are removed:</p> <pre>.line .debug* .stab*</pre> <p>Once this stripping process has been done, limited symbolic debugging access is available for that file. Therefore, this command is normally run only on production modules that have been debugged and tested.</p> <p>If <code>strip</code> is executed on a common archive file (see <code>ar.h(3HEAD)</code>) in addition to processing the members, <code>strip</code> will remove the archive symbol table. The archive symbol table must be restored by executing the <code>ar(1)</code> command with the <code>-s</code> option before the archive can be linked by the <code>ld(1)</code> command. <code>strip</code> will produce appropriate warning messages when this situation arises.</p> <p><code>strip</code> is used to reduce the file storage overhead taken by the object file.</p> |
| <b>OPTIONS</b>               | <p>The amount of information stripped from the ELF object file can be controlled by using any of the following options:</p> <ul style="list-style-type: none"> <li>-l Strip line number information only. Does not strip the symbol table or debugging information.</li> <li>-V Prints, on standard error, the version number of <code>strip</code>.</li> <li>-x Does not strip the symbol table. Debugging and line number information may be stripped.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OPERANDS</b>              | <p>The following operand is supported:</p> <p><i>file</i> A path name referring to an executable file.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>ENVIRONMENT VARIABLES</b> | See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>strip</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>EXIT STATUS</b>           | <p>The following exit values are returned:</p> <ul style="list-style-type: none"> <li>0 Successful completion.</li> <li>&gt;0 An error occurred.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>DESCRIPTION</b>   | <p>The <code>stty</code> utility sets certain terminal I/O options for the device that is the current standard input. Without arguments, <code>stty</code> reports the settings of certain options.</p> <p>In this report, if a character is preceded by a caret (^), then the value of that option is the corresponding control character (for example, “^h” is Control-h. In this case, recall that Control-h is the same as the “back-space” key). The sequence “^^” means that an option has a null value.</p> <p>See <code>termio(7I)</code> for detailed information about the modes listed from Control Modes through Local Modes. For detailed information about the modes listed under Hardware Flow Control Modes and Clock Modes, below, see <code>termiox(7I)</code>.</p> <p>Operands described in the Combination Modes section are implemented using options in the earlier sections. Notice that many combinations of options make no sense, but no sanity checking is performed. Hardware flow control and clock modes options might not be supported by all hardware interfaces.</p> |                 |                                                   |                 |                                                                                      |                 |                                                                        |                 |                                                       |   |                           |                |                                                    |            |                        |
| <b>OPTIONS</b>       | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a       Writes to standard output all of the option settings for the terminal.</li> <li>-g       Reports current settings in a form that can be used as an argument to another <code>stty</code> command. Emits <code>termios</code>-type output if the underlying driver supports it. Otherwise, it emits <code>termio</code>-type output.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                 |                                                   |                 |                                                                                      |                 |                                                                        |                 |                                                       |   |                           |                |                                                    |            |                        |
| <b>OPERANDS</b>      | The following <i>mode</i> operands are supported:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                 |                                                   |                 |                                                                                      |                 |                                                                        |                 |                                                       |   |                           |                |                                                    |            |                        |
| <b>Control Modes</b> | <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;">parenb(-parenb)</td> <td>Enable (disable) parity generation and detection.</td> </tr> <tr> <td>parext(-parext)</td> <td>Enable (disable) extended parity generation and detection for mark and space parity.</td> </tr> <tr> <td>parodd(-parodd)</td> <td>Select odd (even) parity, or mark (space) parity if parext is enabled.</td> </tr> <tr> <td>cs5 cs6 cs7 cs8</td> <td>Select character size (see <code>termio(7I)</code>).</td> </tr> <tr> <td>0</td> <td>Hang up line immediately.</td> </tr> <tr> <td>hupcl (-hupcl)</td> <td>Hang up (do not hang up) connection on last close.</td> </tr> <tr> <td>hup (-hup)</td> <td>Same as hupcl(-hupcl).</td> </tr> </table>                                                                                                                                                                                                                                                                                                                                           | parenb(-parenb) | Enable (disable) parity generation and detection. | parext(-parext) | Enable (disable) extended parity generation and detection for mark and space parity. | parodd(-parodd) | Select odd (even) parity, or mark (space) parity if parext is enabled. | cs5 cs6 cs7 cs8 | Select character size (see <code>termio(7I)</code> ). | 0 | Hang up line immediately. | hupcl (-hupcl) | Hang up (do not hang up) connection on last close. | hup (-hup) | Same as hupcl(-hupcl). |

|                    | vt0 vt1                   | Select style of delay for vertical tabs (see <code>termio(7I)</code> ).                                                                                                                                                                                                          |
| <b>Local Modes</b> | <b>isig(-isig)</b>        | Enable (disable) the checking of characters against the special control characters INTR, QUIT, SWTCH, and SUSP. For information on SWTCH, see NOTES.                                                                                                                             |
|                    | <b>icanon (-icanon)</b>   | Enable (disable) canonical input (ERASE and KILL processing). Does not set MIN or TIME.                                                                                                                                                                                          |
|                    | <b>xcase (-xcase)</b>     | Canonical (unprocessed) upper/lower-case presentation.                                                                                                                                                                                                                           |
|                    | <b>echo (-echo)</b>       | Echo back (do not echo back) every character typed.                                                                                                                                                                                                                              |
|                    | <b>echoe (-echoe)</b>     | Echo (do not echo) ERASE character as a backspace-space-backspace string. This mode erases the ERASEed character on many CRT terminals; however, it does not keep track of column position and, as a result, it might be confusing for escaped characters, tabs, and backspaces. |
|                    | <b>echok(-echok)</b>      | Echo (do not echo) NL after KILL character.                                                                                                                                                                                                                                      |
|                    | <b>lfkc (-lfkc)</b>       | The same as <code>echok(-echok)</code> ; obsolete.                                                                                                                                                                                                                               |
|                    | <b>echonl (-echonl)</b>   | Echo (do not echo) NL.                                                                                                                                                                                                                                                           |
|                    | <b>noflsh (-noflsh)</b>   | Disable (enable) flush after INTR, QUIT, or SUSP.                                                                                                                                                                                                                                |
|                    | <b>stwrap (-stwrap)</b>   | Disable (enable) truncation of lines longer than 79 characters on a synchronous line.                                                                                                                                                                                            |
|                    | <b>tostop (-tostop)</b>   | Send (do not send) SIGTTOU when background processes write to the terminal.                                                                                                                                                                                                      |
|                    | <b>echoctl (-echoctl)</b> | Echo (do not echo) control characters as <code>^char</code> , delete as <code>^?</code> .                                                                                                                                                                                        |
|                    | <b>echoprt (-echoprt)</b> | Echo (do not echo) erase character as character is "erased".                                                                                                                                                                                                                     |
|                    | <b>echoke (-echoke)</b>   | BS-SP-BS erase (do not BS-SP-BS erase) entire line on line kill.                                                                                                                                                                                                                 |

**Control Assignments**

rsetcoff Receiver signal element timing clock not provided.

rsetcrbrg Output receive baud rate generator on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin.

rsetctbrg Output transmit baud rate generator on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin.

rsetctset Output transmitter signal element timing (DCE source) on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin.

rsetcrset Output receiver signal element timing (DCE source) on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin.

*control-character c* Set *control-character* to *c*, where:

*control-character*  
 is *ctab*, *discard*, *dsusp*, *eof*, *eol*, *eol2*, *erase*, *intr*, *kill*, *lnext*, *quit*, *reprint*, *start*, *stop*, *susp*, *swtch*, or *werase* (*ctab* is used with *-stappl*, see *termio(7I)*). For information on *swtch*, see NOTES.

*c*  
 If *c* is a single character, the control character is set to that character.

In the POSIX locale, if *c* is preceded by a caret (^) indicating an escape from the shell and is one of those listed in the ^*c* column of the following table, then its value used (in the Value column) is the corresponding control character (for example, “^d” is a Control-d). “^?” is interpreted as DEL and “^\_” is interpreted as undefined.

| <i>^c</i> | Value | <i>^c</i> | Value | <i>^c</i> | Value |

# stty(1)

ek Reset ERASE and KILL characters back to normal DEL and Control-u, respectively.

sane Reset all modes to some reasonable values.

*term* Set all modes suitable for the terminal type *term*, where *term* is one of `ttty33`, `ttty37`, `vt05`, `tn300`, `ti700`, or `tek`.

async Set normal asynchronous communications where clock settings are `xcibrg`, `rcibrg`, `tsetcoff` and `rsetcoff`.

## Window Size

`rows n` Set window size to *n* rows.

`columns n` Set window size to *n* columns.

`cols n` Set window size to *n* columns. `cols` is a shorthand alias for `columns`.

`ypixels n` Set vertical window size to *n* pixels.

`xpixels n` Set horizontal window size to *n* pixels.

## USAGE

The `-g` flag is designed to facilitate the saving and restoring of terminal state from the shell level. For example, a program can:

```
saveterm="$(stty -g)"      # save terminal state
stty (new settings)      # set new state
...                      # ...
stty $saveterm           # restore terminal state
```

Since the `-a` format is so loosely specified, scripts that save and restore terminal settings should use the `-g` option.

## ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `stty`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

## EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

### /usr/bin/stty

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

### /usr/xpg4/bin/stty

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWxcu4        |

`/usr/xpg6/bin/stty`

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Standard        |

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWxcu6        |
| Interface Stability | Standard        |

**SEE ALSO** [tabs\(1\)](#), [ioctl\(2\)](#), [write\(2\)](#), [getwidth\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#), [ldterm\(7M\)](#), [termio\(7I\)](#), [termiox\(7I\)](#)

**NOTES** Solaris does not support any of the actions implied by `swtch`, which was used by the `sxt` driver on System V release 4. Solaris allows the `swtch` value to be set, and prints it out if set, but it does not perform the `swtch` action.

The job switch functionality on Solaris is actually handled by job control. `susp` is the correct setting for this.

| <b>NAME</b>             | stty – set the options for a terminal                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>         | <code>/usr/ucb/stty [-a] [-g] [-h] [modes]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b>      | stty sets certain terminal I/O options for the device that is the current standard output. Without arguments, stty reports the settings of certain options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>OPTIONS</b>          | <p>In this report, if a character is preceded by a caret (^), then the value of that option is the corresponding CTRL character (for example, “^h” is Control-h. In this case, recall that Control-h is the same as the “back-space” key.) The sequence “^” means that an option has a null value.</p> <p>-a                    Reports all of the option settings.</p> <p>-g                    Reports current settings in a form that can be used as an argument to another stty command.</p> <p>-h                    Reports all the option settings with the control characters in an easy to read column format.</p> <p>Options in the last group are implemented using options in the previous groups. <i>Note:</i> Many combinations of options make no sense, but no sanity checking is performed. Hardware flow control and clock modes options might not be supported by all hardware interfaces. The options are selected from the following:</p> |
| <b>Special Requests</b> | <p>all                    Reports the same option settings as stty without arguments, but with the control characters in column format.</p> <p>everything            Everything stty knows about is printed. Same as -h option.</p> <p>speed                 The terminal speed alone is reported on the standard output.</p> <p>size                  The terminal (window) sizes are printed on the standard output, first rows and then columns. This option is only appropriate if currently running a window system.</p> <p>                       size and speed always report on the settings of /dev/tty, and always report the settings to the standard output.</p>                                                                                                                                                                                                                                                                                   |
| <b>Control Modes</b>    | <p>parenb (-parenb)<br/>  Enable (disable) parity generation and detection.</p> <p>parext (-parext)<br/>  Enable (disable) extended parity generation and detection for mark and space parity.</p> <p>parodd (-parodd)<br/>  Select odd (even) parity, or mark (space) parity if parext is enabled.</p> <p>cs5 cs6 cs7 cs8<br/>  Select character size (see termio(7I)).</p> <p>0<br/>  Hang up line immediately.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

110 300 600 1200 1800 2400 4800 9600 19200 extra 38400 extb  
 Set terminal baud rate to the number given, if possible. (All speeds are not supported by all hardware interfaces.)

ispeed 0 110 300 600 1200 1800 2400 4800 9600 19200 extra 38400  
 extb  
 Set terminal input baud rate to the number given, if possible. (Not all hardware supports split baud rates.) If the input baud rate is set to zero, the input baud rate is specified by the value of the output baud rate.

ospeed 0 110 300 600 1200 1800 2400 4800 9600 19200 extra 38400  
 extb  
 Set terminal output baud rate to the number given, if possible. (Not all hardware supports split baud rates.) If the baud rate is set to zero, the line is hung up immediately.

hupcl (-hupcl)  
 Hang up (do not hang up) connection on last close.

hup (-hup)  
 Same as hupcl (-hupcl).

cstopb (-cstopb)  
 Use two (one) stop bits per character.

cread (-cread)  
 Enable (disable) the receiver.

clocal (-clocal)  
 Assume a line without (with) modem control.

crtstcs (-crtstcs)  
 Enable hardware flow control. Raise the RTS (Request to Send) modem control line. Suspends output until the CTS (Clear to Send) line is raised.

loblk (-loblk)  
 Block (do not block) output from a non-current layer.

**Input Modes**

ignbrk (-ignbrk)           Ignore (do not ignore) break on input.

brkint (-brkint)           Signal (do not signal) INTR on break.

ignpar (-ignpar)           Ignore (do not ignore) parity errors.

parmrk (-parmrk)           Mark (do not mark) parity errors (see `termio(7I)`).

inpck (-inpck)             Enable (disable) input parity checking.

istrip (-istrip)           Strip (do not strip) input characters to seven bits.

inlcr (-inlcr)             Map (do not map) NL to CR on input.

igncr (-igncr)             Ignore (do not ignore) CR on input.

icrnl (-icrnl)             Map (do not map) CR to NL on input.

stty(1B)

|                     |                     |                                                                                                                                                |
|---------------------|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
|                     | iuclc (-iuclc)      | Map (do not map) upper-case alphabetic to lower case on input.                                                                                 |
|                     | ixon (-ixon)        | Enable (disable) START/STOP output control. Output is stopped by sending an STOP and started by sending an START.                              |
|                     | ixany (-ixany)      | Allow any character (only START) to restart output.                                                                                            |
|                     | decctlq (-decctlq)  | Same as -ixany.                                                                                                                                |
|                     | ixoff (-ixoff)      | Request that the system send (not send) START/STOP characters when the input queue is nearly empty/full.                                       |
|                     | tandem (-tandem)    | Same as ixoff.                                                                                                                                 |
|                     | imaxbel (-imaxbel)  | Echo (do not echo) BEL when the input line is too long.                                                                                        |
|                     | iexten (-iexten)    | Enable (disable) extended (implementation-defined) functions for input data.                                                                   |
| <b>Output Modes</b> | opost (-opost)      | Post-process output (do not post-process output; ignore all other output modes).                                                               |
|                     | olcuc (-olcuc)      | Map (do not map) lower-case alphabetic to upper case on output.                                                                                |
|                     | onlcr (-onlcr)      | Map (do not map) NL to CR-NL on output.                                                                                                        |
|                     | ocrnl (-ocrnl)      | Map (do not map) CR to NL on output.                                                                                                           |
|                     | onocr (-onocr)      | Do not (do) output CRs at column zero.                                                                                                         |
|                     | onlret (-onlret)    | On the terminal NL performs (does not perform) the CR function.                                                                                |
|                     | ofill (-ofill)      | Use fill characters (use timing) for delays.                                                                                                   |
|                     | ofdel (-ofdel)      | Fill characters are DELs (NULs).                                                                                                               |
|                     | cr0 cr1 cr2 cr3     | Select style of delay for carriage returns (see <code>termio(7I)</code> ).                                                                     |
|                     | nl0 nl1             | Select style of delay for line-feeds (see <code>termio(7I)</code> ).                                                                           |
|                     | tab0 tab1 tab2 tab3 | Select style of delay for horizontal tabs (see <code>termio(7I)</code> ).                                                                      |
|                     | bs0 bs1             | Select style of delay for backspaces (see <code>termio(7I)</code> ).                                                                           |
|                     | ff0 ff1             | Select style of delay for form-feeds (see <code>termio(7I)</code> ).                                                                           |
|                     | vt0 vt1             | Select style of delay for vertical tabs (see <code>termio(7I)</code> ).                                                                        |
| <b>Local Modes</b>  | isig (-isig)        | Enable (disable) the checking of characters against the special control characters INTR, QUIT, and SWTCH. For information on SWTCH, see NOTES. |

|                      |                                                                                                                                                                                                                                                                                         |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| icanon (-icanon)     | Enable (disable) canonical input (ERASE and KILL processing). Does not set MIN or TIME.                                                                                                                                                                                                 |
| cbreak (-cbreak)     | Equivalent to -icanon min 1 time 0.                                                                                                                                                                                                                                                     |
| xcase (-xcase)       | Canonical (unprocessed) upper/lower-case presentation.                                                                                                                                                                                                                                  |
| echo (-echo)         | Echo back (do not echo back) every character typed.                                                                                                                                                                                                                                     |
| echoe (-echoe)       | Echo (do not echo) ERASE character as a backspace-space-backspace string. Note: This mode erases the ERASEed character on many CRT terminals; however, it does <i>not</i> keep track of column position and, as a result, can be confusing on escaped characters, tabs, and backspaces. |
| crterase (-crterase) | Same as echoe.                                                                                                                                                                                                                                                                          |
| echok (-echok)       | Echo (do not echo) NL after KILL character.                                                                                                                                                                                                                                             |
| lfkc (-lfkc)         | The same as echok (-echok); obsolete.                                                                                                                                                                                                                                                   |
| echonl (-echonl)     | Echo (do not echo) NL.                                                                                                                                                                                                                                                                  |
| noflsh (-noflsh)     | Disable (enable) flush after INTR, QUIT, or SWTCH. For information on SWTCH, see NOTES.                                                                                                                                                                                                 |
| stwrap (-stwrap)     | Disable (enable) truncation of lines longer than 79 characters on a synchronous line. (Does not apply to the 3B2.)                                                                                                                                                                      |
| tostop (-tostop)     | Send (do not send) SIGTTOU for background processes.                                                                                                                                                                                                                                    |
| echoctl (-echoctl)   | Echo (do not echo) control characters as <i>^char</i> , delete as <i>^?</i>                                                                                                                                                                                                             |
| ctlecho (-ctlecho)   | Same as echoctl.                                                                                                                                                                                                                                                                        |
| echoprt (-echoprt)   | Echo (do not echo) erase character as character is "erased".                                                                                                                                                                                                                            |
| prterase (-prterase) | Same as echoprt.                                                                                                                                                                                                                                                                        |
| echoke (-echoke)     | BS-SP-BS erase (do not BS-SP-BS erase) entire line on line kill.                                                                                                                                                                                                                        |
| crtkill (-crtkill)   | Same as echoke.                                                                                                                                                                                                                                                                         |
| flusho (-flusho)     | Output is (is not) being flushed.                                                                                                                                                                                                                                                       |
| pendin (-pendin)     | Retype (do not retype) pending input at next read or input character.                                                                                                                                                                                                                   |
| stflush (-stflush)   | Enable (disable) flush on a synchronous line after every write(2). (Does not apply to the 3B2.)                                                                                                                                                                                         |

stty(1B)

|                                    |                      |                                                                                                                                       |
|------------------------------------|----------------------|---------------------------------------------------------------------------------------------------------------------------------------|
|                                    | stappl (-stappl)     | Use application mode (use line mode) on a synchronous line. (Does not apply to the 3B2.)                                              |
| <b>Hardware Flow Control Modes</b> | rtsxoff (-rtsxoff)   | Enable (disable) RTS hardware flow control on input.                                                                                  |
|                                    | ctsxon (-ctsxon)     | Enable (disable) CTS hardware flow control on output.                                                                                 |
|                                    | dterxoff (-dterxoff) | Enable (disable) DTER hardware flow control on input.                                                                                 |
|                                    | rlsdxon (-rlsdxon)   | Enable (disable) RLSD hardware flow control on output.                                                                                |
|                                    | isxoff (-isxoff)     | Enable (disable) isochronous hardware flow control on input.                                                                          |
| <b>Clock Modes</b>                 | xcibrg               | Get transmit clock from internal baud rate generator.                                                                                 |
|                                    | xctset               | Get the transmit clock from transmitter signal element timing (DCE source) lead, CCITT V.24 circuit 114, EIA-232-D pin 15.            |
|                                    | xcrset               | Get transmit clock from receiver signal element timing (DCE source) lead, CCITT V.24 circuit 115, EIA-232-D pin 17.                   |
|                                    | rcibrg               | Get receive clock from internal baud rate generator.                                                                                  |
|                                    | rctset               | Get receive clock from transmitter signal element timing (DCE source) lead, CCITT V.24 circuit 114, EIA-232-D pin 15.                 |
|                                    | rcrset               | Get receive clock from receiver signal element timing (DCE source) lead, CCITT V.24 circuit 115, EIA-232-D pin 17.                    |
|                                    | tsetcoff             | Transmitter signal element timing clock not provided.                                                                                 |
|                                    | tsetcrc              | Output receive clock on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24, clock source.  |
|                                    | tsetcxc              | Output transmit clock on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24, clock source. |
|                                    | rsetcoff             | Receiver signal element timing clock not provided.                                                                                    |
|                                    | rsetcrc              | Output receive clock on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin, clock source.     |
|                                    | rsetcxc              | Output transmit clock on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin, clock source.    |

|                            |                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Control Assignments</b> | <i>control-character c</i>        | Set <i>control-character</i> to <i>c</i> , where <i>control-character</i> is <i>intr</i> , <i>quit</i> , <i>erase</i> , <i>kill</i> , <i>eof</i> , <i>eol</i> , <i>eol2</i> , <i>swtch</i> , <i>start</i> , <i>stop</i> , <i>susp</i> , <i>dsusp</i> , <i>rprnt</i> , <i>flush</i> , <i>werase</i> , <i>lnext</i> , <i>min</i> , <i>ctab</i> , <i>time</i> , or <i>brk</i> ( <i>ctab</i> is used with <i>-stappl</i> ; <i>min</i> and <i>time</i> are used with <i>-icanon</i> ; see <i>termio(7I)</i> ). If <i>c</i> is preceded by an (escaped from the shell) caret (^), then the value used is the corresponding CTRL character (for example, “^d” is a Control-d). “^?” is interpreted as DEL and “^_” is interpreted as undefined. For information on <i>SWTCH</i> , see <i>NOTES</i> . |
| <b>Combination Modes</b>   | <i>line i</i>                     | Set line discipline to <i>i</i> ( $0 < i < 127$ ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                            | <i>evenp</i> or <i>parity</i>     | Enable <i>parenb</i> and <i>cs7</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                            | <i>-evenp</i> , or <i>-parity</i> | Disable <i>parenb</i> , and set <i>cs8</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                            | <i>even (-even)</i>               | Same as <i>evenp (-evenp)</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                    | <code>xpixelsn</code>                        | Set horizontal window size to <i>n pixels</i> .                                                                                                                                                                         |

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscpu        |

**SEE ALSO** `tabs(1)`, `ioctl(2)`, `attributes(5)`, `termio(7I)`, `termiox(7I)`

**NOTES** Solaris does not support any of the actions implied by `swtch`, which was used by the `sxt` driver on System V release 4. Solaris allows the `swtch` value to be set, and prints it out if set, but it does not perform the `swtch` action.

The job switch functionality on Solaris is actually handled by job control. `susp` is the correct setting for this.

| <b>NAME</b>                  | sum – print checksum and block count for a file                                                                                                                                                                                                    |                |                 |              |         |     |         |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|---------|-----|---------|
| <b>SYNOPSIS</b>              | <b>sum</b> [-r] [ <i>file...</i> ]                                                                                                                                                                                                                 |                |                 |              |         |     |         |
| <b>DESCRIPTION</b>           | The <code>sum</code> utility calculates and prints a 16-bit checksum for the named file and the number of 512-byte blocks in the file. It is typically used to look for bad spots, or to validate a file communicated over some transmission line. |                |                 |              |         |     |         |
| <b>OPTIONS</b>               | The following options are supported:<br>-r        Use an alternate (machine-dependent) algorithm in computing the checksum.                                                                                                                        |                |                 |              |         |     |         |
| <b>OPERANDS</b>              | The following operands are supported:<br><i>file</i> A path name of a file. If no files are named, the standard input is used.                                                                                                                     |                |                 |              |         |     |         |
| <b>USAGE</b>                 | See <code>largefile(5)</code> for the description of the behavior of <code>sum</code> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                                  |                |                 |              |         |     |         |
| <b>ENVIRONMENT VARIABLES</b> | See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>sum</code> : <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .                                  |                |                 |              |         |     |         |
| <b>EXIT STATUS</b>           | The following exit values are returned.<br>0        Successful completion.<br>>0      An error occurred.                                                                                                                                           |                |                 |              |         |     |         |
| <b>ATTRIBUTES</b>            | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                       |                |                 |              |         |     |         |
|                              | <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWesu</td> </tr> <tr> <td>CSI</td> <td>enabled</td> </tr> </tbody> </table>                               | ATTRIBUTE TYPE | ATTRIBUTE VALUE | Availability | SUNWesu | CSI | enabled |
| ATTRIBUTE TYPE               | ATTRIBUTE VALUE                                                                                                                                                                                                                                    |                |                 |              |         |     |         |
| Availability                 | SUNWesu                                                                                                                                                                                                                                            |                |                 |              |         |     |         |
| CSI                          | enabled                                                                                                                                                                                                                                            |                |                 |              |         |     |         |
| <b>SEE ALSO</b>              | <code>cksum(1)</code> , <code>sum(1B)</code> , <code>wc(1)</code> , <code>attributes(5)</code> , <code>environ(5)</code> , <code>largefile(5)</code>                                                                                               |                |                 |              |         |     |         |
| <b>DIAGNOSTICS</b>           | “Read error” is indistinguishable from end of file on most devices; check the block count.                                                                                                                                                         |                |                 |              |         |     |         |
| <b>NOTES</b>                 | Portable applications should use <code>cksum(1)</code> .<br><code>sum</code> and <code>usr/ucb/sum</code> (see <code>sum(1B)</code> ) return different checksums.                                                                                  |                |                 |              |         |     |         |

sum(1B)

**NAME** | sum – calculate a checksum for a file

**SYNOPSIS** | */usr/ucb/sum file...*

**DESCRIPTION** | sum calculates and displays a 16-bit checksum for the named file and displays the size of the file in kilobytes. It is typically used to look for bad spots, or to validate a file communicated over some transmission line. The checksum is calculated by an algorithm which may yield different results on machines with 16-bit ints and machines with 32-bit ints, so it cannot always be used to validate that a file has been transferred between machines with different-sized ints.

**USAGE** | See *largefile(5)* for the description of the behavior of sum when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**ATTRIBUTES** | See *attributes(5)* for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscpu        |

**SEE ALSO** | *sum(1)*, *wc(1)*, *attributes(5)*, *largefile(5)*

**DIAGNOSTICS** | Read error is indistinguishable from EOF on most devices; check the block count.

**NOTES** | *sum* and */usr/bin/sum* (see *sum(1)*) return different checksums.

This utility is obsolete.

**NAME** suspend – shell built-in function to halt the current shell

**SYNOPSIS**

**sh** suspend

**csh** suspend

**ksh** suspend

**DESCRIPTION**

**sh** Stops the execution of the current shell (but not if it is the login shell).

**csh** Stop the shell in its tracks, much as if it had been sent a stop signal with ^Z. This is most often used to stop shells started by `su`.

**ksh** Stops the execution of the current shell (but not if it is the login shell).

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `csh(1)`, `kill(1)`, `ksh(1)`, `sh(1)`, `su(1M)`, `attributes(5)`

## svccprop(1)

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |    |                                                             |    |                                                          |

| <b>DESCRIPTION</b> | <p>The <code>svccprop</code> utility prints values of properties in the service configuration repository. Properties are selected by <code>-p</code> options and <code>FMRI</code> operands.</p> <p>By default, when a single property is selected, its values are printed separated by spaces on a single line. Empty ASCII string values are represented by a pair of double quotes (""). Bourne shell metacharacters (';', '&amp;', '(', ')', ' ', '^', '&lt;', '&gt;', newline, space, tab, backslash, '"', single-quote, '`') in ASCII string values are quoted by backslashes (\).</p> <p>When multiple properties are selected, a single line is printed for each. Each line comprises a property designator, a property type, and the values (as described above), separated by spaces. By default, if a single <code>FMRI</code> operand has been supplied, the property designator consists of the property group name and the property name joined by a slash (/). If multiple <code>FMRI</code> operands are supplied, the designator is the canonical <code>FMRI</code> for the property.</p> <p>A composed property may be selected directly from the entities which match a specified <code>FMRI</code> or from entities which may be used as a source of properties for these matching entities. An example of a composed property is a property which is set on a service, which may be selected when an instance matching an <code>FMRI</code> does not possess the property itself.</p> <p>An un-composed property selection is made against the specified <code>FMRI</code> with no further searching of additional sources of properties other than the entities which match the designated <code>FMRI</code>.</p> <p>Properties are displayed either with or without composition depending on the options which are supplied at invocation. Properties are composed by default.</p> <p>A snapshot, which is a point in time representation of the state of a matching entity's properties at a moment in time, always uses composition because snapshots are always composed.</p> <p>Error messages are printed to the standard error stream.</p> <p>Many properties have specific meanings to the Service Management Facility or the service's restarter.</p> |    |                                                             |    |                                                          |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <table><tr><td>-C</td><td>Retrieves the current property values, without composition.</td></tr><tr><td>-c</td><td>Retrieves the current property values, with composition.</td></tr></table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | -C | Retrieves the current property values, without composition. | -c | Retrieves the current property values, with composition. |
| -C                 | Retrieves the current property values, without composition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |    |                                                             |    |                                                          |
| -c                 | Retrieves the current property values, with composition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |    |                                                             |    |                                                          |

|                                 |                                                                                                                                                                                                                                                                                       |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -f                              | Designates properties by their <i>FMRI</i> s. Implies option -t.                                                                                                                                                                                                                      |
| -p [ <i>name/</i> ] <i>name</i> | Prints values of the named property or property group for each of the property groups, instances, or services specified by the operands.                                                                                                                                              |
| -q                              | Quiet. Produces no output.                                                                                                                                                                                                                                                            |
| -s <i>snapshot</i>              | Uses the named snapshot to retrieve the specified property or property group, with composition (since snapshots are always composed). If the given property group is not present in the snapshot, the current property values are examined.                                           |
| -t                              | Uses the multi-property output format.                                                                                                                                                                                                                                                |
| -v                              | Verbose. Prints error messages for nonexistent properties, even if option -q is also used.                                                                                                                                                                                            |
| -w                              | Waits for the selected property group or property to change before printing anything.                                                                                                                                                                                                 |
|                                 | This option is only valid when a single entity is given. If more than one operand is given, or an operand matches more than one instance, an error message is printed and no action is taken. The -w option always causes <i>svccprop</i> to operate against current property values. |

#### OPERANDS

The following operand is supported:

*FMRI* With no -p options, *FMRI* operands can name a service, instance, property group, or property. For services, service instances, and property groups, all contained properties are selected.

Instances and services can be abbreviated by specifying the instance name, or the trailing portion of the service name. Properties and property groups must be specified by a full *FMRI*. For example, given the *FMRI*:

```
svc:/network/smtp:sendmail
```

The following are valid abbreviations:

```
sendmail
:sendmail
smtp
smtp:sendmail
network/smtp
```

The following are invalid abbreviations:

## svccprop(1)

```
mail
network
network/smt
```

Abbreviated forms of FMRI are unstable and should not be used in scripts or other permanent tools.

Arguments to the `-p` option can name property groups or properties. In the former case, operands can name services or instances, and all properties in the named property group of the named services or instances are printed. In the latter, operands can name services, instances, or property groups, and the named properties belonging to the operands are printed.

By default, all properties are selected from the running snapshot, with composition. If there is no running snapshot, then current properties are selected. The `-w` and `-s` options can be used to change the source of properties.

When walking properties, that is, no `-p` options, current nonpersistent property groups are also selected.

With `-p` options, if the property group doesn't exist in the running snapshot, then if the property group is nonpersistent the current property or property group is selected.

### EXAMPLES **EXAMPLE 1** Displaying the Value of a Single Property

The following example displays the value of the enabled property in the general property group of instance default of service `inetd`.

```
example% svccprop -p general/enabled network/inetd.default
true
```

### **EXAMPLE 2** Displaying All Properties in a Property Group

This example displays all properties in the general property group of service `ntp`.

```
example% svccprop -p general ntp
general/entity_stability astring Unstable
general/single_instance boolean true
```

### **EXAMPLE 3** Verifying the Existence of a Property

This example verifies the existence of the `general/enabled` property for all instances of service `identity`.

```
example% svccprop -q -p general/enabled identity:
example% echo $?
0
```

**EXAMPLE 4** Waiting for Property Change

This example waits for the sendmail instance to change state.

```
example% svcprop -w -p restarter/state sendmail
```

**EXAMPLE 5** Using svcprop in a Script

```
example% cat getval
#!/bin/sh

svcprop -p $1 $2 | (
    read value v2
    if [ -n "$v2" ]; then echo "Multiple values!"; exit; fi
    echo $value
)
```

**EXIT STATUS** The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.
- 2 Invalid command line options were specified.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

## svcs(1)

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | svcs – report service status                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <pre>svcs [-aHpV?] [-o col [,col]...] [-R instance_FMRI]... [-sS col]... [FMRI   pattern...]  svcs {-d   -D} [-HpV?] [-o col [,col]...] [-sS col]... [FMRI   pattern] . . .  svcs -l [FMRI   pattern...]  svcs -x [-v] [FMRI] . . .</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b> | <p>The <code>svcs</code> command displays information about service instances as recorded in the service configuration repository. The first form prints one-line status listings for service instances specified by the arguments. Each instance is listed only once. With no arguments, all enabled service instances, even if temporarily disabled, are listed with the columns indicated below. The second form prints one-line status listings for the dependencies or dependents of the service instances specified by the arguments. The third form prints detailed information about specific services and instances.</p> <p>The fourth form explains the states of service instances. For each argument, a block of human-readable text is displayed which explains what state the service is in, and why it is in that state. With no arguments, problematic services are described.</p> <p>Error messages are printed to the standard error stream.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-? Displays an extended usage message, including column specifiers.</li> <li>-a Show all services, even disabled ones. This option has no effect if services are selected.</li> <li>-d Lists the services or service instances upon which the given service instances depend.</li> <li>-D Lists the service instances that depend on the given services or service instances.</li> <li>-H Omits the column headers.</li> <li>-l (The letter ell.) Displays all available information about the selected services and service instances, with one service attribute displayed for each line. Information for different instances are separated by blank lines.</li> <li>-o col[,col]... Prints the specified columns. Each <i>col</i> should be a column name. See COLUMNS below for available columns.</li> </ul>                                                               |

|                         |                                                                                                                                                                                                                                                                                |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -p                      | Lists processes associated with each service instance. A service instance may have no associated processes. The process ID, start time, and command name (PID, STIME, and CMD fields from <code>ps(1)</code> ) are displayed for each process.                                 |
| -R <i>instance_FMRI</i> | Selects service instances that have the given service instance as their restarter.                                                                                                                                                                                             |
| -s <i>col</i>           | Sorts output by column. <i>col</i> should be a column name. See COLUMNS below for available columns. Multiple -s options behave additively.                                                                                                                                    |
| -S <i>col</i>           | Sorts by <i>col</i> in the opposite order as option -s.                                                                                                                                                                                                                        |
| -v                      | Without -x, displays verbose columns: STATE, NSTATE, STIME, CTID, and FMRI.<br><br>With -x, displays extra information for each explanation.                                                                                                                                   |
| -x                      | Displays explanations for service states.<br><br>Without arguments, the -x option explains the states of services which: <ul style="list-style-type: none"> <li>■ are enabled, but are not running.</li> <li>■ are preventing another enabled service from running.</li> </ul> |

**OPERANDS** The following operands are supported:

|                      |                                                                                                                                                                                    |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>instance_FMRI</i> | An FMRI that specifies an instance.                                                                                                                                                |
| <i>FMRI</i>          | An FMRI that specifies one or more instances. FMRI's can be abbreviated by specifying the instance name, or the trailing portion of the service name. For example, given the FMRI: |

```
svc:/network/smtp:sendmail
```

The following are valid abbreviations:

```
sendmail
:sendmail
smtp
smtp:sendmail
network/smtp
```

The following are invalid abbreviations:

```
mail
network
network/smt
```

svcs(1)

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                  |          |                  |          |                  |                                                     |                  |             |                  |         |                 |        |                 |               |

|       |                                                                                                                                                                                                                                                          |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STATE | The state of the service instance. An asterisk is appended for instances in transition, unless the NSTA or NSTATE column is also being displayed.<br><br>See <code>smf(5)</code> for an explanation of service states.                                   |
| STIME | If the service instance entered the current state within the last 24 hours, this column indicates the time that it did so. Otherwise, this column indicates the date on which it did so, printed with underscores ( <code>_</code> ) in place of blanks. |

**EXAMPLES****EXAMPLE 1** Displaying the Default Output

This example displays default output:

```
example% svcs
STATE          STIME      FMRI
...
legacy_run    13:25:04  lrc:/etc/rc3_d/S42myscript
...
online        13:21:50  svc:/system/svc/restarter:default
...
online        13:25:03  svc:/milestone/multi-user:default
...
online        13:25:07  svc:/milestone/multi-user-server:default
...
```

**EXAMPLE 2** Listing All Local Instances

This example lists all local instances of the `service1` service.

```
example% svcs -o state,nstate,fmri service1
STATE      NSTATE      FMRI
online     -           svc:/service1:instance1
disabled   -           svc:/service1:instance2
```

**EXAMPLE 3** Listing Verbose Information

This example lists verbose information.

```
example% svcs -v smtp
STATE      NSTATE      STIME      CTID      FMRI
online     -           13:25:13   141      svc:/network/smtp:sendmail
```

**EXAMPLE 4** Listing Detailed Information

This example lists detailed information about all instances of `system/service3`. Additional fields can be displayed, as appropriate to the managing restart.

```
example% svcs -l system/service3

fmri          svc:/system/service3:default
description   Example service 3
```

## svcs(1)

### EXAMPLE 4 Listing Detailed Information (Continued)

```
enabled      true
state        online
next_state   none
restarter    svc:/system/svc/restarter:default
dependency   require_all/refresh svc:/system/service2:default (online)
dependency   require_all/none svc:/system/service1:default (online)

fmri         svc:/system/service3:backup
description  Example service 3
enabled      false
state        disabled
next_state   none
restarter    svc:/system/svc/restarter:default
dependency   require_all svc:/system/service2:backup (-)
```

### EXAMPLE 5 Listing Processes

```
example% svcs -p sendmail
STATE      STIME      FMRI
online     13:25:13   svc:/network/smtp:sendmail
           13:25:15   100939 sendmail
13:25:15   100940 sendmail
```

**EXIT STATUS** The following exit values are returned:

- 0 Successful command invocation.
- 1 Fatal error.
- 2 Invalid command line options were specified.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | See below.      |

The human readable output is Unstable. The invocation is Evolving.

| <b>SYNOPSIS</b>    | <b>symorder</b> [-s] <i>objectfile symbolfile</i>                                                                                                                                                                                                                                                                                                                               |                |                 |              |           |
| <b>DESCRIPTION</b> | <p>symorder was used in SunOS 4.x specifically to cut down on the overhead of getting symbols from vmunix. This is no longer applicable as kernel symbol entries are dynamically obtained through /dev/ksyms.</p> <p>This script is provided as a convenience for software developers who need to maintain scripts that are portable across a variety of operating systems.</p> |                |                 |              |           |
| <b>EXIT STATUS</b> | symorder has exit status 0.                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |           |

| <b>NAME</b>        | sysV-make – maintain, update, and regenerate groups of programs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SYNOPSIS</b>    | <code>/usr/lib/svr4.make [-f <i>makefile</i>] [-eiknpqrst] [<i>names</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>This is the “vanilla” System V version of make. If the environment variable <code>USE_SVR4_MAKE</code> is set, then the command <code>make</code> will invoke this version of make. (See also the <code>ENVIRONMENT</code> section.)</p> <p><code>make</code> allows the programmer to maintain, update, and regenerate groups of computer programs. <code>make</code> executes commands in <i>makefile</i> to update one or more target <i>names</i> (<i>names</i> are typically programs). If the <code>-f</code> option is not present, then <code>makefile</code>, <code>Makefile</code>, and the Source Code Control System (SCCS) files <code>s.makefile</code> and <code>s.Makefile</code> are tried in order. If <i>makefile</i> is <code>'-'</code> the standard input is taken. More than one <code>-f makefile</code> argument pair may appear.</p> <p><code>make</code> updates a target only if its dependents are newer than the target. All prerequisite files of a target are added recursively to the list of targets. Missing files are deemed to be outdated.</p> <p>The following list of four directives can be included in <i>makefile</i> to extend the options provided by <code>make</code>. They are used in <i>makefile</i> as if they were targets:</p> <ul style="list-style-type: none"><li><code>.DEFAULT :</code> If a file must be made but there are no explicit commands or relevant built-in rules, the commands associated with the name <code>.DEFAULT</code> are used if it exists.</li><li><code>.IGNORE :</code> Same effect as the <code>-i</code> option.</li><li><code>.PRECIOUS :</code> Dependents of the <code>.PRECIOUS</code> entry will not be removed when quit or interrupt are hit.</li><li><code>.SILENT :</code> Same effect as the <code>-s</code> option.</li></ul> |
| <b>Options</b>     | <p>The options for <code>make</code> are listed below:</p> <ul style="list-style-type: none"><li><code>-e</code> Environment variables override assignments within makefiles.</li><li><code>-f <i>makefile</i></code> Description filename (<i>makefile</i> is assumed to be the name of a description file).</li><li><code>-i</code> Ignore error codes returned by invoked commands.</li><li><code>-k</code> Abandon work on the current entry if it fails, but continue on other branches that do not depend on that entry.</li><li><code>-n</code> No execute mode. Print commands, but do not execute them. Even command lines beginning with an <code>'@'</code> are printed.</li><li><code>-p</code> Print out the complete set of macro definitions and target descriptions.</li><li><code>-q</code> Question. <code>make</code> returns a zero or non-zero status code depending on whether or not the target file has been updated.</li><li><code>-r</code> Do not use the built-in rules.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

- s                    Silent mode. Do not print command lines before executing.
- t                    Touch the target files (causing them to be updated) rather than issue the usual commands.

### Creating the makefile

The makefile invoked with the `-f` option is a carefully structured file of explicit instructions for updating and regenerating programs, and contains a sequence of entries that specify dependencies. The first line of an entry is a blank-separated, non-null list of targets, then a `:`, then a (possibly null) list of prerequisite files or dependencies. Text following a `;` and all following lines that begin with a tab are shell commands to be executed to update the target. The first non-empty line that does not begin with a tab or `#` begins a new dependency or macro definition. Shell commands may be continued across lines with a backslash-new-line (`\-NEWLINE`) sequence. Everything printed by make (except the initial TAB) is passed directly to the shell as is. Thus,

```
echo a\  
b
```

will produce

```
ab
```

exactly the same as the shell would.

Number-sign (`#`) and `NEWLINE` surround comments including contained `\-NEWLINE` sequences.

The following makefile says that `pgm` depends on two files `a.o` and `b.o`, and that they in turn depend on their corresponding source files (`a.c` and `b.c`) and a common file `incl.h`:

```
pgm: a.o b.o  
    cc a.o b.o -o pgm  
a.o: incl.h a.c  
    cc -c a.c  
b.o: incl.h b.c  
    cc -c b.c
```

Command lines are executed one at a time, each by its own shell. The `SHELL` environment variable can be used to specify which shell make should use to execute commands. The default is `/usr/bin/sh`. The first one or two characters in a command can be the following: `@`, `-`, `@-`, or `-@`. If `@` is present, printing of the command is suppressed. If `-` is present, make ignores an error. A line is printed when it is executed unless the `-s` option is present, or the entry `.SILENT:` is included in

## sysV-make(1)

*makefile*, or unless the initial character sequence contains a @. The -n option specifies printing without execution; however, if the command line has the string \$(MAKE) in it, the line is always executed (see the discussion of the MAKEFLAGS macro in the make Environment sub-section below). The -t (touch) option updates the modified date of a file without executing any commands.

Commands returning non-zero status normally terminate make. If the -i option is present, if the entry .IGNORE: is included in *makefile*, or if the initial character sequence of the command contains '-', the error is ignored. If the -k option is present, work is abandoned on the current entry, but continues on other branches that do not depend on that entry.

Interrupt and quit cause the target to be deleted unless the target is a dependent of the directive .PRECIOUS.

### make Environment

The environment is read by make. All variables are assumed to be macro definitions and are processed as such. The environment variables are processed before any makefile and after the internal rules; thus, macro assignments in a makefile override environment variables. The -e option causes the environment to override the macro assignments in a makefile. Suffixes and their associated rules in the makefile will override any identical suffixes in the built-in rules.

The MAKEFLAGS environment variable is processed by make as containing any legal input option (except -f and -p) defined for the command line. Further, upon invocation, make "invents" the variable if it is not in the environment, puts the current options into it, and passes it on to invocations of commands. Thus, MAKEFLAGS always contains the current input options. This feature proves very useful for "super-makes". In fact, as noted above, when the -n option is used, the command \$(MAKE) is executed anyway; hence, one can perform a make -n recursively on a whole software system to see what would have been executed. This result is possible because the -n is put in MAKEFLAGS and passed to further invocations of \$(MAKE). This usage is one way of debugging all of the makefiles for a software project without actually doing anything.

### Include Files

If the string *include* appears as the first seven letters of a line in a *makefile*, and is followed by a blank or a tab, the rest of the line is assumed to be a filename and will be read by the current invocation, after substituting for any macros.

### Macros

Entries of the form *string1* = *string2* are macro definitions. *string2* is defined as all characters up to a comment character or an unescaped NEWLINE. Subsequent appearances of \$(*string1*[:*subst1*=[*subst2*]]) are replaced by *string2*. The parentheses are optional if a single-character macro name is used and there is no substitute sequence. The optional :*subst1*=*subst2* is a substitute sequence. If it is specified, all non-overlapping occurrences of *subst1* in the named macro are replaced by *subst2*. Strings (for the purposes of this type of substitution) are delimited by BLANKs, TABs, NEWLINE characters, and beginnings of lines. An example of the use of the substitute sequence is shown in the Libraries sub-section below.

**Internal Macros**

There are five internally maintained macros that are useful for writing rules for building targets.

- \$\*** The macro `$*` stands for the filename part of the current dependent with the suffix deleted. It is evaluated only for inference rules.
- \$@** The `$@` macro stands for the full target name of the current target. It is evaluated only for explicitly named dependencies.
- \$<** The `$<` macro is only evaluated for inference rules or the `.DEFAULT` rule. It is the module that is outdated with respect to the target (the “manufactured” dependent file name). Thus, in the `.c.o` rule, the `$<` macro would evaluate to the `.c` file. An example for making optimized `.o` files from `.c` files is:
- ```
.c.o:
    cc -c -O $*.c

or:

.c.o:
    cc -c -O $<
```
- \$?** The `$?` macro is evaluated when explicit rules from the makefile are evaluated. It is the list of prerequisites that are outdated with respect to the target, and essentially those modules that must be rebuilt.
- \$%** The `$%` macro is only evaluated when the target is an archive library member of the form `lib(file.o)`. In this case, `$@` evaluates to `lib` and `$%` evaluates to the library member, `file.o`.

Four of the five macros can have alternative forms. When an upper case D or F is appended to any of the four macros, the meaning is changed to “directory part” for D and “file part” for F. Thus, `$(@D)` refers to the directory part of the string `$@`. If there is no directory part, `./` is generated. The only macro excluded from this alternative form is `$?`.

**Suffixes**

Certain names (for instance, those ending with `.o`) have inferable prerequisites such as `.c`, `.s`, etc. If no update commands for such a file appear in *makefile*, and if an inferable prerequisite exists, that prerequisite is compiled to make the target. In this case, *make* has inference rules that allow building files from other files by examining the suffixes and determining an appropriate inference rule to use. The current default inference rules are:

---

<code>.c</code>	<code>.c~</code>	<code>.f</code>	<code>.f~</code>	<code>.s</code>	<code>.s~</code>	<code>.sh</code>	<code>.sh~</code>	<code>.C</code>	<code>.C~</code>
<code>.c.a</code>	<code>.c.o</code>	<code>.c~.a</code>	<code>.c~.c</code>	<code>.c~.o</code>	<code>.f.a</code>	<code>.f.o</code>	<code>.f~.a</code>	<code>.f~.f</code>	<code>.f~.o</code>
<code>.h~.h</code>	<code>.l.c</code>	<code>.l.o</code>	<code>.l~.c</code>	<code>.l~.l</code>	<code>.l~.o</code>	<code>.s.a</code>	<code>.s.o</code>	<code>.s~.a</code>	<code>.s~.o</code>

---

## sysV-make(1)

---

.s~.s	.sh~.sh	.y.c	.y.o	.y~.c	.y~.o	.y~.y	.C.a	.C.o	.C~.a
.C~.C	.C~.o	.L.C	.L.o	.L~.C	.L~.L	.L~.o	.Y.C	.Y.o	.Y~.C
.Y~.o	.Y~.Y								

---

The internal rules for `make` are contained in the source file `make.rules` for the `make` program. These rules can be locally modified. To print out the rules compiled into the `make` on any machine in a form suitable for recompilation, the following command is used:

```
make -pf - 2>/dev/null </dev/null
```

A tilde in the above rules refers to an SCCS file (see `sccsfile(4)`). Thus, the rule `.c~.o` would transform an SCCS C source file into an object file (`.o`). Because the `s.` of the SCCS files is a prefix, it is incompatible with the `make` suffix point of view. Hence, the tilde is a way of changing any file reference into an SCCS file reference.

A rule with only one suffix (for example, `.c:`) is the definition of how to build  $x$  from  $x.c$ . In effect, the other suffix is null. This feature is useful for building targets from only one source file, for example, shell procedures and simple C programs.

Additional suffixes are given as the dependency list for `.SUFFIXES`. Order is significant: the first possible name for which both a file and a rule exist is inferred as a prerequisite. The default list is:

```
.SUFFIXES: .o .c .c~ .y .y~ .l .l~ .s .s~ .sh .sh~ .h .h~ .f .f~ .C  
.C~ .Y .Y~ .L .L~
```

Here again, the above command for printing the internal rules will display the list of suffixes implemented on the current machine. Multiple suffix lists accumulate; `.SUFFIXES:` with no dependencies clears the list of suffixes.

### Inference Rules

The first example can be done more briefly.

```
pgm: a.o b.o  
      cc a.o b.o -o pgm  
a.o b.o: incl.h
```

This abbreviation is possible because `make` has a set of internal rules for building files. The user may add rules to this list by simply putting them in the *makefile*.

Certain macros are used by the default inference rules to permit the inclusion of optional matter in any resulting commands. For example, `CFLAGS`, `LFLAGS`, and `YFLAGS` are used for compiler options to `cc(1B)`. Again, the previous method for examining the current rules is recommended.

The inference of prerequisites can be controlled. The rule to create a file with suffix `.o` from a file with suffix `.c` is specified as an entry with `.c.o`: as the target and no dependents. Shell commands associated with the target define the rule for making a `.o` file from a `.c` file. Any target that has no slashes in it and starts with a dot is identified as a rule and not a true target.

## Libraries

If a target or dependency name contains parentheses, it is assumed to be an archive library, the string within parentheses referring to a member within the library. Thus, `lib(file.o)` and `$(LIB) (file.o)` both refer to an archive library that contains `file.o`. (This example assumes the `LIB` macro has been previously defined.) The expression `$(LIB) (file1.o file2.o)` is not legal. Rules pertaining to archive libraries have the form `.XX.a` where the `XX` is the suffix from which the archive member is to be made. An unfortunate by-product of the current implementation requires the `XX` to be different from the suffix of the archive member. Thus, one cannot have `lib(file.o)` depend upon `file.o` explicitly. The most common use of the archive interface follows. Here, we assume the source files are all C type source:

```
lib:    lib(file1.o) lib(file2.o) lib(file3.o)
        @echo lib is now up-to-date
.c.a:
        $(CC) -c $(CFLAGS) $<
        $(AR) $(ARFLAGS) $@ $*.o
        rm -f $*.o
```

In fact, the `.c.a` rule listed above is built into `make` and is unnecessary in this example. A more interesting, but more limited example of an archive library maintenance construction follows:

```
lib:    lib(file1.o) lib(file2.o) lib(file3.o)
        $(CC) -c $(CFLAGS) $(?:.o=.c)
        $(AR) $(ARFLAGS) lib $?
        rm $?
        @echo lib is now up-to-date
.c.a:;
```

Here the substitution mode of the macro expansions is used. The `$?` list is defined to be the set of object filenames (inside `lib`) whose C source files are outdated. The substitution mode translates the `.o` to `.c`. (Unfortunately, one cannot as yet transform to `.c~`; however, this transformation may become possible in the future.) Also note the disabling of the `.c.a`: rule, which would have created each object file, one by one. This particular construct speeds up archive library maintenance considerably. This type of construct becomes very cumbersome if the archive library contains a mix of assembly programs and C programs.

## ENVIRONMENT VARIABLES

`USE_SVR4_MAKE` If this environment variable is set, then the `make` command will invoke this System V version of `make`. If this variable is not set, then the default version of `make(1S)` is invoked.

`USE_SVR4_MAKE` can be set as follows (Bourne shell):

```
$ USE_SVR4_MAKE=''' ; export USE_SVR4_MAKE
```

## sysV-make(1)

or (C shell):

```
% setenv USE_SVR4_MAKE
```

**FILES** [Mm]akefile  
s. [Mm]akefile default makefiles  
/usr/bin/sh default shell for make  
/usr/share/lib/make/make.rules default rules for make

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWspot

**SEE ALSO** [cc\(1B\)](#), [cd\(1\)](#), [make\(1S\)](#), [sh\(1\)](#), [printf\(3C\)](#), [sccsfile\(4\)](#), [attributes\(5\)](#)

**NOTES** Some commands return non-zero status inappropriately; use `-i` or the `'-'` command line prefix to overcome the difficulty.

Filenames containing the characters `'='`, `':'`, and `'@'` will not work. Commands that are directly executed by the shell, notably [cd\(1\)](#), are ineffectual across NEWLINES in make. The syntax `lib(file1.o file2.o file3.o)` is illegal. You cannot build `lib(file.o)` from `file.o`.

<b>NAME</b>	tabs – set tabs on a terminal
<b>SYNOPSIS</b>	<pre> <b>tabs</b> [-n   <i>--file</i> [ [-code]   -a   -a2   -c   -c2   -c3   -f   -p   -s         -u]] [ +m [n]] [-T <i>type</i>]  <b>tabs</b> [-T <i>type</i>] [ + m [n]] n1 [ , n2 ,...]           </pre>
<b>DESCRIPTION</b>	The <code>tabs</code> utility sets the tab stops on the user's terminal according to a tab specification, after clearing any previous settings. The user's terminal must have remotely settable hardware tabs.
<b>OPTIONS</b>	<p>The following options are supported. If a given flag occurs more than once, the last value given takes effect:</p> <p><code>-T <i>type</i></code>            <code>tabs</code> needs to know the type of terminal in order to set tabs and margins. <i>type</i> is a name listed in <code>term(5)</code>. If no <code>-T</code> flag is supplied, <code>tabs</code> uses the value of the environment variable <code>TERM</code>. If the value of <code>TERM</code> is <code>NULL</code> or <code>TERM</code> is not defined in the environment (see <code>environ(5)</code>), <code>tabs</code> uses <code>ansi+tabs</code> as the terminal type to provide a sequence that will work for many terminals.</p> <p><code>+m [n]</code>                The margin argument may be used for some terminals. It causes all tabs to be moved over <i>n</i> columns by making column <i>n</i>+1 the left margin. If <code>+m</code> is given without a value of <i>n</i>, the value assumed is 10. For a <code>Terminet</code>, the first value in the tab list should be 1, or the margin will move even further to the right. The normal (leftmost) margin on most terminals is obtained by <code>+m0</code>. The margin for most terminals is reset only when the <code>+m</code> flag is given explicitly.</p>
<b>Tab Specification</b>	<p>Four types of tab specification are accepted. They are described below: canned, repetitive (<code>-n</code>), arbitrary (<code>n1,n2,...</code>), and file (<code>-file</code>).</p> <p>If no tab specification is given, the default value is <code>-8</code>, that is, UNIX system "standard" tabs. The lowest column number is 1. Note: For <code>tabs</code>, column 1 always refers to the leftmost column on a terminal, even one whose column markers begin at 0, for example, the DASI 300, DASI 300s, and DASI 450.</p>
<b>Canned -code</b>	<p>Use one of the codes listed below to select a canned set of tabs. If more than one code is specified, the last code option will be used. The legal codes and their meanings are as follows:</p> <pre> -a          1, 10, 16, 36, 72 Assembler, IBM S/370, first format -a2         1, 10, 16, 40, 72            Assembler, IBM S/370, second format -c          1, 8, 12, 16, 20, 55            COBOL, normal format -c2         1, 6, 10, 14, 49           </pre>

## tabs(1)

		COBOL compact format (columns 1-6 omitted). Using this code, the first typed character corresponds to card column 7, one space gets you to column 8, and a tab reaches column 12. Files using this tab setup should include a format specification as follows (see <code>fspec(4)</code> ):
		<code>&lt;:t-c2 m6 s66 d:&gt;</code>
	<code>-c3</code>	1, 6, 10, 14, 18, 22, 26, 30, 34, 38, 42, 46, 50, 54, 58, 62, 67
		COBOL compact format (columns 1-6 omitted), with more tabs than <code>-c2</code> . This is the recommended format for COBOL. The appropriate format specification is (see <code>fspec(4)</code> ):
		<code>&lt;:t-c3 m6 s66 d:&gt;</code>
	<code>-f</code>	1, 7, 11, 15, 19, 23
		FORTRAN
	<code>-p</code>	1, 5, 9, 13, 17, 21, 25, 29, 33, 37, 41, 45, 49, 53, 57, 61
		PL/I
	<code>-s</code>	1, 10, 55
		SNOBOL
	<code>-u</code>	1, 12, 20, 44
		UNIVAC 1100 Assembler
<i>Repetitive</i>	<code>-n</code>	A <i>repetitive</i> specification requests tabs at columns $1+n$ , $1+2*n$ , etc., where $n$ is a single-digit decimal number. Of particular importance is the value 8: this represents the UNIX system "standard" tab setting, and is the most likely tab setting to be found at a terminal. When <code>-0</code> is used, the tab stops are cleared and no new ones are set.
<i>Arbitrary</i>		See OPERANDS.
<i>File</i>	<code>-file</code>	If the name of a <i>file</i> is given, <code>tabs</code> reads the first line of the file, searching for a format specification (see <code>fspec(4)</code> ). If it finds one there, it sets the tab stops according to it, otherwise it sets them as <code>-8</code> . This type of specification may be used to make sure that a tabbed file is printed with correct tab settings, and would be used with the <code>pr</code> command:  <code>example% tabs -file; pr file</code>
		Tab and margin setting is performed via the standard output.
<b>OPERANDS</b>		The following operand is supported:

*n1*[,*n2*, . . .]      The *arbitrary* format consists of tab-stop values separated by commas or spaces. The tab-stop values must be positive decimal integers in ascending order. Up to 40 numbers are allowed. If any number (except the first one) is preceded by a plus sign, it is taken as an increment to be added to the previous value. Thus, the formats 1,10,20,30, and 1,10,+10,+10 are considered identical.

**EXAMPLES**      **EXAMPLE 1** Using the tabs command

The following command is an example using *-code* (*canned* specification) to set tabs to the settings required by the IBM assembler: columns 1, 10, 16, 36, 72:

```
example% tabs -a
```

The next command is an example of using *-n* (*repetitive* specification), where *n* is 8, causes tabs to be set every eighth position: 1+(1\*8), 1+(2\*8), . . . which evaluate to columns 9, 17, . . . :

```
example% tabs -8
```

This command uses *n1,n2,. . .* (*arbitrary* specification) to set tabs at columns 1, 8, and 36:

```
example% tabs 1,8,36
```

The last command is an example of using *-file* (*file* specification) to indicate that tabs should be set according to the first line of `$HOME/fspec.list/att4425` (see `fspec(4)`).

```
example% tabs -$HOME/fspec.list/att4425
```

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `tabs`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**TERM**      Determine the terminal type. If this variable is unset or null, and if the `-T` option is not specified, terminal type `ansi+tabs` will be used.

**EXIT STATUS**      The following exit values are returned:

- 0            Successful completion.
- >0          An error occurred.

**ATTRIBUTES**      See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled
Interface Stability	Standard

tabs(1)

**SEE ALSO** [expand\(1\)](#), [newform\(1\)](#), [pr\(1\)](#), [stty\(1\)](#), [tput\(1\)](#), [fspec\(4\)](#), [terminfo\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [term\(5\)](#), [standards\(5\)](#)

**NOTES** There is no consistency among different terminals regarding ways of clearing tabs and setting the left margin.

tabs clears only 20 tabs (on terminals requiring a long sequence), but is willing to set 64.

The *tabspec* used with the tabs command is different from the one used with the newform command. For example, tabs -8 sets every eighth position; whereas newform -i-8 indicates that tabs are set every eighth position.

<b>NAME</b>	tail – deliver the last part of a file
<b>SYNOPSIS</b>	<pre> /usr/bin/tail [ ± number [lbcrl]] [file] /usr/bin/tail [-lbcrl] [file] /usr/bin/tail [ ± number [lbcfl]] [file] /usr/bin/tail [-lbcfl] [file] /usr/xpg4/bin/tail [-f   -r] [-c number   -n number] [file] /usr/xpg4/bin/tail [ ± number [l   b   c] [fl]] [file] /usr/xpg4/bin/tail [ ± number [l] [fl   r]] [file] </pre>
<b>DESCRIPTION</b>	<p>The <code>tail</code> utility copies the named file to the standard output beginning at a designated place. If no file is named, the standard input is used.</p> <p>Copying begins at a point in the file indicated by the <code>-cnumber</code>, <code>-nnumber</code>, or <code>±number</code> options (if <code>+number</code> is specified, begins at distance number from the beginning; if <code>-number</code> is specified, from the end of the input; if <code>number</code> is NULL, the value 10 is assumed). <code>number</code> is counted in units of lines or byte according to the <code>-c</code> or <code>-n</code> options, or lines, blocks, or bytes, according to the appended option <code>l</code>, <code>b</code>, or <code>c</code>. When no units are specified, counting is by lines.</p>
<b>OPTIONS</b>	<p>The following options are supported for both <code>/usr/bin/tail</code> and <code>/usr/xpg4/bin/tail</code>. The <code>-r</code> and <code>-f</code> options are mutually exclusive. If both are specified on the command line, the <code>-f</code> option will be ignored.</p> <ul style="list-style-type: none"> <li>-b       Units of blocks.</li> <li>-c       Units of bytes.</li> <li>-f       Follow. If the input-file is not a pipe, the program will not terminate after the line of the input-file has been copied, but will enter an endless loop, wherein it sleeps for a second and then attempts to read and copy further records from the input-file. Thus it may be used to monitor the growth of a file that is being written by some other process.</li> <li>-l       Units of lines.</li> <li>-r       Reverse. Copies lines from the specified starting point in the file in reverse order. The default for <code>r</code> is to print the entire file in reverse order.</li> </ul>
<b>/usr/xpg4/bin/tail</b>	<p>The following options are supported for <code>/usr/xpg4/bin/tail</code> only:</p> <ul style="list-style-type: none"> <li>-c <i>number</i>       The <i>number</i> option-argument must be a decimal integer whose sign affects the location in the file, measured in bytes, to begin the copying: <ul style="list-style-type: none"> <li>+       Copying starts relative to the beginning of the file.</li> <li>-       Copying starts relative to the end of the file.</li> <li>none    Copying starts relative to the end of the file.</li> </ul> </li> </ul>

tail(1)

The origin for counting is 1; that is, `-c+1` represents the first byte of the file, `-c-1` the last.

`-n number` Equivalent to `-cnumber`, except the starting location in the file is measured in lines instead of bytes. The origin for counting is 1. That is, `-n+1` represents the first line of the file, `-n-1` the last.

**OPERANDS** The following operand is supported:

*file* A path name of an input file. If no *file* operands are specified, the standard input will be used.

**USAGE** See `largefile(5)` for the description of the behavior of `tail` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**EXAMPLES** **EXAMPLE 1** Using the tail Command

The following command will print the last ten lines of the file `fred`, followed by any lines that are appended to `fred` between the time `tail` is initiated and killed.

```
example% tail -f fred
```

The next command will print the last 15 bytes of the file `fred`, followed by any lines that are appended to `fred` between the time `tail` is initiated and killed:

```
example% tail -15cf fred
```

**ENVIRONMENT VARIABLES** See `environ(5)` for descriptions of the following environment variables that affect the execution of `tail`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.  
>0 An error occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

`/usr/bin/tail`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled

`/usr/xpg4/bin/tail`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
CSI	Enabled
Interface Stability	Standard

tail(1)

**SEE ALSO** [cat\(1\)](#), [head\(1\)](#), [more\(1\)](#), [pg\(1\)](#), [dd\(1M\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

**NOTES** Piped tails relative to the end of the file are stored in a buffer, and thus are limited in length. Various kinds of anomalous behavior may happen with character special files.

## talk(1)

<b>NAME</b>	talk – talk to another user
<b>SYNOPSIS</b>	<b>talk</b> <i>address</i> [ <i>terminal</i> ]
<b>DESCRIPTION</b>	<p>The <code>talk</code> utility is a two-way, screen-oriented communication program.</p> <p>When first invoked, <code>talk</code> sends a message similar to:</p> <pre>Message from TalkDaemon@ her_machine at time... talk: connection requested by your_address talk: respond with: talk your_address</pre> <p>to the specified <i>address</i>. At this point, the recipient of the message can reply by typing:</p> <pre>talk your_address</pre> <p>Once communication is established, the two parties can type simultaneously, with their output displayed in separate regions of the screen. Characters are processed as follows:</p> <ul style="list-style-type: none"><li>■ Typing the alert character will alert the recipient's terminal.</li><li>■ Typing Control-L will cause the sender's screen regions to be refreshed.</li><li>■ Typing the erase and kill characters will affect the sender's terminal in the manner described by the <code>termios(3C)</code> interface.</li><li>■ Typing the interrupt or end-of-file (EOF) characters will terminate the local <code>talk</code> utility. Once the <code>talk</code> session has been terminated on one side, the other side of the <code>talk</code> session will be notified that the <code>talk</code> session has been terminated and will be able to do nothing except exit.</li><li>■ Typing characters from <code>LC_CTYPE</code> classifications <code>print</code> or <code>space</code> will cause those characters to be sent to the recipient's terminal.</li><li>■ When and only when the <code>stty iexten</code> local mode is enabled, additional special control characters and multi-byte or single-byte characters are processed as printable characters if their wide character equivalents are printable.</li><li>■ Typing other non-printable characters will cause them to be written to the recipient's terminal as follows: control characters will appear as a caret ( <code>^</code> ) followed by the appropriate ASCII character, and characters with the high-order bit set will appear in "meta" notation. For example, <code>'\003'</code> is displayed as <code>'^C'</code> and <code>'\372'</code> as <code>'M-Z'</code>.</li></ul> <p>Permission to be a recipient of a <code>talk</code> message can be denied or granted by use of the <code>mesg(1)</code> utility. However, a user's privilege may further constrain the domain of accessibility of other users' terminals. Certain commands, such as <code>pr(1)</code>, disallow messages in order to prevent interference with their output. <code>talk</code> will fail when the user lacks the appropriate privileges to perform the requested action.</p> <p>Certain block-mode terminals do not have all the capabilities necessary to support the simultaneous exchange of messages required for <code>talk</code>. When this type of exchange cannot be supported on such terminals, the implementation may support an exchange with reduced levels of simultaneous interaction or it may report an error describing the terminal-related deficiency.</p>

<b>OPERANDS</b>	<p>The following operands are supported:</p> <p><i>address</i>            The recipient of the <code>talk</code> session. One form of <i>address</i> is the <i>username</i>, as returned by the <code>who(1)</code> utility. If you wish to talk to someone on your own machine, then <i>username</i> is just the person's login name. If you wish to talk to a user on another host, then <i>username</i> is one of the following forms:</p> <pre> host!user host.user host:user user@host </pre> <p>although <i>user@host</i> is perhaps preferred.</p> <p><i>terminal</i>            If the recipient is logged in more than once, <i>terminal</i> can be used to indicate the appropriate terminal name. If <i>terminal</i> is not specified, the <code>talk</code> message will be displayed on one or more accessible terminals in use by the recipient. The format of <i>terminal</i> will be the same as that returned by <code>who</code>.</p>						
<b>ENVIRONMENT VARIABLES</b>	<p>See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>talk</code>: <code>LANG</code>, <code>LC_ALL</code>, <code>LC_CTYPE</code>, <code>LC_MESSAGES</code>, and <code>NLSPATH</code>.</p> <p><code>TERM</code>                Determine the name of the invoker's terminal type. If this variable is unset or null, an unspecified terminal type will be used.</p>						
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <p>0                    Successful completion.</p> <p>&gt;0                   An error occurred, or <code>talk</code> was invoked on a terminal incapable of supporting it.</p>						
<b>FILES</b>	<p><code>/etc/hosts</code>            host name database</p> <p><code>/var/adm/utmpx</code>        user and accounting information for <code>talk</code></p>						
<b>ATTRIBUTES</b>	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWrcmds</td> </tr> <tr> <td>Interface Stability</td> <td>Standard</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWrcmds	Interface Stability	Standard
ATTRIBUTE TYPE	ATTRIBUTE VALUE						
Availability	SUNWrcmds						
Interface Stability	Standard						
<b>SEE ALSO</b>	<p><code>mail(1)</code>, <code>mesg(1)</code>, <code>pr(1)</code>, <code>stty(1)</code>, <code>who(1)</code>, <code>write(1)</code>, <code>termios(3C)</code>, <code>attributes(5)</code>, <code>environ(5)</code>, <code>standards(5)</code></p>						
<b>NOTES</b>	<p>Typing Control-L redraws the screen, while the erase, kill, and word kill characters will work in <code>talk</code> as normal. To exit, type an interrupt character. <code>talk</code> then moves the cursor to the bottom of the screen and restores the terminal to its previous state.</p>						

## tar(1)

<b>NAME</b>	tar – create tape archives and add or extract files						
<b>SYNOPSIS</b>	<pre> <b>tar</b> c [BDeEFhilnopPqvw@[0-7]] [bfk] [X...] [blocksize] [tarfile] [size]       [exclude-file...] {file   -I include-file   -C directory file...}  <b>tar</b> r [BDeEFhilnqv@[0-7]] [bfk] [blocksize] [tarfile] [size] {file         -I include-file   -C directory file...}  <b>tar</b> t [BeFhilnqv[0-7]] [fk] [X...] [tarfile] [size] [exclude-file...] {file         -I include-file...}  <b>tar</b> u [BDeEFhilnqv@[0-7]] [bfk] [blocksize] [tarfile] [size] file...  <b>tar</b> x [BeFhilmnopqvw[0-7]] [fk] [X...] [tarfile] [size] [exclude-file...] [file...] </pre>						
<b>DESCRIPTION</b>	<p>The <code>tar</code> command archives and extracts files to and from a single file called a <i>tarfile</i>. A <i>tarfile</i> is usually a magnetic tape, but it can be any file. <code>tar</code>'s actions are controlled by the <i>key</i> argument. The <i>key</i> is a string of characters containing exactly one function letter (<code>c</code>, <code>r</code>, <code>t</code>, <code>u</code>, or <code>x</code>) and zero or more function modifiers (letters or digits), depending on the function letter used. The <i>key</i> string contains no SPACE characters. Function modifier arguments are listed on the command line in the same order as their corresponding function modifiers appear in the <i>key</i> string.</p> <p>The <code>-I include-file</code>, <code>-C directory file</code>, and <i>file</i> arguments specify which files or directories are to be archived or extracted. In all cases, appearance of a directory name refers to the files and (recursively) subdirectories of that directory. Arguments appearing within braces (<code>{ }</code>) indicate that one of the arguments must be specified.</p>						
<b>OPERANDS</b>	<p>The following operands are supported:</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 20px;"><code>-C directory file</code></td> <td>Performs a <code>chdir</code> (see <code>cd(1)</code>) operation on <i>directory</i> and performs the <code>c</code> (create) or <code>r</code> (replace) operation on <i>file</i>. Use short relative path names for <i>file</i>. If <i>file</i> is <code>."</code>, archive all files in <i>directory</i>. This operand enables archiving files from multiple directories not related by a close common parent.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;"><code>-I include-file</code></td> <td>Opens <i>include-file</i> containing a list of files, one per line, and treats it as if each file appeared separately on the command line. Be careful of trailing white spaces. Also beware of leading white spaces, since, for each line in the included file, the entire line (apart from the newline) will be used to match against the initial string of files to include. In the case where excluded files (see <code>X</code> function modifier) are also specified, they take precedence over all included files. If a file is specified in both the <i>exclude-file</i> and the <i>include-file</i> (or on the command line), it will be excluded.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;"><i>file</i></td> <td>A path name of a regular file or directory to be archived (when the <code>c</code>, <code>r</code> or <code>u</code> functions are specified), extracted (<code>x</code>) or listed (<code>t</code>). When <i>file</i> is the path name of</td> </tr> </table>	<code>-C directory file</code>	Performs a <code>chdir</code> (see <code>cd(1)</code> ) operation on <i>directory</i> and performs the <code>c</code> (create) or <code>r</code> (replace) operation on <i>file</i> . Use short relative path names for <i>file</i> . If <i>file</i> is <code>."</code> , archive all files in <i>directory</i> . This operand enables archiving files from multiple directories not related by a close common parent.	<code>-I include-file</code>	Opens <i>include-file</i> containing a list of files, one per line, and treats it as if each file appeared separately on the command line. Be careful of trailing white spaces. Also beware of leading white spaces, since, for each line in the included file, the entire line (apart from the newline) will be used to match against the initial string of files to include. In the case where excluded files (see <code>X</code> function modifier) are also specified, they take precedence over all included files. If a file is specified in both the <i>exclude-file</i> and the <i>include-file</i> (or on the command line), it will be excluded.	<i>file</i>	A path name of a regular file or directory to be archived (when the <code>c</code> , <code>r</code> or <code>u</code> functions are specified), extracted ( <code>x</code> ) or listed ( <code>t</code> ). When <i>file</i> is the path name of
<code>-C directory file</code>	Performs a <code>chdir</code> (see <code>cd(1)</code> ) operation on <i>directory</i> and performs the <code>c</code> (create) or <code>r</code> (replace) operation on <i>file</i> . Use short relative path names for <i>file</i> . If <i>file</i> is <code>."</code> , archive all files in <i>directory</i> . This operand enables archiving files from multiple directories not related by a close common parent.						
<code>-I include-file</code>	Opens <i>include-file</i> containing a list of files, one per line, and treats it as if each file appeared separately on the command line. Be careful of trailing white spaces. Also beware of leading white spaces, since, for each line in the included file, the entire line (apart from the newline) will be used to match against the initial string of files to include. In the case where excluded files (see <code>X</code> function modifier) are also specified, they take precedence over all included files. If a file is specified in both the <i>exclude-file</i> and the <i>include-file</i> (or on the command line), it will be excluded.						
<i>file</i>	A path name of a regular file or directory to be archived (when the <code>c</code> , <code>r</code> or <code>u</code> functions are specified), extracted ( <code>x</code> ) or listed ( <code>t</code> ). When <i>file</i> is the path name of						

a directory, the action applies to all of the files and (recursively) subdirectories of that directory.

When a file is archived, and the `E` flag (see `Function Modifiers`) is not specified, the filename cannot exceed 256 characters. In addition, it must be possible to split the name between parent directory names so that the prefix is no longer than 155 characters and the name is no longer than 100 characters. If `E` is specified, a name of up to `PATH_MAX` characters may be specified.

For example, a file whose basename is longer than 100 characters could not be archived without using the `E` flag. A file whose directory portion is 200 characters and whose basename is 50 characters could be archived (without using `E`) if a slash appears in the directory name somewhere in character positions 151-156.

## Function Letters

The function portion of the key is specified by one of the following letters:

- `c` Create. Writing begins at the beginning of the tarfile, instead of at the end.
- `r` Replace. The named *files* are written at the end of the tarfile. A file created with extended headers must be updated with extended headers (see `E` flag under `Function Modifiers`). A file created without extended headers cannot be modified with extended headers.
- `t` Table of Contents. The names of the specified files are listed each time they occur in the tarfile. If no *file* argument is given, the names of all files and any associated extended attributes in the tarfile are listed. With the `v` function modifier, additional information for the specified files is displayed.
- `u` Update. The named *files* are written at the end of the tarfile if they are not already in the tarfile, or if they have been modified since last written to that tarfile. An update can be rather slow. A tarfile created on a 5.x system cannot be updated on a 4.x system. A file created with extended headers must be updated with extended headers (see `E` flag under `Function Modifiers`). A file created without extended headers cannot be modified with extended headers.
- `x` Extract or restore. The named *files* are extracted from the tarfile and written to the directory specified in the tarfile, relative to the current directory. Use the relative path names of files and directories to be extracted.  
  
Absolute path names contained in the tar archive are unpacked using the absolute path names, that is, the leading forward slash (/) is *not* stripped off.

## tar(1)

If a named file matches a directory whose contents has been written to the tarfile, this directory is recursively extracted. The owner, modification time, and mode are restored (if possible); otherwise, to restore owner, you must be the super-user. Character-special and block-special devices (created by `mknod(1M)`) can only be extracted by the super-user. If no *file* argument is given, the entire content of the tarfile is extracted. If the tarfile contains several files with the same name, each file is written to the appropriate directory, overwriting the previous one. Filename substitution wildcards cannot be used for extracting files from the archive. Rather, use a command of the form:

```
tar xvf ... /dev/rmt/0 `tar tf ... /dev/rmt/0 | \
  grep 'pattern'`
```

When extracting tapes created with the `r` or `u` functions, directory modification times may not be set correctly. These same functions cannot be used with many tape drives due to tape drive limitations such as the absence of backspace or append capabilities.

When using the `r`, `u`, or `x` functions or the `X` function modifier, the named files must match exactly the corresponding files in the *tarfile*. For example, to extract `./thisfile`, you must specify `./thisfile`, and not `thisfile`. The `t` function displays how each file was archived.

### Function Modifiers

The characters below may be used in conjunction with the letter that selects the desired function.

**b** *blocksize*      Blocking Factor. Use when reading or writing to raw magnetic archives (see `f` below). The *blocksize* argument specifies the number of 512-byte tape blocks to be included in each read or write operation performed on the tarfile. The minimum is 1, the default is 20. The maximum value is a function of the amount of memory available and the blocking requirements of the specific tape device involved (see `mtio(7I)` for details.) The maximum cannot exceed `INT_MAX/512` (4194303).

When a tape archive is being read, its actual blocking factor will be automatically detected, provided that it is less than or equal to the nominal blocking factor (the value of the *blocksize* argument, or the default value if the `b` modifier is not specified). If the actual blocking factor is greater than the nominal blocking factor, a read error will result. See Example 5 in EXAMPLES.

**B**      Block. Force `tar` to perform multiple reads (if necessary) to read exactly enough bytes to fill a block. This function modifier enables `tar` to work across the Ethernet, since pipes and sockets return partial blocks even when more data is coming. When reading from standard input, “-”, this function modifier is selected by default to ensure that `tar` can recover from short reads.

- D** Data change warnings. Used with *c*, *r*, or *u* function letters. Ignored with *t* or *x* function letters. If the size of a file changes while the file is being archived, treat this condition as a warning instead of as an error. A warning message will still be written, but the exit status is not affected.
- e** Error. Exit immediately with a positive exit status if any unexpected errors occur. The *SYSV3* environment variable overrides the default behavior. (See ENVIRONMENT VARIABLES section below.)
- E** Write a tarfile with extended headers. (Used with *c*, *r*, or *u* function letters. Ignored with *t* or *x* function letters.) When a tarfile is written with extended headers, the modification time is maintained with a granularity of microseconds rather than seconds. In addition, filenames no longer than *PATH\_MAX* characters that could not be archived without *E*, and file sizes greater than 8GB, are supported. The *E* flag is required whenever the larger files and/or files with longer names, or whose *UID/GID* exceed 2097151, are to be archived, or if time granularity of microseconds is desired.
- f** File. Use the *tarfile* argument as the name of the tarfile. If *f* is specified, */etc/default/tar* is not searched. If *f* is omitted, *tar* will use the device indicated by the *TAPE* environment variable, if set. Otherwise, *tar* will use the default values defined in */etc/default/tar*. The number matching the *archiveN* string is used as the output device with the blocking and size specifications from the file. For example,
- ```
tar -c 2/tmp/*
```
- writes the output to the device specified as *archive2* in */etc/default/tar*.
- If the name of the tarfile is *"-"*, *tar* writes to the standard output or reads from the standard input, whichever is appropriate. *tar* can be used as the head or tail of a pipeline. *tar* can also be used to move hierarchies with the command:
- ```
example% cd fromdir; tar cf - . | (cd todir; tar xfbp -)
```
- F** With one *F* argument, *tar* excludes all directories named *SCCS* and *RCS* from the tarfile. With two arguments, *FF*, *tar* excludes all directories named *SCCS* and *RCS*, all files with *.o* as their suffix, and all files named *errs*, *core*, and *a.out*. The *SYSV3* environment variable overrides the default behavior. (See ENVIRONMENT VARIABLES section below.)
- h** Follow symbolic links as if they were normal files or directories. Normally, *tar* does not follow symbolic links.

## tar(1)

i	Ignore directory checksum errors.
k <i>size</i>	Requires <code>tar</code> to use the <code>size</code> argument as the size of an archive in kilobytes. This is useful when the archive is intended for a fixed size device such as floppy disks. Large files are then split across volumes if they do not fit in the specified size.
l	Link. Output error message if unable to resolve all links to the files being archived. If <code>l</code> is not specified, no error messages are printed.
m	Modify. The modification time of the file is the time of extraction. This function modifier is valid only with the <code>x</code> function.
n	The file being read is a non-tape device. Reading of the archive is faster since <code>tar</code> can randomly seek around the archive.
o	Ownership. Assign to extracted files the user and group identifiers of the user running the program, rather than those on tarfile. This is the default behavior for users other than root. If the <code>o</code> function modifier is not set and the user is root, the extracted files will take on the group and user identifiers of the files on tarfile (see <a href="#">chown(1)</a> for more information). The <code>o</code> function modifier is only valid with the <code>x</code> function.
p	Restore the named files to their original modes, and ACLs if applicable, ignoring the present <code>umask(1)</code> . This is the default behavior if invoked as super-user with the <code>x</code> function letter specified. If super-user, SETUID, and sticky information are also extracted, and files are restored with their original owners and permissions, rather than owned by root. When this function modifier is used with the <code>c</code> function, ACLs are created in the tarfile along with other information. Errors will occur when a tarfile with ACLs is extracted by previous versions of <code>tar</code> .
P	Suppress the addition of a trailing <code>"/</code> on directory entries in the archive.
q	Stop after extracting the first occurrence of the named file. <code>tar</code> will normally continue reading the archive after finding an occurrence of a file.
v	Verbose. Output the name of each file preceded by the function letter. With the <code>t</code> function, <code>v</code> provides additional information about the tarfile entries. The listing is similar to the format produced by the <code>-l</code> option of the <a href="#">ls(1)</a> command.
w	What. Output the action to be taken and the name of the file, then await the user's confirmation. If the response is affirmative, the action is performed; otherwise, the action is not performed. This function modifier cannot be used with the <code>t</code> function.

- X** Exclude. Use the *exclude-file* argument as a file containing a list of relative path names for files (or directories) to be excluded from the tarfile when using the functions `c`, `x`, or `t`. Be careful of trailing white spaces. Also beware of leading white spaces, since, for each line in the excluded file, the entire line (apart from the newline) will be used to match against the initial string of files to exclude. Lines in the exclude file are matched exactly, so an entry like `"/var"` will *not* exclude the `/var` directory if `tar` is backing up relative pathnames. The entry should read `"/var"` under these circumstances. The `tar` command does not expand shell metacharacters in the exclude file, so specifying entries like `"*.o"` will not have the effect of excluding all files with names suffixed with `".o"`. If a complex list of files is to be excluded, the exclude file should be generated by some means such as the `find(1)` command with appropriate conditions.
- Multiple `X` arguments may be used, with one *exclude-file* per argument. In the case where included files (see `-I include-file` operand) are also specified, the excluded files take precedence over all included files. If a file is specified in both the *exclude-file* and the *include-file* (or on the command line), it will be excluded.
- @** Include extended attributes in archive. By default, `tar` does not place extended attributes in the archive. With this flag, `tar` will look for extended attributes on the files to be placed in the archive and add them to the archive. Extended attributes go in the archive as special files with a special type label. When this modifier is used with the `x` function, extended attributes are extracted from the tape along with the normal file data. Extended attribute files can only be extracted from an archive as part of a normal file extract. Attempts to explicitly extract attribute records are ignored.
- [0-7]** Select an alternative drive on which the tape is mounted. The default entries are specified in `/etc/default/tar`. If no digit or `f` function modifier is specified, the entry in `/etc/default/tar` with digit `"0"` is the default.

**USAGE** See `largefile(5)` for the description of the behavior of `tar` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

The automatic determination of the actual blocking factor may be fooled when reading from a pipe or a socket (see the `B` function modifier below).

1/4" streaming tape has an inherent blocking factor of one 512-byte block. It can be read or written using any blocking factor.

This function modifier works for archives on disk files and block special devices, among others, but is intended principally for tape devices.

## tar(1)

For information on tar header format, see archives(4).

### EXAMPLES

#### EXAMPLE 1 Creating an archive of your home directory

The following is an example using tar to create an archive of your home directory on a tape mounted on drive /dev/rmt/0:

```
example% cd
example% tar cvf /dev/rmt/0 .
messages from tar
```

The `c` function letter means create the archive. The `v` function modifier outputs messages explaining what tar is doing. The `f` function modifier indicates that the tarfile is being specified (/dev/rmt/0 in this example). The dot (.) at the end of the command line indicates the current directory and is the argument of the `f` function modifier.

Display the table of contents of the tarfile with the following command:

```
example% tar tvf /dev/rmt/0
```

The output will be similar to the following for the POSIX locale:

```
rw-r--r-- 1677/40 2123 Nov 7 18:15 1985 ./test.c
...
example%
```

The columns have the following meanings:

- column 1 is the access permissions to ./test.c
- column 2 is the *user-id/group-id* of ./test.c
- column 3 is the size of ./test.c in bytes
- column 4 is the modification date of ./test.c. When the LC\_TIME category is not set to the POSIX locale, a different format and date order field may be used.
- column 5 is the name of ./test.c

To extract files from the archive:

```
example% tar xvf /dev/rmt/0
messages from tar
example%
```

If there are multiple archive files on a tape, each is separated from the following one by an EOF marker. To have tar read the first and second archives from a tape with multiple archives on it, the *non-rewinding* version of the tape device name must be used with the `f` function modifier, as follows:

```
example% tar xvfp /dev/rmt/0n read first archive from tape
messages from tar
example% tar xvfp /dev/rmt/0n read second archive from tape
messages from tar
example%
```

**EXAMPLE 1** Creating an archive of your home directory (Continued)

Notice that in some earlier releases, the above scenario did not work correctly, and intervention with `mt(1)` between `tar` invocations was necessary. To emulate the old behavior, use the non-rewind device name containing the letter `b` for BSD behavior. See the `Close Operations` section of the `mtio(7I)` manual page.

**EXAMPLE 2** Archiving files from `/usr/include` and from `/etc` to default tape drive 0

To archive files from `/usr/include` and from `/etc` to default tape drive 0:

```
example% tar c -C /usr include -C /etc .
```

The table of contents from the resulting tarfile would produce output like the following:

```
include/
include/a.out.h
and all the other files in /usr/include ...
./chown and all the other files in /etc
```

To extract all files in the `include` directory:

```
example% tar xv include
x include/, 0 bytes, 0 tape blocks \
  and all files under include ...
```

**EXAMPLE 3** Transferring files across the network

The following is an example using `tar` to transfer files across the network. First, here is how to archive files from the local machine (`example`) to a tape on a remote system (`host`):

```
example% tar cvfb - 20 files | \
  rsh host dd of=/dev/rmt/0 obs=20b
messages from tar
example%
```

In the example above, we are *creating a tarfile* with the `c` key letter, asking for *verbose* output from `tar` with the `v` function modifier, specifying the name of the output *tarfile* using the `f` function modifier (the standard output is where the *tarfile* appears, as indicated by the `'-'` sign), and specifying the blocksize (`20`) with the `b` function modifier. If you want to change the blocksize, you must change the blocksize arguments both on the `tar` command *and* on the `dd` command.

**EXAMPLE 4** Retrieving files from a tape on the remote system back to the local system

The following is an example that uses `tar` to retrieve files from a tape on the remote system back to the local system:

tar(1)

**EXAMPLE 4** Retrieving files from a tape on the remote system back to the local system  
(Continued)

```
example% rsh -n host dd if=/dev/rmt/0 bs=20b | \  
    tar xvBfb - 20 files  
messages from tar  
example%
```

In the example above, we are *extracting* from the *tarfile* with the *x* key letter, asking for *verbose output* from *tar* with the *v* function modifier, telling *tar* it is reading from a pipe with the *B* function modifier, specifying the name of the input *tarfile* using the *f* function modifier (the standard input is where the *tarfile* appears, as indicated by the “-” sign), and specifying the blocksize (20) with the *b* function modifier.

**EXAMPLE 5** Creating an archive of the home directory

The following example creates an archive of the home directory on `/dev/rmt/0` with an actual blocking factor of 19:

```
example% tar cvfb /dev/rmt/0 19 $HOME
```

To recognize this archive’s actual blocking factor without using the *b* function modifier:

```
example% tar tvf /dev/rmt/0  
tar: blocksize = 19  
...
```

To recognize this archive’s actual blocking factor using a larger nominal blocking factor:

```
example% tar tvf /dev/rmt/0 30  
tar: blocksize = 19  
...
```

Attempt to recognize this archive’s actual blocking factor using a nominal blocking factor that is too small:

```
example% tar tvf /dev/rmt/0 10  
tar: tape read error
```

## ENVIRONMENT VARIABLES

SYSV3	This variable is used to override the default behavior of <code>tar</code> , provide compatibility with INTERACTIVE UNIX Systems and SCO UNIX installation scripts, and should not be used in new scripts. (It is intended for compatibility purposes only.) When set, the following function modifiers behave differently:
<i>F filename</i>	Uses <i>filename</i> to obtain a list of command line switches and files on which to operate.

**e** Prevents files from being split across volumes. If there is insufficient room on one volume, `tar` prompts for a new volume. If the file will not fit on the new volume, `tar` exits with an error.

See `environ(5)` for descriptions of the following environment variables that affect the execution of `tar`: `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `TZ`, and `NLSPATH`.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.  
>0 An error occurred.

**FILES** `/dev/rmt/[0-7][b][n]`  
`/dev/rmt/[0-7]l[b][n]`  
`/dev/rmt/[0-7]m[b][n]`  
`/dev/rmt/[0-7]h[b][n]`  
`/dev/rmt/[0-7]u[b][n]`  
`/dev/rmt/[0-7]c[b][n]`  
`/etc/default/tar`

Settings may look like this:

```
archive0=/dev/rmt/0
archive1=/dev/rmt/0n
archive2=/dev/rmt/1
archive3=/dev/rmt/1n
archive4=/dev/rmt/0
archive5=/dev/rmt/0n
archive6=/dev/rmt/1
archive7=/dev/rmt/1n
```

`/tmp/tar*`

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled
Interface Stability	Stable

tar(1)

<b>DIAGNOSTICS</b>	Diagnostic messages are output for bad key characters and tape read/write errors, and for insufficient memory to hold the link tables.
<b>NOTES</b>	<p>There is no way to access the <i>n</i>-th occurrence of a file.</p> <p>Tape errors are handled ungracefully.</p> <p>When the Volume Management daemon is running, accesses to floppy devices through the conventional device names (for example, <code>/dev/rdiskette</code>) may not succeed. See <code>vold(1M)</code> for further details.</p> <p>The <code>tar</code> archive format allows UIDs and GIDs up to 2097151 to be stored in the archive header. Files with UIDs and GIDs greater than this value will be archived with the UID and GID of 60001.</p> <p>If an archive is created that contains files whose names were created by processes running in multiple locales, a single locale that uses a full 8-bit codeset (for example, the <code>en_US</code> locale) should be used both to create the archive and to extract files from the archive.</p> <p>Neither the <code>r</code> function letter nor the <code>u</code> function letter can be used with quarter-inch archive tapes, since these tape drives cannot backspace.</p> <p>Since <code>tar</code> has no options, the standard “<code>—</code>” argument that is normally used in other utilities to terminate recognition of options is not needed. If used, it is recognized only as the first argument and is ignored.</p> <p>Since <code>-C directory file</code> and <code>-I include-file</code> are multi-argument operands, any of the following methods can be used to archive or extract a file named <code>-C</code> or <code>-I</code>:</p> <ol style="list-style-type: none"><li>1. Specify them using file operands containing a <code>/</code> character on the command line (such as <code>/home/joe/-C</code> or <code>./-I</code>).</li><li>2. Include them in an include file with <code>-I include-file</code>.</li><li>3. Specify the directory in which the file resides: <code>-c directory -C</code>  or <code>-c directory -I</code></li><li>4. Specify the entire directory in which the file resides: <code>-c directory .</code></li></ol>

**NAME** tbl – format tables for nroff or troff

**SYNOPSIS** **tbl** [-me] [-mm] [-ms] [*filename*]...

**DESCRIPTION** tbl is a preprocessor for formatting tables for `nroff(1)` or `troff(1)`. The input *filenames* are copied to the standard output, except that lines between `.TS` and `.TE` command lines are assumed to describe tables and are reformatted.

If no arguments are given, `tbl` reads the standard input, so `tbl` may be used as a filter. When `tbl` is used with `eqn(1)` or `neqn`, the `tbl` command should be first, to minimize the volume of data passed through pipes.

**OPTIONS**

- me Copy the -me macro package to the front of the output file.
- mm Copy the -mm macro package to the front of the output file.
- ms Copy the -ms macro package to the front of the output file.

**EXAMPLES** **EXAMPLE 1** Using `tbl`

As an example, letting '@' (at-sign) represent a TAB, which should be typed as an actual TAB character in the input file

```
.TS
c s s
c c s
c c c
l n n.

<b>NAME</b>	tcopy – copy a magnetic tape				
<b>SYNOPSIS</b>	<b>tcopy</b> <i>source</i> [ <i>destination</i> ]				
<b>DESCRIPTION</b>	<p>The <code>tcopy</code> utility copies the magnetic tape mounted on the tape drive specified by the <code>source</code> argument. The only assumption made about the contents of a tape is that there are two tape marks at the end.</p> <p>When only a source drive is specified, <code>tcopy</code> scans the tape, and displays information about the sizes of records and tape files. If a destination is specified, <code>tcopy</code> makes a copies the source tape onto the <i>destination</i> tape, with blocking preserved. As it copies, <code>tcopy</code> produces the same output as it does when only scanning a tape.</p> <p>The <code>tcopy</code> utility requires the use of Berkeley-compatible device names. For example,</p> <pre>example% tcopy /dev/rmt/1b /dev/rmt/2b</pre>				
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWesu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWesu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWesu				
<b>SEE ALSO</b>	<code>mt(1)</code> , <code>ioctl(2)</code> , <code>attributes(5)</code>				
<b>NOTES</b>	<code>tcopy</code> will only run on systems supporting an associated set of <code>ioctl(2)</code> requests.				

tee(1)

**NAME** tee – replicate the standard output

**SYNOPSIS** tee [-ai] [*file...*]

**DESCRIPTION** The tee utility will copy standard input to standard output, making a copy in zero or more files. tee will not buffer its output. The options determine if the specified files are overwritten or appended to.

**OPTIONS** The following options are supported.

- a Appends the output to the files rather than overwriting them.
- i Ignores interrupts.

**OPERANDS** The following operands are supported:

*file* A path name of an output file. Processing of at least 13 *file* operands will be supported.

**USAGE** See largefile(5) for the description of the behavior of tee when encountering files greater than or equal to 2 Gbyte ( 2<sup>31</sup> bytes).

**ENVIRONMENT VARIABLES** See environ(5) for descriptions of the following environment variables that affect the execution of tee: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**EXIT STATUS** The following exit values are returned:

- 0 The standard input was successfully copied to all output files.
- >0 The number of files that could not be opened or whose status could not be obtained.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled
Interface Stability	Standard

**SEE ALSO** cat(1), attributes(5), environ(5), largefile(5), standards(5)

<b>NAME</b>	telnet – user interface to a remote system using the TELNET protocol
<b>SYNOPSIS</b>	<b>telnet</b> [-8EFKLacdfrx] [-X <i>atype</i> ] [-e <i>escape_char</i> ] [-k <i>realm</i> ] [-l <i>user</i> ] [-n <i>file</i> ] [ [ [!] @hop1 [ @hop2... ] @] <i>host</i> [ <i>port</i> ]]
<b>DESCRIPTION</b>	<p>The <code>telnet</code> utility communicates with another host using the TELNET protocol. If <code>telnet</code> is invoked without arguments, it enters command mode, indicated by its prompt, <code>telnet&gt;</code>. In this mode, it accepts and executes its associated commands. See <a href="#">USAGE</a>, <a href="#">telnet Commands</a>, below. If it is invoked with arguments, it performs an open command with those arguments.</p> <p>If, for example, a <i>host</i> is specified as <code>@hop1@hop2@host</code>, the connection goes through hosts <i>hop1</i> and <i>hop2</i>, using loose source routing to end at <i>host</i>. If a leading <code>!</code> is used, the connection follows strict source routing. Note that when <code>telnet</code> uses IPv6, it can only use loose source routing, and the connection ignores the <code>!</code>.</p> <p>Once a connection has been opened, <code>telnet</code> enters input mode. In this mode, text typed is sent to the remote host. The input mode entered will be either "line mode", "character at a time", or "old line by line", depending upon what the remote system supports.</p> <p>In "line mode", character processing is done on the local system, under the control of the remote system. When input editing or character echoing is to be disabled, the remote system will relay that information. The remote system will also relay changes to any special characters that happen on the remote system, so that they can take effect on the local system.</p> <p>In "character at a time" mode, most text typed is immediately sent to the remote host for processing.</p> <p>In "old line by line" mode, all text is echoed locally, and (normally) only completed lines are sent to the remote host. The "local echo character" (initially <code>^E</code>) may be used to turn off and on the local echo. (Use this mostly to enter passwords without the password being echoed.)</p> <p>If the "line mode" option is enabled, or if the <code>localchars</code> toggle is TRUE (the default in "old line by line" mode), the user's <code>quit</code>, <code>intr</code>, and <code>flush</code> characters are trapped locally, and sent as TELNET protocol sequences to the remote side. If "line mode" has ever been enabled, then the user's <code>susp</code> and <code>eof</code> are also sent as TELNET protocol sequences. <code>quit</code> is then sent as a TELNET ABORT instead of BREAK. The options <code>toggle autoflush</code> and <code>toggle autosynch</code> cause this action to flush subsequent output to the terminal (until the remote host acknowledges the TELNET sequence); and to flush previous terminal input, in the case of <code>quit</code> and <code>intr</code>.</p> <p>While connected to a remote host, the user can enter <code>telnet</code> command mode by typing the <code>telnet</code> escape character (initially <code>^]</code>). When in command mode, the normal terminal editing conventions are available. Pressing RETURN at the <code>telnet</code> command prompt causes <code>telnet</code> to exit command mode.</p>
<b>OPTIONS</b>	The following options are supported:

## telnet(1)

-8	Specifies an 8-bit data path. Negotiating the TELNET BINARY option is attempted for both input and output.
-a	Attempts automatic login. This sends the user name by means of the USER variable of the ENVIRON option, if supported by the remote system. The name used is that of the current user as returned by <code>getlogin(3C)</code> if it agrees with the current user ID. Otherwise, it is the name associated with the user ID.
-c	Disables the reading of the user's <code>telnetrc</code> file. (See the <code>toggle skiprc</code> command on this reference page.)
-d	Sets the initial value of the debug toggle to TRUE.
-e <i>escape_char</i>	Sets the initial escape character to <i>escape_char</i> . <i>escape_char</i> may also be a two character sequence consisting of '^' followed by one character. If the second character is '?', the DEL character is selected. Otherwise, the second character is converted to a control character and used as the escape character. If the escape character is the null string (that is, -e ''), it is disabled.
-E	Stops any character from being recognized as an escape character.
-f	Forwards a copy of the local credentials to the remote system.
-F	Forwards a forwardable copy of the local credentials to the remote system.
-k <i>realm</i>	If Kerberos authentication is being used, requests that <code>telnet</code> obtain tickets for the remote host in <i>realm</i> instead of the remote host's default realm as determined in <code>inkrb5.conf(4)</code> .
-K	Specifies no automatic login to the remote system.
-l <i>user</i>	When connecting to a remote system that understands the ENVIRON option, then <i>user</i> will be sent to the remote system as the value for the ENVIRON variable USER.
-L	Specifies an 8-bit data path on output. This causes the BINARY option to be negotiated on output.
-n <i>tracefile</i>	Opens <i>tracefile</i> for recording trace information. See the <code>set tracefile</code> command below.
-r	Specifies a user interface similar to <code>rlogin</code> . In this mode, the escape character is set to the tilde (~) character, unless modified by the -e option. The <code>rlogin</code> escape character is only recognized when it is preceded by a carriage return. In this mode, the <code>telnet</code> escape character, normally '^]', must still precede a <code>telnet</code> command. The <code>rlogin</code> escape character can also be followed by '.\r' or '^Z', and, like <code>rlogin(1)</code> , closes or suspends the connection, respectively. This option is an uncommitted interface and may change in the future.

- x                    Turns on encryption of the data stream. When this option is turned on, telnet will exit with an error if authentication cannot be negotiated or if encryption cannot be turned on.
- X *atype*            Disables the *atype* type of authentication.

## USAGE

### telnet Commands

The commands described in this section are available with telnet. It is necessary to type only enough of each command to uniquely identify it. (This is also true for arguments to the mode, set, toggle, unset, environ, and display commands.)

**auth** *argument* ...

The auth command manipulates the information sent through the TELNET AUTHENTICATE option. Valid arguments for the auth command are as follows:

- disable** *type*        Disables the specified type of authentication. To obtain a list of available types, use the auth disable ? command.
- enable** *type*        Enables the specified type of authentication. To obtain a list of available types, use the auth enable ? command.
- status**               Lists the current status of the various types of authentication.

**open** [ -l *user* ] [ [!] @*hop1* [@*hop2* ...]@*host* [ *port* ]

Open a connection to the named host. If no port number is specified, telnet will attempt to contact a TELNET server at the default port. The host specification may be either a host name (see hosts(4), ipnodes(4)) or an Internet address specified in the "dot notation" (see inet(7P) or inet6(7P)). If the *host* is specified as @*hop1*@*hop2*@*host*, the connection goes through hosts *hop1* and *hop2*, using loose source routing to end at *host*. The "@" symbol is required as a separator between the hosts specified. If a leading ! is used with IPv4, the connection follows strict source routing.

The -l option passes the *user* as the value of the ENVIRON variable USER to the remote system.

**close**

Close any open TELNET session and exit telnet. An EOF (in command mode) will also close a session and exit.

**encrypt**

The encrypt command manipulates the information sent through the TELNET ENCRYPT option.

Valid arguments for the encrypt command are as follows:

- disable** *type*                    Disables the specified type of encryption. If you omit the input and output, both input and output are disabled. To obtain a list of available types, use the encrypt disable ? command.
- [input | output]

## telnet(1)

<code>enable <i>type</i></code> <code>[input   output]</code>	Enables the specified type of encryption. If you omit input and output, both input and output are enabled. To obtain a list of available types, use the <code>encrypt enable ?</code> command.
<code>input</code>	This is the same as the <code>encrypt start input</code> command.
<code>-input</code>	This is the same as the <code>encrypt stop input</code> command.
<code>output</code>	This is the same as the <code>encrypt start output</code> command.
<code>-output</code>	This is the same as the <code>encrypt stop output</code> command.
<code>start [input   output]</code>	Attempts to start encryption. If you omit input and output, both input and output are enabled. To obtain a list of available types, use the <code>encrypt enable ?</code> command.
<code>status</code>	Lists the current status of encryption.
<code>stop [input   output]</code>	Stops encryption. If you omit input and output, encryption is on both input and output.
<code>type <i>type</i></code>	Sets the default type of encryption to be used with later <code>encrypt start</code> or <code>encrypt stop</code> commands.
<code>quit</code>	Same as <code>close</code> .
<code>z</code>	Suspend <code>telnet</code> . This command only works when the user is using a shell that supports job control, such as <code>sh(1)</code> .
<code>mode <i>type</i></code>	The remote host is asked for permission to go into the requested mode. If the remote host is capable of entering that mode, the requested mode will be entered. The argument <i>type</i> is one of the following:
<code>character</code>	Disable the TELNET LINEMODE option, or, if the remote side does not understand the LINEMODE option, then enter "character at a time" mode.
<code>line</code>	Enable the TELNET LINEMODE option, or, if the remote side does not understand the LINEMODE option, then attempt to enter "old-line-by-line" mode.
<code>isig (-isig)</code>	Attempt to enable (disable) the TRAPSIG mode of the LINEMODE option. This requires that the LINEMODE option be enabled.

<code>edit (-edit)</code>	Attempt to enable (disable) the EDIT mode of the LINEMODE option. This requires that the LINEMODE option be enabled.
<code>softtabs (-softtabs)</code>	Attempt to enable (disable) the SOFT_TAB mode of the LINEMODE option. This requires that the LINEMODE option be enabled.
<code>litecho (-litecho)</code>	Attempt to enable (disable) the LIT_ECHO mode of the LINEMODE option. This requires that the LINEMODE option be enabled.
<code>?</code>	Prints out help information for the mode command.
<code>status</code>	Show the current status of telnet. This includes the peer one is connected to, as well as the current mode.
<code>display</code>	[ <i>argument . . .</i> ] Display all, or some, of the set and toggle values (see <i>toggle argument . . .</i> ).
<code>?</code>	[ <i>command</i> ] Get help. With no arguments, telnet prints a help summary. If a command is specified, telnet will print the help information for just that command.
<code>send <i>argument . . .</i></code>	Send one or more special character sequences to the remote host. The following are the arguments that can be specified (more than one argument may be specified at a time):
<code>escape</code>	Send the current telnet escape character (initially ^]).
<code>synch</code>	Send the TELNET SYNCH sequence. This sequence discards all previously typed, but not yet read, input on the remote system. This sequence is sent as TCP urgent data and may not work if the remote system is a 4.2 BSD system. If it does not work, a lower case "r" may be echoed on the terminal.
<code>brk or break</code>	Send the TELNET BRK (Break) sequence, which may have significance to the remote system.
<code>ip</code>	Send the TELNET IP (Interrupt Process) sequence, which aborts the currently running process on the remote system.
<code>abort</code>	Send the TELNET ABORT (Abort Process) sequence.
<code>ao</code>	Send the TELNET AO (Abort Output) sequence, which flushes all output from the remote system to the user's terminal.
<code>ayt</code>	Send the TELNET AYT (Are You There) sequence, to which the remote system may or may not respond.

## telnet(1)

<code>ec</code>	Send the TELNET EC (Erase Character) sequence, which erases the last character entered.
<code>el</code>	Send the TELNET EL (Erase Line) sequence, which should cause the remote system to erase the line currently being entered.
<code>eof</code>	Send the TELNET EOF (End Of File) sequence.
<code>eor</code>	Send the TELNET EOR (End Of Record) sequence.
<code>ga</code>	Send the TELNET GA (Go Ahead) sequence, which probably has no significance for the remote system.
<code>getstatus</code>	If the remote side supports the TELNET STATUS command, <code>getstatus</code> will send the subnegotiation to request that the server send its current option status.
<code>nop</code>	Send the TELNET NOP (No Operation) sequence.
<code>susp</code>	Send the TELNET SUSP (Suspend Process) sequence.
<code>do option</code>	Send the TELNET protocol option negotiation indicated. Option may be the text name of the protocol option, or the number corresponding to the option. The command will be silently ignored if the option negotiation indicated is not valid in the current state. If the <i>option</i> is given as 'help' or '?', the list of option names known is listed. This command is mostly useful for unusual debugging situations.
<code>dont option</code>	
<code>will option</code>	
<code>wont option</code>	
<code>?</code>	Print out help information for the <code>send</code> command.
<code>set argument [ value ]</code>	Set any one of a number of <code>telnet</code> variables to a specific value. The special value "off" turns off the function associated with the variable. The values of variables may be interrogated with the <code>display</code> command. If <i>value</i> is omitted, the value is taken to be true, or "on". If the <code>unset</code> form is used, the value is taken to be false, or "off." The variables that may be specified are:
<code>unset argument</code>	
<code>echo</code>	This is the value (initially ^E) that, when in "line by line" mode, toggles between local echoing of entered characters for normal processing, and suppressing echoing of entered characters, for example, entering a password.
<code>escape</code>	This is the <code>telnet</code> escape character (initially ^]) that enters <code>telnet</code> command mode when connected to a remote system.

interrupt	If telnet is in localchars mode (see toggle, localchars) and the interrupt character is typed, a TELNET IP sequence (see send and ip) is sent to the remote host. The initial value for the interrupt character is taken to be the terminal's intr character.
quit	If telnet is in localchars mode and the quit character is typed, a TELNET BRK sequence (see send, brk) is sent to the remote host. The initial value for the quit character is taken to be the terminal's quit character.
flushoutput	If telnet is in localchars mode and the flushoutput character is typed, a TELNET AO sequence (see send, ao) is sent to the remote host. The initial value for the flush character is taken to be the terminal's flush character.
erase	If telnet is in localchars mode <i>and</i> operating in "character at a time" mode, then when the erase character is typed, a TELNET EC sequence (see send, ec) is sent to the remote system. The initial value for the erase character is taken to be the terminal's erase character.
kill	If telnet is in localchars mode <i>and</i> operating in "character at a time" mode, then when the kill character is typed, a TELNET EL sequence (see send, el) is sent to the remote system. The initial value for the kill character is taken to be the terminal's kill character.
eof	If telnet is operating in "line by line" mode, entering the eof character as the first character on a line sends this character to the remote system. The initial value of eof is taken to be the terminal's eof character.
ayt	If telnet is in localchars mode, or LINEMODE is enabled, and the status character is typed, a TELNET AYT ("Are You There") sequence is sent to the remote host. (See send, ayt above.) The initial value for ayt is the terminal's status character.
forw1 forw2	If telnet is operating in LINEMODE, and the forw1 or forw2 characters are typed, this causes the forwarding of partial lines to the remote system. The initial values for the forwarding characters come from the terminal's eol and eol2 characters.
lnext	If telnet is operating in LINEMODE or "old line by line" mode, then the lnext character is assumed to be the terminal's lnext character. The initial value for the lnext character is taken to be the terminal's lnext character.

## telnet(1)

reprint	If telnet is operating in LINEMODE or "old line by line" mode, then the reprint character is assumed to be the terminal's reprint character. The initial value for reprint is taken to be the terminal's reprint character.
rlogin	This is the rlogin escape character. If set, the normal telnet escape character is ignored, unless it is preceded by this character at the beginning of a line. The rlogin character, at the beginning of a line followed by a "." closes the connection. When followed by a ^Z, the rlogin command suspends the telnet command. The initial state is to disable the rlogin escape character.
start	If the TELNET TOGGLE-FLOW-CONTROL option has been enabled, then the start character is taken to be the terminal's start character. The initial value for the kill character is taken to be the terminal's start character.
stop	If the TELNET TOGGLE-FLOW-CONTROL option has been enabled, then the stop character is taken to be the terminal's stop character. The initial value for the kill character is taken to be the terminal's stop character.
susp	If telnet is in localchars mode, or LINEMODE is enabled, and the suspend character is typed, a TELNET SUSP sequence (see send, susp above) is sent to the remote host. The initial value for the suspend character is taken to be the terminal's suspend character.
tracefile	This is the file to which the output, generated when the netdata or the debug option is TRUE, will be written. If tracefile is set to "-", then tracing information will be written to standard output (the default).
worderase	If telnet is operating in LINEMODE or "old line by line" mode, then this character is taken to be the terminal's worderase character. The initial value for the worderase character is taken to be the terminal's worderase character.
?	Displays the legal set and unset commands.

### slc state

The `slc` (Set Local Characters) command is used to set or change the state of special characters when the TELNET LINEMODE option has been enabled. Special characters are characters that get mapped to TELNET commands sequences (like `ip` or `quit`) or line editing characters (like `erase` and `kill`). By default, the local special characters are exported. The following values for *state* are valid:

check	Verifies the settings for the current special characters. The remote side is requested to send all the current special character settings. If there are any discrepancies with the local side, the local settings will switch to the remote values.
export	Switches to the local defaults for the special characters. The local default characters are those of the local terminal at the time when <code>telnet</code> was started.
import	Switches to the remote defaults for the special characters. The remote default characters are those of the remote system at the time when the TELNET connection was established.
?	Prints out help information for the <code>slc</code> command.

toggle *argument...*

Toggle between TRUE and FALSE the various flags that control how `telnet` responds to events. More than one argument may be specified. The state of these flags may be interrogated with the `display` command. Valid arguments are:

authdebug	Turns on debugging information for the authentication code.
autodecrypt	When the TELNET ENCRYPT option is negotiated, by default the actual encryption (decryption) of the data stream does not start automatically. The <code>autoencrypt</code> ( <code>autodecrypt</code> ) command states that encryption of the output (input) stream should be enabled as soon as possible.
autologin	If the remote side supports the TELNET AUTHENTICATION option, <code>telnet</code> attempts to use it to perform automatic authentication. If the AUTHENTICATION option is not supported, the user's login name is propagated through the TELNET ENVIRON option. This command is the same as specifying the <code>-a</code> option on the <code>open</code> command.
autoflush	If <code>autoflush</code> and <code>localchars</code> are both TRUE, then when the <code>ao</code> , <code>intr</code> , or <code>quit</code> characters are recognized (and transformed into TELNET sequences; see <code>set</code> for details), <code>telnet</code> refuses to display any data on the user's terminal until the remote system acknowledges (using a TELNET Timing Mark option) that it has processed those TELNET sequences. The initial value for this toggle is TRUE if the terminal user has not done an "stty noflsh". Otherwise, the value is FALSE (see <code>stty(1)</code> ).
autosynch	If <code>autosynch</code> and <code>localchars</code> are both TRUE, then when either the <code>interrupt</code> or <code>quit</code> characters are typed (see <code>set</code> for descriptions of <code>interrupt</code> and <code>quit</code> ), the resulting TELNET sequence sent is followed by the TELNET SYNCH sequence. This procedure <i>should</i> cause the remote system to

## telnet(1)

	begin throwing away all previously typed input until both of the TELNET sequences have been read and acted upon. The initial value of this toggle is FALSE.
binary	Enable or disable the TELNET BINARY option on both input and output.
inbinary	Enable or disable the TELNET BINARY option on input.
outbinary	Enable or disable the TELNET BINARY option on output.
crlf	Determines how carriage returns are sent. If the value is TRUE, then carriage returns will be sent as <CR><LF>. If the value is FALSE, then carriage returns will be sent as <CR><NUL>. The initial value for this toggle is FALSE.
crmod	Toggle RETURN mode. When this mode is enabled, most RETURN characters received from the remote host will be mapped into a RETURN followed by a line feed. This mode does not affect those characters typed by the user, only those received from the remote host. This mode is useful only for remote hosts that send RETURN but never send LINEFEED. The initial value for this toggle is FALSE.
debug	Toggle socket level debugging (only available to the super-user). The initial value for this toggle is FALSE.
encdebug	Turns on debugging information for the encryption code.
localchars	If this toggle is TRUE, then the flush, interrupt, quit, erase, and kill characters (see set) are recognized locally, and transformed into appropriate TELNET control sequences, respectively ao, ip, brk, ec, and e1 (see send). The initial value for this toggle is TRUE in "line by line" mode, and FALSE in "character at a time" mode. When the LINEMODE option is enabled, the value of localchars is ignored, and assumed always to be TRUE. If LINEMODE has ever been enabled, then quit is sent as abort, and eof and suspend are sent as eof and susp (see send above).
netdata	Toggle the display of all network data (in hexadecimal format). The initial value for this toggle is FALSE.
options	Toggle the display of some internal TELNET protocol processing (having to do with telnet options). The initial value for this toggle is FALSE.

<code>prettydump</code>	When the <code>netdata</code> toggle is enabled, if <code>prettydump</code> is enabled, the output from the <code>netdata</code> command will be formatted in a more user readable format. Spaces are put between each character in the output. The beginning of any TELNET escape sequence is preceded by an asterisk (*) to aid in locating them.
<code>skiprc</code>	When the <code>skiprc</code> toggle is TRUE, TELNET skips the reading of the <code>.telnetrc</code> file in the user's home directory when connections are opened. The initial value for this toggle is FALSE.
<code>termdata</code>	Toggles the display of all terminal data (in hexadecimal format). The initial value for this toggle is FALSE.
<code>verbose_encrypt</code>	When the <code>verbose_encrypt</code> flag is TRUE, TELNET prints out a message each time encryption is enabled or disabled. The initial value for this toggle is FALSE.
<code>?</code>	Display the legal toggle commands.

`environ` *argument* ...

The `environ` command is used to manipulate variables that may be sent through the TELNET ENVIRON option. The initial set of variables is taken from the users environment. Only the `DISPLAY` and `PRINTER` variables are exported by default. Valid arguments for the `environ` command are:

<code>define</code> <i>variable</i> <i>value</i>	Define <i>variable</i> to have a value of <i>value</i> . Any variables defined by this command are automatically exported. The <i>value</i> may be enclosed in single or double quotes, so that tabs and spaces may be included.
<code>undefine</code> <i>variable</i>	Remove <i>variable</i> from the list of environment variables.
<code>export</code> <i>variable</i>	Mark the <i>variable</i> to be exported to the remote side.
<code>unexport</code> <i>variable</i>	Mark the <i>variable</i> to not be exported unless explicitly requested by the remote side.
<code>list</code>	List the current set of environment variables. Those marked with an asterisk (*) will be sent automatically. Other variables will be sent only if explicitly requested.
<code>?</code>	Prints out help information for the <code>environ</code> command.

`logout`

Sends the `telnet logout` option to the remote side. This command is similar to a `close` command. However, if the remote side does not support the `logout` option, nothing happens. If, however, the remote side does support the `logout` option, this

telnet(1)

command should cause the remote side to close the TELNET connection. If the remote side also supports the concept of suspending a user's session for later reattachment, the `logout` argument indicates that the remote side should terminate the session immediately.

**FILES** `$HOME/.telnetrc` file that contains commands to be executed before initiating a telnet session

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWtnetc

**SEE ALSO** `rlogin(1)`, `sh(1)`, `stty(1)`, `getlogin(3C)`, `hosts(4)`, `ipnodes(4)`, `krb5.conf(4)`, `nologin(4)`, `telnetrc(4)`, `attributes(5)`, `inet(7P)`, `inet6(7P)`

**DIAGNOSTICS** `NO LOGINS`: System going down in *N* minutes  
The machine is in the process of being shut down and logins have been disabled.

**NOTES** On some remote systems, echo has to be turned off manually when in "line by line" mode.

In "old line by line" mode, or `LINEMODE`, the terminal's EOF character is only recognized (and sent to the remote system) when it is the first character on a line.

<b>NAME</b>	test – evaluate condition(s)
<b>SYNOPSIS</b>	<pre>/usr/bin/test [condition] [ [condition] ]</pre>
<b>sh</b>	<pre>test [condition] [ [condition] ]</pre>
<b>csh</b>	<pre>test [condition] [ [condition] ]</pre>
<b>ksh</b>	<pre>test [condition] [ [condition] ]</pre>
<b>DESCRIPTION</b>	<p>The <code>test</code> utility evaluates the <i>condition</i> and indicates the result of the evaluation by its exit status. An exit status of zero indicates that the condition evaluated as true and an exit status of 1 indicates that the condition evaluated as false.</p> <p>In the first form of the utility shown using the SYNOPSIS:</p> <pre>test [ condition ]</pre> <p>the square brackets denote that <i>condition</i> is an optional operand and are not to be entered on the command line.</p> <p>In the second form of the utility shown using the SYNOPSIS:</p> <pre>[ [ condition ] ]</pre> <p>the first open square bracket, [, is the required utility name. <i>condition</i> is optional, as denoted by the inner pair of square brackets. The final close square bracket, ], is a required operand.</p> <p>See <code>largefile(5)</code> for the description of the behavior of <code>test</code> when encountering files greater than or equal to 2 Gbyte (2<sup>31</sup> bytes).</p> <p>The <code>test</code> and [ utilities evaluate the condition <i>condition</i> and, if its value is true, set exit status to 0. Otherwise, a non-zero (false) exit status is set. <code>test</code> and [ also set a non-zero exit status if there are no arguments. When permissions are tested, the effective user ID of the process is used.</p> <p>All operators, flags, and brackets (brackets used as shown in the last SYNOPSIS line) must be separate arguments to these commands. Normally these arguments are separated by spaces.</p>
<b>OPERANDS</b>	<p>The primaries listed below with two elements of the form:</p> <pre>-primary_operator primary_operand</pre> <p>are known as <i>unary primaries</i>. The primaries with three elements in either of the two forms:</p>

test(1)

```
primary_operand -primary_operator primary_operand  
primary_operand primary_operator primary_operand
```

are known as *binary primaries*.

If any file operands except for `-h` and `-L` primaries refer to symbolic links, the symbolic link is expanded and the test is performed on the resulting file.

If you test a file you own (the `-r` `-w` or `-x` tests), but the permission tested does not have the *owner* bit set, a non-zero (false) exit status will be returned even though the file may have the *group* or *other* bit set for that permission.

The `=` and `!=` primaries have a higher precedence than the unary primaries. The `=` and `!=` primaries always expect arguments; therefore, `=` and `!=` cannot be used as an argument to the unary primaries.

The following primaries can be used to construct *condition*:

<code>-a file</code>	True if <i>file</i> exists. (Not available in sh.)
<code>-b file</code>	True if <i>file</i> exists and is a block special file.
<code>-c file</code>	True if <i>file</i> exists and is a character special file.
<code>-d file</code>	True if <i>file</i> exists and is a directory.
<code>-e file</code>	True if <i>file</i> exists. (Not available in sh.)
<code>-f file</code>	True if <i>file</i> exists and is a regular file. Alternatively, if <code>/usr/bin/sh</code> users specify <code>/usr/ucb</code> before <code>/usr/bin</code> in their <code>PATH</code> environment variable, then <code>test</code> will return true if <i>file</i> exists and is (not-a-directory). The <code>cs</code> test and <code>[</code> built-ins always use this alternative behavior.
<code>-g file</code>	True if <i>file</i> exists and its set group ID flag is set.
<code>-G file</code>	True if <i>file</i> exists and its group matches the effective group ID of this process. (Not available in sh.)
<code>-h file</code>	True if <i>file</i> exists and is a symbolic link.
<code>-k file</code>	True if <i>file</i> exists and has its sticky bit set.
<code>-L file</code>	True if <i>file</i> exists and is a symbolic link.
<code>-n string</code>	True if the length of <i>string</i> is non-zero.
<code>-o option</code>	True if option named <i>option</i> is on. (Not available in <code>cs</code> or <code>sh</code> .)
<code>-O file</code>	True if <i>file</i> exists and is owned by the effective user ID of this process. (Not available in sh.)
<code>-p file</code>	True if <i>file</i> is a named pipe (FIFO).

<code>-r file</code>	True if <i>file</i> exists and is readable.
<code>-s file</code>	True if <i>file</i> exists and has a size greater than zero.
<code>-S file</code>	True if <i>file</i> exists and is a socket. (Not available in sh.)
<code>-t [file_descriptor]</code>	True if the file whose file descriptor number is <i>file_descriptor</i> is open and is associated with a terminal. If <i>file_descriptor</i> is not specified, 1 is used as a default value.
<code>-u file</code>	True if <i>file</i> exists and its set-user-ID flag is set.
<code>-w file</code>	True if <i>file</i> exists and is writable. True will indicate only that the write flag is on. The <i>file</i> will not be writable on a read-only file system even if this test indicates true.
<code>-x file</code>	True if <i>file</i> exists and is executable. True will indicate only that the execute flag is on. If <i>file</i> is a directory, true indicates that <i>file</i> can be searched.
<code>-z string</code>	True if the length of string <i>string</i> is zero.
<code>file1 -nt file2</code>	True if <i>file1</i> exists and is newer than <i>file2</i> . (Not available in sh.)
<code>file1 -ot file2</code>	True if <i>file1</i> exists and is older than <i>file2</i> . (Not available in sh.)
<code>file1 -ef file2</code>	True if <i>file1</i> and <i>file2</i> exist and refer to the same file. (Not available in sh.)
<code>string</code>	True if the string <i>string</i> is not the null string.
<code>string1 = string2</code>	True if the strings <i>string1</i> and <i>string2</i> are identical.
<code>string1 != string2</code>	True if the strings <i>string1</i> and <i>string2</i> are not identical.
<code>n1 -eq n2</code>	True if the integers <i>n1</i> and <i>n2</i> are algebraically equal.
<code>n1 -ne n2</code>	True if the integers <i>n1</i> and <i>n2</i> are not algebraically equal.
<code>n1 -gt n2</code>	True if the integer <i>n1</i> is algebraically greater than the integer <i>n2</i> .
<code>n1 -ge n2</code>	True if the integer <i>n1</i> is algebraically greater than or equal to the integer <i>n2</i> .
<code>n1 -lt n2</code>	True if the integer <i>n1</i> is algebraically less than the integer <i>n2</i> .
<code>n1 -le n2</code>	True if the integer <i>n1</i> is algebraically less than or equal to the integer <i>n2</i> .

test(1)

*condition1* -a *condition2* True if both *condition1* and *condition2* are true. The -a binary primary is left associative and has higher precedence than the -o binary primary.

*condition1* -o *condition2* True if either *condition1* or *condition2* is true. The -o binary primary is left associative.

These primaries can be combined with the following operators:

! *condition* True if *condition* is false.

( *condition* ) True if *condition* is true. The parentheses ( ) can be used to alter the normal precedence and associativity. Notice also that parentheses are meaningful to the shell and, therefore, must be quoted.

The algorithm for determining the precedence of the operators and the return value that will be generated is based on the number of arguments presented to `test`. (However, when using the [ . . . ] form, the right-bracket final argument will not be counted in this algorithm.)

In the following list, \$1, \$2, \$3 and \$4 represent the arguments presented to `test` as a *condition*, *condition1*, or *condition2*.

0 arguments: Exit false (1).

1 argument: Exit true (0) if \$1 is not null. Otherwise, exit false.

2 arguments:

- If \$1 is !, exit true if \$2 is null, false if \$2 is not null.
- If \$1 is a unary primary, exit true if the unary test is true, false if the unary test is false.
- Otherwise, produce unspecified results.

3 arguments:

- If \$2 is a binary primary, perform the binary test of \$1 and \$3.
- If \$1 is !, negate the two-argument test of \$2 and \$3.
- Otherwise, produce unspecified results.

4 arguments:

- If \$1 is !, negate the three-argument test of \$2, \$3, and \$4.
- Otherwise, the results are unspecified.

**USAGE** Scripts should be careful when dealing with user-supplied input that could be confused with primaries and operators. Unless the application writer knows all the cases that produce input to the script, invocations like `test "$1" -a "$2"` should be written as `test "$1" && test "$2"` to avoid problems if a user supplied values

such as \$1 set to ! and \$2 set to the null string. That is, in cases where maximal portability is of concern, replace `test expr1 -a expr2` with `test expr1 && test expr2`, and replace `test expr1 -o expr2` with `test expr1 || test expr2`. But notice that, in `test`, `-a` has *higher* precedence than `-o`, while `&&` and `||` have *equal* precedence in the shell.

Parentheses or braces can be used in the shell command language to effect grouping.

Parentheses must be escaped when using `sh`. For example:

```
test \( expr1 -a expr2 \) -o expr3
```

This command is not always portable outside XSI-conformant systems. The following form can be used instead:

```
( test expr1 && test expr2 ) || test expr3
```

The two commands:

```
test "$1"
test ! "$1"
```

could not be used reliably on some historical systems. Unexpected results would occur if such a *string* condition were used and \$1 expanded to !, (, or a known unary primary. Better constructs are, respectively,

```
test -n "$1"
test -z "$1"
```

Historical systems have also been unreliable given the common construct:

```
test "$response" = "expected string"
```

One of the following is a more reliable form:

```
test "X$response" = "Xexpected string"
test "expected string" = "$response"
```

Notice that the second form assumes that `expected string` could not be confused with any unary primary. If `expected string` starts with `-`, `(`, `!` or even `=`, the first form should be used instead. Using the preceding rules without the marked extensions, any of the three comparison forms is reliable, given any input. (However, observe that the strings are quoted in all cases.)

Because the string comparison binary primaries, `=` and `!=`, have a higher precedence than any unary primary in the `>4` argument case, unexpected results can occur if arguments are not properly prepared. For example, in

```
test -d $1 -o -d $2
```

test(1)

If \$1 evaluates to a possible directory name of =, the first three arguments are considered a string comparison, which causes a syntax error when the second -d is encountered. One of the following forms prevents this; the second is preferred:

```
test \( -d "$1" \) -o \( -d "$2" \)
test -d "$1" || test -d "$2"
```

Also in the >4 argument case:

```
test "$1" = "bat" -a "$2" = "ball"
```

Syntax errors will occur if \$1 evaluates to ( or !. One of the following forms prevents this; the third is preferred:

```
test "X$1" = "Xbat" -a "X$2" = "Xball"
test "$1" = "bat" && test "$2" = "ball"
test "X$1" = "Xbat" && test "X$2" = "Xball"
```

#### EXAMPLES

In the if command examples, three conditions are tested, and if all three evaluate as true or successful, then their validities are written to the screen. The three tests are:

- if a variable set to 1 is greater than 0,
- if a variable set to 2 is equal to 2, and
- if the word "root" is included in the text file /etc/passwd.

#### /usr/bin/test

**EXAMPLE 1** Using /usr/bin/test

Perform a mkdir if a directory does not exist:

```
test ! -d tempdir && mkdir tempdir
```

Wait for a file to become non-readable:

```
while test -r thefile
do
    sleep 30
done
echo "thefile" is no longer readable'
```

Perform a command if the argument is one of three strings (two variations), using the open bracket version [ of the test command:

```
if [ "$1" = "pear" ] || [ "$1" = "grape" ] || [ "$1" = "apple" ]
then
    command
fi
case "$1" in
    pear|grape|apple) command;;
esac
```

#### The test built-in

The two forms of the test built-in follow the Bourne shell's if example.

**EXAMPLE 2** Using the sh built-in

```
ZERO=0 ONE=1 TWO=2 ROOT=root

if [ $ONE -gt $ZERO ]

[ $TWO -eq 2 ]

grep $ROOT /etc/passwd >&1 > /dev/null # discard output

then

    echo "$ONE is greater than 0, $TWO equals 2, and $ROOT is" \
        "a user-name in the password file"

else

    echo "At least one of the three test conditions is false"

fi
```

**EXAMPLE 3** Using the test built-in

Examples of the test built-in:

```
test `grep $ROOT /etc/passwd >&1 /dev/null` # discard output

echo $? # test for success
[ `grep nosuchname /etc/passwd >&1 /dev/null` ]

echo $? # test for failure
```

**cs** **EXAMPLE 4** Using the csh built-in

```
@ ZERO = 0; @ ONE = 1; @ TWO = 2; set ROOT = root
grep $ROOT /etc/passwd >&1 /dev/null # discard output
# $status must be tested for immediately following grep
if ( "$status" == "0" && $ONE > $ZERO && $TWO == 2 ) then
    echo "$ONE is greater than 0, $TWO equals 2, and $ROOT is" \
        "a user-name in the password file"
endif
```

**ksh** **EXAMPLE 5** Using the ksh built-in

```
ZERO=0 ONE=1 TWO=$((ONE+ONE)) ROOT=root
if ((ONE > ZERO)) # arithmetical comparison
[[ $TWO = 2 ]] # string comparison
[ `grep $ROOT /etc/passwd >&1 /dev/null` ] # discard output
then
    echo "$ONE is greater than 0, $TWO equals 2, and $ROOT is" \
        "a user-name in the password file"

else

    echo "At least one of the three test conditions is false"

fi
```

test(1)

**Using -e option in sh**

**EXAMPLE 6** Using /usr/bin/test for the -e option

If one really wants to use the -e option in sh, use /usr/bin/test, as in the following:

```
if [ ! -h $PKG_INSTALL_ROOT$rLink ] && /usr/bin/test -e
$PKG_INSTALL_ROOT/usr/bin/$rFile ; then
    ln -s $rFile $PKG_INSTALL_ROOT$rLink
fi
```

**ENVIRONMENT VARIABLES**

See environ(5) for descriptions of the following environment variables that affect the execution of test: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**EXIT STATUS**

The following exit values are returned:

- 0            *condition* evaluated to true.
- 1            *condition* evaluated to false or *condition* was missing.
- >1          An error occurred.

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Standard

**SEE ALSO**

**NOTES**

The not-a-directory alternative to the -f option is a transition aid for BSD applications and may not be supported in future releases.

<b>NAME</b>	test – condition evaluation command
<b>SYNOPSIS</b>	<code>/usr/ucb/test</code> <i>expression</i> <i>expression</i>
<b>DESCRIPTION</b>	<p><code>test</code> evaluates the expression <i>expression</i> and, if its value is true, sets 0 (true) exit status; otherwise, a non-zero (false) exit status is set. <code>test</code> also sets a non-zero exit status if there are no arguments. When permissions are tested, the effective user ID of the process is used.</p> <p>All operators, flags, and brackets (brackets used as shown in the second <b>SYNOPSIS</b> line) must be separate arguments to the <code>test</code> command; normally these items are separated by spaces.</p>
<b>USAGE</b>	
<b>Primitives</b>	<p>The following primitives are used to construct <i>expression</i>:</p> <ul style="list-style-type: none"> <li><code>-r filename</code> True if <i>filename</i> exists and is readable.</li> <li><code>-w filename</code> True if <i>filename</i> exists and is writable.</li> <li><code>-x filename</code> True if <i>filename</i> exists and is executable.</li> <li><code>-f filename</code> True if <i>filename</i> exists and is a regular file. Alternatively, if <code>/usr/bin/sh</code> users specify <code>/usr/ucb</code> before <code>/usr/bin</code> in their <code>PATH</code> environment variable, then <code>test</code> will return true if <i>filename</i> exists and is (<code>not-a-directory</code>). This is also the default for <code>/usr/bin/csh</code> users.</li> <li><code>-d filename</code> True if <i>filename</i> exists and is a directory.</li> <li><code>-c filename</code> True if <i>filename</i> exists and is a character special file.</li> <li><code>-b filename</code> True if <i>filename</i> exists and is a block special file.</li> <li><code>-p filename</code> True if <i>filename</i> exists and is a named pipe (fifo).</li> <li><code>-u filename</code> True if <i>filename</i> exists and its set-user- ID bit is set.</li> <li><code>-g filename</code> True if <i>filename</i> exists and its set-group- ID bit is set.</li> <li><code>-k filename</code> True if <i>filename</i> exists and its sticky bit is set.</li> <li><code>-s filename</code> True if <i>filename</i> exists and has a size greater than zero.</li> <li><code>-t[ <i>fildev</i> ]</code> True if the open file whose file descriptor number is <i>fildev</i> (1 by default) is associated with a terminal device.</li> <li><code>-z <i>s1</i></code> True if the length of string <i>s1</i> is zero.</li> <li><code>-n <i>s1</i></code> True if the length of the string <i>s1</i> is non-zero.</li> <li><code><i>s1</i> = <i>s2</i></code> True if strings <i>s1</i> and <i>s2</i> are identical.</li> <li><code><i>s1</i> != <i>s2</i></code> True if strings <i>s1</i> and <i>s2</i> are <i>not</i> identical.</li> </ul>

## test(1B)

*s1* True if *s1* is *not* the null string.  
*n1 -eq n2* True if the integers *n1* and *n2* are algebraically equal. Any of the comparisons *-ne*, *-gt*, *-ge*, *-lt*, and *-le* may be used in place of *-eq*.

**Operators** These primaries may be combined with the following operators:

! Unary negation operator.  
-a Binary *and* operator.  
-o Binary *or* operator (*-a* has higher precedence than *-o*).  
(*expression*) Parentheses for grouping. Notice also that parentheses are meaningful to the shell and, therefore, must be quoted.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

**SEE ALSO** `find(1)`, `sh(1)`, `attributes(5)`

**NOTES** The `not-a-directory` alternative to the `-f` option is a transition aid for BSD applications and may not be supported in future releases.

If you test a file you own (the `-r`, `-w`, or `-x` tests), but the permission tested does not have the *owner* bit set, a non-zero (false) exit status will be returned even though the file may have the *group* or *other* bit set for that permission. The correct exit status will be set if you are super-user.

The `=` and `!=` operators have a higher precedence than the `-r` through `-n` operators, and `=` and `!=` always expect arguments; therefore, `=` and `!=` cannot be used with the `-r` through `-n` operators.

If more than one argument follows the `-r` through `-n` operators, only the first argument is examined; the others are ignored, unless a `-a` or a `-o` is the second argument.

<b>NAME</b>	test – condition evaluation command																												
<b>SYNOPSIS</b>	<b>test</b> <i>expression</i> <i>expression</i>																												
<b>DESCRIPTION</b>	<p><b>test</b> evaluates the expression <i>expression</i> and if its value is true, sets a 0 (TRUE) exit status; otherwise, a non-zero (FALSE) exit status is set; <b>test</b> also sets a non-zero exit status if there are no arguments. Normally these items are separated by spaces.</p>																												
<b>USAGE</b>																													
<b>Primitives</b>	<p>The following primitives are used to construct <i>expression</i>:</p> <table border="0"> <tr> <td style="padding-right: 20px;">-r <i>filename</i></td> <td>True if <i>filename</i> exists and is readable.</td> </tr> <tr> <td style="padding-right: 20px;">-w <i>filename</i></td> <td>True if <i>filename</i> exists and is writable.</td> </tr> <tr> <td style="padding-right: 20px;">-x <i>filename</i></td> <td>True if <i>filename</i> exists and is executable.</td> </tr> <tr> <td style="padding-right: 20px;">-f <i>filename</i></td> <td>True if <i>filename</i> exists and is a regular file.</td> </tr> <tr> <td style="padding-right: 20px;">-d <i>filename</i></td> <td>True if <i>filename</i> exists and is a directory.</td> </tr> <tr> <td style="padding-right: 20px;">-c <i>filename</i></td> <td>True if <i>filename</i> exists and is a character special file.</td> </tr> <tr> <td style="padding-right: 20px;">-b <i>filename</i></td> <td>True if <i>filename</i> exists and is a block special file.</td> </tr> <tr> <td style="padding-right: 20px;">-p <i>filename</i></td> <td>True if <i>filename</i> exists and is a named pipe (FIFO).</td> </tr> <tr> <td style="padding-right: 20px;">-u <i>filename</i></td> <td>True if <i>filename</i> exists and its set-user-ID bit is set.</td> </tr> <tr> <td style="padding-right: 20px;">-g <i>filename</i></td> <td>True if <i>filename</i> exists and its set-group-ID bit is set.</td> </tr> <tr> <td style="padding-right: 20px;">-k <i>filename</i></td> <td>True if <i>filename</i> exists and its sticky bit is set.</td> </tr> <tr> <td style="padding-right: 20px;">-s <i>filename</i></td> <td>True if <i>filename</i> exists and has a size greater than 0.</td> </tr> <tr> <td style="padding-right: 20px;">-t[ <i>fildev</i> ]</td> <td>True if the open file whose file descriptor number is <i>fildev</i> (1 by default) is associated with a terminal device.</td> </tr> <tr> <td style="padding-right: 20px;">-z <i>s1</i></td> <td>True if the length of string <i>s1</i> is 0.</td> </tr> </table>	-r <i>filename</i>	True if <i>filename</i> exists and is readable.	-w <i>filename</i>	True if <i>filename</i> exists and is writable.	-x <i>filename</i>	True if <i>filename</i> exists and is executable.	-f <i>filename</i>	True if <i>filename</i> exists and is a regular file.	-d <i>filename</i>	True if <i>filename</i> exists and is a directory.	-c <i>filename</i>	True if <i>filename</i> exists and is a character special file.	-b <i>filename</i>	True if <i>filename</i> exists and is a block special file.	-p <i>filename</i>	True if <i>filename</i> exists and is a named pipe (FIFO).	-u <i>filename</i>	True if <i>filename</i> exists and its set-user-ID bit is set.	-g <i>filename</i>	True if <i>filename</i> exists and its set-group-ID bit is set.	-k <i>filename</i>	True if <i>filename</i> exists and its sticky bit is set.	-s <i>filename</i>	True if <i>filename</i> exists and has a size greater than 0.	-t[ <i>fildev</i> ]	True if the open file whose file descriptor number is <i>fildev</i> (1 by default) is associated with a terminal device.	-z <i>s1</i>	True if the length of string <i>s1</i> is 0.
-r <i>filename</i>	True if <i>filename</i> exists and is readable.																												
-w <i>filename</i>	True if <i>filename</i> exists and is writable.																												
-x <i>filename</i>	True if <i>filename</i> exists and is executable.																												
-f <i>filename</i>	True if <i>filename</i> exists and is a regular file.																												
-d <i>filename</i>	True if <i>filename</i> exists and is a directory.																												
-c <i>filename</i>	True if <i>filename</i> exists and is a character special file.																												
-b <i>filename</i>	True if <i>filename</i> exists and is a block special file.																												
-p <i>filename</i>	True if <i>filename</i> exists and is a named pipe (FIFO).																												
-u <i>filename</i>	True if <i>filename</i> exists and its set-user-ID bit is set.																												
-g <i>filename</i>	True if <i>filename</i> exists and its set-group-ID bit is set.																												
-k <i>filename</i>	True if <i>filename</i> exists and its sticky bit is set.																												
-s <i>filename</i>	True if <i>filename</i> exists and has a size greater than 0.																												
-t[ <i>fildev</i> ]	True if the open file whose file descriptor number is <i>fildev</i> (1 by default) is associated with a terminal device.																												
-z <i>s1</i>	True if the length of string <i>s1</i> is 0.																												

## test(1F)

<code>-n s1</code>	True if the length of the string <code>s1</code> is non-zero.
<code>s1 = s2</code>	True if strings <code>s1</code> and <code>s2</code> are identical.
<code>s1 != s2</code>	True if strings <code>s1</code> and <code>s2</code> are <i>not</i> identical.
<code>s1</code>	True if <code>s1</code> is <i>not</i> the null string.
<code>n1 -eq n2</code>	True if the integers <code>n1</code> and <code>n2</code> are algebraically equal. Any of the comparisons <code>-ne</code> , <code>-gt</code> , <code>-ge</code> , <code>-lt</code> , and <code>-le</code> may be used in place of <code>-eq</code> .

**Operators** These primaries may be combined with the following operators:

<code>!</code>	Unary negation operator.
<code>-a</code>	Binary <i>and</i> operator.
<code>-o</code>	Binary <i>or</i> operator ( <code>-a</code> has higher precedence than <code>-o</code> ).
<code>'( expression )'</code>	Parentheses for grouping. Notice also that parentheses are meaningful to the shell and, therefore, must be quoted.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO** `find(1)`, `sh(1)`, `attributes(5)`

**NOTES** If you test a file you own (the `-r`, `-w`, or `-x` tests), but the permission tested does not have the *owner* bit set, a non-zero (false) exit status will be returned even though the file may have the *group* or *other* bit set for that permission. The correct exit status will be set if you are super-user.

The `=` and `!=` operators have a higher precedence than the `-r` through `-n` operators, and `=` and `!=` always expect arguments; therefore, `=` and `!=` cannot be used with the `-r` through `-n` operators.

If more than one argument follows the `-r` through `-n` operators, only the first argument is examined; the others are ignored, unless a `-a` or a `-o` is the second argument.

<b>NAME</b>	tftp – trivial file transfer program
<b>SYNOPSIS</b>	<b>tftp</b> [ <i>host</i> [ <i>port</i> ] ]
<b>DESCRIPTION</b>	tftp is the user interface to the Internet TFTP (Trivial File Transfer Protocol), which allows users to transfer files to and from a remote machine. The remote <i>host</i> and optional <i>port</i> may be specified on the command line, in which case tftp uses <i>host</i> as the default host, and if specified, <i>port</i> as the default port, for future transfers. See the connect command below.
<b>USAGE</b>	Once tftp is running, it issues the prompt tftp> and recognizes the following commands:
<b>Commands</b>	<p>connect <i>host-name</i> [ <i>port</i> ]</p> <p>Set the <i>host</i>, and optionally <i>port</i>, for transfers. The TFTP protocol, unlike the FTP protocol, does not maintain connections between transfers; thus, the connect command does not actually create a connection, but merely remembers what host is to be used for transfers. You do not have to use the connect command; the remote host can be specified as part of the get or put commands.</p> <p>mode <i>transfer-mode</i></p> <p>Set the mode for transfers; <i>transfer-mode</i> may be one of <i>ascii</i> or <i>binary</i>. The default is <i>ascii</i>.</p> <p>put <i>filename</i></p> <p>put <i>localfile remotefile</i></p> <p>put <i>filename1 filename2 . . . filenameN remote-directory</i></p> <p>Transfer a file, or a set of files, to the specified remote file or directory. The destination can be in one of two forms: a filename on the remote host if the host has already been specified, or a string of the form:</p> <p><i>host:filename</i></p> <p>to specify both a <i>host</i> and <i>filename</i> at the same time. If the latter form is used, the specified host becomes the default for future transfers. If the remote-directory form is used, the remote host is assumed to be running the UNIX system.</p> <p>The <i>host</i> can be a host name (see <i>hosts(4)</i> or <i>ipnodes(4)</i>) or an IPv4 or IPv6 address string (see <i>inet(7P)</i> or <i>inet6(7P)</i>). Since IPv6 addresses already contain ":"s, the <i>host</i> should be enclosed in square brackets when an IPv6 address is used. Otherwise, the first occurrence of a colon will be interpreted as the separator between the <i>host</i> and the <i>filename</i>. For example,</p> <p>[1080::8:800:200c:417A]:myfile</p> <p>Files may be written only if they already exist and are publicly writable. See <i>in.tftpd(1M)</i>.</p> <p>get <i>filename</i></p> <p>get <i>remotename localname</i></p> <p>get <i>filename1 filename2 filename3 . . . filenameN</i></p>

## tftp(1)

Get a file or set of files (three or more) from the specified remote *sources*. *source* can be in one of two forms: a filename on the remote host if the host has already been specified, or a string of the form:

*host :filename*

to specify both a host and filename at the same time. If the latter form is used, the last host specified becomes the default for future transfers. See the `put` command regarding specifying a *host*.

`quit`

Exit `tftp`. An EOF also exits.

`verbose`

Toggle verbose mode.

`trace`

Toggle packet tracing.

`status`

Show current status.

`rexmt` *retransmission-timeout*

Set the per-packet retransmission timeout, in seconds.

`timeout` *total-transmission-timeout*

Set the total transmission timeout, in seconds.

`ascii`

Shorthand for mode `ascii`.

`binary`

Shorthand for mode `binary`.

`blksize` *transfer-blocksize*

The value of the transfer blocksize option to negotiate with the server. A value of 0 disables the negotiation of this option.

`srexmt` *server-retransmission-timeout*

The value of the retransmission timeout option to request that the server uses. A value of 0 disables the negotiation of this option.

`tsize`

A toggle that sends the transfer size option to the server. By default, the option is not sent. The transfer size option is not sent with a `write` request when the *transfer-mode* is `ascii`.

? [ *command-name* ... ]

Print help information.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWtftp

**SEE ALSO** `in.tftpd(1M)`, `hosts(4)`, `ipnodes(4)`, `attributes(5)`, `inet(7P)`, `inet6(7P)`

Malkin, G. and Harkin, A. *RFC 2347, TFTP Option Extension*. The Internet Society. May 1998

Malkin, G. and Harkin, A. *RFC 2348, TFTP Blocksize Option*. The Internet Society. May 1998

Malkin, G. and Harkin, A. *RFC 2349, TFTP Timeout Interval and Transfer Size Options*. The Internet Society. May 1998

Sollins, K.R. *RFC 1350, The TFTP Protocol (Revision 2)*. Network Working Group. July 1992.

**NOTES** The default *transfer-mode* is `ascii`. This differs from pre-SunOS 4.0 and pre-4.3BSD systems, so explicit action must be taken when transferring non-ASCII binary files such as executable commands.

Because there is no user-login or validation within the TFTP protocol, many remote sites restrict file access in various ways. Approved methods for file access are specific to each site, and therefore cannot be documented here.

When using the `get` command to transfer multiple files from a remote host, three or more files must be specified. If two files are specified, the second file is used as a local file.

## time(1)

<b>NAME</b>	time – time a simple command
<b>SYNOPSIS</b>	<b>time</b> [-p] <i>utility</i> [ <i>argument...</i> ]
<b>DESCRIPTION</b>	<p>The <code>time</code> utility invokes <i>utility</i> operand with <i>argument</i>, and writes a message to standard error that lists timing statistics for <i>utility</i>. The message includes the following information:</p> <ul style="list-style-type: none"><li>■ The elapsed (real) time between invocation of <i>utility</i> and its termination.</li><li>■ The User CPU time, equivalent to the sum of the <code>tms_utime</code> and <code>tms_cutime</code> fields returned by the <code>times(2)</code> function for the process in which <i>utility</i> is executed.</li><li>■ The System CPU time, equivalent to the sum of the <code>tms_stime</code> and <code>tms_cstime</code> fields returned by the <code>times()</code> function for the process in which <i>utility</i> is executed.</li></ul> <p>When <code>time</code> is used as part of a pipeline, the times reported are unspecified, except when it is the sole command within a grouping command in that pipeline. For example, the commands on the left are unspecified; those on the right report on utilities <code>a</code> and <code>c</code>, respectively:</p> <pre>time a   b   c          { time a }   b   c a   b   time c         a   b   (time c)</pre>
<b>OPTIONS</b>	<p>The following option is supported:</p> <p><code>-p</code>           Writes the timing output to standard error in the following format:</p> <pre>real %f\nuser %f\nsys %f\n &lt; real seconds&gt;, &lt;user seconds&gt;, &lt;system seconds&gt;</pre>
<b>OPERANDS</b>	<p>The following operands are supported:</p> <p><i>utility</i>           The name of the utility that is to be invoked.</p> <p><i>argument</i>         Any string to be supplied as an argument when invoking <i>utility</i>.</p>
<b>USAGE</b>	<p>The <code>time</code> utility returns exit status 127 if an error occurs so that applications can distinguish “failure to find a utility” from “invoked utility exited with an error indication.” The value 127 was chosen because it is not commonly used for other meanings. Most utilities use small values for “normal error conditions” and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked.</p>
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Using the time command</p> <p>It is frequently desirable to apply <code>time</code> to pipelines or lists of commands. This can be done by placing pipelines and command lists in a single file. This single file can then be invoked as a utility, and the <code>time</code> applies to everything in the file.</p> <p>Alternatively, the following command can be used to apply <code>time</code> to a complex command:</p> <pre>example% time sh -c 'complex-command-line'</pre>

**EXAMPLE 2** Using time in the csh shell

The following two examples show the differences between the `csh` version of `time` and the version in `/usr/bin/time`. These examples assume that `csh` is the shell in use.

```
example% time find / -name csh.1 -print
/usr/share/man/man1/csh.1
95.0u 692.0s 1:17:52 16% 0+0k 0+0io 0pf+0w
```

See [csh\(1\)](#) for an explanation of the format of `time` output.

```
example% /usr/bin/time find / -name csh.1 -print
/usr/share/man/man1/csh.1
real 1:23:31.5
user 1:33.2
sys 11:28.2
```

**ENVIRONMENT VARIABLES**

See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `time`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, `LC_NUMERIC`, `NLSPATH`, and `PATH`.

**EXIT STATUS**

If *utility* is invoked, the exit status of `time` will be the exit status of *utility*. Otherwise, the `time` utility will exit with one of the following values:

1-125	An error occurred in the <code>time</code> utility.
126	<i>utility</i> was found but could not be invoked.
127	<i>utility</i> could not be found.

**ATTRIBUTES**

See [attributes\(5\)](#) for descriptions of the following attributes:

Interface Stability	Standard

**SEE ALSO**

[csh\(1\)](#), [shell\\_builtins\(1\)](#), [timex\(1\)](#), [times\(2\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**NOTES**

When the `time` command is run on a multiprocessor machine, the total of the values printed for `user` and `sys` can exceed `real`. This is because on a multiprocessor machine it is possible to divide the task between the various processors.

When the command being timed is interrupted, the timing values displayed may not always be accurate.

**BUGS**

Elapsed time is accurate to the second, while the CPU times are measured to the 100th second. Thus the sum of the CPU times can be up to a second larger than the elapsed time.

## times(1)

<b>NAME</b>	times – shell built-in function to report time usages of the current shell				
<b>SYNOPSIS</b>					
<b>sh</b>	<b>times</b>				
<b>ksh</b>	<b>times</b>				
<b>DESCRIPTION</b>					
<b>sh</b>	Print the accumulated user and system times for processes run from the shell.				
<b>ksh</b>	Print the accumulated user and system times for the shell and for processes run from the shell.				
	On this man page, <a href="#">ksh(1)</a> commands that are preceded by one or two * (asterisks) are treated specially in the following ways:				
	<ol style="list-style-type: none"><li>1. Variable assignment lists preceding the command remain in effect when the command completes.</li><li>2. I/O redirections are processed after variable assignments.</li><li>3. Errors cause a script that contains them to abort.</li><li>4. Words, following a command preceded by ** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.</li></ol>				
<b>ATTRIBUTES</b>	See <a href="#">attributes(5)</a> for descriptions of the following attributes:				
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu

<b>NAME</b>	timex – time a command; report process data and system activity
<b>SYNOPSIS</b>	<b>timex</b> [-o] [ -p [-fhkmrt]] [-s] <i>command</i>
<b>DESCRIPTION</b>	<p>The given <i>command</i> is executed; the elapsed time, user time and system time spent in execution are reported in seconds. Optionally, process accounting data for the <i>command</i> and all its children can be listed or summarized, and total system activity during the execution interval can be reported.</p> <p>The output of <i>timex</i> is written on standard error.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-o Report the total number of blocks read or written and total characters transferred by <i>command</i> and all its children. This option works only if the process accounting software is installed.</li> <li>-p List process accounting records for <i>command</i> and all its children. This option works only if the process accounting software is installed. Suboptions <i>f</i>, <i>h</i>, <i>k</i>, <i>m</i>, <i>r</i>, and <i>t</i> modify the data items reported. The options are as follows: <ul style="list-style-type: none"> <li>-f Print the <i>fork(2)</i>/<i>exec(2)</i> flag and system exit status columns in the output.</li> <li>-h Instead of mean memory size, show the fraction of total available CPU time consumed by the process during its execution. This “hog factor” is computed as (total CPU time)/(elapsed time).</li> <li>-k Instead of memory size, show total kcore-minutes.</li> <li>-m Show mean core size (the default).</li> <li>-r Show CPU factor (user time/(system-time + user-time)).</li> <li>-t Show separate system and user CPU times. The number of blocks read or written and the number of characters transferred are always reported.</li> </ul> </li> <li>-s Report total system activity (not just that due to <i>command</i>) that occurred during the execution interval of <i>command</i>. All the data items listed in <a href="#">sar(1)</a> are reported.</li> </ul>
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Examples of <i>timex</i>.</p> <p>A simple example:</p> <pre>example% timex -ops sleep 60</pre> <p>A terminal session of arbitrary complexity can be measured by timing a sub-shell:</p> <pre>example% timex -opskmt sh           session commands EOT</pre>

timex(1)

**EXAMPLE 1** Examples of `timex`. (Continued)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWaccu

**SEE ALSO** `sar(1)`, `time(1)`, `exec(2)`, `fork(2)`, `times(2)`, `attributes(5)`

**NOTES** Process records associated with `command` are selected from the accounting file `/var/adm/pacct` by inference, since process genealogy is not available. Background processes having the same user ID, terminal ID, and execution time window will be spuriously included.

<b>NAME</b>	tip – connect to remote system
<b>SYNOPSIS</b>	<b>tip</b> [-v] [-speed-entry] { <i>hostname</i>   <i>phone-number</i>   <i>device</i> }
<b>DESCRIPTION</b>	<p>The <code>tip</code> utility establishes a full-duplex terminal connection to a remote host. Once the connection is established, a remote session using <code>tip</code> behaves like an interactive session on a local terminal.</p> <p>The <code>remote</code> file contains entries describing remote systems and line speeds used by <code>tip</code>.</p> <p>Each host has a default baud rate for the connection, or you can specify a speed with the <code>-speed-entry</code> command line argument.</p> <p>When <i>phone-number</i> is specified, <code>tip</code> looks for an entry in the <code>remote</code> file of the form:</p> <pre>tip -speed-entry</pre> <p>When <code>tip</code> finds such an entry, it sets the connection speed accordingly. If it finds no such entry, <code>tip</code> interprets <code>-speed-entry</code> as if it were a system name, resulting in an error message.</p> <p>If you omit <code>-speed-entry</code>, <code>tip</code> uses the <code>tip0</code> entry to set a speed for the connection.</p> <p>When <i>device</i> is specified, <code>tip</code> attempts to open that device, but will do so using the access privileges of the user, rather than <code>tip</code>'s usual access privileges (<code>setuid uucp</code>). The user must have read/write access to the device. The <code>tip</code> utility interprets any character string beginning with the slash character ( / ) as a device name.</p> <p>When establishing the connection, <code>tip</code> sends a connection message to the remote system. The default value for this message can be found in the <code>remote</code> file.</p> <p>When <code>tip</code> attempts to connect to a remote system, it opens the associated device with an exclusive-open <code>ioctl(2)</code> call. Thus, only one user at a time may access a device. This is to prevent multiple processes from sampling the terminal line. In addition, <code>tip</code> honors the locking protocol used by <code>uucp(1C)</code>.</p> <p>When <code>tip</code> starts up, it reads commands from the file <code>.tiprc</code> in your home directory.</p>
<b>OPTIONS</b>	<code>-v</code> Display commands from the <code>.tiprc</code> file as they are executed.
<b>USAGE</b>	<p>Typed characters are normally transmitted directly to the remote machine, which does the echoing as well.</p> <p>At any time that <code>tip</code> prompts for an argument (for example, during setup of a file transfer), the line typed may be edited with the standard erase and kill characters. A null line in response to a prompt, or an interrupt, aborts the dialogue and returns you to the remote machine.</p>
<b>Commands</b>	A tilde (~) appearing as the first character of a line is an escape signal which directs <code>tip</code> to perform some special action. <code>tip</code> recognizes the following escape sequences:

## tip(1)

~^D	
~.	Drop the connection and exit (you may still be logged in on the remote machine). <i>Note:</i> If you rlogin and then run <code>tip</code> on the remote host, you must type <code>~.</code> (tilde tilde dot) to end the <code>tip</code> session. If you type <code>~.</code> (tilde dot), it terminates the rlogin.
~c [ <i>name</i> ]	Change directory to <i>name</i> . No argument implies change to your home directory.
~!	Escape to an interactive shell on the local machine. Exiting the shell returns you to <code>tip</code> .
~>	Copy file from local to remote.
~<	Copy file from remote to local.
~p <i>from</i> [ <i>to</i> ]	Send a file to a remote host running the UNIX system. When you use the put command, the remote system runs the command string  <code>cat &gt; to</code>  while <code>tip</code> sends it the <i>from</i> file. If the <i>to</i> file is not specified, the <i>from</i> file name is used. This command is actually a UNIX-system-specific version of the ' <code>~&gt;</code> ' command.
~t <i>from</i> [ <i>to</i> ]	Take a file from a remote host running the UNIX system. As in the put command the <i>to</i> file defaults to the <i>from</i> file name if it is not specified. The remote host executes the command string  <code>cat from ; echo ^A</code>  to send the file to <code>tip</code> .
~	Pipe the output from a remote command to a local process. The command string sent to the local system is processed by the shell.
~C	Connect a program to the remote machine. The command string sent to the program is processed by the shell. The program inherits file descriptors 0 as remote line input, 1 as remote line output, and 2 as tty standard error.
~\$	Pipe the output from a local process to the remote host. The command string sent to the local system is processed by the shell.
~#	Send a BREAK to the remote system.
~s	Set a variable (see the discussion below).
~^Z	Stop <code>tip</code> . Only available when run under a shell that supports job control, such as the C shell.
~^Y	Stop only the "local side" of <code>tip</code> . Only available when run under a shell that supports job control, such as the C shell. The "remote side" of <code>tip</code> , that is, the side that displays output from the remote host, is left running.

~? Get a summary of the tilde escapes.

Copying files requires some cooperation on the part of the remote host. When a ~> or ~< escape is used to send a file, `tip` prompts for a file name (to be transmitted or received) and a command to be sent to the remote system, in case the file is being transferred from the remote system. While `tip` is transferring a file, the number of lines transferred will be continuously displayed on the screen. A file transfer may be aborted with an interrupt.

#### Auto-call Units

`tip` may be used to dial up remote systems using a number of auto-call unit's (ACUs). When the remote system description contains the `du` capability, `tip` uses the call-unit (`cu`), ACU type (`at`), and phone numbers (`pn`) supplied. Normally, `tip` displays verbose messages as it dials.

Depending on the type of auto-dialer being used to establish a connection, the remote host may have garbage characters sent to it upon connection. The user should never assume that the first characters typed to the foreign host are the first ones presented to it. The recommended practice is to immediately type a `kill` character upon establishing a connection (most UNIX systems either support `@` or Control-U as the initial kill character).

`tip` currently supports the Ventel MD-212+ modem and DC Hayes-compatible modems.

When `tip` initializes a Hayes-compatible modem for dialing, it sets up the modem to auto-answer. Normally, after the conversation is complete, `tip` drops DTR, which causes the modem to "hang up."

Most modems can be configured so that when DTR drops, they re-initialize themselves to a preprogrammed state. This can be used to reset the modem and disable auto-answer, if desired.

Additionally, it is possible to start the phone number with a Hayes `S` command so that you can configure the modem before dialing. For example, to disable auto-answer, set up all the phone numbers in `/etc/remote` using something like `pn=S0=0DT5551212`. The `S0=0` disables auto-answer.

#### Remote Host Description

Descriptions of remote hosts are normally located in the system-wide file `/etc/remote`. However, a user may maintain personal description files (and phone numbers) by defining and exporting the `REMOTE` shell variable. The `remote` file must be readable by `tip`, but a secondary file describing phone numbers may be maintained readable only by the user. This secondary phone number file is `/etc/phones`, unless the shell variable `PHONES` is defined and exported. The phone number file contains lines of the form:

*system-name phone-number*

tip(1)

**tip Internal Variables**

Each phone number found for a system is tried until either a connection is established, or an end of file is reached. Phone numbers are constructed from '0123456789-=\*', where the '=' and '\*' are used to indicate a second dial tone should be waited for (ACU dependent).

tip maintains a set of variables which are used in normal operation. Some of these variables are read-only to normal users (root is allowed to change anything of interest). Variables may be displayed and set through the ~s escape. The syntax for variables is patterned after vi(1) and mail(1). Supplying all as an argument to the ~s escape displays all variables that the user can read. Alternatively, the user may request display of a particular variable by attaching a ? to the end. For example, '~s escape?' displays the current escape character.

Variables are numeric (num), string (str), character (char), or Boolean (bool) values. Boolean variables are set merely by specifying their name. They may be reset by prepending a ! to the name. Other variable types are set by appending an = and the value. The entire assignment must not have any blanks in it. A single set command may be used to interrogate as well as set a number of variables.

Variables may be initialized at run time by placing set commands (without the ~s prefix) in a .tiprc file in one's home directory. The -v option makes tip display the sets as they are made. Comments preceded by a # sign can appear in the .tiprc file.

Finally, the variable names must either be completely specified or an abbreviation may be given. The following list details those variables known to tip.

beautify	(bool) Discard unprintable characters when a session is being scripted; abbreviated be. If the nb capability is present, beautify is initially set to off. Otherwise, beautify is initially set to on.
baudrate	(num) The baud rate at which the connection was established; abbreviated ba. If a baud rate was specified on the command line, baudrate is initially set to the specified value. Or, if the br capability is present, baudrate is initially set to the value of that capability. Otherwise, baudrate is set to 300 baud. Once tip has been started, baudrate can only be changed by the super-user.
dialtimeout	(num) When dialing a phone number, the time (in seconds) to wait for a connection to be established; abbreviated dial. dialtimeout is initially set to 60 seconds, and can only be changed by the super-user.
disconnect	(str) The string to send to the remote host to disconnect from it; abbreviated di. If the di capability is present, disconnect is initially set to the value of that capability. Otherwise, disconnect is set to a null string ("").

echocheck	(bool) Synchronize with the remote host during file transfer by waiting for the echo of the last character transmitted; abbreviated <code>ec</code> . If the <code>ec</code> capability is present, <code>echocheck</code> is initially set to <code>on</code> . Otherwise, <code>echocheck</code> is initially set to <code>off</code> .
eofread	(str) The set of characters which signify an end-of-transmission during a <code>~&lt;</code> file transfer command; abbreviated <code>eofr</code> . If the <code>ie</code> capability is present, <code>eofread</code> is initially set to the value of that capability. Otherwise, <code>eofread</code> is set to a null string ( <code>" "</code> ).
eofwrite	(str) The string sent to indicate end-of-transmission during a <code>~&gt;</code> file transfer command; abbreviated <code>eofw</code> . If the <code>oe</code> capability is present, <code>eofread</code> is initially set to the value of that capability. Otherwise, <code>eofread</code> is set to a null string ( <code>" "</code> ).
eol	(str) The set of characters which indicate an end-of-line. <code>tip</code> will recognize escape characters only after an end-of-line. If the <code>e1</code> capability is present, <code>eol</code> is initially set to the value of that capability. Otherwise, <code>eol</code> is set to a null string ( <code>" "</code> ).
escape	(char) The command prefix (escape) character; abbreviated <code>es</code> . If the <code>es</code> capability is present, <code>escape</code> is initially set to the value of that capability. Otherwise, <code>escape</code> is set to <code>' ~ '</code> .
etimeout	(num) The amount of time, in seconds, that <code>tip</code> should wait for the echo-check response when <code>echocheck</code> is set; abbreviated <code>et</code> . If the <code>et</code> capability is present, <code>etimeout</code> is initially set to the value of that capability. Otherwise, <code>etimeout</code> is set to 10 seconds.
exceptions	(str) The set of characters which should not be discarded due to the beautification switch; abbreviated <code>ex</code> . If the <code>ex</code> capability is present, <code>exceptions</code> is initially set to the value of that capability. Otherwise, <code>exceptions</code> is set to <code>'\t\n\f\b'</code> .
force	(char) The character used to force literal data transmission; abbreviated <code>fo</code> . If the <code>fo</code> capability is present, <code>force</code> is initially set to the value of that capability. Otherwise, <code>force</code> is set to <code>\377</code> (which disables it).
framesize	(num) The amount of data (in bytes) to buffer between file system writes when receiving files; abbreviated <code>fr</code> . If the <code>fs</code> capability is present, <code>framesize</code> is initially set to the value of that capability. Otherwise, <code>framesize</code> is set to 1024.
halfduplex	(bool) Do local echoing because the host is half-duplex; abbreviated <code>hdx</code> . If the <code>hd</code> capability is present, <code>halfduplex</code> is initially set to <code>on</code> . Otherwise, <code>halfduplex</code> is initially set to <code>off</code> .
hardwareflow	(bool) Do hardware flow control; abbreviated <code>hf</code> . If the <code>hf</code> capability is present, <code>hardwareflow</code> is initially set to <code>on</code> . Otherwise, <code>hardwareflowcontrol</code> is initially set to <code>off</code> .

## tip(1)

host	(str) The name of the host to which you are connected; abbreviated <code>ho</code> . <code>host</code> is permanently set to the name given on the command line or in the <code>HOST</code> environment variable.
localecho	(bool) A synonym for <code>halfduplex</code> ; abbreviated <code>le</code> .
log	(str) The name of the file to which to log information about outgoing phone calls. <code>log</code> is initially set to <code>/var/adm/aculog</code> , and can only be inspected or changed by the super-user.
parity	(str) The parity to be generated and checked when talking to the remote host; abbreviated <code>par</code> . The possible values are:  none> zero      Parity is not checked on input, and the parity bit is set to zero on output.  one        Parity is not checked on input, and the parity bit is set to one on output.  even       Even parity is checked for on input and generated on output.  odd        Odd parity is checked for on input and generated on output.  If the <code>pa</code> capability is present, <code>parity</code> is initially set to the value of that capability; otherwise, <code>parity</code> is set to <code>none</code> .
phones	The file in which to find hidden phone numbers. If the environment variable <code>PHONES</code> is set, <code>phones</code> is set to the value of <code>PHONES</code> . Otherwise, <code>phones</code> is set to <code>/etc/phones</code> . The value of <code>phones</code> cannot be changed from within <code>tip</code> .
prompt	(char) The character which indicates an end-of-line on the remote host; abbreviated <code>pr</code> . This value is used to synchronize during data transfers. The count of lines transferred during a file transfer command is based on receipt of this character. If the <code>pr</code> capability is present, <code>prompt</code> is initially set to the value of that capability. Otherwise, <code>prompt</code> is set to <code>\n</code> .
raise	(bool) Upper case mapping mode; abbreviated <code>ra</code> . When this mode is enabled, all lower case letters will be mapped to upper case by <code>tip</code> for transmission to the remote machine. If the <code>ra</code> capability is present, <code>raise</code> is initially set to <code>on</code> . Otherwise, <code>raise</code> is initially set to <code>off</code> .
raisechar	(char) The input character used to toggle upper case mapping mode; abbreviated <code>rc</code> . If the <code>rc</code> capability is present, <code>raisechar</code> is initially set to the value of that capability. Otherwise, <code>raisechar</code> is set to <code>\377</code> (which disables it).

rawftp	(bool) Send all characters during file transfers; do not filter non-printable characters, and do not do translations like <code>\n</code> to <code>\r</code> . Abbreviated <code>raw</code> . If the <code>rw</code> capability is present, <code>rawftp</code> is initially set to <code>on</code> . Otherwise, <code>rawftp</code> is initially set to <code>off</code> .
record	(str) The name of the file in which a session script is recorded; abbreviated <code>rec</code> . If the <code>re</code> capability is present, <code>record</code> is initially set to the value of that capability. Otherwise, <code>record</code> is set to <code>tip.record</code> .
remote	The file in which to find descriptions of remote systems. If the environment variable <code>REMOTE</code> is set, <code>remote</code> is set to the value of <code>REMOTE</code> . Otherwise, <code>remote</code> is set to <code>/etc/remote</code> . The value of <code>remote</code> cannot be changed from within <code>tip</code> .
script	(bool) Session scripting mode; abbreviated <code>sc</code> . When <code>script</code> is <code>on</code> , <code>tip</code> will record everything transmitted by the remote machine in the script record file specified in <code>record</code> . If the <code>beautify</code> switch is <code>on</code> , only printable ASCII characters will be included in the script file (those characters between 040 and 0177). The variable <code>exceptions</code> is used to indicate characters which are an exception to the normal beautification rules. If the <code>sc</code> capability is present, <code>script</code> is initially set to <code>on</code> . Otherwise, <code>script</code> is initially set to <code>off</code> .
tabexpand	(bool) Expand TAB characters to SPACE characters during file transfers; abbreviated <code>tab</code> . When <code>tabexpand</code> is <code>on</code> , each <code>tab</code> is expanded to eight SPACE characters. If the <code>tb</code> capability is present, <code>tabexpand</code> is initially set to <code>on</code> . Otherwise, <code>tabexpand</code> is initially set to <code>off</code> .
tandem	(bool) Use <code>XON/XOFF</code> flow control to limit the rate that data is sent by the remote host; abbreviated <code>ta</code> . If the <code>nt</code> capability is present, <code>tandem</code> is initially set to <code>off</code> . Otherwise, <code>tandem</code> is initially set to <code>on</code> .
verbose	(bool) Verbose mode; abbreviated <code>verb</code> ; When verbose mode is enabled, <code>tip</code> prints messages while dialing, shows the current number of lines transferred during a file transfer operations, and more. If the <code>nv</code> capability is present, <code>verbose</code> is initially set to <code>off</code> . Otherwise, <code>verbose</code> is initially set to <code>on</code> .
SHELL	(str) The name of the shell to use for the <code>~!</code> command; default value is <code>/bin/sh</code> , or taken from the environment.
HOME	(str) The home directory to use for the <code>~c</code> command. Default value is taken from the environment.

**EXAMPLES** **EXAMPLE 1** Using the `tip` command

An example of the dialog used to transfer files is given below.

tip(1)

**EXAMPLE 1** Using the tip command (Continued)

```
arpa% tip monet
[connected]
...(assume we are talking to a UNIX system)...
ucbmonet login: sam
Password:
monet% cat sylvester.c
-> Filename: sylvester.c
32 lines transferred in 1 minute 3 seconds
monet%
monet% ~< Filename: reply.c
List command for remote host: cat reply.c
65 lines transferred in 2 minutes
monet%
...(or, equivalently)...
monet% ~p sylvester.c
...(actually echoes as ~[put] sylvester.c)...
32 lines transferred in 1 minute 3 seconds
monet%
monet% ~t reply.c
...(actually echoes as ~[take] reply.c)...
65 lines transferred in 2 minutes
monet%
...(to print a file locally)...
monet% ~|Local command: pr h sylvester.c | lpr
List command for remote host: cat sylvester.c
monet% ~^D
[EOT]
...(back on the local system)...
```

**ENVIRONMENT  
VARIABLES**

The following environment variables are read by tip.

- REMOTE The location of the remote file.
- PHONES The location of the file containing private phone numbers.
- HOST A default host to connect to.
- HOME One's log-in directory (for chdirs).
- SHELL The shell to fork on a '~!' escape.

**FILES**

- /etc/phones
- /etc/remote
- /var/spool/locks/LCK.\* lock file to avoid conflicts with UUCP
- /var/adm/aculog file in which outgoing calls are logged
- ~/.tiprc initialization file

tip(1)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO** `cu(1C)`, `mail(1)`, `uucp(1C)`, `vi(1)`, `ioct1(2)`, `attributes(5)`

**BUGS** There are two additional variables, `chardelay` and `linedelay`, that are currently not implemented.

## tnfdump(1)

<b>NAME</b>	tnfdump – convert binary TNF file to ASCII
<b>SYNOPSIS</b>	<b>tnfdump</b> [-r] [-x] <i>tnf_file...</i>
<b>DESCRIPTION</b>	The <code>tnfdump</code> utility converts the specified binary TNF trace files to ASCII. The ASCII output can be used to do performance analysis. The default mode (without the <code>-r</code> option) prints all the event records (that were generated by <code>TNF_PROBE(3TNF)</code> ) and the event descriptor records only. It also orders the events by time.
<b>OPTIONS</b>	The following option is supported:  -r Does a raw conversion of TNF to ASCII. The output is a literal translation of the binary TNF file and includes all the records in the file. This output is useful only if you have a good understanding of TNF. A sample output is listed in <b>EXAMPLES</b> below.  -x Prints all TNF unsigned type argument values in hexadecimal format instead of decimal format.
<b>RETURN VALUES</b>	tnfdump returns 0 on successful exit.
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Converting a file into ASCII</p> <p>To convert the file <code>/tmp/trace-2130</code> into ASCII, use the <code>tnfdump</code> command and the name of the binary trace file. Be aware that the <code>tnfdump</code> output goes to <code>stdout</code> by default.</p> <pre>example% tnfDump /tmp/trace-2130 probe tnf_name: "inloop" tnf_string: "keys cookie main loop;\       file cookie2.c;line 50;sunw%debug in the loop" probe tnf_name: "end" tnf_string: "keys cookie main end;\       file cookie2.c;line 41;sunw%debug exiting program" ----- Elapsed (ms)  Delta (ms)   PID  LWPID  TID  CPU Probe      Data/               Name        Description . . . -----       0.000000    0.000000    8792   1      0  - inloop  loop_count: 0                                 total_iterations: 0       0.339000    0.339000    8792   1      0  - inloop  loop_count: 1                                 total_iterations: 1       0.350500    0.011500    8792   1      0  - inloop  loop_count: 2                                 total_iterations: 2       0.359500    0.009000    8792   1      0  - inloop  loop_count: 3                                 total_iterations: 3       0.369500    0.010000    8792   1      0  - inloop  loop_count: 4                                 total_iterations: 4     7775.969500  7775.600000    8792   1      0  - inloop  loop_count: 0                                 total_iterations: 5     7776.016000    0.046500    8792   1      0  - inloop  loop_count: 1                                 total_iterations: 6     7776.025000    0.009000    8792   1      0  - inloop  loop_count: 2                                 total_iterations: 7     7776.034000    0.009000    8792   1      0  - inloop  loop_count: 3                                 total_iterations: 8</pre>

**EXAMPLE 1** Converting a file into ASCII (Continued)

```

7776.043000      0.009000   8792   1     0 - inloop  loop_count: 4
                                         total_iterations: 9
7776.052000      0.009000   8792   1     0 - inloop  loop_count: 5
                                         total_iterations: 10
7776.061000      0.009000   8792   1     0 - inloop  loop_count: 6
                                         total_iterations: 11
9475.979500  1699.918500   8792   1     0 - end    node_struct:
                                         { type: node_tnf
                                         cur_sum: 9 max_cnt: 12 }

```

All probes that are encountered during execution have a description of it printed out. The description is one per line prefixed by the keyword 'probe'. The name of the probe is in double quotes after the keyword 'tnf\_name'. The description of this probe is in double quotes after the keyword 'tnf\_string'.

A heading is printed after all the description of the probes are printed. The first column gives the elapsed time in milli-seconds since the first event. The second column gives the elapsed time in milli-seconds since the previous event. The next four columns are the process id, lwp id, thread id, and cpu number. The next column is the name of the probe that generated this event. This can be matched to the probe description explained above. The last column is the data that the event contains, formatted as `arg_name_n` (see `TNF_PROBE(3TNF)`) followed by a colon and the value of that argument. The format of the value depends on its type. `tnf_opaque` arguments are printed in hexadecimal. All other integers are printed in decimal. Strings are printed in double quotes and user-defined records are enclosed in braces '{ }'. The first field of a user defined record indicates its TNF type (see `TNF_DECLARE_RECORD(3TNF)`). The rest of the fields are the members of the record.

A '-' in any column indicates that there is no data for that particular column.

**EXAMPLE 2** To do a raw conversion of a file into ASCII

To do a raw conversion of the file `/tmp/trace-4000` into ASCII, use:

```
example% tnfdump -r /tmp/trace-4000
```

The output will look like the following:

```

0x10e00 : {
            tnf_tag 0x109c0   tnf_block_header
            generation 1
            bytes_valid 320
            A_lock 0
            B_lock 0
            next_block 0x0
        }
0x10e10 : {
            tnf_tag 0x10010   probe1
            tnf_tag_arg 0x10e24 <tnf_sched_rec>
            time_delta 128

```

tnfdump(1)

**EXAMPLE 2** To do a raw conversion of a file into ASCII (Continued)

```

        test_ulong 4294967295
        test_long -1
    }

            2 0x10b84    tnfn_tag_arg
    }

```

**EXAMPLE 2** To do a raw conversion of a file into ASCII (Continued)

```

    }
0x11130 : {
            tnf_tag 0x10210    tnf_slot_types
            tnf_self_size 28
                0 0x10bd0    tnf_probe_event
                1 0x10c20    tnf_time_delta
                2 0x1114c    tnf_uint64
                3 0x10d54    tnf_int64
                4 0x11188    tnf_float32
    }

```

The first number is the file offset of the record. The record is enclosed in braces '{ }'. The first column in a record is the slot name (for records whose fields do not have names, it is the type name). The second column in the record is the value of that slot if it is a scalar (only scalars that are of type `tnf_opaque` are printed in hex), or the offset of the record if it is a reference to another record.

The third column in a record is optional. It does not exist for scalar slots of records. If it exists, the third column is a type name with or without angle brackets, or a string in double quotes. Unadorned names indicate a reference to the named metatag record (that is, a reference to a record with that name in the `tnf_name` field). Type names in angled brackets indicate a reference to a record that is an instance of that type (that is, a reference to a record with that name in the `tnf_tag` field). The content of strings are printed out in double quotes at the reference site.

Records that are arrays have their array elements follow the header slots, and are numbered 0, 1, 2, and so on, except strings where the string is written as the 'chars' (pseudo-name) slot.

Records that are events (generated by `TNF_PROBE(3TNF)`) will have a slot name of `tnf_tag_arg` as their second field which is a reference to the schedule record. Schedule records describe more information about the event like the thread-id, process-id, and the `time_base`. The `time_delta` of an event can be added to the `time_base` of the schedule record that the event references, to give an absolute time. This time is expressed as nanoseconds since some arbitrary time in the past (see `gethrtime(3C)`).

**EXAMPLE 3** Printing TNF unsigned arguments in hexadecimal

To print TNF unsigned arguments in hexadecimal for the file `/tmp/trace-2192`, use:

```
example% tnfdump -x /tmp/trace-2192
```

The output will look like the following:

```

probe      tnf_name: "start" tnf_string: "keys cookie main;
file test17.c;line 20;sunw%debug starting main"
probe      tnf_name: "inloop" tnf_string: "keys cookie main

```

tnfdump(1)

**EXAMPLE 3** Printing TNF unsigned arguments in hexadecimal (Continued)

```

loop;file test17.c;line 41;sunw%debug in the loop"
probe      tnf_name: "final" tnf_string: "keys cookie main
final;file test17.c;line 32;sunw%debug in the final"

<b>NAME</b>	tnfextract – extract kernel probes output into a trace file
<b>SYNOPSIS</b>	<b>tnfextract</b> [ -d <i>dumpfile</i> -n <i>namelist</i> ] <i>tnf_file</i>
<b>DESCRIPTION</b>	<p>The <b>tnfextract</b> utility collects kernel trace output from an in-core buffer in the Solaris kernel, or from the memory image of a crashed system, and generates a binary TNF trace file like those produced directly by user programs being traced.</p> <p>Either both or neither of the -d and -n options must be specified. If neither is specified, trace output is extracted from the running kernel. If both are specified, the -d argument names the file containing the (crashed) system memory image, and the -n argument names the file containing the symbol table for the system memory image.</p> <p>The TNF trace file <i>tnf_file</i> produced is exactly the same size as the in-core buffer; it is essentially a snapshot of that buffer. It is legal to run <b>tnfextract</b> while kernel tracing is active, i.e., while the in-core buffer is being written. <b>tnfextract</b> insures that the output file it generates is low-level consistent, that is, that only whole probes are written out, and that internal data structures in the buffer are not corrupted because the buffer is being concurrently written.</p> <p>The TNF trace file generated is suitable as input to <b>tnfdump(1)</b>, which will generate an ASCII file.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <p>-d <i>dumpfile</i>      Uses <i>dumpfile</i> as the system memory image, instead of the running kernel. The <i>dumpfile</i> is normally the path name of a file generated by the <b>savecore</b> utility.</p> <p>-n <i>namelist</i>      Uses <i>namelist</i> as the file containing the symbol table information for the given <i>dumpfile</i>.</p>
<b>OPERANDS</b>	<p>The following operand is supported:</p> <p><i>tnf_file</i>      Output file generated by <b>tnfextract</b> based on kernel trace output from an in-core buffer in the Solaris kernel.</p>
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Extracting probes from a running kernel</p> <p>Extract probes from the running kernel into <i>ktrace.out</i>:</p> <pre>example% tnfextract ktrace.out</pre> <p><b>EXAMPLE 2</b> Extracting probes from a kernel crash dump</p> <p>Extract probes from a kernel crash dump into <i>ktrace.out</i>:</p> <pre>example% tnfextract -d /var/crash/`uname -n`/vmcore.0 \ -n /var/crash/`uname -n`/unix.0 ktrace.out</pre>
<b>EXIT STATUS</b>	The following exit values are returned:

tnfextract(1)

0 Successful completion.  
>0 An error occurred.

<b>NAME</b>	touch, settime – change file access and modification times
<b>SYNOPSIS</b>	<pre>touch [-acm] [-r ref_file   -t time] file... touch [-acm] [date_time] file... settime [-f ref_file] [date_time] file...</pre>
<b>DESCRIPTION</b>	<p>The touch utility sets the access and modification times of each file. The <i>file</i> operand is created if it does not already exist.</p> <p>The time used can be specified by <i>-t time</i>, by the corresponding time fields of the file referenced by <i>-r ref_file</i>, or by the <i>date_time</i> operand. If none of these are specified, touch uses the current time (the value returned by the <code>time(2)</code> function).</p> <p>If neither the <i>-a</i> nor <i>-m</i> options are specified, touch updates both the modification and access times.</p> <p>A user with write access to a file, but who is not the owner of the file or a super-user, can change the modification and access times of that file only to the current time. Attempts to set a specific time with touch will result in an error.</p> <p>The <code>settime</code> utility is equivalent to <code>touch -c [date_time] file</code>.</p>
<b>OPTIONS</b>	<p>The following options are supported in the touch and settime utilities:</p> <p><b>touch</b> The following options are supported for the touch utility:</p> <ul style="list-style-type: none"> <li><i>-a</i> Changes the access time of <i>file</i>. Does not change the modification time unless <i>-m</i> is also specified.</li> <li><i>-c</i> Does not create a specified <i>file</i> if it does not exist. Does not write any diagnostic messages concerning this condition.</li> <li><i>-m</i> Changes the modification time of <i>file</i>. Does not change the access time unless <i>-a</i> is also specified.</li> <li><i>-r ref_file</i> Uses the corresponding times of the file named by <i>ref_file</i> instead of the current time.</li> <li><i>-t time</i> Uses the specified <i>time</i> instead of the current time. <i>time</i> will be a decimal number of the form: <ul style="list-style-type: none"> <li>[ [CC] YY] MMDDhhmm [.SS]</li> </ul> <p>where each two digits represent the following:</p> <ul style="list-style-type: none"> <li><i>MM</i> The month of the year [01-12].</li> <li><i>DD</i> The day of the month [01-31].</li> <li><i>hh</i> The hour of the day [00-23].</li> <li><i>mm</i> The minute of the hour [00-59].</li> <li><i>CC</i> The first two digits of the year.</li> </ul> </li> </ul>

touch(1)

*YY* The second two digits of the year.

*SS* The second of the minute [00-61].

Both *CC* and *YY* are optional. If neither is given, the current year will be assumed. If *YY* is specified, but *CC* is not, *CC* will be derived as follows:

If <i>YY</i> is:	<i>CC</i> becomes:
69-99	19
00-38	20
39-68	ERROR

The resulting time will be affected by the value of the *TZ* environment variable. If the resulting time value precedes the Epoch, *touch* will exit immediately with an error status. The range of valid times is the Epoch to January 18, 2038.

The range for *SS* is [00-61] rather than [00-59] because of leap seconds. If *SS* is 60 or 61, and the resulting time, as affected by the *TZ* environment variable, does not refer to a leap second, the resulting time will be one or two seconds after a time where *SS* is 59. If *SS* is not given, it is assumed to be 0.

**settime** The following option is supported for the *settime* utility:

*-f ref\_file* Uses the corresponding times of the file named by *ref\_file* instead of the current time.

**OPERANDS** The following operands are supported for the *touch* and *settime* utilities:

*file* A path name of a file whose times are to be modified.

*date\_time* Uses the specified *date\_time* instead of the current time. This operand is a decimal number of the form:

*MMDDhhmm* [*YY*]

where each two digits represent the following:

*MM* The month of the year [01-12].

*DD* The day of the month [01-31].

*hh* The hour of the day [00-23].

*mm* The minute of the hour [00-59].

*YY* The second two digits of the year.

touch(1)

YY is optional. If it is omitted, the current year will be assumed. If YY is specified, the year will be derived as follows:

YY	Corresponding Year
69-99	1969-1999
00-38	2000-2038
39-68	ERROR

If no `-r` option is specified, no `-t` option is specified, at least two operands are specified, and the first operand is an eight- or ten-digit decimal integer, the first operand will be assumed to be a *date\_time* operand. Otherwise, the first operand will be assumed to be a *file* operand.

**USAGE** See `largefile(5)` for the description of the behavior of `touch` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**ENVIRONMENT VARIABLES** See `environ(5)` for descriptions of the following environment variables that affect the execution of `touch`: `LANG`, `LC_ALL`, `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**TZ** Determine the timezone to be used for interpreting the *time* option-argument or the *date\_time* operand.

**EXIT STATUS** The following exit values are returned:

- 0 The `touch` utility executed successfully and all requested changes were made.
- >0 An error occurred. The `touch` utility returned the number of files for which the times could not be successfully modified.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	enabled
Interface Stability	Standard

**SEE ALSO** `time(2)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `standards(5)`

**NOTES** Users familiar with the BSD environment will find that for the `touch` utility, the `-f` option is accepted but ignored. The `-f` option is unnecessary because `touch` will succeed for all files owned by the user regardless of the permissions on the files.

touch(1B)

**NAME** touch – change file access and modification times

**SYNOPSIS** /usr/ucb/touch [-acfm] file...

**DESCRIPTION** touch sets the access and modification times of each file to the current time. file is created if it does not already exist.

**OPTIONS**

- a Change the access time of file. Do not change the modification time unless -m is also specified.
- c Do not create file if it does not exist.
- f Attempt to force the touch in spite of read and write permissions on file.
- m Change the modification time of file. Do not change the access time unless -a is also specified.

**USAGE** See largefile(5) for the description of the behavior of touch when encountering files greater than or equal to 2 Gbyte ( 2<sup>31</sup> bytes).

**EXIT STATUS** The following exit values are returned:

- 0 touch executed successfully and all requested changes were made.
- >0 An error occurred. touch returns the number of files for which the times could not be successfully modified.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

## tput(1)

<b>NAME</b>	tput – initialize a terminal or query terminfo database
<b>SYNOPSIS</b>	<b>tput</b> [-T <i>type</i> ] <i>capname</i> [ <i>parm...</i> ] <b>tput</b> -S <<
<b>DESCRIPTION</b>	The <b>tput</b> utility uses the <b>terminfo</b> database to make the values of terminal-dependent capabilities and information available to the shell (see <b>sh(1)</b> ); to clear, initialize or reset the terminal; or to return the long name of the requested terminal type. <b>tput</b> outputs a string if the capability attribute ( <i>capname</i> ) is of type string, or an integer if the attribute is of type integer. If the attribute is of type boolean, <b>tput</b> simply sets the exit status (0 for TRUE if the terminal has the capability, 1 for FALSE if it does not), and produces no output. Before using a value returned on standard output, the user should test the exit status ( $\$?$ , see <b>sh(1)</b> ) to be sure it is 0. See the EXIT STATUS section.
<b>OPTIONS</b>	The following options are supported:  -T <i>type</i> Indicates the <i>type</i> of terminal. Normally this option is unnecessary, because the default is taken from the environment variable TERM. If -T is specified, then the shell variables LINES and COLUMNS and the layer size will not be referenced.  -S                            Allows more than one capability per invocation of <b>tput</b> . The capabilities must be passed to <b>tput</b> from the standard input instead of from the command line (see the example in the EXAMPLES section). Only one <i>capname</i> is allowed per line. The -S option changes the meaning of the 0 and 1 boolean and string exit statuses (see the EXAMPLES section).
<b>OPERANDS</b>	The following operands are supported:  <i>capname</i> Indicates the capability attribute from the <b>terminfo</b> database. See <b>terminfo(4)</b> for a complete list of capabilities and the <i>capname</i> associated with each.  The following strings will be supported as operands by the implementation in the "C" locale:  clear                        Display the clear-screen sequence.  init                         If the <b>terminfo</b> database is present and an entry for the user's terminal exists (see -T <i>type</i> , above), the following will occur:  1. if present, the terminal's initialization strings will be output ( <i>is1</i> , <i>is2</i> , <i>is3</i> , <i>if</i> , <i>iprogram</i> ), 2. any delays (for instance, newline) specified in the entry will be set in the tty driver,

3. tabs expansion will be turned on or off according to the specification in the entry, and
4. if tabs are not expanded, standard tabs will be set (every 8 spaces). If an entry does not contain the information needed for any of the four above activities, that activity will silently be skipped.

`reset` Instead of putting out initialization strings, the terminal's reset strings will be output if present (`rs1`, `rs2`, `rs3`, `rf`). If the reset strings are not present, but initialization strings are, the initialization strings will be output. Otherwise, `reset` acts identically to `init`.

`longname` If the `terminfo` database is present and an entry for the user's terminal exists (see `-Ttype` above), then the long name of the terminal will be put out. The long name is the last name in the first line of the terminal's description in the `terminfo` database (see `term(5)`).

*parm* If the attribute is a string that takes parameters, the argument *parm* will be instantiated into the string. An all numeric argument will be passed to the attribute as a number.

#### EXAMPLES **EXAMPLE 1** Initializing the terminal according to TERM

This example initializes the terminal according to the type of terminal in the environment variable `TERM`. This command should be included in everyone's `.profile` after the environment variable `TERM` has been exported, as illustrated on the `profile(4)` manual page.

```
example% tput init
```

#### **EXAMPLE 2** Resetting a terminal

This example resets an AT&T 5620 terminal, overriding the type of terminal in the environment variable `TERM`:

```
example% tput -T5620 reset
```

#### **EXAMPLE 3** Moving the cursor

The following example sends the sequence to move the cursor to row 0, column 0 (the upper left corner of the screen, usually known as the "home" cursor position).

```
example% tput cup 0 0
```

## tput(1)

### **EXAMPLE 3** Moving the cursor *(Continued)*

This next example sends the sequence to move the cursor to row 23, column 4.

```
example% tput cup 23 4
```

### **EXAMPLE 4** Echoing the clear-screen sequence

This example echos the clear-screen sequence for the current terminal.

```
example% tput clear
```

### **EXAMPLE 5** Printing the number of columns

This command prints the number of columns for the current terminal.

```
example% tput cols
```

The following command prints the number of columns for the 450 terminal.

```
example% tput -T450 cols
```

### **EXAMPLE 6** Setting shell variables

This example sets the shell variables `bold`, to begin stand-out mode sequence, and `offbold`, to end standout mode sequence, for the current terminal. This might be followed by a prompt:

```
echo "${bold}Please type in your name: ${offbold}\c"  
example% bold='tput smso'  
example% offbold='tput rmso'
```

### **EXAMPLE 7** Setting the exit status

This example sets the exit status to indicate if the current terminal is a hardcopy terminal.

```
example% tput hc
```

### **EXAMPLE 8** Printing the long name from terminfo

This command prints the long name from the `terminfo` database for the type of terminal specified in the environment variable `TERM`.

```
example% tput longname
```

**EXAMPLE 9** Processing several capabilities with one invocation

This example shows `tput` processing several capabilities in one invocation. This example clears the screen, moves the cursor to position 10, 10 and turns on `bold` (extra bright) mode. The list is terminated by an exclamation mark (!) on a line by itself.

```
example% tput -S <<!
> clear
> cup 10 10
> bold
> !
```

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `tput`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**TERM** Determine the terminal type. If this variable is unset or null, and if the `-T` option is not specified, an unspecified default terminal type will be used.

**EXIT STATUS**

The following exit values are returned:

0

- If *capname* is of type boolean and `-S` is not specified, indicates `TRUE`.
- If *capname* is of type string and `-S` is not specified, indicates *capname* is defined for this terminal type.
- If *capname* is of type boolean or string and `-S` is specified, indicates that all lines were successful.
- *capname* is of type integer.
- The requested string was written successfully.

1

- If *capname* is of type boolean and `-S` is not specified, indicates `FALSE`.
- If *capname* is of type string and `-S` is not specified, indicates that *capname* is not defined for this terminal type.

2 Usage error.

3 No information is available about the specified terminal type.

4 The specified operand is invalid.

>4 An error occurred.

-1 *capname* is a numeric variable that is not specified in the `terminfo` database. For instance, `tput -T450 lines` and `tput -T2621 xmc`.

**FILES**

`/usr/include/curses.h` `curses(3CURSES)` header  
`/usr/include/term.h` `terminfo` header

tput(1)

/usr/lib/tabset/\*

Tab settings for some terminals, in a format appropriate to be output to the terminal (escape sequences that set margins and tabs). For more information, see the "Tabs and Initialization" section of `terminfo(4)`

<b>NAME</b>	tr – translate characters
<b>SYNOPSIS</b>	<pre> /usr/bin/tr [-cs] string1 string2 /usr/bin/tr -s   -d [-c] string1 /usr/bin/tr -ds [-c] string1 string2 /usr/xpg4/bin/tr [-cs] string1 string2 /usr/xpg4/bin/tr -s   -d [-c] string1 /usr/xpg4/bin/tr -ds [-c] string1 string2 /usr/xpg6/bin/tr [-c   -C] [-s] string1 string2 /usr/xpg6/bin/tr -s [-c   -C] string1 /usr/xpg6/bin/tr -d [-c   -C] string1 /usr/xpg6/bin/tr -ds [-c   -C] string1 string2 </pre>
<b>DESCRIPTION</b>	<p>The <code>tr</code> utility copies the standard input to the standard output with substitution or deletion of selected characters. The options specified and the <code>string1</code> and <code>string2</code> operands control translations that occur while copying characters and single-character collating elements.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-c       Complements the set of values specified by <code>string1</code>.</li> <li>-C       Complements the set of characters specified by <code>string1</code>.</li> <li>-d       Deletes all occurrences of input characters that are specified by <code>string1</code>.</li> <li>-s       Replaces instances of repeated characters with a single character.</li> </ul> <p>When the <code>-d</code> option is not specified:</p> <ul style="list-style-type: none"> <li>■ Each input character found in the array specified by <code>string1</code> is replaced by the character in the same relative position in the array specified by <code>string2</code>. When the array specified by <code>string2</code> is shorter than the one specified by <code>string1</code>, the results are unspecified.</li> <li>■ If the <code>-c</code> option is specified, the complements of the values specified by <code>string1</code> are placed in the array in ascending order by binary value.</li> <li>■ If the <code>-C</code> option is specified, the complements of the characters specified by <code>string1</code> (the set of all characters in the current character set, as defined by the current setting of <code>LC_CTYPE</code>, except for those actually specified in the <code>string1</code> operand) are placed in the array in ascending collation sequence, as defined by the current setting of <code>LC_COLLATE</code>.</li> <li>■ Because the order in which characters specified by character class expressions or equivalence class expressions is undefined, such expressions should only be used if the intent is to map several characters into one. An exception is case conversion, as described previously.</li> </ul>

tr(1)

When the `-d` option is specified:

- Input characters found in the array specified by *string1* are deleted.
- When the `-C` option is specified with `-d`, all values except those specified by *string1* are deleted. The contents of *string2* are ignored, unless the `-s` option is also specified.
- If the `-c` option is specified, the complements of the values specified by *string1* are placed in the array in ascending order by binary value.
- The same string cannot be used for both the `-d` and the `-s` option. When both options are specified, both *string1* (used for deletion) and *string2* (used for squeezing) are required.

When the `-s` option is specified, after any deletions or translations have taken place, repeated sequences of the same character will be replaced by one occurrence of the same character, if the character is found in the array specified by the last operand. If the last operand contains a character class, such as the following example:

```
tr -s '[:space:]'
```

the last operand's array will contain all of the characters in that character class. However, in a case conversion, as described previously, such as

```
tr -s '[:upper:]' '[:lower:]'
```

the last operand's array will contain only those characters defined as the second characters in each of the `toupper` or `tolower` character pairs, as appropriate. (See `toupper(3C)` and `tolower(3C)`).

An empty string used for *string1* or *string2* produces undefined results.

## OPERANDS

The following operands are supported:

*string1*

*string2*

Translation control strings. Each string represents a set of characters to be converted into an array of characters used for the translation.

The operands *string1* and *string2* (if specified) define two arrays of characters. The constructs in the following list can be used to specify characters or single-character collating elements. If any of the constructs result in multi-character collating elements, `tr` excludes, without a diagnostic, those multi-character elements from the resulting array.

*character*

Any character not described by one of the conventions below represents itself.

`\ octal`

Octal sequences can be used to represent characters with specific coded values. An octal sequence consists of a backslash followed by the longest sequence of one-, two-, or three-octal-digit characters (01234567). The sequence causes the character whose

		encoding is represented by the one-, two- or three-digit octal integer to be placed into the array. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading <code>\</code> for each byte.
	<code>\character</code>	The backslash-escape sequences <code>\a</code> , <code>\b</code> , <code>\f</code> , <code>\n</code> , <code>\r</code> , <code>\t</code> , and <code>\v</code> are supported. The results of using any other character, other than an octal digit, following the backslash are unspecified.
<code>/usr/xpg4/bin/tr</code>	<code>c-c</code>	
<code>/usr/bin/tr</code>	<code>[c-c]</code>	Represents the range of collating elements between the range endpoints, inclusive, as defined by the current setting of the <code>LC_COLLATE</code> locale category. The starting endpoint must precede the second endpoint in the current collation order. The characters or collating elements in the range are placed in the array in ascending collation sequence.
	<code>[:class:]</code>	Represents all characters belonging to the defined character class, as defined by the current setting of the <code>LC_CTYPE</code> locale category. The following character class names are accepted when specified in <i>string1</i> : <p>alnum blank digit lower punct upper alpha cntrl graph print space xdigit</p> <p>In addition, character class expressions of the form <code>[:name:]</code> are recognized in those locales where the <i>name</i> keyword has been given a <code>charclass</code> definition in the <code>LC_CTYPE</code> category.</p> <p><i>Note:</i> <code>/usr/bin/tr</code> supports character class expressions only in singlebyte locales. Use <code>/usr/xpg4/bin/tr</code> to support these expressions in any locale.</p> <p>When both the <code>-d</code> and <code>-s</code> options are specified, any of the character class names are accepted in <i>string2</i>. Otherwise, only character class names <code>lower</code> or <code>upper</code> are valid in <i>string2</i> and then only if the corresponding character class <code>upper</code> and <code>lower</code>, respectively, is specified in the same relative position in <i>string1</i>. Such a specification is interpreted as a request for case conversion. When <code>[:lower:]</code> appears in <i>string1</i> and <code>[:upper:]</code> appears in <i>string2</i>, the arrays contain the characters from the <code>toupper</code> mapping in the <code>LC_CTYPE</code> category of the current locale. When <code>[:upper:]</code> appears in <i>string1</i> and <code>[:lower:]</code> appears in <i>string2</i>, the arrays contain the characters from the <code>tolower</code> mapping in the <code>LC_CTYPE</code> category of the current locale. The first character from each mapping pair is in the array for <i>string1</i> and the is in the array for <i>string2</i> in the same relative position.</p>

tr(1)

	<p>Except for case conversion, the characters specified by a character class expression are placed in the array in an unspecified order.</p> <p>If the name specified for <i>class</i> does not define a valid character class in the current locale, the behavior is undefined.</p>
[ <i>=equiv=</i> ]	<p>Represents all characters or collating elements belonging to the same equivalence class as <i>equiv</i>, as defined by the current setting of the LC_COLLATE locale category. An equivalence class expression is allowed only in <i>string1</i>, or in <i>string2</i> when it is being used by the combined -d and -s options. The characters belonging to the equivalence class are placed in the array in an unspecified order.</p>
[ <i>x*n</i> ]	<p>Represents <i>n</i> repeated occurrences of the character <i>x</i>. Because this expression is used to map multiple characters to one, it is only valid when it occurs in <i>string2</i>. If <i>n</i> is omitted or is 0, it is interpreted as large enough to extend the <i>string2</i>-based sequence to the length of the <i>string1</i>-based sequence. If <i>n</i> has a leading 0, it is interpreted as an octal value. Otherwise, it is interpreted as a decimal value.</p>
<b>USAGE</b>	<p>See <code>largefile(5)</code> for the description of the behavior of <code>tr</code> when encountering files greater than or equal to 2 Gbyte (2<sup>31</sup> bytes).</p>
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Creating a list of words</p> <p>The following example creates a list of all words in <i>file1</i>, one per line in <i>file2</i>, where a word is taken to be a maximal string of letters.</p> <pre>tr -cs "[:alpha:]" "[\n*]" &lt;file1 &gt;file2</pre> <p><b>EXAMPLE 2</b> Translating characters</p> <p>This example translates all lower-case characters in <i>file1</i> to upper-case and writes the results to standard output.</p> <pre>tr "[:lower:]" "[:upper:]" &lt;file1</pre> <p>Notice that the caveat expressed in the corresponding example in XPG3 is no longer in effect. This case conversion is now a special case that employs the <code>tolower</code> and <code>toupper</code> classifications, ensuring that proper mapping is accomplished (when the locale is correctly defined).</p> <p><b>EXAMPLE 3</b> Identifying equivalent characters</p> <p>This example uses an equivalence class to identify accented variants of the base character <i>e</i> in <i>file1</i>, which are stripped of diacritical marks and written to <i>file2</i>.</p> <pre>tr "[=e]" e &lt;file1 &gt;file2</pre>

**ENVIRONMENT VARIABLES** See `environ(5)` for descriptions of the following environment variables that affect the execution of `tr`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS** The following exit values are returned:

0 All input was processed successfully.

>0 An error occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

	ATTRIBUTE TYPE	ATTRIBUTE VALUE
<b>/usr/bin/tr</b>	Availability	SUNWcsu
	CSI	Not enabled

	ATTRIBUTE TYPE	ATTRIBUTE VALUE
<b>/usr/xpg4/bin/tr</b>	Availability	SUNWxcu4
	CSI	Enabled
	Interface Stability	Standard

	ATTRIBUTE TYPE	ATTRIBUTE VALUE
<b>/usr/xpg6/bin/tr</b>	Availability	SUNWxcu6

**SEE ALSO** `ed(1)`, `sed(1)`, `sh(1)`, `tolower(3C)`, `toupper(3C)`, `ascii(5)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `standards(5)`

**NOTES** Unlike some previous versions, `/usr/xpg4/bin/tr` correctly processes NUL characters in its input stream. NUL characters can be stripped by using `tr -d '\000'`.

tr(1B)

<b>NAME</b>	tr – translate characters				
<b>SYNOPSIS</b>	<code>/usr/ucb/tr [-c ds] [ string1 [string2] ]</code>				
<b>DESCRIPTION</b>	<p>The <code>tr</code> utility copies the standard input to the standard output with substitution or deletion of selected characters. The arguments <i>string1</i> and <i>string2</i> are considered sets of characters. Any input character found in <i>string1</i> is mapped into the character in the corresponding position within <i>string2</i>. When <i>string2</i> is short, it is padded to the length of <i>string1</i> by duplicating its last character.</p> <p>In either string the notation:</p> <p><i>a-b</i></p> <p>denotes a range of characters from <i>a</i> to <i>b</i> in increasing ASCII order. The character <code>\</code>, followed by 1, 2 or 3 octal digits stands for the character whose ASCII code is given by those digits. As with the shell, the escape character <code>\</code>, followed by any other character, escapes any special meaning for that character.</p>				
<b>OPTIONS</b>	<p>Any combination of the options <code>-c</code>, <code>-d</code>, or <code>-s</code> may be used:</p> <ul style="list-style-type: none"><li><code>-c</code> Complement the set of characters in <i>string1</i> with respect to the universe of characters whose ASCII codes are 01 through 0377 octal.</li><li><code>-d</code> Delete all input characters in <i>string1</i>.</li><li><code>-s</code> Squeeze all strings of repeated output characters that are in <i>string2</i> to single characters.</li></ul>				
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Creating a list of all the words in a filename</p> <p>The following example creates a list of all the words in <i>filename1</i>, one per line, in <i>filename2</i>, where a word is taken to be a maximal string of alphabetic. The second string is quoted to protect <code>' \ '</code> from the shell. 012 is the ASCII code for NEWLINE.</p> <pre>example% tr -cs A-Za-z '\012' &lt; filename1 &gt; filename2</pre>				
<b>ATTRIBUTES</b>	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWscpu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWscpu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWscpu				
<b>SEE ALSO</b>	<code>ed(1)</code> , <code>ascii(5)</code> , <code>attributes(5)</code>				
<b>NOTES</b>	Will not handle ASCII NUL in <i>string1</i> or <i>string2</i> . <code>tr</code> always deletes NUL from input.				

<b>NAME</b>	trap, onintr – shell built-in functions to respond to (hardware) signals
<b>SYNOPSIS</b>	<pre>sh trap [ argument n [n2...]] csh onintr [-   label] ksh *trap [ arg sig [ sig2...]]</pre>
<b>DESCRIPTION</b>	<p><b>sh</b> The <code>trap</code> command <i>argument</i> is to be read and executed when the shell receives numeric or symbolic signal(s) (<i>n</i>). (Note: <i>argument</i> is scanned once when the trap is set and once when the trap is taken.) Trap commands are executed in order of signal number or corresponding symbolic names. Any attempt to set a trap on a signal that was ignored on entry to the current shell is ineffective. An attempt to trap on signal 11 (memory fault) produces an error. If <i>argument</i> is absent all trap(s) <i>n</i> are reset to their original values. If <i>argument</i> is the null string this signal is ignored by the shell and by the commands it invokes. If <i>n</i> is 0 the command <i>argument</i> is executed on exit from the shell. The <code>trap</code> command with no arguments prints a list of commands associated with each signal number.</p> <p><b>csh</b> <code>onintr</code> controls the action of the shell on interrupts. With no arguments, <code>onintr</code> restores the default action of the shell on interrupts. (The shell terminates shell scripts and returns to the terminal command input level). With the <code>-</code> argument, the shell ignores all interrupts. With a <i>label</i> argument, the shell executes a <code>goto label</code> when an interrupt is received or a child process terminates because it was interrupted.</p> <p><b>ksh</b> <code>trap</code> uses <i>arg</i> as a command to be read and executed when the shell receives signal(s) <i>sig</i>. (Note that <i>arg</i> is scanned once when the trap is set and once when the trap is taken.) Each <i>sig</i> can be given as a number or as the name of the signal. <code>trap</code> commands are executed in order of signal number. Any attempt to set a trap on a signal that was ignored on entry to the current shell is ineffective. If <i>arg</i> is omitted or is <code>-</code>, then the trap(s) for each <i>sig</i> are reset to their original values. If <i>arg</i> is the null (the empty string, e.g., <code>""</code>) string then this signal is ignored by the shell and by the commands it invokes. If <i>sig</i> is <code>ERR</code> then <i>arg</i> will be executed whenever a command has a non-zero exit status. If <i>sig</i> is <code>DEBUG</code> then <i>arg</i> will be executed after each command. If <i>sig</i> is 0 or <code>EXIT</code> for a <code>trap</code> set outside any function then the command <i>arg</i> is executed on exit from the shell. The <code>trap</code> command with no arguments prints a list of commands associated with each signal number.</p> <p>On this man page, <a href="#">ksh(1)</a> commands that are preceded by one or two * (asterisks) are treated specially in the following ways:</p> <ol style="list-style-type: none"> <li>1. Variable assignment lists preceding the command remain in effect when the command completes.</li> <li>2. I/O redirections are processed after variable assignments.</li> <li>3. Errors cause a script that contains them to abort.</li> </ol>

trap(1)

4. Words, following a command preceded by **\*\*** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

<b>NAME</b>	troff – typeset or format documents
<b>SYNOPSIS</b>	<b>troff</b> [-a] [-f] [-F <i>dir</i> ] [-i] [-m <i>name</i> ] [-n <i>N</i> ] [-o <i>list</i> ] [-r <i>aN</i> ] [-s <i>N</i> ] [-T <i>dest</i> ] [-u <i>N</i> ] [-z] [ <i>filename...</i> ]
<b>DESCRIPTION</b>	<p>troff formats text in the <i>filenames</i> for typesetting or laser printing. Input to troff is expected to consist of text interspersed with formatting requests and macros. If no <i>filename</i> argument is present, troff reads standard input. A minus sign (-) as a <i>filename</i> indicates that standard input should be read at that point in the list of input files.</p> <p>The output of troff is usually piped through <a href="#">dpost(1)</a> to create a printable postscript file (see <a href="#">EXAMPLES</a>).</p>
<b>OPTIONS</b>	<p>The following options are supported. They may appear in any order, but all must appear before the first <i>filename</i>.</p> <ul style="list-style-type: none"> <li>-a                    Send an ASCII approximation of formatted output to standard output. (Note: a rough ASCII version can also be printed out on ordinary terminals with an old and rarely used command, /usr/bin/ta.)</li> <li>-f                    Do not print a trailer after the final page of output or cause the postprocessor to relinquish control of the device.</li> <li>-F<i>dir</i>                Search directory <i>dir</i> for font width or terminal tables instead of the system default directory.</li> <li>-i                    Read standard input after all input files are exhausted.</li> <li>-m<i>name</i>              Prepend the macro file /usr/share/lib/tmac/<i>name</i> to the input <i>filenames</i>. Note: most references to macro packages include the leading <i>m</i> as part of the name; for example, the man(5) macros reside in /usr/share/lib/tmac/an. The macro directory can be changed by setting the TROFFMACS environment variable to a specific path. Be certain to include the trailing ' / ' (slash) at the end of the path.</li> <li>-n<i>N</i>                 Number the first generated page <i>N</i>.</li> <li>-o<i>list</i>              Print only pages whose page numbers appear in the comma-separated <i>list</i> of numbers and ranges. A range <i>N-M</i> means pages <i>N</i> through <i>M</i>; an initial -<i>N</i> means from the beginning to page <i>N</i>; and a final <i>N-</i> means from <i>N</i> to the end.</li> <li>-q                    Quiet mode in nroff; ignored in troff.</li> <li>-r<i>aN</i>                Set register <i>a</i> (one-character names only) to <i>N</i>.</li> <li>-s<i>N</i>                 Stop the phototypesetter every <i>N</i> pages. On some devices, troff produces a trailer so you can change cassettes; resume by pressing the typesetter's start button.</li> </ul>

## troff(1)

**-Tdest** Prepare output for typesetter *dest*. The following values can be supplied for *dest*:

**post** A PostScript printer; this is the default value. The output of the **-T** option must go through **dpost(1)** before it is sent to a PostScript printer to obtain the proper output.

**aps** Autologic APS-5.

**-uN** Set the emboldening factor for the font mounted in position 3 to *N*. If *N* is missing, then set the emboldening factor to 0.

**-z** Suppress formatted output. Only diagnostic messages and messages output using the **.tm** request are output.

**OPERANDS** The following operand is supported:

*filename* The file containing text to be processed by **troff**.

**EXAMPLES** **EXAMPLE 1** Using **troff**

The following example shows how to print an input text file *mytext*, coded with formatting requests and macros. The input file contains equations and tables and must go through the **tbl(1)** and **eqn(1)** preprocessors before it is formatted by **troff** with **ms** macros, processed by **dpost(1)**, and printed by **lp(1)**:

```
tbl mytext | eqn | troff -ms | dpost | lp
```

**FILES**

<code>/tmp/trtmp</code>	temporary file
<code>/usr/share/lib/tmac/*</code>	standard macro files
<code>/usr/lib/font/*</code>	font width tables for alternate mounted <b>troff</b> fonts
<code>/usr/share/lib/nterm/*</code>	terminal driving tables for <b>nroff</b>

**ATTRIBUTES** See **attributes(5)** for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdoc

**SEE ALSO** **checknr(1)**, **col(1)**, **dpost(1)**, **eqn(1)**, **lp(1)**, **man(1)**, **nroff(1)**, **tbl(1)**, **attributes(5)**, **man(5)**, **me(5)**, **ms(5)**

**NOTES** **troff** is not 8-bit clean because it is by design based on 7-bit ASCII.

Previous documentation incorrectly described the numeric register `yr` as being the "Last two digits of current year". `yr` is in actuality the number of years since 1900. To correctly obtain the last two digits of the current year through the year 2099, the definition given below of string register `yy` may be included in a document and subsequently used to display a two-digit year. Note that any other available one- or two-character register name may be substituted for `yy`.

```
.\" definition of new string register yy--last two digits of year
.\" use yr (# of years since 1900) if it is < 100
.ie \n(yr<100 .ds yy \n(yr
.el \{
    .\" else, subtract 100 from yr, store in ny
.nr ny \n(yr-100
.ie \n(ny>9 \{
    .\" use ny if it is two digits
.ds yy \n(ny
.\" remove temporary number register ny
.rr ny \}
.el \{.ds yy 0
.\" if ny is one digit, append it to 0
.as yy \n(ny
.rr ny \} \}
```

true(1)

**NAME** true, false – provide truth values

**SYNOPSIS** **true**  
**false**

**DESCRIPTION** The `true` utility does nothing, successfully. The `false` utility does nothing, unsuccessfully. They are typically used in a shell script `sh` as:

```
while true
do
    command
done
```

which executes *command* forever.

**EXIT STATUS** `true` has exit status 0.  
`false` always will exit with a non-zero value.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

<b>NAME</b>	truss – trace system calls and signals
<b>SYNOPSIS</b>	<pre>truss [-fcaeildDE] [ - [tTvX] [!] syscall ,...] [ - [sS] [!] signal ,...]       [ - [mM] [!] fault ,...] [ - [rw] [!] fd ,...] [ - [uU] [!] lib ,... :       [:] [!] func ,...] [-o outfile] command   -p pid [/twps]...</pre>
<b>DESCRIPTION</b>	<p>The <code>truss</code> utility executes the specified command and produces a trace of the system calls it performs, the signals it receives, and the machine faults it incurs. Each line of the trace output reports either the fault or signal name or the system call name with its arguments and return value(s). System call arguments are displayed symbolically when possible using defines from relevant system headers. For any path name pointer argument, the pointed-to string is displayed. Error returns are reported using the error code names described in <code>intro(3)</code>. If, in the case of an error, the kernel reports a missing privilege, a privilege name as described in <code>privileges(5)</code> is reported in square brackets ( [ ] ) after the error code name.</p> <p>Optionally (see the <code>-u</code> option), <code>truss</code> also produce an entry/exit trace of user-level function calls executed by the traced process, indented to indicate nesting.</p>
<b>OPTIONS</b>	<p>For those options that take a list argument, the name <code>all</code> can be used as a shorthand to specify all possible members of the list. If the list begins with a <code>!</code>, the meaning of the option is negated (for example, exclude rather than trace). Multiple occurrences of the same option can be specified. For the same name in a list, subsequent options (those to the right) override previous ones (those to the left).</p> <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a Shows the argument strings that are passed in each <code>exec ( )</code> system call.</li> <li>-c Counts traced system calls, faults, and signals rather than displaying the trace line-by-line. A summary report is produced after the traced command terminates or when <code>truss</code> is interrupted. If <code>-f</code> is also specified, the counts include all traced system calls, faults, and signals for child processes.</li> <li>-d Includes a time stamp on each line of trace output. The time stamp appears as a field containing <i>seconds . fraction</i> at the start of the line. This represents a time in seconds relative to the beginning of the trace. The first line of the trace output shows the base time from which the individual time stamps are measured, both as seconds since the epoch (see <code>time(2)</code>) and as a date string (see <code>ctime(3C)</code> and <code>date(1)</code>). The times that are reported are the times that the event in question occurred. For all system calls, the event is the completion of the system call, not the start of the system call.</li> <li>-D Includes a time delta on each line of trace output. The value appears as a field containing <i>seconds . fraction</i> and represents the elapsed time for the LWP that incurred the event since the last reported event incurred by that LWP. Specifically, for system calls, this is not the time spent within the system call.</li> </ul>

## truss(1)

- e  
Shows the environment strings that are passed in each `exec()` system call.
- E  
Includes a time delta on each line of trace output. The value appears as a field containing *seconds.fraction* and represents the difference in time elapsed between the beginning and end of a system call.  
  
In contrast to the `-D` option, this is the amount of time spent within the system call.
- f  
Follows all children created by `fork()` or `vfork()` and includes their signals, faults, and system calls in the trace output. Normally, only the first-level command or process is traced. When `-f` is specified, the process-id is included with each line of trace output to indicate which process executed the system call or received the signal.
- i  
Does not display interruptible sleeping system calls. Certain system calls, such as `open()` and `read()` on terminal devices or pipes, can sleep for indefinite periods and are interruptible. Normally, `truss` reports such sleeping system calls if they remain asleep for more than one second. The system call is reported again a second time when it completes. The `-i` option causes such system calls to be reported only once, when they complete.
- l  
Includes the id of the responsible lightweight process (*LWP*) with each line of trace output. If `-f` is also specified, both the process-id and the *LWP*-id are included.
- m [!]*fault*,...  
Machine faults to trace or exclude. Those faults specified in the comma-separated list are traced. Faults can be specified by name or number (see `<sys/fault.h>`). If the list begins with a `!`, the specified faults are excluded from the trace output. Default is `-mall -m!fltpage`.
- M [!]*fault*,...  
Machine faults that stop the process. The specified faults are added to the set specified by `-m`. If one of the specified faults is incurred, `truss` leaves the process stopped and abandoned (see the `-T` option). Default is `-M!all`.
- o *outfile*  
File to be used for the trace output. By default, the output goes to standard error.
- p  
Interprets the *command* arguments to `truss` as a list of process-ids for existing processes (see `ps(1)`) rather than as a command to be executed. `truss` takes control of each process and begins tracing it provided that the *userid* and *groupid* of the process match those of the user or that the user is a privileged user. Users can trace only selected threads by appending */thread-id* to the process-id. Multiple threads can be selected using the `-` and `,` delimiters. For example `/1,2,7-9` traces threads 1, 2, 7, 8, and 9. Processes can also be specified by their names in the `/proc` directory, for example, `/proc/12345`.

**-r** [!] *fd*,...

Shows the full contents of the I/O buffer for each `read()` on any of the specified file descriptors. The output is formatted 32 bytes per line and shows each byte as an ASCII character (preceded by one blank) or as a 2-character C language escape sequence for control characters such as horizontal tab (`\t`) and newline (`\n`). If ASCII interpretation is not possible, the byte is shown in 2-character hexadecimal representation. (The first 12 bytes of the I/O buffer for each traced `read()` are shown even in the absence of `-r`.) Default is `-r!all`.

**-s** [!] *signal*,...

Signals to trace or exclude. Those signals specified in the comma-separated list are traced. The trace output reports the receipt of each specified signal, even if the signal is being ignored (not blocked). (Blocked signals are not received until they are unblocked.) Signals can be specified by name or number (see `<sys/signal.h>`). If the list begins with a `!`, the specified signals are excluded from the trace output. Default is `-sall`.

**-S** [!] *signal*,...

Signals that stop the process. The specified signals are added to the set specified by `-s`. If one of the specified signals is received, `truss` leaves the process stopped and abandoned (see the `-T` option). Default is `-S!all`.

**-t** [!] *syscall*,...

System calls to trace or exclude. Those system calls specified in the comma-separated list are traced. If the list begins with a `!`, the specified system calls are excluded from the trace output. Default is `-tall`.

**-T** [!] *syscall*,...

Specifies system calls that stop the process. The specified system calls are added to the set specified by `-t`. If one of the specified system calls is encountered, `truss` leaves the process stopped and abandoned. That is, `truss` releases the process and exits but leaves the process in the stopped state at completion of the system call in question. A debugger or other process inspection tool (see [proc\(1\)](#)) can then be applied to the stopped process. `truss` can be reapplied to the stopped process with the same or different options to continue tracing. Default is `-T!all`.

A process left stopped in this manner cannot be restarted by the application of `kill -CONT` because it is stopped on an event of interest via `/proc`, not by the default action of a stopping signal (see `signal.h(3HEAD)`). The [prun\(1\)](#) command described in [proc\(1\)](#) can be used to set the stopped process running again.

**-u** [!] *lib*,...[:][!] *func*,...

User-level function call tracing. *lib*,... is a comma-separated list of dynamic library names, excluding the `".so.n"` suffix. *func*,... is a comma-separated list of function names. In both cases the names can include name-matching metacharacters `*`, `?`, `[]` with the same meanings as those of [sh\(1\)](#) but as applied to the library/function name spaces, not to files. An empty library or function list defaults to `*`, trace all libraries or functions in a library. A leading `!` on either list specifies an exclusion list, names of libraries or functions not to be traced. Excluding a library excludes all functions in that library; any function list following a library exclusion list is ignored.

## truss(1)

A single `:` separating the library list from the function list means to trace calls into the libraries from outside the libraries, but omit calls made to functions in a library from other functions in the same library. A double `:` means to trace all calls, regardless of origin.

Library patterns do not match either the executable file or the dynamic linker unless there is an exact match (`l*` does not match `ld.so.1`). To trace functions in either of these objects, the names must be specified exactly, as in:

```
truss -u a.out -u ld ...
```

`a.out` is the literal name to be used for this purpose; it does not stand for the name of the executable file. Tracing `a.out` function calls implies all calls (default is `:`).

Multiple `-u` options can be specified and they are honored left-to-right. The `id` of the thread that performed the function call is included in the trace output for the call. `truss` searches the dynamic symbol table in each library to find function names and also searches the standard symbol table if it has not been stripped.

`-U [!]lib, ... :[:][!]func, ...`

User-level function calls that stop the process. The specified functions are added to the set specified by `-u`. If one of the specified functions is called, `truss` leaves the process stopped and abandoned (see the `-T` option).

`-v [!]syscall,...`

Verbose. Displays the contents of any structures passed by address to the specified system calls (if traced by `-t`). Input values as well as values returned by the operating system are shown. For any field used as both input and output, only the output value is shown. Default is `-v!all`.

`-w [!]fd,...`

Shows the contents of the I/O buffer for each `write()` on any of the specified file descriptors (see the `-r` option). Default is `-w!all`.

`-x [!]syscall,...`

Displays the arguments to the specified system calls (if traced by `-t`) in raw form, usually hexadecimal, rather than symbolically. This is for unredeemed hackers who must see the raw bits to be happy. Default is `-x!all`.

See *man pages section 2: System Calls* for system call names accepted by the `-t`, `-T`, `-v`, and `-x` options. System call numbers are also accepted.

If `truss` is used to initiate and trace a specified command and if the `-o` option is used or if standard error is redirected to a non-terminal file, then `truss` runs with hangup, interrupt, and quit signals ignored. This facilitates tracing of interactive programs that catch interrupt and quit signals from the terminal.

If the trace output remains directed to the terminal, or if existing processes are traced (the `-p` option), then `truss` responds to hangup, interrupt, and quit signals by releasing all traced processes and exiting. This enables the user to terminate excessive trace output and to release previously-existing processes. Released processes continue normally, as though they had never been touched.

**EXAMPLES****EXAMPLE 1** Tracing a Command

The following example produces a trace of the `find(1)` command on the terminal:

```
example$ truss find . -print >find.out
```

**EXAMPLE 2** Tracing Common System Calls

The following example shows only a trace of the `open`, `close`, `read`, and `write` system calls:

```
example$ truss -t open,close,read,write find . -print >find.out
```

**EXAMPLE 3** Tracing a Shell Script

The following example produces a trace of the `spell(1)` command on the file `truss.out`:

```
example$ truss -f -o truss.out spell document
```

`spell` is a shell script, so the `-f` flag is needed to trace not only the shell but also the processes created by the shell. (The `spell` script runs a pipeline of eight processes.)

**EXAMPLE 4** Abbreviating Output

The following example abbreviates output:

```
example$ truss nroff -mm document >nroff.out
```

because 97% of the output reports `lseek()`, `read()`, and `write()` system calls. To abbreviate it:

```
example$ truss -t !lseek,read,write nroff -mm document >nroff.out
```

**EXAMPLE 5** Tracing Library Calls From Outside the C Library

The following example traces all user-level calls made to any function in the C library from outside the C library:

```
example$ truss -u libc ...
```

**EXAMPLE 6** Tracing library calls from within the C library

The following example includes calls made to functions in the C library from within the C library itself:

```
example$ truss -u libc:: ...
```

**EXAMPLE 7** Tracing Library Calls Other Than the C Library

The following example traces all user-level calls made to any library other than the C library:

## truss(1)

### EXAMPLE 7 Tracing Library Calls Other Than the C Library *(Continued)*

```
example$ truss -u '*' -u libc ...
```

### EXAMPLE 8 Tracing printf and scanf Function Calls

The following example traces all user-level calls to functions in the printf and scanf family contained in the C library:

```
example$ truss -u 'libc:*printf,*scanf' ...
```

### EXAMPLE 9 Tracing Every User-level Function Call

The following example traces every user-level function call from anywhere to anywhere:

```
example$ truss -u a.out -u ld:: -u :: ...
```

### EXAMPLE 10 Tracing a System Call Verbosely

The following example verbosely traces the system call activity of process #1, init(1M) (if you are a privileged user):

```
example# truss -p -v all 1
```

Interrupting truss returns init to normal operation.

**FILES** /proc/\* Process files

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWtoo

**SEE ALSO** [date\(1\)](#), [find\(1\)](#), [proc\(1\)](#), [ps\(1\)](#), [sh\(1\)](#), [spell\(1\)](#), [init\(1M\)](#), [intro\(3\)](#), [exec\(2\)](#), [fork\(2\)](#), [lseek\(2\)](#), [open\(2\)](#), [read\(2\)](#), [time\(2\)](#), [vfork\(2\)](#), [write\(2\)](#), [ctime\(3C\)](#), [signal.h\(3HEAD\)](#), [proc\(4\)](#), [attributes\(5\)](#), [privileges\(5\)](#), [threads\(5\)](#)

*man pages section 2: System Calls*

**NOTES** Some of the system calls described in *man pages section 2: System Calls* differ from the actual operating system interfaces. Do not be surprised by minor deviations of the trace output from the descriptions in that document.

Every machine fault (except a page fault) results in the posting of a signal to the LWP that incurred the fault. A report of a received signal immediately follows each report of a machine fault (except a page fault) unless that signal is being blocked.

The operating system enforces certain security restrictions on the tracing of processes. In particular, any command whose object file (a.out) cannot be read by a user cannot be traced by that user; set-uid and set-gid commands can be traced only by a

privileged user. Unless it is run by a privileged user, `truss` loses control of any process that performs an `exec()` of a set-id or unreadable object file; such processes continue normally, though independently of `truss`, from the point of the `exec()`.

To avoid collisions with other controlling processes, `truss` does not trace a process that it detects is being controlled by another process via the `/proc` interface. This allows `truss` to be applied to `proc(4)`-based debuggers as well as to another instance of itself.

The trace output contains tab characters under the assumption that standard tab stops are set (every eight positions).

The trace output for multiple processes or for a multithreaded process (one that contains more than one LWP) is not produced in strict time order. For example, a `read()` on a pipe can be reported before the corresponding `write()`. For any one LWP (a traditional process contains only one), the output is strictly time-ordered.

When tracing more than one process, `truss` runs as one controlling process for each process being traced. For the example of the `spell` command shown above, `spell` itself uses 9 process slots, one for the shell and 8 for the 8-member pipeline, while `truss` adds another 9 processes, for a total of 18.

Not all possible structures passed in all possible system calls are displayed under the `-v` option.

## tset(1B)

<b>NAME</b>	tset, reset – establish or restore terminal characteristics
<b>SYNOPSIS</b>	<b>tset</b> [-InQrs] [-ec] [-kc] [ -m [ <i>port-ID</i> [ <i>baudrate</i> ] : <i>type...</i> ] ] [ <i>type</i> ] <b>reset</b> [-] [-ec] [-I] [-kc] [-n] [-Q] [-r] [-s] [ -m [ <i>indent</i> ] [ <i>test baudrate</i> ] : <i>type...</i> ] [ <i>type</i> ]
<b>DESCRIPTION</b>	<p>The <code>tset</code> utility sets up your terminal, typically when you first log in. It does terminal dependent processing such as setting erase and kill characters, setting or resetting delays, sending any sequences needed to properly initialize the terminal, and the like. <code>tset</code> first determines the <code>type</code> of terminal involved, and then does necessary initializations and mode settings. If a port is not wired permanently to a specific terminal (not hardwired) it is given an appropriate generic identifier such as <code>dialup</code>.</p> <p><code>reset</code> clears the terminal settings by turning off CBREAK and RAW modes, output delays and parity checking, turns on NEWLINE translation, echo and TAB expansion, and restores undefined special characters to their default state. It then sets the modes as usual, based on the terminal type (which will probably override some of the above). See <code>stty(1)</code> for more information. All arguments to <code>tset</code> may be used with <code>reset</code>. <code>reset</code> also uses <code>rs=</code> and <code>rf=</code> to reset the initialization string and file. This is useful after a program dies and leaves the terminal in a funny state. Often in this situation, characters will not echo as you type them. You may have to type <code>LINEFEED reset LINEFEED</code> since <code>RETURN</code> may not work.</p> <p>When no arguments are specified, <code>tset</code> reads the terminal type from the <code>TERM</code> environment variable and re-initializes the terminal, and performs initialization of mode, environment and other options at login time to determine the terminal type and set up terminal modes.</p> <p>When used in a startup script (<code>.profile</code> for <code>sh(1)</code> users or <code>.login</code> for <code>csh(1)</code> users) it is desirable to give information about the type of terminal you will usually use on ports that are not hardwired. Any of the alternate generic names given in the file <code>/etc/termcap</code> are possible identifiers. Refer to the <code>-m</code> option below for more information. If no mapping applies and a final type option, not preceded by a <code>-m</code>, is given on the command line then that type is used.</p> <p>It is usually desirable to return the terminal type, as finally determined by <code>tset</code>, and information about the terminal's capabilities, to a shell's environment. This can be done using the <code>-</code>, <code>-s</code>, or <code>-S</code> options.</p> <p>For the Bourne shell, put this command in your <code>.profile</code> file:</p> <pre>eval `tset -s options...`</pre> <p>or using the C shell, put these commands in your <code>.login</code> file:</p> <pre>set noglob eval `tset -s options...`unset noglob</pre> <p>With the C shell, it is also convenient to make an alias in your <code>.cshrc</code> file:</p> <pre>alias ts `eval `tset -s \!*``</pre>

This also allows the command:

```
ts 2621
```

to be invoked at any time to set the terminal and environment. It is not possible to get this aliasing effect with a Bourne shell script, because shell scripts cannot set the environment of their parent. If a process could set its parent's environment, none of this nonsense would be necessary in the first place.

Once the terminal type is known, `tset` sets the terminal driver mode. This normally involves sending an initialization sequence to the terminal, setting the single character erase (and optionally the line-kill (full line erase)) characters, and setting special character delays. TAB and NEWLINE expansion are turned off during transmission of the terminal initialization sequence.

On terminals that can backspace but not overstrike (such as a CRT), and when the erase character is '#', the erase character is changed as if `-e` had been used.

## OPTIONS

- The name of the terminal finally decided upon is output on the standard output. This is intended to be captured by the shell and placed in the `TERM` environment variable.
- ec Set the erase character to be the named character *c* on all terminals. Default is the BACKSPACE key on the keyboard, usually `^H` (CTRL-H). The character *c* can either be typed directly, or entered using the circumflex-character notation used here.
- ic Set the interrupt character to be the named character *c* on all terminals. Default is `^C` (CTRL-C). The character *c* can either be typed directly, or entered using the circumflex-character notation used here.
- I Suppress transmitting terminal-initialization strings.
- kc Set the line kill character to be the named character *c* on all terminals. Default is `^U` (CTRL-U). The kill character is left alone if `-k` is not specified. Control characters can be specified by prefixing the alphabetical character with a circumflex (as in CTRL-U) instead of entering the actual control key itself. This allows you to specify control keys that are currently assigned.
- n Specify that the new tty driver modes should be initialized for this terminal. Probably useless since `stty new` is the default.
- Q Suppress printing the 'Erase set to' and 'Kill set to' messages.
- r In addition to other actions, reports the terminal type.
- s Output commands to set and export `TERM`. This can be used with
 

```
set noglob
eval 'tset -s . . . .'
unset noglob
```

## tset(1B)

to bring the terminal information into the environment. Doing so makes programs such as `vi(1)` start up faster. If the `SHELL` environment variable ends with `csh`, C shell commands are output, otherwise Bourne shell commands are output.

`-m [ port-ID [ baudrate ] : ttype ] . . .`

Specify (map) a terminal type when connected to a generic port (such as *dialup* or *plugboard*) identified by *port-ID*. The *baudrate* argument can be used to check the baudrate of the port and set the terminal type accordingly. The target rate is prefixed by any combination of the following operators to specify the conditions under which the mapping is made:

- > Greater than
- @ Equals or "at"
- < Less than
- ! It is not the case that (negates the above operators)
- ? Prompt for the terminal type. If no response is given, then *ttype* is selected by default.

In the following example, the terminal type is set to `adm3a` if the port is a dialup with a speed of greater than 300 or to `dw2` if the port is a dialup at 300 baud or less. In the third case, the question mark preceding the terminal type indicates that the user is to verify the type desired. A NULL response indicates that the named type is correct. Otherwise, the user's response is taken to be the type desired.

```
tset -m 'dialup>300:adm3a' -m 'dialup:dw2' -m 'plugboard:?adm3a'
```

To prevent interpretation as metacharacters, the entire argument to `-m` should be enclosed in single quotes. When using the C shell, exclamation points should be preceded by a backslash (`\`).

**EXAMPLES** These examples all use the `'-'` option. A typical use of `tset` in a `.profile` or `.login` will also use the `-e` and `-k` options, and often the `-n` or `-Q` options as well. These options have been omitted here to keep the examples short.

### EXAMPLE 1 Selecting a terminal

To select a 2621, you might put the following sequence of commands in your `.login` file (or `.profile` for Bourne shell users).

```
set noglob
eval `tset -s 2621`
unset noglob
```

If you want to make the selection based only on the baud rate, you might use the following:

```
set noglob
eval `tset -s -m '>1200:wy' 2621`
unset noglob
```

**EXAMPLE 1** Selecting a terminal (Continued)**EXAMPLE 2** Selecting terminals according to speed or baud rate

If you have a switch which connects to various ports (making it impractical to identify which port you may be connected to), and use various terminals from time to time, you can select from among those terminals according to the *speed* or baud rate. In the example below, `tset` will prompt you for a terminal type if the baud rate is greater than 1200 (say, 9600 for a terminal connected by an RS-232 line), and use a Wyse® 50 by default. If the baud rate is less than or equal to 1200, it will select a 2621. Note the placement of the question mark, and the quotes to protect the `>` and `?` from interpretation by the shell.

```
set noglob
eval `tset -s -m 'switch>1200:?wy' -m 'switch<=1200:2621'`
unset noglob
```

**EXAMPLE 3** Selecting the terminal used most often

The following entry is appropriate if you always dial up, always at the same baud rate, on many different kinds of terminals, and the terminal you use most often is an `adm3a`.

```
set noglob
eval `tset -s ?adm3a`
unset noglob
```

**EXAMPLE 4** Selecting a terminal with specific settings

The following example quietly sets the erase character to BACKSPACE, and kill to CTRL-U. If the port is switched, it selects a Concept™ 100 for speeds less than or equal to 1200, and asks for the terminal type otherwise (the default in this case is a Wyse 50). If the port is a direct dialup, it selects Concept 100 as the terminal type. If logging in over the ARPANET, the terminal type selected is a Datamedia® 2500 terminal or emulator. Note the backslash escaping the NEWLINE at the end of the first line in the example.

```
set noglob
eval `tset -e -k^U -Q -s -m 'switch<=1200:concept100' -m \
'switch:?wy' -m dialup:concept100 -m arpanet:dm2500`
unset noglob
```

**FILES**

```
.login
.profile
/etc/termcap
```

tset(1B)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

**SEE ALSO** `csh(1)`, `sh(1)`, `stty(1)`, `vi(1)`, `attributes(5)`, `environ(5)`

**NOTES** The `tset` command is one of the first commands a user must master when getting started on a UNIX system. Unfortunately, it is one of the most complex, largely because of the extra effort the user must go through to get the environment of the login shell set. Something needs to be done to make all this simpler, either the `login` program should do this stuff, or a default shell alias should be made, or a way to set the environment of the parent should exist.

This program cannot intuit personal choices for erase, interrupt and line kill characters, so it leaves these set to the local system standards.

It could well be argued that the shell should be responsible for ensuring that the terminal remains in a sane state; this would eliminate the need for the `reset` program.

<b>NAME</b>	tsort – topological sort						
<b>SYNOPSIS</b>	<code>/usr/ccs/bin/tsort</code> [ <i>file</i> ]						
<b>DESCRIPTION</b>	<p>The <code>tsort</code> command produces on the standard output a totally ordered list of items consistent with a partial ordering of items mentioned in the input <i>file</i>.</p> <p>The input consists of pairs of items (nonempty strings) separated by blanks. Pairs of different items indicate ordering. Pairs of identical items indicate presence, but not ordering.</p>						
<b>OPERANDS</b>	<p>The following operand is supported:</p> <p><i>file</i>            A path name of a text file to order. If no <i>file</i> operand is given, the standard input is used.</p>						
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> An example of the <code>tsort</code> command</p> <p>The command:</p> <pre>example% tsort &lt;&lt;EOF a b c c d e g g f g e f EOF</pre> <p>produces the output:</p> <pre>a b c d e f g</pre>						
<b>ENVIRONMENT VARIABLES</b>	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>tsort</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .						
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <p>0            Successful completion.</p> <p>&gt;0          An error occurred.</p>

**DIAGNOSTICS** Odd data: there are an odd number of fields in the input file.

<b>NAME</b>	tty – return user’s terminal name								
<b>SYNOPSIS</b>	tty [-l] [-s]								
<b>DESCRIPTION</b>	The tty utility writes to the standard output the name of the terminal that is open as standard input. The name that is used is equivalent to the string that would be returned by the ttyname(3C) function.								
<b>OPTIONS</b>	The following options are supported: <ul style="list-style-type: none"> <li>-l Prints the synchronous line number to which the user’s terminal is connected, if it is on an active synchronous line.</li> <li>-s Inhibits printing of the terminal path name, allowing one to test just the exit status.</li> </ul>								
<b>ENVIRONMENT VARIABLES</b>	See environ(5) for descriptions of the following environment variables that affect the execution of tty: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.								
<b>EXIT STATUS</b>	The following exit values are returned: <ul style="list-style-type: none"> <li>0 Standard input is a terminal.</li> <li>1 Standard input is not a terminal.</li> <li>&gt;1 An error occurred.</li> </ul>								
<b>ATTRIBUTES</b>	See attributes(5) for descriptions of the following attributes: <table border="1" data-bbox="457 1096 1429 1276" style="margin-left: 20px;"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> <tr> <td>CSI</td> <td>enabled</td> </tr> <tr> <td>Interface Stability</td> <td>Standard</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu	CSI	enabled	Interface Stability	Standard
ATTRIBUTE TYPE	ATTRIBUTE VALUE								
Availability	SUNWcsu								
CSI	enabled								
Interface Stability	Standard								
<b>SEE ALSO</b>	isatty(3C), ttyname(3C), attributes(5), environ(5), standards(5)								
<b>DIAGNOSTICS</b>	not on an active synchronous line The standard input is not a synchronous terminal and -l is specified.  not a tty The standard input is not a terminal and -s is not specified.								
<b>NOTES</b>	The -s option is useful only if the exit status is wanted. It does not rely on the ability to form a valid path name. Portable applications should use test -t.								

## type(1)

<b>NAME</b>	type – write a description of command type
<b>SYNOPSIS</b>	<b>type</b> <i>name</i> ...
<b>DESCRIPTION</b>	<p>The <code>type</code> utility indicates how each <i>name</i> operand would be interpreted if used as a command. <code>type</code> displays information about each operand identifying the operand as a shell built-in, function, alias, hashed command, or keyword, and where applicable, may display the operand's path name.</p> <p>There is also a shell built-in version of <code>type</code> that is similar to the <code>type</code> utility.</p>
<b>OPERANDS</b>	<p>The following operand is supported:</p> <p><i>name</i>      A name to be interpreted.</p>
<b>ENVIRONMENT VARIABLES</b>	<p>See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>type</code>: <code>LANG</code>, <code>LC_ALL</code>, <code>LC_CTYPE</code>, <code>LC_MESSAGES</code>, and <code>NLSPATH</code>.</p> <p><code>PATH</code>      Determine the location of <i>name</i>.</p>
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <p>0            Successful completion.</p> <p>&gt;0          An error occurred.</p>
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Standard

**SEE ALSO** `typeset(1)`, `attributes(5)`, `environ(5)`, `standards(5)`

<b>NAME</b>	typeset, whence – shell built-in functions to set/get attributes and values for shell variables and functions
<b>SYNOPSIS</b>	<b>typeset</b> [ ± HLRZfilrtux [ <i>n</i> ] ] [ <i>name</i> [ = <i>value</i> ] ] ... <b>whence</b> [-pv] <i>name</i> ...
<b>DESCRIPTION</b>	<p>typeset sets attributes and values for shell variables and functions. When typeset is invoked inside a function, a new instance of the variables <i>name</i> is created. The variables <i>value</i> and <i>type</i> are restored when the function completes. The following list of attributes may be specified:</p> <ul style="list-style-type: none"> <li>-H        This flag provides UNIX to host-name file mapping on non-UNIX machines.</li> <li>-L        Left justify and remove leading blanks from <i>value</i>. If <i>n</i> is non-zero it defines the width of the field; otherwise, it is determined by the width of the value of first assignment. When the variable is assigned to, it is filled on the right with blanks or truncated, if necessary, to fit into the field. Leading zeros are removed if the -Z flag is also set. The -R flag is turned off.</li> <li>-R        Right justify and fill with leading blanks. If <i>n</i> is non-zero it defines the width of the field, otherwise it is determined by the width of the value of first assignment. The field is left filled with blanks or truncated from the end if the variable is reassigned. The -L flag is turned off.</li> <li>-Z        Right justify and fill with leading zeros if the first non-blank character is a digit and the -L flag has not been set. If <i>n</i> is non-zero it defines the width of the field; otherwise, it is determined by the width of the value of first assignment.</li> <li>-f        The names refer to function names rather than variable names. No assignments can be made and the only other valid flags are -t, -u and -x. The flag -t turns on execution tracing for this function. The flag -u causes this function to be marked undefined. The FPATH variable will be searched to find the function definition when the function is referenced. The flag -x allows the function definition to remain in effect across shell procedures invoked by name.</li> <li>-i        Parameter is an integer. This makes arithmetic faster. If <i>n</i> is non-zero it defines the output arithmetic base; otherwise, the first assignment determines the output base.</li> <li>-l        All upper-case characters are converted to lower-case. The upper-case flag, -u is turned off.</li> <li>-r        The given <i>names</i> are marked readonly and these names cannot be changed by subsequent assignment.</li> <li>-t        Tags the variables. Tags are user definable and have no special meaning to the shell.</li> </ul>

## typeset(1)

- u All lower-case characters are converted to upper-case characters. The lower-case flag, -l is turned off.
- x The given *names* are marked for automatic export to the environment of subsequently-executed commands.

The -i attribute can not be specified along with -R, -L, -Z, or -f.

Using + rather than - causes these flags to be turned off. If no *name* arguments are given but flags are specified, a list of *names* (and optionally the *values*) of the *variables* which have these flags set is printed. (Using + rather than - keeps the values from being printed.) If no *names* and flags are given, the *names* and *attributes* of all *variables* are printed.

For each *name*, *whence* indicates how it would be interpreted if used as a command name.

The -v flag produces a more verbose report.

The -p flag does a path search for *name* even if name is an alias, a function, or a reserved word.

On this man page, [ksh\(1\)](#) commands that are preceded by one or two \* (asterisks) are treated specially in the following ways:

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by \*\* that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

**ATTRIBUTES** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

**NAME** ucblinks – adds /dev entries to give SunOS 4.x compatible names to SunOS 5.x devices

**SYNOPSIS** /usr/ucb/ucblinks [-e *rulebase*] [-r *rootdir*]

**DESCRIPTION** ucblinks creates symbolic links under the /dev directory for devices whose SunOS 5.x names differ from their SunOS 4.x names. Where possible, these symbolic links point to the device's SunOS 5.x name rather than to the actual /devices entry.

ucblinks does not remove unneeded compatibility links; these must be removed by hand.

ucblinks should be called each time the system is reconfiguration-booted, after any new SunOS 5.x links that are needed have been created, since the reconfiguration may have resulted in more compatibility names being needed.

In releases prior to SunOS 5.4, ucblinks used a *nawk* rule-base to construct the SunOS 4.x compatible names. ucblinks no longer uses *nawk* for the default operation, although *nawk* rule-bases can still be specified with the *-e* option. The *nawk* rule-base equivalent to the SunOS 5.4 default operation can be found in /usr/ucblib/ucblinks.awk.

**OPTIONS**

*-e rulebase* Specify *rulebase* as the file containing *nawk*(1) pattern-action statements.

*-r rootdir* Specify *rootdir* as the directory under which *dev* and *devices* will be found, rather than the standard root directory /.

**FILES** /usr/ucblib/ucblinks.awk sample rule-base for compatibility links

**ATTRIBUTES** See *attributes*(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

**SEE ALSO** *devlinks*(1M), *disks*(1M), *ports*(1M), *tapes*(1M), *attributes*(5)

ul(1)

**NAME** | ul – do underlining

**SYNOPSIS** | **ul** [-i] [-t *terminal*] [*filename...*]

**DESCRIPTION** | ul reads the named *filenames* (or the standard input if none are given) and translates occurrences of underscores to the sequence which indicates underlining for the terminal in use, as specified by the environment variable TERM. ul uses the /usr/share/lib/terminfo entry to determine the appropriate sequences for underlining. If the terminal is incapable of underlining, but is capable of a standout mode then that is used instead. If the terminal can overstrike, or handles underlining automatically, ul degenerates to [cat\(1\)](#). If the terminal cannot underline, underlining is ignored.

**OPTIONS** | -t *terminal* | Override the terminal kind specified in the environment. If the terminal cannot underline, underlining is ignored. If the terminal name is not found, no underlining is attempted.

| -i | Indicate underlining by a separate line containing appropriate dashes '-'; this is useful when you want to look at the underlining which is present in an [nroff\(1\)](#) output stream on a CRT-terminal.

**RETURN VALUES** | ul returns exit code 1 if the file specified is not found.

**FILES** | /usr/share/lib/terminfo/\*

**ATTRIBUTES** | See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdoc

**SEE ALSO** | [cat\(1\)](#), [man\(1\)](#), [nroff\(1\)](#), [attributes\(5\)](#)

**BUGS** | nroff usually generates a series of backspaces and underlines intermixed with the text to indicate underlining. ul makes attempt to optimize the backward motion.

<b>NAME</b>	umask – get or set the file mode creation mask
<b>SYNOPSIS</b>	<code>/usr/bin/umask [-S] [mask]</code>
<b>sh</b>	<code>umask [000]</code>
<b>csh</b>	<code>umask [000]</code>
<b>ksh</b>	<code>umask [-S] [mask]</code>
<b>DESCRIPTION</b>	<p>The <code>umask</code> utility sets the file mode creation mask of the current shell execution environment to the value specified by the <i>mask</i> operand. This mask affects the initial value of the file permission bits of subsequently created files. If <code>umask</code> is called in a subshell or separate utility execution environment, such as one of the following:</p> <pre>(umask 002) nohup umask ... find . -exec umask ...</pre> <p>it does not affect the file mode creation mask of the caller's environment. For this reason, the <code>/usr/bin/umask</code> utility cannot be used to change the <code>umask</code> in an ongoing session. Its usefulness is limited to checking the caller's <code>umask</code>. To change the <code>umask</code> of an ongoing session you must use one of the shell builtins.</p> <p>If the <i>mask</i> operand is not specified, the <code>umask</code> utility writes the value of the invoking process's file mode creation mask to standard output.</p> <p><b>sh</b> The user file-creation mode mask is set to <i>000</i>. The three octal digits refer to read/write/execute permissions for owner, group, and other, respectively (see <a href="#">chmod(1)</a>, <a href="#">chmod(2)</a>, and <a href="#">umask(2)</a>). The value of each specified digit is subtracted from the corresponding "digit" specified by the system for the creation of a file (see <a href="#">creat(2)</a>). For example, <code>umask 022</code> removes write permission for group and other (files normally created with mode 777 become mode 755. Files created with mode 666 become mode 644).</p> <ul style="list-style-type: none"> <li>■ If <i>000</i> is omitted, the current value of the mask is printed.</li> <li>■ <code>umask</code> is recognized and executed by the shell.</li> <li>■ <code>umask</code> can be included in the user's <code>.profile</code> (see <a href="#">profile(4)</a>) and invoked at login to automatically set the user's permissions on files or directories created.</li> </ul> <p><b>csh</b> See the description above for the Bourne shell (<code>sh</code>)<code>umask</code> built-in.</p> <p><b>ksh</b> The user file-creation mask is set to <i>mask</i>. <i>mask</i> can either be an octal number or a symbolic value as described in <a href="#">chmod(1)</a>. If a symbolic value is given, the new <code>umask</code> value is the complement of the result of applying <i>mask</i> to the complement of the previous <code>umask</code> value. If <i>mask</i> is omitted, the current value of the mask is printed.</p> <p><b>OPTIONS</b> The following option is supported:</p> <p><code>-S</code> Produces symbolic output.</p>

## umask(1)

The default output style is unspecified, but will be recognized on a subsequent invocation of `umask` on the same system as a *mask* operand to restore the previous file mode creation mask.

**OPERANDS** The following operand is supported:

*mask* A string specifying the new file mode creation mask. The string is treated in the same way as the *mode* operand described in the `chmod(1)` manual page.

For a *symbolic\_mode* value, the new value of the file mode creation mask is the logical complement of the file permission bits portion of the file mode specified by the *symbolic\_mode* string.

In a *symbolic\_mode* value, the permissions *op* characters + and – are interpreted relative to the current file mode creation mask. + causes the bits for the indicated permissions to be cleared in the mask. – causes the bits of the indicated permissions to be set in the mask.

The interpretation of *mode* values that specify file mode bits other than the file permission bits is unspecified.

The file mode creation mask is set to the resulting numeric value.

The default output of a prior invocation of `umask` on the same system with no operand will also be recognized as a *mask* operand. The use of an operand obtained in this way is not obsolescent, even if it is an octal number.

**OUTPUT** When the *mask* operand is not specified, the `umask` utility will write a message to standard output that can later be used as a `umask mask` operand.

If `-s` is specified, the message will be in the following format:

```
"u=%s,g=%s,o=%s\n", owner permissions, group permissions, \
                        other permissions
```

where the three values will be combinations of letters from the set {r, w, x}. The presence of a letter will indicate that the corresponding bit is clear in the file mode creation mask.

If a *mask* operand is specified, there will be no output written to standard output.

**EXAMPLES** **EXAMPLE 1** Using the `umask` command

The examples in this section refer to the `/usr/bin/umask` utility and the `ksh umask` builtin.

Either of the commands:

```
umask a=rx,ug+w
umask 002
```

**EXAMPLE 1** Using the umask command (Continued)

sets the mode mask so that subsequently created files have their `S_IWOTH` bit cleared.

After setting the mode mask with either of the above commands, the `umask` command can be used to write the current value of the mode mask:

```
example$ umask
0002
```

The output format is unspecified, but historical implementations use the obsolescent octal integer mode format.

```
example$ umask -S
u=rwx,g=rwx,o=rX
```

Either of these outputs can be used as the mask operand to a subsequent invocation of the `umask` utility.

Assuming the mode mask is set as above, the command:

```
umask g-w
```

sets the mode mask so that subsequently created files have their `S_IWGRP` and `S_IWOTH` bits cleared.

The command:

```
umask --w
```

sets the mode mask so that subsequently created files have all their write bits cleared. Notice that *mask* operands `r`, `w`, `x`, or anything beginning with a hyphen (`-`), must be preceded by `-` to keep it from being interpreted as an option.

## ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `umask`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

## EXIT STATUS

The following exit values are returned:

0	The file mode creation mask was successfully changed, or no <i>mask</i> operand was supplied.
>0	An error occurred.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Standard

umask(1)

<b>NAME</b>	uname – print name of current system
<b>SYNOPSIS</b>	<pre>uname [-aimnprsvX] uname [-S <i>system_name</i>]</pre>
<b>DESCRIPTION</b>	<p>The <code>uname</code> utility prints information about the current system on the standard output. When options are specified, symbols representing one or more system characteristics will be written to the standard output. If no options are specified, <code>uname</code> prints the current operating system's name. The options print selected information returned by <code>uname(2)</code>, <code>sysinfo(2)</code>, or both.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a                Prints basic information currently available from the system.</li> <li>-i                Prints the name of the platform.</li> <li>-m                Prints the machine hardware name (class). Use of this option is discouraged. Use <code>uname -p</code> instead. See NOTES section below.</li> <li>-n                Prints the nodename (the nodename is the name by which the system is known to a communications network).</li> <li>-p                Prints the current host's ISA or processor type.</li> <li>-r                Prints the operating system release level.</li> <li>-s                Prints the name of the operating system. This is the default.</li> <li>-S <i>system_name</i>    The nodename may be changed by specifying a system name argument. The system name argument is restricted to <code>SYS_NMLN</code> characters. <code>SYS_NMLN</code> is an implementation specific value defined in <code>&lt;sys/utsname.h&gt;</code>. Only the super-user is allowed this capability. This change does not persist across reboots of the system. Use <code>sys-unconfig(1M)</code> to change a host's name permanently.</li> <li>-v                Prints the operating system version.</li> <li>-X                Prints expanded system information, one information element per line, as expected by SCO UNIX. The displayed information includes: <ul style="list-style-type: none"> <li>■ system name, node, release, version, machine, and number of CPUs.</li> <li>■ BusType, Serial, and Users (set to "unknown" in Solaris)</li> <li>■ OEM# and Origin# (set to 0 and 1, respectively)</li> </ul> </li> </ul>
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Printing the OS name and release level</p> <p>The following command:</p> <pre>example% <b>uname -sr</b></pre>

uname(1)

**EXAMPLE 1** Printing the OS name and release level (Continued)

prints the operating system name and release level, separated by one SPACE character.

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `uname`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**SYSV3** This variable is used to override the default behavior of `uname`. This is necessary to make it possible for some INTERACTIVE UNIX Systems and SCO UNIX programs and scripts to work properly. Many scripts use `uname` to determine the `SYSV3` type or the version of the OS to ensure software is compatible with that OS. Setting `SYSV3` to an empty string will make `uname` print the following default values:

```
nodename nodename 3.2 2 i386
```

The individual elements that `uname` displays can also be modified by setting `SYSV3` in the following format:

*os,sysname,node,rel,ver,mach*

- os* Operating system (IUS or SCO).
- sysname* System name.
- node* Nodename as displayed by the `-n` option.
- rel* Release level as displayed by the `-r` option.
- ver* Version number as displayed by the `-v` option.
- mach* Machine name as displayed by `-m` option.

Do not put spaces between the elements. If an element is omitted, the current system value will be used.

**EXIT STATUS**

The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Standard

**SEE ALSO**

`arch(1)`, `isalist(1)`, `sys-unconfig(1M)`, `sysinfo(2)`, `uname(2)`, `nodename(4)`, `attributes(5)`, `environ(5)`, `standards(5)`

**NOTES** Independent software vendors (ISVs) and others who need to determine detailed characteristics of the platform on which their software is either being installed or executed should use the `uname` command.

To determine the operating system name and release level, use `uname -sr`. To determine only the operating system release level, use `uname -r`. Notice that operating system release levels are not guaranteed to be in *x.y* format (such as 5.3, 5.4, 5.5, and so forth); future releases could be in the *x.y.z* format (such as 5.3.1, 5.3.2, 5.4.1, and so forth).

In SunOS 4.x releases, the `arch(1)` command was often used to obtain information similar to that obtained by using the `uname` command. The `arch(1)` command output "sun4" was often incorrectly interpreted to signify a SunOS SPARC system. If hardware platform information is desired, use `uname -sp`.

The `arch -k` and `uname -m` commands return equivalent values; however, the use of either of these commands by third party programs is discouraged, as is the use of the `arch` command in general. To determine the machine's Instruction Set Architecture (ISA or processor type), use `uname` with the `-p` option.

## unifdef(1)

<b>NAME</b>	unifdef – resolve and remove ifdef'ed lines from C program source
<b>SYNOPSIS</b>	<b>unifdef</b> [-c] [-Dname] [-Uname] [-iDname] [-iUname] ... [filename]
<b>DESCRIPTION</b>	<p>unifdef removes <code>ifdef</code>d lines from a file while otherwise leaving the file alone. It is smart enough to deal with the nested <code>ifdef</code>s, comments, single and double quotes of C syntax, but it does not do any including or interpretation of macros. Neither does it strip out comments, though it recognizes and ignores them. You specify which symbols you want defined with <code>-D</code> options, and which you want undefined with <code>-U</code> options. Lines within those <code>ifdef</code>s will be copied to the output, or removed, as appropriate. Any <code>ifdef</code>, <code>ifndef</code>, <code>else</code>, and <code>endif</code> lines associated with <i>filename</i> will also be removed.</p> <p><code>ifdef</code>s involving symbols you do not specify are untouched and copied out along with their associated <code>ifdef</code>, <code>else</code>, and <code>endif</code> lines.</p> <p>If an <code>ifdefX</code> occurs nested inside another <code>ifdefX</code>, then the inside <code>ifdef</code> is treated as if it were an unrecognized symbol. If the same symbol appears in more than one argument, only the first occurrence is significant.</p> <p>unifdef copies its output to the standard output and will take its input from the standard input if no <i>filename</i> argument is given.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"><li>-c Complement the normal operation. Lines that would have been removed or blanked are retained, and vice versa.</li><li>-l Replace "lines removed" lines with blank lines.</li><li>-t Plain text option. unifdef refrains from attempting to recognize comments and single and double quotes.</li><li>-Dname Lines associated with the defined symbol <i>name</i>.</li><li>-Uname Lines associated with the undefined symbol <i>name</i>.</li><li>-iDname Ignore, but print out, lines associated with the defined symbol <i>name</i>. If you use <code>ifdef</code>s to delimit non-C lines, such as comments or code which is under construction, then you must tell unifdef which symbols are used for that purpose so that it will not try to parse for quotes and comments within them.</li><li>-iUname Ignore, but print out, lines associated with the undefined symbol <i>name</i>.</li></ul>
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <ul style="list-style-type: none"><li>0 Successful operation.</li><li>1 Operation failed.</li></ul>

unifdef(1)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

**DIAGNOSTICS** Premature EOF Inappropriate else or endif.

## uniq(1)

<b>NAME</b>	uniq – report or filter out repeated lines in a file
<b>SYNOPSIS</b>	<b>uniq</b> [-c   -d   -u] [-f <i>fields</i> ] [-s <i>char</i> ] [ <i>input_file</i> [ <i>output_file</i> ] ] <b>uniq</b> [-c   -d   -u] [-n] [ + <i>m</i> ] [ <i>input_file</i> [ <i>output_file</i> ] ]
<b>DESCRIPTION</b>	<p>The <code>uniq</code> utility will read an input file comparing adjacent lines, and write one copy of each input line on the output. The second and succeeding copies of repeated adjacent input lines will not be written.</p> <p>Repeated lines in the input will not be detected if they are not adjacent.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"><li>-c                   Precedes each output line with a count of the number of times the line occurred in the input.</li><li>-d                   Suppresses the writing of lines that are not repeated in the input.</li><li>-f <i>fields</i>           Ignores the first <i>fields</i> fields on each input line when doing comparisons, where <i>fields</i> is a positive decimal integer. A field is the maximal string matched by the basic regular expression:                    [[:blank:]]* [ ^ [[:blank:]]*  If <i>fields</i> specifies more fields than appear on an input line, a null string will be used for comparison.</li><li>-s <i>chars</i>           Ignores the first <i>chars</i> characters when doing comparisons, where <i>chars</i> is a positive decimal integer. If specified in conjunction with the -f option, the first <i>chars</i> characters after the first <i>fields</i> fields will be ignored. If <i>chars</i> specifies more characters than remain on an input line, a null string will be used for comparison.</li><li>-u                   Suppresses the writing of lines that are repeated in the input.</li><li>-n                   Equivalent to -f <i>fields</i> with <i>fields</i> set to <i>n</i>.</li><li>+<i>m</i>                 Equivalent to -s <i>chars</i> with <i>chars</i> set to <i>m</i>.</li></ul>
<b>OPERANDS</b>	<p>The following operands are supported:</p> <ul style="list-style-type: none"><li><i>input_file</i>         A path name of the input file. If <i>input_file</i> is not specified, or if the <i>input_file</i> is -, the standard input will be used.</li><li><i>output_file</i>        A path name of the output file. If <i>output_file</i> is not specified, the standard output will be used. The results are unspecified if the file named by <i>output_file</i> is the file named by <i>input_file</i>.</li></ul>
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Using the <code>uniq</code> command</p> <p>The following example lists the contents of the <code>uniq.test</code> file and outputs a copy of the repeated lines.</p>

**EXAMPLE 1** Using the unq command (Continued)

```
example% cat unq.test
This is a test.
This is a test.
TEST.
Computer.
TEST.
TEST.
Software.

example% unq -d unq.test
This is a test.
TEST.
example%
```

The next example outputs just those lines that are not repeated in the unq.test file.

```
example% unq -u unq.test
TEST.
Computer.
Software.
example%
```

The last example outputs a report with each line preceded by a count of the number of times each line occurred in the file:

```
example% unq -c unq.test
 2 This is a test.
 1 TEST.
 1 Computer.
 2 TEST.
 1 Software.
example%
```

**ENVIRONMENT VARIABLES**

See environ(5) for descriptions of the following environment variables that affect the execution of unq: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**EXIT STATUS**

The following exit values are returned:

```
0          Successful completion.
>0        An error occurred.
```

<b>NAME</b>	units – converts quantities expressed in standard scales to other scales
<b>SYNOPSIS</b>	<b>units</b>
<b>DESCRIPTION</b>	<p>units converts quantities expressed in various standard scales to their equivalents in other scales. It works interactively in this fashion:</p> <pre>You have:~~inch You want:~~cm       * 2.540000e+00 / 3.937008e-01</pre> <p>A quantity is specified as a multiplicative combination of units optionally preceded by a numeric multiplier. Powers are indicated by suffixed positive integers, division by the usual sign:</p> <pre>You have:~~15 lbs force/in2 You want:~~atm       * 1.020689e+00 / 9.797299e-01</pre> <p>units only does multiplicative scale changes; thus it can convert Kelvin to Rankine, but not Celsius to Fahrenheit. Most familiar units, abbreviations, and metric prefixes are recognized, together with a generous leavening of exotica and a few constants of nature including:</p> <pre>pi      ratio of circumference to diameter, c       speed of light, e       charge on an electron, g       acceleration of gravity, force   same as g, mole    Avogadro's number, water   pressure head per unit height of water, au      astronomical unit.</pre> <p>Pound is not recognized as a unit of mass; lb is. Compound names are run together, (for example, lightyear). British units that differ from their U.S. counterparts are prefixed thus: brgallon. For a complete list of units, type:</p> <pre>cat /usr/share/lib/unittab</pre>

**NAME** unix2dos – convert text file from ISO format to DOS format

**SYNOPSIS** **unix2dos** [-ascii] [-iso] [-7] [-437 | -850 | -860 | -863 | -865] *originalfile convertedfile*

**DESCRIPTION** The `unix2dos` utility converts ISO standard characters to the corresponding characters in the DOS extended character set.

This command may be invoked from either DOS or SunOS. However, the filenames must conform to the conventions of the environment in which the command is invoked.

If the original file and the converted file are the same, `unix2dos` will rewrite the original file after converting it.

**OPTIONS** The following options are supported:

- ascii            Adds carriage returns and converts end of file characters in SunOS format text files to conform to DOS requirements.
- iso              This is the default. Converts ISO standard characters to the corresponding character in the DOS extended character set.
- 7                Converts 8 bit SunOS characters to 7 bit DOS characters.

On non-i386 systems, `unix2dos` will attempt to obtain the keyboard type to determine which code page to use. Otherwise, the default is US. The user may override the code page with one of the following options:

- 437             Use US code page
- 850             Use multilingual code page
- 860             Use Portuguese code page
- 863             Use French Canadian code page
- 865             Use Danish code page

**OPERANDS** The following operands are required:

- originalfile*    The original file in ISO format that is being converted to DOS format.
- convertedfile*   The new file in DOS format that has been converted from the original ISO file format.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

Availability	SUNWesu

**SEE ALSO** `dos2unix(1)`, `ls(1)`, `attributes(5)`

unix2dos(1)

**DIAGNOSTICS**

File *filename* not found, or no read permission

The input file you specified does not exist, or you do not have read permission. Check with the SunOS command, `ls -l` (see `ls(1)`).

Bad output filename *filename*, or no write permission

The output file you specified is either invalid, or you do not have write permission for that file or the directory that contains it. Check also that the drive or diskette is not write-protected.

Error while writing to temporary file

An error occurred while converting your file, possibly because there is not enough space on the current drive. Check the amount of space on the current drive using the `DIR` command. Also be certain that the default diskette or drive is write-enabled (not write-protected). Notice that when this error occurs, the original file remains intact.

Translated tmpfile name = *filename*.

Could not rename tmpfile to *filename*.

The program could not perform the final step in converting your file. Your converted file is stored under the name indicated on the second line of this message.

<b>NAME</b>	uptime – show how long the system has been up				
<b>SYNOPSIS</b>	<b>uptime</b>				
<b>DESCRIPTION</b>	The <code>uptime</code> command prints the current time, the length of time the system has been up, and the average number of jobs in the run queue over the last 1, 5 and 15 minutes. It is, essentially, the first line of a <code>w(1)</code> command.				
<b>EXAMPLES</b>	Below is an example of the output <code>uptime</code> provides:  <pre>example% uptime 10:47am up 27 day(s), 50 mins,  1 user,  load average: 0.18, 0.26, 0.20</pre>				
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
<b>SEE ALSO</b>	<code>w(1)</code> , <code>who(1)</code> , <code>whodo(1M)</code> , <code>attributes(5)</code>				
<b>NOTES</b>	<code>who -b</code> gives the time the system was last booted.				

users(1B)

**NAME** users – display a compact list of users logged in

**SYNOPSIS** /usr/ucb/users [*filename*]

**DESCRIPTION** The users utility lists the login names of the users currently on the system in a compact, one-line format.

Specifying *filename* tells users where to find its information; by default it checks /var/adm/utmpx.

Typing users is equivalent to typing who -q.

**EXAMPLES** **EXAMPLE 1** Listing current users

```
example% users
paul george ringoexample%
```

**FILES** /var/adm/utmpx

<b>NAME</b>	uucp, uulog, uuname – UNIX-to-UNIX system copy
<b>SYNOPSIS</b>	<pre> <b>uucp</b> [-c   -C] [-d   -f] [-ggrade] [-jmr] [-nuser] [-sfile]       [-xdebug_level] source-file destination-file  <b>uulog</b> [-ssys] [-fsystem] [-x] [-number] system  <b>uuname</b> [-c   -l] </pre>
<b>DESCRIPTION</b>	
<b>uucp</b>	The uucp utility copies files named by the <i>source-file</i> arguments to the <i>destination-file</i> argument.
<b>uulog</b>	The uulog utility queries a log file of uucp or uuxqt transactions in file <i>/var/uucp/.Log/uucico/system</i> or <i>/var/uucp/.Log/uuxqt/system</i> .
<b>uuname</b>	The uuname utility lists the names of systems known to uucp.
<b>OPTIONS</b>	
<b>uucp</b>	The following options are supported by uucp:
-c	Does not copy local file to the spool directory for transfer to the remote machine (default).
-C	Forces the copy of local files to the spool directory for transfer.
-d	Makes all necessary directories for the file copy (default).
-f	Does not make intermediate directories for the file copy.
-g <i>grade</i>	<i>grade</i> can be either a single letter, number, or a string of alphanumeric characters defining a service grade. The <code>uuglist</code> command can determine whether it is appropriate to use the single letter, number, or a string of alphanumeric characters as a service grade. The output from the <code>uuglist</code> command will be a list of service grades that are available, or a message that says to use a single letter or number as a grade of service.
-j	Prints the uucp job identification string on standard output. This job identification can be used by <code>uustat</code> to obtain the status of a uucp job or to terminate a uucp job. The uucp job is valid as long as the job remains queued on the local system.
-m	Sends mail to the requester when the copy is complete.
-n <i>user</i>	Notifies <i>user</i> on the remote system that a file was sent.
-r	Does not start the file transfer, just queue the job.
-s <i>file</i>	Reports status of the transfer to <i>file</i> . This option is accepted for compatibility, but it is ignored because it is insecure.

## uucp(1C)

	<p><b>-x</b> <i>debug_level</i>      Produce debugging output on standard output. <i>debug_level</i> is a number between 0 and 9. As <i>debug_level</i> increases to 9, more detailed debugging information is given. This option may not be available on all systems.</p>
<b>uulog</b>	<p>The following options cause <code>uulog</code> to print logging information:</p> <p><b>-s</b> <i>sys</i>                Prints information about file transfer work involving system <i>sys</i>.</p> <p><b>-f</b> <i>system</i>             Executes a <code>tail -f</code> command of the file transfer log for <i>system</i>. You must press <code>BREAK</code> to exit this function.</p> <p>Other options used in conjunction with the above options are:</p> <p><b>-x</b>                      Looks in the <code>uuxqt</code> log file for the given system.</p> <p><b>-number</b>                Executes a <code>tail</code> command of <i>number</i> lines.</p>
<b>uuname</b>	<p>The following options are supported by <code>uuname</code>:</p> <p><b>-c</b>                      Displays the names of systems known to <code>cu</code>. The two lists are the same, unless your machine is using different <code>Systems</code> files for <code>cu</code> and <code>uucp</code>. See the <code>Sysfiles</code> file.</p> <p><b>-l</b>                      Displays the local system name.</p>
<b>OPERANDS</b>	<p>The source file name may be a path name on your machine, or may have the form:</p> <p><i>system-name!pathname</i></p> <p>where <i>system-name</i> is taken from a list of system names that <code>uucp</code> knows about. <i>source_file</i> is restricted to no more than one <i>system-name</i>. The destination <i>system-name</i> may also include a list of system names such as</p> <p><i>system-name!system-name!...!system-name!pathname</i></p> <p>In this case, an attempt is made to send the file, using the specified route, to the destination. Care should be taken to ensure that intermediate nodes in the route are willing to forward information (see <code>NOTES</code> below for restrictions).</p> <p>For C-Shell users, the exclamation point (!) character must be surrounded by single quotes ('), or preceded by a backslash (\).</p> <p>The shell metacharacters <code>?</code>, <code>*</code> and <code>[...]</code> appearing in <i>pathname</i> will be expanded on the appropriate system.</p> <p>Pathnames may be one of the following:</p> <ol style="list-style-type: none"><li>1. An absolute pathname.</li><li>2. A pathname preceded by <code>~user</code> where <i>user</i> is a login name on the specified system and is replaced by that user's login directory.</li></ol>

3. A pathname preceded by `~/destination` where *destination* is appended to `/var/spool/uucppublic`. (Note: This destination will be treated as a filename unless more than one file is being transferred by this request or the destination is already a directory. To ensure that the destination is a directory, follow it with a forward slash (/). For example, `~/dan/` as the destination will create the directory `/var/spool/uucppublic/dan` if it does not exist and put the requested file(s) in that directory).

Anything else is prefixed by the current directory.

If the result is an erroneous path name for the remote system, the copy will fail. If the *destination-file* is a directory, the last part of the *source-file* name is used.

Invoking `uucp` with shell wildcard characters as the remote *source-file* invokes the `uux(1C)` command to execute the `uucp` command on the remote machine. The remote `uucp` command spools the files on the remote machine. After the first session terminates, if the remote machine is configured to transfer the spooled files to the local machine, the remote machine will initiate a call and send the files; otherwise, the user must "call" the remote machine to transfer the files from the spool directory to the local machine. This call can be done manually using `Uutry(1M)`, or as a side effect of another `uux(1C)` or `uucp` call.

Notice that the local machine must have permission to execute the `uucp` command on the remote machine in order for the remote machine to send the spooled files.

`uucp` removes execute permissions across the transmission and gives 0666 read and write permissions (see `chmod(2)`).

## ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `uucp`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `NLS_PATH`, and `TZ`.

## EXIT STATUS

The following exit values are returned:

- 0           Successful completion.  
>0          An error occurred.

## FILES

<code>/etc/uucp/*</code>	other data files
<code>/var/spool/uucp</code>	spool directories
<code>/usr/lib/uucp/*</code>	other program files
<code>/var/spool/uucppublic/*</code>	public directory for receiving and sending

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbnuu

## uucp(1C)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Standard

**SEE ALSO** mail(1), [uuglist\(1C\)](#), [uustat\(1C\)](#), [uux\(1C\)](#), [Uutry\(1M\)](#), [uuxqt\(1M\)](#), [chmod\(2\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**NOTES** For security reasons, the domain of remotely accessible files may be severely restricted. You will probably not be able to access files by path name; ask a responsible person on the remote system to send them to you. For the same reasons you will probably not be able to send files to arbitrary path names. As distributed, the remotely accessible files are those whose names begin `/var/spool/uucppublic` (equivalent to `~/`).

All files received by `uucp` will be owned by `uucp`.

The `-m` option will only work when sending files or receiving a single file. Receiving multiple files specified by special shell characters `?`, `&`, and `[ . . . ]` will not activate the `-m` option.

The forwarding of files through other systems may not be compatible with the previous version of `uucp`. If forwarding is used, all systems in the route must have compatible versions of `uucp`.

Protected files and files that are in protected directories that are owned by the requester can be sent by `uucp`. However, if the requester is `root`, and the directory is not searchable by "other" or the file is not readable by "other", the request will fail.

Strings that are passed to remote systems may not be evaluated in the same locale as the one in use by the process that invoked `uucp` on the local system.

Configuration files must be treated as C (or POSIX) locale text files.

<b>NAME</b>	uuencode, uudecode – encode a binary file, or decode its encoded representation
<b>SYNOPSIS</b>	<p><b>uuencode</b> [<i>source-file</i>] <i>decode_pathname</i></p> <p><b>uuencode</b> [-m] [<i>source-file</i>] <i>decode_pathname</i></p> <p><b>uudecode</b> [-p] [<i>encoded-file</i>]</p> <p><b>uudecode</b> [-o <i>outfile</i>] [<i>encoded-file</i>]</p>
<b>DESCRIPTION</b>	<p>These commands encode and decode files as follows:</p> <p><b>uuencode</b> The uuencode utility converts a binary file into an encoded representation that can be sent using mail(1). It encodes the contents of <i>source-file</i>, or the standard input if no <i>source-file</i> argument is given. The <i>decode_pathname</i> argument is required. The <i>decode_pathname</i> is included in the encoded file's header as the name of the file into which uudecode is to place the binary (decoded) data. uuencode also includes the permission modes of <i>source-file</i> (except setuid, setgid, and sticky-bits), so that <i>decode_pathname</i> is recreated with those same permission modes.</p> <p><b>uudecode</b> The uudecode utility reads an <i>encoded-file</i>, strips off any leading and trailing lines added by mailer programs, and recreates the original binary data with the filename and the mode specified in the header.</p> <p>The encoded file is an ordinary portable character set text file; it can be edited by any text editor. It is best only to change the mode or <i>decode_pathname</i> in the header to avoid corrupting the decoded binary.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <p><b>uuencode</b> -m Encodes <i>source-file</i> using Base64 encoding and sends it to standard output.</p> <p><b>uudecode</b> -o <i>outfile</i> Specifies a file pathname that should be used instead of any pathname contained in the input data. Specifying an <i>outfile</i> option-argument of /dev/stdout indicates standard output. This allows uudecode to be used in a pipeline.</p> <p>-p Decodes <i>encoded-file</i> and sends it to standard output. This allows uudecode to be used in a pipeline.</p>
<b>OPERANDS</b>	<p>The following operands are supported by uuencode and uudecode:</p> <p><b>uuencode</b> <i>decode_pathname</i> The pathname of the file into which the uudecode utility will place the decoded file. If there are characters in <i>decode_pathname</i> that are not in the portable filename character set, the results are unspecified.</p> <p><i>source-file</i> A pathname of the file to be encoded.</p> <p><b>uudecode</b> <i>encoded-file</i> The pathname of a file containing the output of uuencode.</p>
<b>USAGE</b>	See largefile(5) for the description of the behavior of uuencode and uudecode when encountering files greater than or equal to 2 Gbyte ( 2 <sup>31</sup> bytes).

## uuencode(1C)

### ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `uuencode` and `uudecode`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

### OUTPUT

`stdout`

### uuencode Base64 Algorithm

The standard output is a text file, encoded in the character set of the current locale, that begins with the line:

```
begin-base64 %s %s\  
, mode, decode_pathname
```

and ends with the line:

```
====\  
\\
```

In both cases, the lines have no preceding or trailing blank characters.

The encoding process represents 24-bit groups of input bits as output strings of four encoded characters. Proceeding from left to right, a 24-bit input group is formed by concatenating three 8-bit input groups. Each 24-bit input group is then treated as four concatenated 6-bit groups, each of which is translated into a single digit in the Base64 alphabet. When encoding a bit stream by means of the Base64 encoding, the bit stream is presumed to be ordered with the most-significant bit first. That is, the first bit in the stream is the high-order bit in the first byte, and the eighth bit is the low-order bit in the first byte, and so on. Each 6-bit group is used as an index into an array of 64 printable characters, as shown in the following table.

Value	Encoding	Value	Encoding	Value	Encoding	Value	Encoding
0	A	17	R	34	i	51	z
1	B	18	S	35	j	52	0
2	C	19	T	36	k	53	1
3	D	20	U	37	l	54	2
4	E	21	V	38	m	55	3
5	F	22	W	39	n	56	4
6	G	23	X	40	o	57	5
7	H	24	Y	41	p	58	6
8	I	25	Z	42	q	59	7
9	J	26	a	43	r	60	8
10	K	27	b	44	s	61	9
11	L	28	c	45	t	62	+
12	M	29	d	46	u	63	/
13	N	30	e	47	v		
14	O	31	f	48	w	(pad)	=
15	P	32	g	49	x		
16	Q	33	h	50	y		

The character referenced by the index is placed in the output string.

The output stream (encoded bytes) is represented in lines of no more than 76 characters each. All line breaks or other characters not found in the table are ignored by decoding software (see `uudecode`).

Special processing is performed if fewer than 24 bits are available at the end of a message or encapsulated part of a message. A full encoding quantum is always completed at the end of a message. When fewer than 24 input bits are available in an input group, zero bits are added on the right to form an integral number of 6-bit groups. Output character positions that are not required to represent actual input data are set to the equals (=) character. Since all Base64 input is an integral number of octets, only the following cases can arise:

1. The final quantum of encoding input is an integral multiple of 24 bits. Here, the final unit of encoded output is an integral multiple of four characters with no '=' padding.
2. The final quantum of encoding input is exactly 16 bits. Here, the final unit of encoded output is three characters followed by one '=' padding character.
3. The final quantum of encoding input is exactly 8 bits. Here, the final unit of encoded output is two characters followed by two '=' padding characters.

A terminating "====" evaluates to nothing and denotes the end of the encoded data.

### uuencode Historical Algorithm

The standard output is a text file (encoded in the character set of the current locale) that begins with the line:

```
begin %s %s\n, mode, decode_pathname
```

and ends with the line:

```
end\n
```

In both cases, the lines have no preceding or trailing blank characters.

The algorithm that is used for lines between `begin` and `end` takes three octets as input and writes four characters of output by splitting the input at six-bit intervals into four octets, containing data in the lower six bits only. These octets are converted to characters by adding a value of `0x20` to each octet, so that each octet is in the range `0x20–0x5E`, and each octet is assumed to represent a printable character. Each octet is then translated into the corresponding character codes for the codeset in use in the current locale. For example, the octet `0x41`, representing 'A', would be translated to 'A' in the current codeset, such as `0xc1` if the codeset were EBCDIC.

Where the bits of two octets are combined, the least significant bits of the first octet are shifted left and combined with the most significant bits of the second octet shifted right. Thus, the three octets `A`, `B`, `C` are converted into the four octets:

```
0x20 + (( A >> 2                                     ) & 0x3F)
0x20 + (((A << 4) ((B >> 4) & 0xF)) & 0x3F)
0x20 + (((B << 2) ((C >> 6) & 0x3)) & 0x3F)
0x20 + (( C                                     ) & 0x3F)
```

## uuencode(1C)

These octets are then translated into the local character set.

Each encoded line contains a length character, equal to the number of characters to be decoded plus 0x20 translated to the local character set as described above, followed by the encoded characters. The maximum number of octets to be encoded on each line is 45.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
Interface Stability	Standard

**SEE ALSO** `mail(1)`, `mailx(1)`, `uucp(1C)`, `uux(1C)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `standards(5)`

**NOTES** The size of the encoded file is expanded by 35% (3 bytes become 4, plus control information), causing it to take longer to transmit than the equivalent binary.

The user on the remote system who is invoking `uudecode` (typically `uucp`) must have write permission on the file specified in the `decode_pathname`.

If you invoke `uuencode` and then execute `uudecode` on a file in the same directory, you will overwrite the original file.

**NAME** uuglist – print the list of service grades that are available on this UNIX system

**SYNOPSIS** **uuglist** [-u]

**DESCRIPTION** uuglist prints the list of service grades that are available on the system to use with the -g option of **uucp(1C)** and **uux(1C)**.

**OPTIONS** -u List the names of the service grades that the user is allowed to use with the -g option of the uucp and uux commands.

**FILES** /etc/uucp/Grades contains the list of service grades

**ATTRIBUTES** See **attributes(5)** for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbnuu

**SEE ALSO** **uucp(1C)**, **uux(1C)**, **attributes(5)**

## uustat(1C)

<b>NAME</b>	uustat – uucp status inquiry and job control
<b>SYNOPSIS</b>	<b>uustat</b> [ [-m]   [-p]   [-q]   [ -k <i>jobid</i> [-n]]   [ -r <i>jobid</i> [-n]] ] <b>uustat</b> [-a] [ -s <i>system</i> [-j]] [-u <i>user</i> ] [-S <i>qric</i> ] <b>uustat</b> -t <i>system</i> [-c] [-d <i>number</i> ]
<b>DESCRIPTION</b>	The uustat utility functions in the following three areas: <ol style="list-style-type: none"><li>1. Displays the general status of, or cancels, previously specified uucp commands.</li><li>2. Provides remote system performance information, in terms of average transfer rates or average queue times.</li><li>3. Provides general remote system-specific and user-specific status of uucp connections to other systems.</li></ol>
<b>OPTIONS</b>	The following options are supported:
<b>General Status</b>	These options obtain general status of, or cancel, previously specified uucp commands: <ul style="list-style-type: none"><li>-a Lists all jobs in queue.</li><li>-j Lists the total number of jobs displayed. The -j option can be used in conjunction with the -a or the -s option.</li><li>-k<i>jobid</i> Kills the uucp request whose job identification is <i>jobid</i>. The killed uucp request must belong to the user issuing the uustat command unless the user is the super-user or uucp administrator. If the job is killed by the super-user or uucp administrator, electronic mail is sent to the user.</li><li>-m Reports the status of accessibility of all machines.</li><li>-n Suppresses all standard output, but not standard error. The -n option is used in conjunction with the -k and -r options.</li><li>-p Executes the command <code>ps -flp</code> for all the process-ids that are in the lock files.</li><li>-q Lists the jobs queued for each machine. If a status file exists for the machine, its date, time and status information are reported. In addition, if a number appears in parentheses next to the number of C or X files, it is the age in days of the oldest C./X. file for that system. The <code>Retry</code> field represents the number of hours until the next possible call. The <code>Count</code> is the number of failure attempts. <i>Note:</i> For systems with a moderate number of outstanding jobs, this could take 30 seconds or more of real-time to execute. An example of the output produced by the -q option is: <pre>eagle    3C    04/07-11:07    NO DEVICES AVAILABLE mh3bs3   2C    07/07-10:42    SUCCESSFUL</pre></li></ul>

This indicates the number of command files that are waiting for each system. Each command file may have zero or more files to be sent (zero means to call the system and see if work is to be done). The date and time refer to the previous interaction with the system followed by the status of the interaction.

**-r*jobid*** Rejuvenates *jobid*. The files associated with *jobid* are touched so that their modification time is set to the current time. This prevents the cleanup daemon from deleting the job until the jobs' modification time reaches the limit imposed by the daemon.

### Remote System Status

These options provide remote system performance information, in terms of average transfer rates or average queue times. The **-c** and **-d** options can only be used in conjunction with the **-t** option:

**-t*system*** Reports the average transfer rate or average queue time for the past 60 minutes for the remote *system*. The following parameters can only be used with this option:

**-c** Average queue time is calculated when the **-c** parameter is specified and average transfer rate when **-c** is not specified. For example, the command:

```
example% uustat -teagle -d50 -c
```

produces output in the following format:

```
average queue time to eagle for last 50 minutes: 5 seconds
```

The same command without the **-c** parameter produces output in the following format:

```
average transfer rate with eagle for last 50 minutes: 2000.88 bytes/sec
```

**-d*number*** *number* is specified in minutes. Used to override the 60 minute default used for calculations. These calculations are based on information contained in the optional performance log and therefore may not be available. Calculations can only be made from the time that the performance log was last cleaned up.

### User- or System-Specific Status

These options provide general remote system-specific and user-specific status of uucp connections to other systems. Either or both of the following options can be specified with `uustat`. The **-j** option can be used in conjunction with the **-s** option to list the total number of jobs displayed:

**-s*system*** Reports the status of all uucp requests for remote system *system*.

**-u*user*** Reports the status of all uucp requests issued by *user*.

Output for both the **-s** and **-u** options has the following format:

## uustat(1C)

```
eagleN1bd7 4/07-11:07 S eagle dan 522 /home/dan/A
eagleC1bd8 4/07-11:07 S eagle dan 59 D.3b2a12ce4924
           4/07-11:07 S eagle dan rmail mike
```

With the above two options, the first field is the *jobid* of the job. This is followed by the date/time. The next field is an S if the job is sending a file or an R if the job is requesting a file. The next field is the machine where the file is to be transferred. This is followed by the user-id of the user who queued the job. The next field contains the size of the file, or in the case of a remote execution (rmail is the command used for remote mail), the name of the command. When the size appears in this field, the file name is also given. This can either be the name given by the user or an internal name (for example, D.3b2a12ce4924) that is created for data files associated with remote executions (rmail in this example).

**-Sqrlic** Reports the job state:

q	for queued jobs
r	for running jobs
i	for interrupted jobs
c	for completed jobs

A job is queued if the transfer has not started. A job is running when the transfer has begun. A job is interrupted if the transfer began but was terminated before the file was completely transferred. A completed job is a job that successfully transferred. The completed state information is maintained in the accounting log, which is optional and therefore may be unavailable. The parameters can be used in any combination, but at least one parameter must be specified. The **-s** option can also be used with **-s** and **-u** options. The output for this option is exactly like the output for **-s** and **-u** except that the job states are appended as the last output word. Output for a completed job has the following format:

```
eagleC1bd3 completed
```

When no options are given, **uustat** writes to standard output the status of all **uucp** requests issued by the current user.

### ENVIRONMENT VARIABLES

See **environ(5)** for descriptions of the following environment variables that affect the execution of **uustat**: **LANG**, **LC\_ALL**, **LC\_COLLATE**, **LC\_CTYPE**, **LC\_MESSAGES**, **LC\_TIME**, **NLSPATH**, and **TZ**.

### EXIT STATUS

The following exit values are returned:

0	Successful completion.
>0	An error occurred.

### FILES

<b>/var/spool/uucp/*</b>	spool directories
<b>/var/uucp/.Admin/account</b>	accounting log

/var/uucp/.Admin/perflog            performance log

**ATTRIBUTES**    See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbnuu
Interface Stability	Standard

**SEE ALSO**    `uucp(1C)`, `attributes(5)`, `environ(5)`, `standards(5)`

**DIAGNOSTICS**    The `-t` option produces no message when the data needed for the calculations is not being recorded.

**NOTES**        After the user has issued the `uucp` request, if the file to be transferred is moved, deleted or was not copied to the spool directory (`-C` option) when the `uucp` request was made, `uustat` reports a file size of `-99999`. This job will eventually fail because the file(s) to be transferred can not be found.

## uuto(1C)

<b>NAME</b>	uuto, uupick – public UNIX-to-UNIX system file copy														
<b>SYNOPSIS</b>	<b>uuto</b> [-mp] <i>source-file... destination</i> <b>uupick</b> [-s <i>system</i> ]														
<b>DESCRIPTION</b>	<p><b>uuto</b> uuto sends <i>source-file</i> to <i>destination</i>. uuto uses the <b>uucp(1C)</b> facility to send files, while it allows the local system to control the file access. A source-file name is a path name on your machine. Destination has the form:</p> <p><i>system</i>[!<i>system</i>] ... !<i>user</i></p> <p>where <i>system</i> is taken from a list of system names that uucp knows about. <i>User</i> is the login name of someone on the specified system.</p> <p>The files (or sub-trees if directories are specified) are sent to PUBDIR on <i>system</i>, where PUBDIR is a public directory defined in the uucp source. By default, this directory is /var/spool/uucppublic. Specifically the files are sent to</p> <p>PUBDIR/<i>receive</i>/<i>user</i>/<i>mysystem</i>/files.</p> <p>The recipient is notified by mail(1) of the arrival of files.</p> <p><b>uupick</b> uupick accepts or rejects the files transmitted to the user. Specifically, uupick searches PUBDIR for files destined for the user. For each entry (file or directory) found, the following message is printed on standard output:</p> <p>from <i>system sysname</i>: [file <i>file-name</i>] [dir <i>dirname</i>] ?</p> <p>uupick then reads a line from standard input to determine the disposition of the file:</p> <table><tr><td>&lt;new-line&gt;</td><td>Go to next entry.</td></tr><tr><td>d</td><td>Delete the entry.</td></tr><tr><td>m [ <i>dir</i> ]</td><td>Move the entry to named directory <i>dir</i>. If <i>dir</i> is not specified as a complete path name (in which \$HOME is legitimate), a destination relative to the current directory is assumed. If no destination is given, the default is the current directory.</td></tr><tr><td>a [ <i>dir</i> ]</td><td>Same as m above, except it moves all the files sent from <i>system</i>.</td></tr><tr><td>p</td><td>Print the content of the file.</td></tr><tr><td>q</td><td>Stop.</td></tr><tr><td>EOT (control-d)</td><td>Same as q.</td></tr></table>	<new-line>	Go to next entry.	d	Delete the entry.	m [ <i>dir</i> ]	Move the entry to named directory <i>dir</i> . If <i>dir</i> is not specified as a complete path name (in which \$HOME is legitimate), a destination relative to the current directory is assumed. If no destination is given, the default is the current directory.	a [ <i>dir</i> ]	Same as m above, except it moves all the files sent from <i>system</i> .	p	Print the content of the file.	q	Stop.	EOT (control-d)	Same as q.
<new-line>	Go to next entry.														
d	Delete the entry.														
m [ <i>dir</i> ]	Move the entry to named directory <i>dir</i> . If <i>dir</i> is not specified as a complete path name (in which \$HOME is legitimate), a destination relative to the current directory is assumed. If no destination is given, the default is the current directory.														
a [ <i>dir</i> ]	Same as m above, except it moves all the files sent from <i>system</i> .														
p	Print the content of the file.														
q	Stop.														
EOT (control-d)	Same as q.														

!command                   Escape to the shell to do command.  
 \*                            Print a command summary.

**OPTIONS**

**uuto**   The following options are supported by uuto:

-m       Send mail to the sender when the copy is complete.  
 -p       Copy the source file into the spool directory before transmission.

**uupick**   The following option is supported by uupick:

-s *system*       Search only the PUBDIR for files sent from *system*.

**OPERANDS**   The following operands are supported for uuto:

*destination*       A string of the form:  
                       *system-name ! user*

where *system-name* is taken from a list of system names that uucp knows about; see uuname. The argument *user* is the login name of someone on the specified system. The destination *system-name* can also be a list of names such as

*system-name ! system-name ! ... ! system-name ! user*

in which case, an attempt is made to send the file via the specified route to the destination. Care should be taken to ensure that intermediate nodes in the route are willing to forward information.

*source-file*       A pathname of a file on the local system to be copied to *destination*.

**ENVIRONMENT VARIABLES**   See `environ(5)` for descriptions of the following environment variables that affect the execution of uuto and uupick: LC\_TYPE, LC\_MESSAGES, and NLSPATH.

**EXIT STATUS**   The following exit values are returned:

0        Successful completion.  
 >0       An error occurred.

**FILES**   PUBDIR   /var/spool/uucppublic public directory

**ATTRIBUTES**   See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbnuu

uuto(1C)

**SEE ALSO** mail(1), [uucp\(1C\)](#), [uustat\(1C\)](#), [uux\(1C\)](#), [uucleanup\(1M\)](#), [attributes\(5\)](#)

**NOTES** In order to send files that begin with a dot (for instance, `.profile`), the files must be qualified with a dot. For example, the following files are correct:

```
.profile .prof* .profil?
```

The following files are incorrect:

```
*prof* ?profile
```

<b>NAME</b>	uux – UNIX-to-UNIX system command execution
<b>SYNOPSIS</b>	<b>uux</b> [-] [-bcCjnprz] [-a <i>name</i> ] [-g <i>grade</i> ] [-s <i>filename</i> ] [-x <i>debug_level</i> ] <i>command-string</i>
<b>DESCRIPTION</b>	<p>The uux utility will gather zero or more files from various systems, execute a command on a specified system and then send standard output to a file on a specified system.</p> <p><i>Note:</i> For security reasons, most installations limit the list of commands executable on behalf of an incoming request from uux, permitting only the receipt of mail (see mail(1)). (Remote execution permissions are defined in /etc/uucp/Permissions.)</p> <p>The <i>command-string</i> is made up of one or more arguments that look like a shell command line, except that the command and file names may be prefixed by <i>system-name!</i>. A null <i>system-name</i> is interpreted as the local system.</p> <p>File names may be one of the following:</p> <ul style="list-style-type: none"> <li>■ An absolute path name.</li> <li>■ A path name preceded by <i>~xxx</i>, where <i>xxx</i> is a login name on the specified system and is replaced by that user's login directory.</li> </ul> <p>Anything else is prefixed by the current directory.</p> <p>As an example, the command:</p> <pre>example% uux "!diff sys1!/home/dan/filename1 \           sys2!/a4/dan/filename2 &gt; !~/dan/filename.diff"</pre> <p>will get the <i>filename1</i> and <i>filename2</i> files from the <i>sys1</i> and <i>sys2</i> machines, execute a <i>diff(1)</i> command and put the results in <i>filename.diff</i> in the local <i>PUBDIR/dan/</i> directory. <i>PUBDIR</i> is a public directory defined in the uucp source. By default, this directory is <i>/var/spool/uucppublic</i>.</p> <p>Any special shell characters (such as <i>&lt; &gt; ;  </i>) should be quoted either by quoting the entire <i>command-string</i>, or quoting the special characters as individual arguments. The redirection operators <i>&gt;&gt;</i>, <i>&lt;&lt;</i>, <i>&gt; </i>, and <i>&gt;&amp;</i> cannot be used.</p> <p>uux will attempt to get all appropriate files to the specified system where they will be processed. For files that are output files, the file name must be escaped using parentheses. For example, the command:</p> <pre>example% uux "a!cut -f1 b!/usr/filename &gt; c!/usr/filename"</pre> <p>gets <i>/usr/filename</i> from system <i>b</i> and sends it to system <i>a</i>, performs a <i>cut</i> command on that file and sends the result of the <i>cut</i> command to system <i>c</i>.</p> <p>uux will notify you if the requested command on the remote system was disallowed. This notification can be turned off by the <i>-n</i> option. The response comes by remote mail from the remote machine.</p>
<b>OPTIONS</b>	The following options are supported:

## uux(1C)

-	The standard input to uux is made the standard input to the <i>command-string</i> .				
-a <i>name</i>	Uses <i>name</i> as the user job identification replacing the initiator user-id. (Notification will be returned to user-id <i>name</i> .)				
-b	Returns whatever standard input was provided to the uux command if the exit status is non-zero.				
-c	Does not copy local file to the spool directory for transfer to the remote machine (default).				
-C	Forces the copy of local files to the spool directory for transfer.				
-g <i>grade</i>	<i>grade</i> can be either a single letter, number, or a string of alphanumeric characters defining a service grade. The <a href="#">uuglist(1C)</a> command determines whether it is appropriate to use the single letter, number, or a string of alphanumeric characters as a service grade. The output from the <i>uuglist</i> command will be a list of service grades that are available or a message that says to use a single letter or number as a grade of service.				
-j	Outputs the jobid string on the standard output which is the job identification. This job identification can be used by <a href="#">uustat(1C)</a> to obtain the status or terminate a job.				
-n	Does not notify the user if the command fails.				
-p	Same as -. The standard input to uux is made the standard input to the <i>command-string</i> .				
-r	Does not start the file transfer, but just queues the job.				
-s <i>filename</i>	Reports status of the transfer in <i>filename</i> . This option is accepted for compatibility, but it is ignored because it is insecure.				
-x <i>debug_level</i>	Produces debugging output on the standard output. <i>debug_level</i> is a number between 0 and 9. As <i>debug_level</i> increases to 9, more detailed debugging information is given.				
-z	Sends success notification to the user.				
<b>ENVIRONMENT VARIABLES</b>	See <a href="#">environ(5)</a> for descriptions of the following environment variables that affect the execution of uux: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.				
<b>EXIT STATUS</b>	The following exit values are returned: 0 Successful completion. >0 An error occurred.				
<b>FILES</b>	<table><tr><td>/etc/uucp/*</td><td>other data and programs</td></tr><tr><td>/etc/uucp/Permissions</td><td>remote execution permissions</td></tr></table>	/etc/uucp/*	other data and programs	/etc/uucp/Permissions	remote execution permissions
/etc/uucp/*	other data and programs				
/etc/uucp/Permissions	remote execution permissions				

/usr/lib/uucp/\*                    other programs  
 /var/spool/uucp                    pool directories

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbnuu
Interface Stability	Standard

**SEE ALSO** cut(1), mail(1), [uucp\(1C\)](#), [uuglist\(1C\)](#), [uustat\(1C\)](#), attributes(5), environ(5), standards(5)

**NOTES** The execution of commands on remote systems takes place in an execution directory known to the uucp system.

All files required for the execution will be put into this directory unless they already reside on that machine. Therefore, the simple file name (without path or machine reference) must be unique within the uux request. The following command will NOT work:

```
example% uux "a!diff b!/home/dan/xyz c!/home/dan/xyz > !xyz.diff"
```

But the command:

```
example% uux "a!diff a!/home/dan/xyz c!/home/dan/xyz > !xyz.diff"
```

*will* work (if `diff` is a permitted command.)

Protected files and files that are in protected directories that are owned by the requester can be sent in commands using uux. However, if the requester is root, and the directory is not searchable by "other", the request will fail.

The following restrictions apply to the shell pipeline processed by uux:

- In gathering files from different systems, pathname expansion is not performed by uux. Thus, a request such as

```
uux "c89 remsys!~/*.c"
```

would attempt to copy the file named literally `*.c` to the local system.

- Only the first command of a shell pipeline may have a *system-name*!. All other commands are executed on the system of the first command.
- The use of the shell metacharacter `*` will probably not do what you want it to do.
- The shell tokens `<<` and `>>` are not implemented.
- The redirection operators `>>`, `<<`, `>|`, and `>&` cannot be used.
- The reserved word `!` cannot be used at the head of the pipeline to modify the exit status.

uux(1C)

- Alias substitution is not performed.

<b>NAME</b>	vacation – reply to mail automatically
<b>SYNOPSIS</b>	<p><b>vacation</b> [-I]</p> <p><b>vacation</b> [-a <i>alias</i>] [-e <i>filter_file</i>] [-f <i>database_file</i>] [-j] [-m <i>message_file</i>]  [-s <i>sender</i>] [-tN] <i>username</i></p>
<b>DESCRIPTION</b>	The <code>vacation</code> utility automatically replies to incoming mail.
<b>Installation</b>	<p>The installation consists of an interactive program which sets up <code>vacation</code>'s basic configuration.</p> <p>To install <code>vacation</code>, type it with no arguments on the command line. The program creates a <code>.vacation.msg</code> file, which contains the message that is automatically sent to all senders when <code>vacation</code> is enabled, and starts an editor for you to modify the message. (See USAGE section.) Which editor is invoked is determined by the <code>VISUAL</code> or <code>EDITOR</code> environment variable, or <code>vi(1)</code> if neither of those environment variables are set.</p> <p>A <code>.forward</code> file is also created if one does not exist in your home directory. Once created, the <code>.forward</code> file will contain a line of the form:</p> <p>One copy of an incoming message is sent to the <i>username</i> and another copy is piped into <code>vacation</code>:</p> <pre>\username, " usr/bin/vacation username"</pre> <p>If a <code>.forward</code> file is present in your home directory, it will ask whether you want to remove it, which disables <code>vacation</code> and ends the installation.</p> <p>The program automatically creates <code>.vacation.pag</code> and <code>.vacation.dir</code>, which contain a list of senders when <code>vacation</code> is enabled.</p>
<b>Activation and Deactivation</b>	The presence of the <code>.forward</code> file determines whether or not <code>vacation</code> is disabled or enabled. To disable <code>vacation</code> , remove the <code>.forward</code> file, or move it to a new name.
<b>Initialization</b>	The <code>-I</code> option clears the <code>vacation</code> log files, <code>.vacation.pag</code> and <code>.vacation.dir</code> , erasing the list of senders from a previous <code>vacation</code> session. (See OPTIONS section.)
<b>Additional Configuration</b>	<code>vacation</code> provides configuration options that are not part of the installation, these being <code>-a</code> , <code>-e</code> , <code>-f</code> , <code>-j</code> , <code>-m</code> , <code>-s</code> , and <code>-t</code> . (See OPTIONS section.)
<b>OPTIONS</b>	<p>The following options are supported:</p> <p><code>-I</code>        Initializes the <code>.vacation.pag</code> and <code>.vacation.dir</code> files and enables <code>vacation</code>. If the <code>-I</code> flag is not specified, and a <i>user</i> argument is given, <code>vacation</code> reads the first line from the standard input (for a <code>From:</code> line, no colon). If absent, it produces an error message.</p> <p>Options <code>-a</code>, <code>-e</code>, <code>-f</code>, <code>-j</code>, <code>-m</code>, <code>-s</code>, and <code>-t</code> are configuration options to be used in conjunction with <code>vacation</code> in the <code>.forward</code> file, not on the command line. For example,</p>

## vacation(1)

```
\username, "|/usr/bin/vacation -t1m username"
```

repeats replies to the sender every minute.

- a *alias* Indicates that *alias* is one of the valid aliases for the user running *vacation*, so that mail addressed to that alias generates a reply.
- e *filter\_file* Uses *filter\_file* instead of *.vacation.filter* as the source of the domain and email address filters.
- f *database\_file* Uses *database\_file* instead of *.vacation* as the base name for the database file.
- j Does not check whether the recipient appears in the *To:* or the *Cc:* line. Warning: use of this option can result in vacation replies being sent to mailing lists and other inappropriate places; its use is therefore strongly discouraged.
- m *message\_file* Uses *~/message\_file* as the message to send for the reply instead of *~/vacation.msg*. *message\_file* is a relative path to the desired vacation message file. To prevent directory/file "not found" errors, *message\_file* should be on the same disk partition as *~/forward*.
- s *sender* Replies to *sender* instead of the value read from the UNIX *From* line of the incoming message.
- tN Changes the interval between repeat replies to the same sender. The default is 1 week. A trailing *s*, *m*, *h*, *d*, or *w* scales *N* to seconds, minutes, hours, days, or weeks, respectively.

### USAGE

*.vacation.msg* should include a header with at least a *Subject:* line (it should not include a *To:* line). For example:

```
Subject: I am on vacation
I am on vacation until July 22. If you have something urgent,
please contact Joe Jones (jones@fB0).
--John
```

If the string *\$\$SUBJECT* appears in the *.vacation.msg* file, it is replaced with the subject of the original message when the reply is sent. Thus, a *.vacation.msg* file such as

```
Subject: I am on vacation
I am on vacation until July 22.
Your mail regarding "$SUBJECT" will be read when I return.
If you have something urgent, please contact
Joe Jones (jones@fB0).
--John
```

will include the subject of the message in the reply.

No message is sent if the `To:` or the `Cc:` line does not list the user to whom the original message was sent or one of a number of aliases for them, if the initial `From` line includes the string `-REQUEST@`, or if a `Precedence: bulk` or `Precedence: junk` line is included in the header.

`vacation` will also not respond to mail from either `postmaster` or `Mailer-Daemon`.

In addition to the above criteria, if a `.vacation.filter` file exists, it is used to constrain further the set of addresses to which a reply is sent. Each line in that file should be either a domain name or an email address. If the incoming sender address matches one of the lines in the file, a reply is sent. If no lines match, no reply is sent. For lines containing an email address, the match must be exact, except for case, which is ignored. For lines containing a domain name, the sender address must be either `something@domain-name` or `something@something.domain-name`. A sample filter file might look like the following:

```
sun.com
mydomain.com
onefriend@hisisp.com
anotherfriend@herisp.com
```

*Note:* Blank lines and lines starting with “#” are ignored.

#### FILES

```
~/ .forward
~/ .vacation.filter
~/ .vacation.msg
```

A list of senders is kept in the dbm format files `.vacation.pag` and `.vacation.dir` in your home directory. These files are dbm files and cannot be viewed directly with text editors.

vc(1)

<b>NAME</b>	vc – version control		
<b>SYNOPSIS</b>	<b>vc</b> [-a] [-t] [-c <i>char</i> ] [-s] [ <i>keyword=value... keyword=value</i> ]		
<b>DESCRIPTION</b>	<p>This command is obsolete and will be removed in the next release.</p> <p>The <b>vc</b> command copies lines from the standard input to the standard output under control of its arguments and of “control statements” encountered in the standard input. In the process of performing the copy operation, user-declared <i>keywords</i> may be replaced by their string <i>value</i> when they appear in plain text and/or control statements.</p> <p>The copying of lines from the standard input to the standard output is conditional, based on tests (in control statements) of keyword values specified in control statements or as <b>vc</b> command arguments.</p> <p>A control statement is a single line beginning with a control character, except as modified by the <b>-t</b> keyletter (see below). The default control character is colon (:), except as modified by the <b>-c</b> keyletter (see below). Input lines beginning with a backslash (\) followed by a control character are not control lines and are copied to the standard output with the backslash removed. Lines beginning with a backslash followed by a non-control character are copied in their entirety.</p> <p>A keyword is composed of 9 or less alphanumeric; the first must be alphabetic. A value is any ASCII string that can be created with <b>ed</b>; a numeric value is an unsigned string of digits. Keyword values may not contain blanks or tabs.</p> <p>Replacement of keywords by values is done whenever a keyword surrounded by control characters is encountered on a version control statement. The <b>-a</b> keyletter (see below) forces replacement of keywords in all lines of text. An uninterpreted control character may be included in a value by preceding it with \. If a literal \ is desired, then it too must be preceded by \.</p>		
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"><li><b>-a</b> Forces replacement of keywords surrounded by control characters with their assigned value in all text lines and not just in <b>vc</b> statements.</li><li><b>-t</b> All characters from the beginning of a line up to and including the first tab character are ignored for the purpose of detecting a control statement. If a control statement is found, all characters up to and including the tab are discarded.</li><li><b>-cchar</b> Specifies a control character to be used in place of the “:” default.</li><li><b>-s</b> Silences warning messages (not error) that are normally printed on the diagnostic output.</li></ul> <p><b>vc</b> recognizes the following version control statements:</p> <table><tr><td><code>:dc1 keyword[, ..., keyword]</code></td><td>Declare keywords. All keywords must be declared.</td></tr></table>	<code>:dc1 keyword[, ..., keyword]</code>	Declare keywords. All keywords must be declared.
<code>:dc1 keyword[, ..., keyword]</code>	Declare keywords. All keywords must be declared.		

```
:asg keyword=value
```

Assign values to keywords. An `asg` statement overrides the assignment for the corresponding keyword on the `vc` command line and all previous `asg` statements for that keyword. Keywords that are declared but are not assigned values have null values.

```
:if condition
```

```
...
```

```
:end
```

Skip lines of the standard input. If the condition is true, all lines between the `if` statement and the matching `end` statement are copied to the standard output. If the condition is false, all intervening lines are discarded, including control statements. Note: Intervening `if` statements and matching `end` statements are recognized solely for the purpose of maintaining the proper `if-end` matching.

The syntax of a condition is:

```
<cond>      ::= [ "not" ] <or>
<or>        ::= <and> | <and> " | "
              <or>
<and>       ::= <exp> | <exp> "&"
              <and>
<exp>       ::= " (" <or> ")" |
              <value> <op> <value>
<op>        ::= "=" | "!=" | "<" |
              ">"
<value>     ::= <arbitrary ASCII
              string> | <numeric
              string>
```

The available operators and their meanings are:

```
=          equal
!=         not equal
&         and
|         or
>         greater than
```

vc(1)

	<	less than
	( )	used for logical groupings
	not	may only occur immediately after the <code>if</code> , and when present, inverts the value of the entire condition
	The <code>&gt;</code> and <code>&lt;</code> operate only on unsigned integer values (for example, <code>: 012 &gt; 12</code> is false). All other operators take strings as arguments (for example, <code>: 012 != 12</code> is true).	
	The precedence of the operators (from highest to lowest) is:	
	<code>= != &gt; &lt;</code>	all of equal precedence
	<code>&amp;</code>	
	<code> </code>	
	Parentheses may be used to alter the order of precedence.	
	Values must be separated from operators or parentheses by at least one blank or tab.	
<code>: :text</code>	Replace keywords on lines that are copied to the standard output. The two leading control characters are removed, and keywords surrounded by control characters in text are replaced by their value before the line is copied to the output file. This action is independent of the <code>-a</code> keyletter.	
<code>:on</code>		
<code>:off</code>	Turn on or off keyword replacement on all lines.	
<code>:ctl char</code>	Change the control character to <i>char</i> .	
<code>:msg message</code>	Print <i>message</i> on the diagnostic output.	
<code>:err message</code>	Print <i>message</i> followed by:	
	ERROR: err statement on line ... (915)	

vc(1)

on the diagnostic output. vc halts execution, and returns an exit code of 1.

## vgrind(1)

<b>NAME</b>	vgrind – grind nice program listings								
<b>SYNOPSIS</b>	<b>vgrind</b> [-2fntwx] [-d <i>defs-file</i> ] [-h <i>header</i> ] [-l <i>language</i> ] [-s <i>n</i> ] [-o <i>pagelist</i> ] [-P <i>printer</i> ] [-T <i>output-device</i> ] <i>filename...</i>								
<b>DESCRIPTION</b>	<p>The vgrind utility formats the program sources named by the <i>filename</i> arguments in a nice style using troff(1). Comments are placed in italics, keywords in bold face, and as each function is encountered its name is listed on the page margin.</p> <p>vgrind runs in two basic modes, filter mode or regular mode. In filter mode, vgrind acts as a filter in a manner similar to tbl(1). The standard input is passed directly to the standard output except for lines bracketed by the troff-like macros:</p> <pre>.vS      starts processing .vE      ends processing</pre> <p>These lines are formatted as described above. The output from this filter can be passed to troff for output. There need be no particular ordering with eqn(1) or tbl(1).</p> <p>In regular mode, vgrind accepts input <i>filenames</i>, processes them, and passes them to troff for output. Use a hyphen ('-') to specify standard input; otherwise, vgrind will exit without attempting to read from the standard input. Filenames must be specified after all other option arguments.</p> <p>In regular mode, if the -t or -P option is specified, the output is:</p> <ul style="list-style-type: none"><li>■ emitted (in troff format) to stdout if the -t option is specified.</li><li>■ printed (as PostScript) to the named printer if the -P option is specified.</li></ul> <p>Otherwise, the output is:</p> <ul style="list-style-type: none"><li>■ printed (as PostScript) on the system default printer, if one is defined, and the command's stdout is a tty.</li><li>■ emitted (as PostScript) to stdout if it is not a tty (that is, if stdout is a pipe or a redirect to a file).</li></ul> <p>In both modes, vgrind passes any lines beginning with a decimal point without conversion.</p>								
<b>OPTIONS</b>	<p>The following options are supported:</p> <table><tr><td>-2</td><td>Produces two-column output. Specifying this option changes the default point size to 8 (as if the -s8 option were supplied). It also arranges for output to appear in landscape mode.</td></tr><tr><td>-f</td><td>Forces filter mode.</td></tr><tr><td>-n</td><td>Does not make keywords boldface.</td></tr><tr><td>-w</td><td>Considers TAB characters to be spaced four columns apart instead of the usual eight.</td></tr></table>	-2	Produces two-column output. Specifying this option changes the default point size to 8 (as if the -s8 option were supplied). It also arranges for output to appear in landscape mode.	-f	Forces filter mode.	-n	Does not make keywords boldface.	-w	Considers TAB characters to be spaced four columns apart instead of the usual eight.
-2	Produces two-column output. Specifying this option changes the default point size to 8 (as if the -s8 option were supplied). It also arranges for output to appear in landscape mode.								
-f	Forces filter mode.								
-n	Does not make keywords boldface.								
-w	Considers TAB characters to be spaced four columns apart instead of the usual eight.								

-x	Outputs the index file in a “pretty” format. The index file itself is produced whenever <code>vgrind</code> is run with a file called <code>index</code> that is present in the current directory. The index of function definitions can then be run off by giving <code>vgrind</code> the <code>-x</code> option and the file <code>index</code> as argument.
-d <i>defs-file</i>	Specifies an alternate language definitions file (default is <code>/usr/lib/vgrindefs</code> ).
-h <i>header</i>	Specifies a header to appear in the center of every output page. Use quotes to specify headers with embedded spaces.
-l <i>language</i>	Specifies the language to use. Among the <i>languages</i> currently known are: Bourne shell ( <code>-lsh</code> ), C ( <code>-lc</code> , the default), C++ ( <code>-lc++</code> ), C shell ( <code>-lcs</code> ), emacs MLisp ( <code>-lm1</code> ), FORTRAN ( <code>-lf</code> ), Icon ( <code>-lI</code> ), ISP ( <code>-i</code> ), LDL ( <code>-lLDL</code> ), Model ( <code>-lm</code> ), Pascal ( <code>-lp</code> ), and RATFOR ( <code>-lr</code> ).
-P <i>printer</i>	Sends output to the named <i>printer</i> .
-s <i>n</i>	Specifies a point size to use on output (exactly the same as the argument of a <code>troff .ps</code> point size request).

`vgrind` passes the following options to the formatter specified by the `TROFF` environment variable. See ENVIRONMENT VARIABLES.

-t	Similar to the same option in <code>troff</code> ; that is, formatted text goes to the standard output.
-o <i>pagelist</i>	Prints only those pages whose page numbers appear in the comma-separated <i>pagelist</i> of numbers and ranges. A range <code>N-M</code> means pages <code>N</code> through <code>M</code> ; an initial <code>-N</code> means from the beginning to page <code>N</code> ; and a final <code>N-</code> means from <code>N</code> to the end.
-T <i>output-device</i>	Formats output for the specified <i>output-device</i> .

**OPERANDS** The following operand is supported:

<i>filename</i>	Name of the program source to be processed by <code>vgrind</code> . Use ‘-’ to specify the standard input.
-----------------	--

**ENVIRONMENT VARIABLES** In regular mode, `vgrind` feeds its intermediate output to the text formatter given by the value of the `TROFF` environment variable, or to `/usr/bin/troff` if this variable is not defined in the environment. This mechanism allows for local variations in `troff`’s name.

<b>FILES</b>	<code>index</code>	file where source for index is created
	<code>/usr/lib/vgrindefs</code>	language descriptions
	<code>/usr/lib/vfontedpr</code>	preprocessor
	<code>/usr/share/lib/tmac/tmac.vgrind</code>	macro package

vgrind(1)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdoc

**SEE ALSO** `cs(1)`, `ctags(1)`, `eqn(1)`, `tbl(1)`, `troff(1)`, `attributes(5)`, `vgrindefs(5)`

**BUGS** `vgrind` assumes that a certain programming style is followed:

C	Function names can be preceded on a line only by SPACE, TAB, or an asterisk (*). The parenthesized arguments must also be on the same line.
FORTRAN	Function names need to appear on the same line as the keywords <code>function</code> or <code>subroutine</code> .
MLisp	Function names should not appear on the same line as the preceding <code>defun</code> .
Model	Function names need to appear on the same line as the keywords <code>is beginproc</code> .
Pascal	Function names need to appear on the same line as the keywords <code>function</code> or <code>procedure</code> .

If these conventions are not followed, the indexing and marginal function name comment mechanisms will fail.

More generally, arbitrary formatting styles for programs usually give unsightly results. To prepare a program for `vgrind` output, use TAB rather than SPACE characters to align source code properly, since `vgrind` uses variable width fonts.

The mechanism of `ctags(1)` in recognizing functions should be used here.

The `-w` option is annoying, but there is no other way to achieve the desired effect.

The macros defined in `tmac.vgrind` do not coexist gracefully with those of other macro packages, making filter mode difficult to use effectively.

`vgrind` does not process certain special characters in `cs(1)` scripts correctly.

The `tmac.vgrind` formatting macros wire in the page height and width used in two-column mode, effectively making two column output useless for paper sizes other than the standard American size of 8.5 inches by 11 inches. For other paper sizes, it is necessary to edit the size values given in `tmac.vgrind`. A better solution would be to create a `troff` output device specification intended specifically for landscape output and record size information there.

<b>NAME</b>	vi, view, vedit – screen-oriented (visual) display editor based on ex
<b>SYNOPSIS</b>	<pre> /usr/bin/vi [ -   -s] [-l] [-L] [-R] [ -r [filename]] [-S] [-t tag] [-v] [-V] [-x] [-wn] [-C] [+command   -c command] filename...  /usr/bin/view [ -   -s] [-l] [-L] [-R] [ -r [filename]] [-S] [-t tag] [-v] [-V] [-x] [-wn] [-C] [+command   -c command] filename...  /usr/bin/vedit [ -   -s] [-l] [-L] [-R] [ -r [filename]] [-S] [-t tag] [-v] [-V] [-x] [-wn] [-C] [+command   -c command] filename...  /usr/xpg4/bin/vi [ -   -s] [-l] [-L] [-R] [ -r [filename]] [-S] [-t tag] [-v] [-V] [-x] [-wn] [-C] [+command   -c command] filename...  /usr/xpg4/bin/view [ -   -s] [-l] [-L] [-R] [ -r [filename]] [-S] [-t tag] [-v] [-V] [-x] [-wn] [-C] [+command   -c command] filename...  /usr/xpg4/bin/vedit [ -   -s] [-l] [-L] [-R] [ -r [filename]] [-S] [-t tag] [-v] [-V] [-x] [-wn] [-C] [+command   -c command] filename...  /usr/xpg6/bin/vi [ -   -s] [-l] [-L] [-R] [ -r [filename]] [-S] [-t tag] [-v] [-V] [-x] [-wn] [-C] [+command   -c command] filename...  /usr/xpg6/bin/view [ -   -s] [-l] [-L] [-R] [ -r [filename]] [-S] [-t tag] [-v] [-V] [-x] [-wn] [-C] [+command   -c command] filename...  /usr/xpg6/bin/vedit [ -   -s] [-l] [-L] [-R] [ -r [filename]] [-S] [-t tag] [-v] [-V] [-x] [-wn] [-C] [+command   -c command] filename... </pre>
<b>DESCRIPTION</b>	<p>The vi (visual) utility is a display-oriented text editor based on an underlying line editor ex. It is possible to use the command mode of ex from within vi and to use the command mode of vi from within ex. The visual commands are described on this manual page; how to set options (like automatically numbering lines and automatically starting a new output line when you type carriage return) and all ex line editor commands are described on the <a href="#">ex(1)</a> manual page.</p> <p>When using vi, changes you make to the file are reflected in what you see on your terminal screen. The position of the cursor on the screen indicates the position within the file.</p> <p>The view invocation is the same as vi except that the readonly flag is set.</p> <p>The vedit invocation is intended for beginners. It is the same as vi except that the report flag is set to 1, the showmode and novice flags are set, and magic is turned off. These defaults make it easier to learn how to use vi.</p>

vi(1)

<b>OPTIONS</b>	The following options are supported:
<b>Invocation Options</b>	The following invocation options are interpreted by <code>vi</code> (previously documented options are discussed under NOTES):
<code>-l -s</code>	Suppresses all interactive user feedback. This is useful when processing editor scripts.
<code>-C</code>	Encryption option. Same as the <code>-x</code> option, except that <code>vi</code> simulates the <code>C</code> command of <code>ex</code> . The <code>C</code> command is like the <code>X</code> command of <code>ex</code> , except that all text read in is assumed to have been encrypted.
<code>-l</code>	Sets up for editing LISP programs.
<code>-L</code>	Lists the name of all files saved as the result of an editor or system crash.
<code>-r filename</code>	Edits <i>filename</i> after an editor or system crash. (Recovers the version of <i>filename</i> that was in the buffer when the crash occurred.)
<code>-R</code>	Readonly mode. The <code>readonly</code> flag is set, preventing accidental overwriting of the file.
<code>-S</code>	This option is used in conjunction with the <code>-t tag</code> option to tell <code>vi</code> that the tags file can not be sorted and that, if the binary search (which relies on a sorted tags file) for <i>tag</i> fails to find it, the much slower linear search should also be done. Since the linear search is slow, users of large tags files should ensure that the tags files are sorted rather than use this flag. Creation of tags files normally produces sorted tags files. See <a href="#">ctags(1)</a> for more information on tags files.
<code>-t tag</code>	Edits the file containing <i>tag</i> and position the editor at its definition. It is an error to specify more than one <code>-t</code> option.
<code>-v</code>	Starts up in display editing state, using <code>vi</code> . You can achieve the same effect by typing the <code>vi</code> command itself.
<code>-V</code>	Verbose. When <code>ex</code> commands are read by means of standard input, the input is echoed to standard error. This can be useful when processing <code>ex</code> commands within shell scripts.
<code>-wn</code>	Sets the default window size to <i>n</i> . This is useful when using the editor over a slow speed line.

	-x	Encryption option. When used, <i>vi</i> simulates the <i>X</i> command of <i>ex</i> and prompts the user for a key. This key is used to encrypt and decrypt text using the algorithm of the <i>crypt</i> command. The <i>X</i> command makes an educated guess to determine whether text read in is encrypted or not. The temporary buffer file is encrypted also, using a transformed version of the key typed in for the <i>-x</i> option. If an empty encryption key is entered (that is, if the return key is pressed right after the prompt), the file is not encrypted. This is a good way to decrypt a file erroneously encrypted with a mistyped encryption key, such as a backspace or undo key.
	<i>+command</i>   <i>-c command</i>	Begins editing by executing the specified editor <i>command</i> (usually a search or positioning command).
<i>/usr/xpg4/bin/vi</i> and <i>/usr/xpg6/bin/vi</i>		If both the <i>-t tag</i> and the <i>-c command</i> options are given, the <i>-t tag</i> option is processed first. That is, the file containing <i>tag</i> is selected by <i>-t</i> and then the command is executed.
<b>OPERANDS</b>		The following operands are supported:
	<i>filename</i>	A file to be edited.
<b>COMMAND SUMMARY</b> <b>vi Modes</b>		The <i>vi</i> command modes are summarized in this section.
	Command	Normal and initial mode. Other modes return to command mode upon completion. ESC (escape) is used to cancel a partial command.
	Input	Entered by setting any of the following options:  a A i I o O c C s S R  Arbitrary text can then be entered. Input mode is normally terminated with the ESC character, or, abnormally, with an interrupt.
	Last line	Reading input for : / ? or !. Terminate by typing a carriage return. An interrupt cancels termination.
<b>Sample Commands</b>		In the descriptions, CR stands for carriage return and ESC stands for the escape key.
	←, →	
	down-arrow	
	up-arrow	arrow keys move the cursor
	h j k l	same as arrow keys
	<i>itext</i> ESC	insert <i>text</i>
	<i>cwnew</i> ESC	change word to <i>new</i>

vi(1)

	easESC	pluralize word (end of word; append s; escape from input state)
	x	delete a character
	dw	delete a word
	dd	delete a line
	3dd	delete 3 lines
	u	undo previous change
	ZZ	exit vi, saving changes
	:q!CR	quit, discarding changes
	/textCR	search for <i>text</i>
	^U ^D	scroll up or down
	:cmdCR	any ex or ed command
<b>Counts Before vi Commands</b>	Numbers can be typed as a prefix to some commands. They are interpreted in one of these ways:	
	line/column number	z G
	scroll amount	^D ^U
	repeat effect	most of the rest
<b>Interrupting, Canceling</b>	ESC	end insert or incomplete command
	DEL	(delete or rubout) interrupts
<b>File Manipulation</b>	ZZ	if file modified, write and exit; otherwise, exit
	:wCR	write back changes
	:w!CR	forced write, if permission originally not valid
	:qCR	quit
	:q!CR	quit, discard changes
	:e nameCR	edit file <i>name</i>
	:e!CR	reedit, discard changes
	:e + nameCR	edit, starting at end
	:e +nCR	edit, starting at line <i>n</i>
	:e #CR	edit alternate file
	:e! #CR	edit alternate file, discard changes
	:w nameCR	write file <i>name</i>
	:w! nameCR	overwrite file <i>name</i>

Positioning Within  
a File

```

:shCR      run shell, then return
:!cmdCR   run cmd, then return
:nCR       edit next file in arglist
:n argsCR specify new arglist
^G         show current file and line
:ta tagCR position cursor to tag

```

In general, any `ex` or `ed` command (such as *substitute* or *global*) can be typed, preceded by a colon and followed by a carriage return.

```

F         forward screen
^B       backward screen
^D       scroll down half screen
^U       scroll up half screen
nG       go to the beginning of the specified line (end default), where n is a
         line number
/pat    next line matching pat
?pat    previous line matching pat
n        repeat last / or ? command
N        reverse last / or ? command
/pat/+n nth line after pat
?pat?-n nth line before pat
]]       next section/function
[[       previous section/function
(        beginning of sentence
)        end of sentence
{        beginning of paragraph
}        end of paragraph
%        find matching ( ) or { }
^L       clear and redraw window
^R       clear and redraw window if ^L is → key
zCR      redraw screen with current line at top of window
z-CR     redraw screen with current line at bottom of window
z.CR     redraw screen with current line at center of window

```

Adjusting the  
Screen

vi(1)

	<code>/pat/z-CR</code>	move <i>pat</i> line to bottom of window
	<code>zn.CR</code>	use <i>n</i> -line window
	<code>^E</code>	scroll window down one line
	<code>^Y</code>	scroll window up one line
<b>Marking and Returning</b>	<code>``</code>	move cursor to previous context
	<code>``</code>	move cursor to first non-white space in line
	<code>m<math>x</math></code>	mark current position with the ASCII lower-case letter $x$
	<code>`<math>x</math></code>	move cursor to mark $x$
<b>Line Positioning</b>	<code>´<math>x</math></code>	move cursor to first non-white space in line marked by $x$
	<code>H</code>	top line on screen
	<code>L</code>	last line on screen
	<code>M</code>	middle line on screen
	<code>+</code>	next line, at first non-white space character
	<code>-</code>	previous line, at first non-white space character
	<code>CR</code>	return, same as <code>+</code>
	<code>down-arrow</code> or <code>j</code>	next line, same column
	<code>up-arrow</code> or <code>k</code>	previous line, same column
	<b>Character Positioning</b>	<code>^</code>
<code>0</code>		beginning of line
<code>\$</code>		end of line
<code>l</code> or <code>→</code>		forward
<code>h</code> or <code>←</code>		backward
<code>^H</code>		same as <code>←</code> (backspace)
<code>space</code>		same as <code>→</code> (space bar)
<code>f<math>x</math></code>		find next $x$
<code>F<math>x</math></code>		find previous $x$
<code>t<math>x</math></code>		move to character following the next $x$
<code>T<math>x</math></code>		move to character following the previous $x$
<code>;</code>		repeat last <code>f</code> , <code>F</code> , <code>t</code> , or <code>T</code>
<code>,</code>		repeat inverse of last <code>f</code> , <code>F</code> , <code>t</code> , or <code>T</code>

	<i>n</i> l	move to column <i>n</i>
	%	find matching ( ) or { }
<b>Words, Sentences, Paragraphs</b>	w	forward a word
	b	back a word
	e	end of word
	)	to next sentence
	}	to next paragraph
	(	back a sentence
	{	back a paragraph
	W	forward a blank-delimited word
	B	back a blank-delimited word
	E	end of a blank-delimited word
<b>Corrections During Insert</b>	^H	erase last character (backspace)
	^W	erase last word
	erase	your erase character, same as ^H (backspace)
	kill	your kill character, erase this line of input
	\	quotes your erase and kill characters
	ESC	ends insertion, back to command mode
	Control-C	interrupt, suspends insert mode
	^D	backtab one character; reset left margin of <i>autoindent</i>
	^^D	caret (^) followed by control-d (^D); backtab to beginning of line; do not reset left margin of <i>autoindent</i>
	0^D	backtab to beginning of line; reset left margin of <i>autoindent</i>
<b>Insert and Replace</b>	^V	quote non-printable character
	a	append after cursor
	A	append at end of line
	i	insert before cursor
	I	insert before first non-blank
	o	open line below
	O	open line above
	rx	replace single character with <i>x</i>

	<i>RtextESC</i>	replace characters
<b>Operators</b>	Operators are followed by a cursor motion and affect all text that would have been moved over. For example, since <i>w</i> moves over a word, <i>dw</i> deletes the word that would be moved over. Double the operator, for example <i>dd</i> , to affect whole lines.	
	<i>d</i>	delete
	<i>c</i>	change
	<i>y</i>	yank lines to buffer
	<i>&lt;</i>	left shift
	<i>&gt;</i>	right shift
	<i>!</i>	filter through command
<b>Miscellaneous Operations</b>	<i>C</i>	change rest of line ( <i>c\$</i> )
	<i>D</i>	delete rest of line ( <i>d\$</i> )
	<i>s</i>	substitute characters ( <i>c1</i> )
	<i>S</i>	substitute lines ( <i>cc</i> )
	<i>J</i>	join lines
	<i>x</i>	delete characters ( <i>d1</i> )
	<i>X</i>	delete characters before cursor ( <i>dh</i> )
	<i>Y</i>	yank lines ( <i>yy</i> )
<b>Yank and Put</b>	Put inserts the text most recently deleted or yanked; however, if a buffer is named (using the ASCII lower-case letters <i>a - z</i> ), the text in that buffer is put instead.	
	<i>3yy</i>	yank 3 lines
	<i>3yl</i>	yank 3 characters
	<i>p</i>	put back text after cursor
	<i>P</i>	put back text before cursor
	<i>"xp</i>	put from buffer <i>x</i>
	<i>"xy</i>	yank to buffer <i>x</i>
	<i>"xd</i>	delete into buffer <i>x</i>
<b>Undo, Redo, Retrieve</b>	<i>u</i>	undo last change
	<i>U</i>	restore current line
	<i>.</i>	repeat last change
	<i>"dp</i>	retrieve <i>d</i> 'th last delete

<b>USAGE</b>	See <code>largefile(5)</code> for the description of the behavior of <code>vi</code> and <code>view</code> when encountering files greater than or equal to 2 Gbyte (2 <sup>31</sup> bytes).								
<b>ENVIRONMENT VARIABLES</b>	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>vi</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_COLLATE</code> , <code>LC_CTYPE</code> , <code>LC_TIME</code> , <code>LC_MESSAGES</code> , <code>NLSPATH</code> , <code>PATH</code> , <code>SHELL</code> , and <code>TERM</code> .								
	<code>COLUMNS</code> Override the system-selected horizontal screen size.								
	<code>EXINIT</code> Determine a list of <code>ex</code> commands that are executed on editor start-up, before reading the first file. The list can contain multiple commands by separating them using a vertical-line ( ) character.								
	<code>LINES</code> Override the system-selected vertical screen size, used as the number of lines in a screenful and the vertical screen size in visual mode.								
<b>FILES</b>	<table border="0"> <tr> <td style="vertical-align: top;"><code>/var/tmp</code></td> <td>default directory where temporary work files are placed; it can be changed using the <code>directory</code> option (see the <code>ex(1)</code> command)</td> </tr> <tr> <td style="vertical-align: top;"><code>/usr/share/lib/terminfo/?/*</code></td> <td>compiled terminal description database</td> </tr> <tr> <td style="vertical-align: top;"><code>/usr/lib/.COREterm/?/*</code></td> <td>subset of compiled terminal description database</td> </tr> </table>	<code>/var/tmp</code>	default directory where temporary work files are placed; it can be changed using the <code>directory</code> option (see the <code>ex(1)</code> command)	<code>/usr/share/lib/terminfo/?/*</code>	compiled terminal description database	<code>/usr/lib/.COREterm/?/*</code>	subset of compiled terminal description database		
<code>/var/tmp</code>	default directory where temporary work files are placed; it can be changed using the <code>directory</code> option (see the <code>ex(1)</code> command)								
<code>/usr/share/lib/terminfo/?/*</code>	compiled terminal description database								
<code>/usr/lib/.COREterm/?/*</code>	subset of compiled terminal description database								
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:

vi(1)

<b>SEE ALSO</b>	<p><a href="#">intro(1)</a>, <a href="#">ctags(1)</a>, <a href="#">ed(1)</a>, <a href="#">edit(1)</a>, <a href="#">ex(1)</a>, <a href="#">attributes(5)</a>, <a href="#">environ(5)</a>, <a href="#">largefile(5)</a>, <a href="#">standards(5)</a></p> <p><i>Solaris Advanced User's Guide</i></p>
<b>AUTHOR</b>	<p>vi and ex were developed by The University of California, Berkeley California, Computer Science Division, Department of Electrical Engineering and Computer Science.</p>
<b>NOTES</b>	<p>Two options, although they continue to be supported, have been replaced in the documentation by options that follow the Command Syntax Standard (see <a href="#">intro(1)</a>). An -r option that is not followed with an option-argument has been replaced by -L and +command has been replaced by -c command.</p> <p>The message file too large to recover with -r option, which is seen when a file is loaded, indicates that the file can be edited and saved successfully, but if the editing session is lost, recovery of the file with the -r option is not possible.</p> <p>The editing environment defaults to certain configuration options. When an editing session is initiated, vi attempts to read the EXINIT environment variable. If it exists, the editor uses the values defined in EXINIT; otherwise the values set in \$HOME/.exrc are used. If \$HOME/.exrc does not exist, the default values are used.</p> <p>To use a copy of .exrc located in the current directory other than \$HOME, set the exrc option in EXINIT or \$HOME/.exrc. Options set in EXINIT can be turned off in a local .exrc only if exrc is set in EXINIT or \$HOME/.exrc. In order to be used, .exrc in \$HOME or the current directory must fulfill these conditions:</p> <ul style="list-style-type: none"><li>■ It must exist.</li><li>■ It must be owned by the same userid as the real userid of the process, or the process has appropriate privileges.</li><li>■ It is not writable by anyone other than the owner.</li></ul> <p>Tampering with entries in /usr/share/lib/terminfo/?/* or /usr/share/lib/terminfo/?/* (for example, changing or removing an entry) can affect programs such as vi that expect the entry to be present and correct. In particular, removing the "dumb" terminal can cause unexpected problems.</p> <p>Software tabs using ^T work only immediately after the <i>autoindent</i>.</p> <p>Left and right shifts on intelligent terminals do not make use of insert and delete character operations in the terminal.</p> <p>Loading an alternate malloc() library using the environment variable LD_PRELOAD can cause problems for /usr/bin/vi.</p>

**NAME** vipw – edit the password file

**SYNOPSIS** /usr/ucb/vipw

**DESCRIPTION** vipw edits the password file while setting the appropriate locks, and does any necessary processing after the password file is unlocked. If the password file is already being edited, then you will be told to try again later. The vi(1) editor will be used unless the environment variable VISUAL or EDITOR indicates an alternate editor.

vipw performs a number of consistency checks on the password entry for root, and will not allow a password file with a “mangled” root entry to be installed. It also checks the /etc/shells file to verify the login shell for root.

**FILES** /etc/ptmp  
/etc/shells

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

**SEE ALSO** passwd(1), vi(1), passwd(4), attributes(5)

## volcancel(1)

<b>NAME</b>	volcancel – cancel user's request for removable media that is not currently in drive
<b>SYNOPSIS</b>	<code>/usr/lib/vold/volcancel [-n] [volume]</code>
<b>DESCRIPTION</b>	<p>volcancel cancels a user's request to access a particular floppy or CD-ROM file system. This command is useful when the removable media containing the file system is not currently in the drive.</p> <p>Use the path <code>/vol/rdisk/name_of_volume</code> to specify the volume. If called without a volume name to cancel, volcancel checks for Volume Management running.</p>
<b>OPTIONS</b>	<p>-n            Display the nickname to the device name translation table.</p>
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> A sample of the volcancel command.</p> <p>To cancel a request to access an unnamed CD-ROM, use</p> <pre>example% /usr/lib/vold/volcancel vol/rdisk/unnamed_cdrom</pre> <p>To check if volume management is running, use:</p> <pre>example% /usr/lib/vold/volcancel    echo volmgmt not running</pre>
<b>ATTRIBUTES</b>	See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWvolu

**SEE ALSO** rmmount(1M), volcheck(1), vold(1M), volmissing(1), rmmount.conf(4), vold.conf(4), attributes(5), volfs(7FS)

<b>NAME</b>	volcheck – checks for media in a drive and by default checks all floppy media				
<b>SYNOPSIS</b>	<b>volcheck</b> [-v] [-i <i>secs</i> ] [-t <i>secs</i> ] <i>pathname</i>				
<b>DESCRIPTION</b>	<p>The <code>volcheck</code> utility tells Volume Management to look at each <code>dev/pathname</code> in sequence and determine if new media has been inserted in the drive.</p> <p>The default action is to <code>volcheck</code> all checkable media managed by volume management.</p>				
<b>OPTIONS</b>	<p>The following options are supported:</p> <p><code>-i secs</code> Set the frequency of device checking to <i>secs</i> seconds. The default is 2 seconds. The minimum frequency is 1 second.</p> <p><code>-t secs</code> Check the named device(s) for the next <i>secs</i> seconds. The maximum number of seconds allowed is 28800, which is 8 hours. The frequency of checking is specified by <code>-i</code>. There is no default total time.</p> <p><code>-v</code> Verbose.</p>				
<b>OPERANDS</b>	<p>The following operands are supported:</p> <p><i>pathname</i> The path name of a media device.</p>				
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> A sample of the <code>volcheck</code> command.</p> <p>The following example</p> <pre>example% volcheck -v /dev/diskette /dev/diskette has media</pre> <p>asks Volume Management to examine the floppy drive for new media.</p> <p>The following example</p> <pre>example% volcheck -i 2 -t 600 /dev/diskette1 &amp;</pre> <p>asks Volume Management if there is a floppy in the floppy drive every 2 seconds for 600 seconds (10 minutes).</p>				
<b>FILES</b>	<code>/dev/volctl</code> Volume Management control port				
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWvolu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWvolu

Availability	SUNWvolu				
<b>SEE ALSO</b>	<code>eject(1)</code> , <code>volcancel(1)</code> , <code>volmissing(1)</code> <code>rmmount(1M)</code> , <code>vold(1M)</code> , <code>rmmount.conf(4)</code> , <code>vold.conf(4)</code> , <code>attributes(5)</code> , <code>volfs(7FS)</code>				

volcheck(1)

**WARNINGS** | Due to a hardware limitation in many floppy drives, the act of checking for media causes mechanical action in the floppy drive. Continuous polling of the floppy drive will cause the drive to wear out. It is recommended that polling the drive only be performed during periods of high use.

<b>NAME</b>	volmissing – notify user that volume requested is not in the CD-ROM or floppy drive					
<b>SYNOPSIS</b>	<code>/usr/lib/vold/volmissing [-c] [-p] [-s] [-m <i>alias</i>]</code>					
<b>DESCRIPTION</b>	<p>volmissing informs a user when a requested volume is not available. Depending on the option selected, users are notified through their console window, syslogd(1M), or a mail message.</p> <p>volmissing -p is the default action taken by vold(1M), the Volume Management daemon, when it needs to notify a user that the requested volume is not available. If you want to change this default event, modify the <code>/etc/vold.conf</code> file. See vold.conf(4).</p> <p>You can change the notification method for your system by editing the <code>vold.conf</code> configuration file and providing a new option for volmissing in the notify entry under the Events category.</p>					
<b>OPTIONS</b>	-c	Send a message to the user's console requesting the volume be inserted. To end the notification without inserting the requested volume, use volcancel(1).				
	-p	All volmissing events will be handled through a GUI, provided a window system is running on the console. If this option is specified, and no window system is running, all messages go to the system console.				
	-s	Send one message to the syslogd(1M).				
	-m <i>alias</i>	Send a mail message to the specified mail alias about the missing volume.				
<b>FILES</b>	<code>/etc/vold.conf</code>	Volume Management daemon configuration file. Directs the Volume Management daemon to control certain devices, and causes action to be taken when specific criteria is met.				
	<code>/usr/lib/vold/volmissing_popup</code>	Pop-up used when the -p option is supplied and a window system is running.				
<b>ATTRIBUTES</b>	See attributes(5) for descriptions of the following attributes:					
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWvolu</td> </tr> </tbody> </table>		ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWvolu
ATTRIBUTE TYPE	ATTRIBUTE VALUE

## volrmmount(1)

<b>NAME</b>	volrmmount – call rmmount to mount or unmount media
<b>SYNOPSIS</b>	<b>volrmmount</b> [-i   -e] [ <i>name</i>   <i>nickname</i> ] <b>volrmmount</b> [-d]
<b>DESCRIPTION</b>	<p>The <code>volrmmount</code> utility calls <code>rmmount(1M)</code> to, in effect, simulate an insertion (-i) or an ejection (-e). Simulating an insertion often means that <code>rmmount</code> will mount the media. Conversely, simulating an ejection often means that <code>rmmount</code> will unmount the media. However, these actions can vary depending on the <code>rmmount</code> configuration and media type (see <code>rmmount.conf(4)</code>).</p> <p>For example, if you use the default <code>/etc/rmmount.conf</code> and insert a music CD, it will not be mounted. However, you can configure <code>rmmount</code> so that it calls <code>workman</code> whenever a music CD is inserted.</p> <p>This command allows you to override Volume Management's usual handling of media (see <b>EXAMPLES</b> below).</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"><li>-i Simulates an insertion of the specified media by calling <code>rmmount</code>.</li><li>-e Simulates an ejection of the specified media by calling <code>rmmount</code>.</li><li>-d Displays the name of the default device for <code>volrmmount</code> to handle. This device is used if no <i>name</i> or <i>nickname</i> is supplied.</li></ul>
<b>OPERANDS</b>	<p>The following operands are supported:</p> <p><i>name</i> The name that Volume Management recognizes as the device's name. See <code>vofls(7FS)</code>.</p> <p><i>nickname</i> A shortened version of the device's name. Following is the list of recognized nicknames:</p>

Nickname	Path
fd	/dev/rdiskette
fd0	/dev/rdiskette
fd1	/dev/rdiskette1
diskette	/dev/rdiskette
diskette0	/dev/rdiskette0
diskette1	/dev/rdiskette1
rdiskette	/dev/rdiskette
rdiskette0	/dev/rdiskette0

Nickname	Path
rdiskette1	/dev/rdiskette1
floppy	/dev/rdiskette
floppy0	/dev/rdiskette0
floppy1	/dev/rdiskette1
cdrom0	/vol/dev/rdisk/cXtYdZ/ <i>label</i>
zip0	/vol/dev/rdisk/cXtYdZ/ <i>label</i>
jaz0	/vol/dev/rdisk/cXtYdZ/ <i>label</i>
rmdisk0	/vol/dev/rdisk/cXtYdZ/ <i>label</i>

**EXAMPLES** **EXAMPLE 1** Using the volrmmount command

When Volume Management finds a floppy that contains a filesystem, it calls `rmmount` to mount it. If you wish to run `tar(1)` or `cpio(1)` on that floppy, it must first be unmounted. To unmount the floppy use:

```
example% volrmmount -e floppy0
```

After `volrmmount` unmounts the floppy, if you wish to re-mount it (rather than ejecting it and reinserting it) use:

```
example% volrmmount -i floppy0
```

Notice that if you are using a named floppy, you can use its name in place of `floppy0`.

**FILES** /dev/volctl                      Volume Management control port

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWvolu

**SEE ALSO** `cpio(1)`, `eject(1)`, `tar(1)`, `rmmount(1M)`, `vold(1M)`, `rmmount.conf(4)`, `attributes(5)`, `volfs(7FS)`

**NOTES** Volume Management (`vold`) must be running to use this command.

vsig(1F)

**NAME** vsig – synchronize a co-process with the controlling FMLI application

**SYNOPSIS** **vsig**

**DESCRIPTION** The `vsig` executable sends a SIGUSR2 signal to the controlling FMLI process. This signal/alarm causes FMLI to execute the FMLI built-in command `checkworld` which causes all posted objects with a `reread` descriptor evaluating to TRUE to be reread. `vsig` takes no arguments.

**EXAMPLES** **EXAMPLE 1** A sample output of `vsig` command.

The following is a segment of a shell program:

```
echo "Sending this string to an FMLI process"  
vsig
```

The `vsig` executable will flush the output buffer *before* it sends the SIGUSR2 signal to make sure the string is actually in the pipe created by the `cocreate` function.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

**SEE ALSO** `coproc(1F)`, `kill(1)`, `kill(2)`, `signal(3C)`, `attributes(5)`

**NOTES** Because `vsig` synchronize with FMLI, it should be used rather than `kill` to send a SIGUSR2 signal to FMLI.

<b>NAME</b>	w – display information about currently logged-in users
<b>SYNOPSIS</b>	<b>w</b> [-hlsuw] [ <i>user</i> ]
<b>DESCRIPTION</b>	<p>The <b>w</b> command displays a summary of the current activity on the system, including what each user is doing. The heading line shows the current time, the length of time the system has been up, the number of users logged into the system, and the average number of jobs in the run queue over the last 1, 5 and 15 minutes.</p> <p>The fields displayed are: the user’s login name, the name of the tty the user is on, the time of day the user logged on (in <i>hours:minutes</i>), the idle time—that is, the number of minutes since the user last typed anything (in <i>hours:minutes</i>), the CPU time used by all processes and their children on that terminal (in <i>minutes:seconds</i>), the CPU time used by the currently active processes (in <i>minutes:seconds</i>), and the name and arguments of the current process.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-h        Suppresses the heading.</li> <li>-l        Produces a long form of output, which is the default.</li> <li>-s        Produces a short form of output. In the short form, the tty is abbreviated, the login time and CPU times are left off, as are the arguments to commands.</li> <li>-u        Produces the heading line which shows the current time, the length of time the system has been up, the number of users logged into the system, and the average number of jobs in the run queue over the last 1, 5 and 15 minutes.</li> <li>-w        Produces a long form of output, which is also the same as the default.</li> </ul>
<b>OPERANDS</b>	<i>user</i> Name of a particular user for whom login information is displayed. If specified, output is restricted to that user.
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Sample Output From the <b>w</b> Command</p> <pre>example% w 10:54am up 27 day(s), 57 mins, 1 user, load average: 0.28, 0.26, 0.22 User      tty      login@    idle      JCPU      PCPU      what ralph    console 7:10am    1         10:05    4:31     w</pre>
<b>ENVIRONMENT VARIABLES</b>	See <a href="#">environ(5)</a> for descriptions of the following environment variables that affect the execution of <b>w</b> : <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>LC_TIME</code> .
<b>FILES</b>	<code>/var/adm/utmpx</code> user and accounting information
<b>ATTRIBUTES</b>	See <a href="#">attributes(5)</a> for descriptions of the following attributes:

w(1)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO** [ps\(1\)](#), [who\(1\)](#), [whodo\(1M\)](#), [utmpx\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**NOTES** The notion of the “current process” is unclear. The current algorithm is “the highest numbered process on the terminal that is not ignoring interrupts, or, if there is none, the highest numbered process on the terminal”. This fails, for example, in critical sections of programs like the shell and editor, or when faulty programs running in the background fork and fail to ignore interrupts. In cases where no process can be found, w prints –.

The CPU time is only an estimate, in particular, if someone leaves a background process running after logging out, the person currently on that terminal is “charged” with the time.

Background processes are not shown, even though they account for much of the load on the system.

Sometimes processes, typically those in the background, are printed with null or garbaged arguments. In these cases, the name of the command is printed in parentheses.

w does not know about the conventions for detecting background jobs. It will sometimes find a background job instead of the right one.

<b>NAME</b>	wait – await process completion
<b>SYNOPSIS</b>	
/bin/sh	<b>wait</b> [ <i>pid</i> ...]
/bin/jsh /bin/ksh	<b>wait</b> [ <i>pid</i> ...]
/usr/xpg4/bin/sh	<b>wait</b> [ % <i>jobid</i> ...]
/bin/csh	<b>wait</b>
<b>DESCRIPTION</b>	<p>The shell itself executes <code>wait</code>, without creating a new process. If you get the error message <code>cannot fork, too many processes</code>, try using the <code>wait</code> command to clean up your background processes. If this doesn't help, the system process table is probably full or you have too many active foreground processes. There is a limit to the number of process IDs associated with your login, and to the number the system can keep track of.</p> <p>Not all the processes of a pipeline with three or more stages are children of the shell, and thus cannot be waited for.</p>
/bin/sh, /bin/jsh	<p>Wait for your background process whose process ID is <i>pid</i> and report its termination status. If <i>pid</i> is omitted, all your shell's currently active background processes are waited for and the return code will be 0. The <code>wait</code> utility accepts a job identifier, when Job Control is enabled (jsh), and the argument, <i>jobid</i>, is preceded by a percent sign (%).</p> <p>If <i>pid</i> is not an active process ID, the <code>wait</code> utility will return immediately and the return code will be 0.</p>
<b>csh</b>	Wait for your background processes.
<b>ksh</b>	<p>When an asynchronous list is started by the shell, the process ID of the last command in each element of the asynchronous list becomes known in the current shell execution environment.</p> <p>If the <code>wait</code> utility is invoked with no operands, it will wait until all process IDs known to the invoking shell have terminated and exit with an exit status of 0.</p> <p>If one or more <i>pid</i> or <i>jobid</i> operands are specified that represent known process IDs (or jobids), the <code>wait</code> utility will wait until all of them have terminated. If one or more <i>pid</i> or <i>jobid</i> operands are specified that represent unknown process IDs (or jobids), <code>wait</code> will treat them as if they were known process IDs (or jobids) that exited with exit status 127. The exit status returned by the <code>wait</code> utility will be the exit status of the process requested by the last <i>pid</i> or <i>jobid</i> operand.</p> <p>The known process IDs are applicable only for invocations of <code>wait</code> in the current shell execution environment.</p>
<b>OPERANDS</b>	<p>The following operands are supported:</p> <p>One of the following:</p>

wait(1)

*pid* The unsigned decimal integer process ID of a command, for which the utility is to wait for the termination.

*jobid* A job control job ID that identifies a background process group to be waited for. The job control job ID notation is applicable only for invocations of `wait` in the current shell execution environment, and only on systems supporting the job control option.

**USAGE** On most implementations, `wait` is a shell built-in. If it is called in a subshell or separate utility execution environment, such as one of the following,

```
(wait)
nohup wait ...
find . -exec wait ... \;
```

it will return immediately because there will be no known process IDs to wait for in those environments.

**EXAMPLES** **EXAMPLE 1** Using A Script To Identify The Termination Signal

Although the exact value used when a process is terminated by a signal is unspecified, if it is known that a signal terminated a process, a script can still reliably figure out which signal is using `kill`, as shown by the following (`/bin/ksh` and `/usr/xpg4/bin/sh`):

```
sleep 1000&
pid=$!
kill -kill $pid
wait $pid
echo $pid was terminated by a SIG$(kill -l ${ $?-128}) signal.
```

**EXAMPLE 2** Returning The Exit Status Of A Process

If the following sequence of commands is run in less than 31 seconds (`/bin/ksh` and `/usr/xpg4/bin/sh`):

```
sleep 257 | sleep 31 &

jobs -l %%
```

then either of the following commands will return the exit status of the second `sleep` in the pipeline:

```
wait <pid of sleep 31>
wait %%
```

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `wait`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

wait(1)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

## wc(1)

<b>NAME</b>	wc – display a count of lines, words and characters in a file
<b>SYNOPSIS</b>	<b>wc</b> [-c   -m   -C] [-lw] [ <i>file...</i> ]
<b>DESCRIPTION</b>	<p>The <b>wc</b> utility reads one or more input files and, by default, writes the number of newline characters, words and bytes contained in each input file to the standard output.</p> <p>The utility also writes a total count for all named files, if more than one input file is specified.</p> <p><b>wc</b> considers a <i>word</i> to be a non-zero-length string of characters delimited by white space (for example, <code>SPACE</code>, <code>TAB</code>). See <code>iswspace(3C)</code> or <code>isspace(3C)</code>.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-c        Counts bytes.</li> <li>-C        Same as -m.</li> <li>-l        Counts lines.</li> <li>-m        Counts characters.</li> <li>-w        Counts words delimited by white space characters or new line characters. Delimiting characters are Extended Unix Code (EUC) characters from any code set defined by <code>iswspace()</code>.</li> </ul> <p>If no option is specified, the default is <code>-lwc</code> (counts lines, words, and bytes.)</p>
<b>OPERANDS</b>	<p>The following operand is supported:</p> <p><i>file</i>     A path name of an input file. If no <i>file</i> operands are specified, the standard input will be used.</p>
<b>USAGE</b>	See <code>largefile(5)</code> for the description of the behavior of <b>wc</b> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).
<b>ENVIRONMENT VARIABLES</b>	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <b>wc</b> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <ul style="list-style-type: none"> <li>0        Successful completion.</li> <li>&gt;0      An error occurred.</li> </ul>

## what(1)

<b>NAME</b>	what – extract SCCS version information from a file						
<b>SYNOPSIS</b>	<b>what</b> [-s] <i>filename</i> ...						
<b>DESCRIPTION</b>	The <i>what</i> utility searches each <i>filename</i> for occurrences of the pattern @(#) that the SCCS <i>get</i> command (see <a href="#">sccs-get(1)</a> ) substitutes for the %Z% ID keyword, and prints what follows up to a ", >, NEWLINE, \, or NULL character.						
<b>OPTIONS</b>	The following option is supported:  -s            Stops after the first occurrence of the pattern.						
<b>EXAMPLES</b>	<b>EXAMPLE 1</b> Extracting SCCS version information  If a C program in file <i>program.c</i> contains <pre>char sccsid[ ] = " @(#)identification information ";</pre> and <i>program.c</i> is compiled to yield <i>program.o</i> and <i>a.out</i> , the command: <pre>example% what program.c program.o a.out</pre> produces: <pre>program.c:      identification information program.o:      identification information a.out:          identification information</pre>						
<b>EXIT STATUS</b>	The following exit values are returned:  0            Any matches were found. 1            No matches found.						
<b>ENVIRONMENT VARIABLES</b>	See <a href="#">environ(5)</a> for descriptions of the following environment variables that affect the execution of <i>what</i> : LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.						
<b>ATTRIBUTES</b>	See <a href="#">attributes(5)</a> for descriptions of the following attributes:						
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWspot</td></tr><tr><td>Interface Stability</td><td>Standard</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWspot	Interface Stability	Standard

<b>DIAGNOSTICS</b>	Use the SCCS <i>help</i> command for explanations (see <a href="#">sccs-help(1)</a> ).						

what(1)

**BUGS** | There is a remote possibility that a spurious occurrence of the '@(#)' pattern could be found by what.

whatis(1)

**NAME** | `whatis` – display a one-line summary about a keyword

**SYNOPSIS** | `whatis` *command*...

**DESCRIPTION** | `whatis` looks up a given *command* and displays the header line from the manual section. You can then run the `man(1)` command to get more information. If the line starts '*name (section) ...*' you can do '`man -s section name`' to get the documentation for it. Try '`whatis ed`' and then you should do '`man -s 1 ed`' to get the manual page for `ed(1)`.

`whatis` is actually just the `-f` option to the `man(1)` command.

`whatis` uses the `/usr/share/man/windex` database. This database is created by `catman(1M)`. If this database does not exist, `whatis` will fail.

**FILES** | `/usr/share/man/windex` | Table of contents and keyword database

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdoc
CSI	enabled

**SEE ALSO** | `apropos(1)`, `man(1)`, `catman(1M)`, `attributes(5)`

<b>NAME</b>	whereis – locate the binary, source, and manual page files for a command
<b>SYNOPSIS</b>	<code>/usr/ucb/whereis [-bmsu] [ -BMS <i>directory...</i> -f] <i>filename...</i></code>
<b>DESCRIPTION</b>	<p>The <code>whereis</code> utility locates source/binary and manuals sections for specified files. The supplied names are first stripped of leading pathname components and any (single) trailing extension of the form <code>.ext</code>, for example, <code>.c</code>. Prefixes of <code>s.</code> resulting from use of source code control are also dealt with. <code>whereis</code> then attempts to locate the desired program in a list of standard places:</p> <pre> etc /sbin /usr/bin /usr/ccs/bin /usr/ccs/lib /usr/lang /usr/lbin /usr/lib /usr/sbin /usr/ucb /usr/ucblib /usr/ucbinclude /usr/games /usr/local /usr/local/bin /usr/new /usr/old /usr/hosts /usr/include /usr/etc </pre>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-b        Searches only for binaries.</li> <li>-B        Changes or otherwise limits the places where <code>whereis</code> searches for binaries.</li> <li>-f        Terminates the last directory list and signals the start of file names, and <i>must</i> be used when any of the <code>-B</code>, <code>-M</code>, or <code>-S</code> options are used.</li> <li>-m        Searches only for manual sections.</li> <li>-M        Changes or otherwise limits the places where <code>whereis</code> searches for manual sections.</li> <li>-s        Searches only for sources.</li> <li>-S        Changes or otherwise limit the places where <code>whereis</code> searches for sources.</li> <li>-u        Searches for unusual entries. A file is said to be unusual if it does not have one entry of each requested type. Thus <code>'whereis -m -u *'</code> asks for those files in the current directory which have no documentation.</li> </ul>

whereis(1B)

**EXAMPLES**

**EXAMPLE 1** Finding files

Find all files in /usr/bin which are not documented in /usr/share/man/man1 with source in /usr/src/cmd:

```
example% cd /usr/ucb
example% whereis -u -M /usr/share/man/man1 -S /usr/src/cmd -f *
```

**FILES**

```
/usr/src/*
/usr/{doc,man}/*
/etc,
/usr/{lib,bin,ucb,old,new,local}
```

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

**SEE ALSO**

chdir(2), attributes(5)

**BUGS**

Since whereis uses chdir(2) to run faster, pathnames given with the -M, -S, or -B must be full; that is, they must begin with a '/'.

- NAME** which – locate a command; display its pathname or alias
- SYNOPSIS** **which** [*filename...*]
- DESCRIPTION** which takes a list of names and looks for the files which would be executed had these names been given as commands. Each argument is expanded if it is aliased, and searched for along the user's path. Both aliases and path are taken from the user's .cshrc file.
- FILES** ~/ .cshrc source of aliases and path values  
/usr/bin/which
- ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

- SEE ALSO** [csh\(1\)](#), [attributes\(5\)](#)
- DIAGNOSTICS** A diagnostic is given for names which are aliased to more than a single word, or if an executable file with the argument name was not found in the path.
- NOTES** which is not a shell built-in command; it is the UNIX command, /usr/bin/which
- BUGS** Only aliases and paths from ~/ .cshrc are used; importing from the current environment is not attempted. Must be executed by [csh\(1\)](#), since only csh knows about aliases.
- To compensate for ~/ .cshrc files in which aliases depend upon the prompt variable being set, which sets this variable to NULL. If the ~/ .cshrc produces output or prompts for input when prompt is set, which may produce some strange results.

## who(1)

<b>NAME</b>	who – who is on the system																
<b>SYNOPSIS</b>	<pre>/usr/bin/who [-abdHlmpqrstTu] [file] /usr/bin/who -q [-n x] [file] /usr/bin/who am i /usr/bin/who am I /usr/xpg4/bin/who [-abdHlmpqrstTu] [file] /usr/xpg4/bin/who -q [-n x] [file] /usr/xpg4/bin/who -s [-bdHlmpqrtu] [file] /usr/xpg4/bin/who am i /usr/xpg4/bin/who am I</pre>																
<b>DESCRIPTION</b>	<p>The who utility can list the user's name, terminal line, login time, elapsed time since activity occurred on the line, and the process-ID of the command interpreter (shell) for each current UNIX system user. It examines the <code>/var/adm/utmpx</code> file to obtain its information. If <i>file</i> is given, that file (which must be in utmpx(4) format) is examined. Usually, <i>file</i> will be <code>/var/adm/wtmpx</code>, which contains a history of all the logins since the file was last created.</p> <p>The general format for output is:</p> <pre>name [state] line time [idle] [pid] [comment] [exit]</pre> <p>where:</p> <table><tr><td><i>name</i></td><td>User's login name</td></tr><tr><td><i>state</i></td><td>Capability of writing to the terminal</td></tr><tr><td><i>line</i></td><td>Name of the line found in <code>/dev</code></td></tr><tr><td><i>time</i></td><td>Time since user's login</td></tr><tr><td><i>idle</i></td><td>Time elapsed since the user's last activity</td></tr><tr><td><i>pid</i></td><td>User's process id</td></tr><tr><td><i>comment</i></td><td>Comment line in <code>inittab(4)</code></td></tr><tr><td><i>exit</i></td><td>Exit status for dead processes</td></tr></table>	<i>name</i>	User's login name	<i>state</i>	Capability of writing to the terminal	<i>line</i>	Name of the line found in <code>/dev</code>	<i>time</i>	Time since user's login	<i>idle</i>	Time elapsed since the user's last activity	<i>pid</i>	User's process id	<i>comment</i>	Comment line in <code>inittab(4)</code>	<i>exit</i>	Exit status for dead processes
<i>name</i>	User's login name																
<i>state</i>	Capability of writing to the terminal																
<i>line</i>	Name of the line found in <code>/dev</code>																
<i>time</i>	Time since user's login																
<i>idle</i>	Time elapsed since the user's last activity																
<i>pid</i>	User's process id																
<i>comment</i>	Comment line in <code>inittab(4)</code>																
<i>exit</i>	Exit status for dead processes																
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"><li>-a Processes <code>/var/adm/utmpx</code> or the named <i>file</i> with <code>-b</code>, <code>-d</code>, <code>-l</code>, <code>-p</code>, <code>-r</code>, <code>-t</code>, <code>-T</code>, and <code>-u</code> options turned on.</li><li>-b Indicates the time and date of the last reboot.</li></ul>																

	-d	Displays all processes that have expired and not been respawned by <code>init</code> . The <code>exit</code> field appears for dead processes and contains the termination and exit values (as returned by <code>wait(3UCB)</code> ), of the dead process. This can be useful in determining why a process terminated.
	-H	Outputs column headings above the regular output.
	-l	Lists only those lines on which the system is waiting for someone to login. The <code>name</code> field is <code>LOGIN</code> in such cases. Other fields are the same as for user entries except that the <code>state</code> field does not exist.
	-m	Outputs only information about the current terminal.
	-n <i>x</i>	Takes a numeric argument, <i>x</i> , which specifies the number of users to display per line. <i>x</i> must be at least 1. The <code>-n</code> option can only be used with <code>-q</code> .
	-p	Lists any other process that is currently active and has been previously spawned by <code>init</code> . The <code>name</code> field is the name of the program executed by <code>init</code> as found in <code>/sbin/inittab</code> . The <code>state</code> , <code>line</code> , and <code>idle</code> fields have no meaning. The <code>comment</code> field shows the <code>id</code> field of the line from <code>/sbin/inittab</code> that spawned this process. See <code>inittab(4)</code> .
	-q	(Quick who) Displays only the names and the number of users currently logged on. When this option is used, all other options are ignored.
	-r	Indicates the current <i>run-level</i> of the <code>init</code> process.
	-s	(Default) Lists only the <code>name</code> , <code>line</code> , and <code>time</code> fields.
<code>/usr/bin/who</code>	-T	Same as the <code>-s</code> option, except that the <code>state</code> , <code>idle</code> , <code>pid</code> , and <code>comment</code> , fields are also written. <code>state</code> is one of the following characters: <ul style="list-style-type: none"> <li>+ The terminal allows write access to other users.</li> <li>- The terminal denies write access to other users.</li> <li>? The terminal write-access state cannot be determined.</li> </ul>
<code>/usr/xpg4/bin/who</code>	-T	Same as the <code>-s</code> option, except that the <code>state</code> field is also written. <code>state</code> is one of the characters listed under the <code>/usr/bin/who</code> version of this option. If the <code>-u</code> option is used with <code>-T</code> , the <code>idle</code> time is added to the end of the previous format.
	-t	Indicates the last change to the system clock (using the <code>date</code> utility) by <code>root</code> . See <code>su(1M)</code> and <code>date(1)</code> .
	-u	Lists only those users who are currently logged in. The <code>name</code> is the user's login name. The <code>line</code> is the name of the line as found in the directory <code>/dev</code> . The <code>time</code> is the time that the user logged in. The <code>idle</code> column contains the number of hours and minutes since activity last occurred on that particular line. A dot (.) indicates that the terminal has seen activity in the last minute and is therefore "current." If more than twenty-four hours have elapsed or the line has not been used since boot time, the entry is marked

## who(1)

old. This field is useful when trying to determine whether a person is working at the terminal or not. The *pid* is the process-ID of the user's shell. The *comment* is the comment field associated with this line as found in `/sbin/inittab` (see `inittab(4)`). This can contain information about where the terminal is located, the telephone number of the dataset, type of terminal if hard-wired, and so forth.

**OPERANDS** The following operands are supported:

`am i`  
`am I` In the "C" locale, limits the output to describing the invoking user, equivalent to the `-m` option. The `am` and `i` or `I` must be separate arguments.

*file* Specifies a path name of a file to substitute for the database of logged-on users that `who` uses by default.

**ENVIRONMENT VARIABLES** See `environ(5)` for descriptions of the following environment variables that affect the execution of `who`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, and `NLSPATH`.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.  
>0 An error occurred.

**FILES**

<code>/sbin/inittab</code>	Script for <code>init</code>
<code>/var/adm/utmpx</code>	Current user and accounting information
<code>/var/adm/wtmpx</code>	Historic user and accounting information

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

`/usr/bin/who`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

`/usr/xpg4/bin/who`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
Interface Stability	Standard

**SEE ALSO** `date(1)`, `login(1)`, `mesg(1)`, `init(1M)`, `su(1M)`, `wait(3UCB)`, `inittab(4)`, `utmpx(4)`, `attributes(5)`, `environ(5)`, `standards(5)`

**NOTES** *Superuser:* After a shutdown to the single-user state, `who` returns a prompt. Since `/var/adm/utmpx` is updated at login time and there is no login in single-user state, `who` cannot report accurately on this state. The command, `who am i`, however, returns the correct information.

**NAME** | whoami – display the effective current username

**SYNOPSIS** | `/usr/ucb/whoami`

**DESCRIPTION** | whoami displays the login name corresponding to the current effective user ID. If you have used `su` to temporarily adopt another user, whoami will report the login name associated with that user ID. whoami gets its information from the `geteuid` and `getpwuid` library routines (see `getuid` and `getpwnam(3C)`, respectively).

**FILES** | `/etc/passwd`                      username data base

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

## whocalls(1)

<b>NAME</b>	whocalls – report on the calls to a specific procedure				
<b>SYNOPSIS</b>	<code>/usr/ccs/bin/whocalls [-l <i>wholib</i>] [-s] <i>funcname executable</i> [<i>arguments...</i>]</code>				
<b>DESCRIPTION</b>	<p>whocalls is a simple example of a utility based on the <i>Link-Auditing</i> functionality of <a href="#">ld.so.1(1)</a> that permits the tracking of a given function call. See the <i>Linker and Libraries Guide</i> for a detailed description of the <i>Link-Auditing</i> mechanism. The <i>executable</i> is run as normal with any associated arguments. Each time the procedure <i>funcname</i> is called, both the arguments to that procedure and a stack trace are displayed on standard output.</p>				
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"><li>-l <i>wholib</i> Specifies an alternate <code>who.so</code> <i>Link-Auditing</i> library to use.</li><li>-s When available, examines and uses the <code>.symtab</code> symbol table for local symbols. This is a little more expensive than using the <code>.dynsym</code> symbol table, but can produce more detailed stack trace information.</li></ul>				
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Tracking function calls</p> <p>This example tracks the calls to <code>printf()</code> made by a simple <code>helloworld</code> program:</p> <pre>example% whocalls printf helloworld printf(0x106e4, 0xef625310, 0xef621ba8)     helloworld:main+0x10     helloworld:_start+0x5c Hello World</pre>				
<b>ATTRIBUTES</b>	<p>See <a href="#">attributes(5)</a> for descriptions of the following attributes:</p> <table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWtoo</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWtoo
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWtoo				
<b>SEE ALSO</b>	<p><a href="#">ld.so.1(1)</a>, <a href="#">sotruss(1)</a>, <a href="#">attributes(5)</a></p> <p><i>Linker and Libraries Guide</i></p>				

<b>NAME</b>	whois – Internet user name directory service				
<b>SYNOPSIS</b>	<b>whois</b> [-h <i>host</i> ] <i>identifier</i>				
<b>DESCRIPTION</b>	<p><b>whois</b> searches for an Internet directory entry for an <i>identifier</i> which is either a name (such as “Smith”) or a handle (such as “SRI-NIC”). To force a name-only search, precede the name with a period; to force a handle-only search, precede the handle with an exclamation point.</p> <p>To search for a group or organization entry, precede the argument with * (an asterisk). The entire membership list of the group will be displayed with the record.</p> <p>You may of course use an exclamation point and asterisk, or a period and asterisk together.</p>				
<b>EXAMPLES</b>	<p><b>EXAMPLE 1</b> Using The <b>whois</b> Command</p> <p>The command:</p> <pre>example% whois Smith</pre> <p>looks for the name or handle SMITH.</p> <p>The command:</p> <pre>example% whois !SRI-NIC</pre> <p>looks for the handle SRI-NIC only.</p> <p>The command:</p> <pre>example% whois .Smith, John</pre> <p>looks for the name JOHN SMITH only.</p> <p>Adding . . . to the name or handle argument will match anything from that point; that is, ZU . . . will match ZUL, ZUM, and so on.</p>				
<b>ATTRIBUTES</b>	See <b>attributes(5)</b> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWrcmdc</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWrcmdc
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWrcmdc				
<b>SEE ALSO</b>	<b>attributes(5)</b>				

## write(1)

<b>NAME</b>	write – write to another user
<b>SYNOPSIS</b>	<b>write</b> <i>user</i> [ <i>terminal</i> ]
<b>DESCRIPTION</b>	<p>The <code>write</code> utility reads lines from the user's standard input and writes them to the terminal of another user. When first invoked, it writes the message:</p> <pre>Message from <i>sender-login-id</i> (<i>sending-terminal</i>) [<i>date</i>]...</pre> <p>to <i>user</i>. When it has successfully completed the connection, the sender's terminal will be alerted twice to indicate that what the sender is typing is being written to the recipient's terminal.</p> <p>If the recipient wants to reply, this can be accomplished by typing</p> <pre>write <i>sender-login-id</i> [<i>sending-terminal</i>]</pre> <p>upon receipt of the initial message. Whenever a line of input as delimited by a NL, EOF, or EOL special character is accumulated while in canonical input mode, the accumulated data will be written on the other user's terminal. Characters are processed as follows:</p> <ul style="list-style-type: none"><li>■ Typing the alert character will write the alert character to the recipient's terminal.</li><li>■ Typing the erase and kill characters will affect the sender's terminal in the manner described by the <code>termios(3C)</code> interface.</li><li>■ Typing the interrupt or end-of-file characters will cause <code>write</code> to write an appropriate message (EOT\n in the "C" locale) to the recipient's terminal and exit.</li><li>■ Typing characters from LC_CTYPE classifications <code>print</code> or <code>space</code> will cause those characters to be sent to the recipient's terminal.</li><li>■ When and only when the <code>stty iexten</code> local mode is enabled, additional special control characters and multi-byte or single-byte characters are processed as printable characters if their wide character equivalents are printable.</li><li>■ Typing other non-printable characters will cause them to be written to the recipient's terminal as follows: control characters will appear as a '^' followed by the appropriate ASCII character, and characters with the high-order bit set will appear in "meta" notation. For example, '\003' is displayed as '^C' and '\372' as 'M-z'.</li></ul> <p>To write to a user who is logged in more than once, the <i>terminal</i> argument can be used to indicate which terminal to write to. Otherwise, the recipient's terminal is the first writable instance of the user found in <code>/usr/adm/utmpx</code>, and the following informational message will be written to the sender's standard output, indicating which terminal was chosen:</p> <pre><i>user</i> is logged on more than one place. You are connected to <i>terminal</i>. Other locations are:<i>terminal</i></pre>

Permission to be a recipient of a `write` message can be denied or granted by use of the `mesg` utility. However, a user's privilege may further constrain the domain of accessibility of other users' terminals. The `write` utility will fail when the user lacks the appropriate privileges to perform the requested action.

If the character `!` is found at the beginning of a line, `write` calls the shell to execute the rest of the line as a command.

`write` runs `setgid()` (see `setuid(2)`) to the group ID `tty`, in order to have write permissions on other user's terminals.

The following protocol is suggested for using `write`: when you first `write` to another user, wait for them to `write` back before starting to send. Each person should end a message with a distinctive signal (that is, `(o)` for "over") so that the other person knows when to reply. The signal `(oo)` (for "over and out") is suggested when conversation is to be terminated.

**OPERANDS** The following operands are supported:

*user*                    User (login) name of the person to whom the message will be written. This operand must be of the form returned by the `who(1)` utility.

*terminal*                Terminal identification in the same format provided by the `who` utility.

**ENVIRONMENT VARIABLES** See `environ(5)` for descriptions of the following environment variables that affect the execution of `write`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS** The following exit values are returned:

0                    Successful completion.

>0                    The addressed user is not logged on or the addressed user denies permission.

**FILES** `/var/adm/utmpx`                user and accounting information for `write`  
`/usr/bin/sh`                        Bourne shell executable file

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	enabled
Interface Stability	Standard

**SEE ALSO** `mail(1)`, `mesg(1)`, `pr(1)`, `sh(1)`, `talk(1)`, `who(1)`, `setuid(2)`, `termios(3C)`, `attributes(5)`, `environ(5)`, `standards(5)`

write(1)

**DIAGNOSTICS**

user is not logged on

The person you are trying to write to is not logged on.

Permission denied

The person you are trying to write to denies that permission (with mesg).

Warning: cannot respond, set mesg -y

Your terminal is set to mesg n and the recipient cannot respond to you.

Can no longer write to user

The recipient has denied permission (mesg n) after you had started writing.

<b>NAME</b>	xargs – construct argument lists and invoke utility
<b>SYNOPSIS</b>	<pre> /usr/bin/xargs [-t] [-p] [ -e [eofstr]] [-E eofstr] [-I replstr] [ -i [replstr]] [-L number] [ -l [number]] [ -n number [-x]] [-s size] [ utility [ argument...]]  /usr/xpg6/bin/xargs [-t] [-p] [ -e [eofstr]] [-E eofstr] [-I replstr] [ -i [replstr]] [-L number] [ -l [number]] [ -n number [-x]] [-s size] [ utility [ argument...]] </pre>
<b>DESCRIPTION</b>	<p>The <i>xargs</i> utility constructs a command line consisting of the <i>utility</i> and <i>argument</i> operands specified followed by as many arguments read in sequence from standard input as will fit in length and number constraints specified by the options. The <i>xargs</i> utility then invokes the constructed command line and waits for its completion. This sequence is repeated until an end-of-file condition is detected on standard input or an invocation of a constructed command line returns an exit status of 255.</p> <p>Arguments in the standard input must be separated by unquoted blank characters, or unescaped blank characters or newline characters. A string of zero or more non-double-quote (") and non-newline characters can be quoted by enclosing them in double-quotes. A string of zero or more non-apostrophe (') and non-newline characters can be quoted by enclosing them in apostrophes. Any unquoted character can be escaped by preceding it with a backslash (\). The <i>utility</i> will be executed one or more times until the end-of-file is reached. The results are unspecified if the utility named by <i>utility</i> attempts to read from its standard input.</p> <p>The generated command line length will be the sum of the size in bytes of the utility name and each argument treated as strings, including a null byte terminator for each of these strings. The <i>xargs</i> utility will limit the command line length such that when the command line is invoked, the combined argument and environment lists will not exceed {ARG_MAX}-2048 bytes. Within this constraint, if neither the <i>-n</i> nor the <i>-s</i> option is specified, the default command line length will be at least {LINE_MAX}.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <p><i>-e [eofstr]</i>      Uses <i>eofstr</i> as the logical end-of-file string. Underscore ( _ ) is assumed for the logical EOF string if neither <i>-e</i> nor <i>-E</i> is used. When the <i>eofstr</i> option-argument is omitted, the logical EOF string capability is disabled and underscores are taken literally. The <i>xargs</i> utility reads standard input until either end-of-file or the logical EOF string is encountered.</p> <p><i>-E eofstr</i>      In <i>/usr/bin/args</i>:</p> <p>                  Specifies a logical end-of-file string to replace the default underscore. The <i>xargs</i> utility reads standard input until either end-of-file or the logical EOF string is encountered. The <i>eofstr</i> cannot be a null string.</p> <p>                  In <i>/usr/xpg6/bin/args</i>:</p>

## xargs(1)

	Specifies a logical end-of-file string to replace the default underscore. The <i>xargs</i> utility reads standard input until either end-of-file or the logical EOF string is encountered. When <i>eofstr</i> is a null string, the logical end-of-file string capability is disabled and underscore characters are taken literally.
-I <i>replstr</i>	Insert mode. <i>utility</i> is executed for each line from standard input, taking the entire line as a single argument, inserting it in <i>argument s</i> for each occurrence of <i>replstr</i> . A maximum of five arguments in <i>arguments</i> can each contain one or more instances of <i>replstr</i> . Any blank characters at the beginning of each line are ignored. Constructed arguments cannot grow larger than 255 bytes. Option -x is forced on. The -I and -i options are mutually exclusive; the last one specified takes effect.
-i [ <i>replstr</i> ]	This option is equivalent to -I <i>replstr</i> . The string { } is assumed for <i>replstr</i> if the option-argument is omitted.
-L <i>number</i>	The <i>utility</i> is executed for each non-empty <i>number</i> lines of arguments from standard input. The last invocation of <i>utility</i> will be with fewer lines of arguments if fewer than <i>number</i> remain. A line is considered to end with the first newline character unless the last character of the line is a blank character; a trailing blank character signals continuation to the next non-empty line, inclusive. The -L, -l, and -n options are mutually exclusive; the last one specified takes effect.
-l [ <i>number</i> ]	(The letter ell.) This option is equivalent to -L <i>number</i> . If <i>number</i> is omitted, 1 is assumed. Option -x is forced on.
-n <i>number</i>	Invokes <i>utility</i> using as many standard input arguments as possible, up to <i>number</i> (a positive decimal integer) arguments maximum. Fewer arguments will be used if: <ul style="list-style-type: none"><li>■ The command line length accumulated exceeds the size specified by the -s option (or {LINE_MAX} if there is no -s option), or</li><li>■ The last iteration has fewer than <i>number</i>, but not zero, operands remaining.</li></ul>
-p	Prompt mode. The user is asked whether to execute <i>utility</i> at each invocation. Trace mode (-t) is turned on to write the command instance to be executed, followed by a prompt to standard error. An affirmative response (specific to the user's locale) read from /dev/tty will execute the command; otherwise, that particular invocation of <i>utility</i> is skipped.
-s <i>size</i>	Invokes <i>utility</i> using as many standard input arguments as possible yielding a command line length less than <i>size</i> (a positive decimal integer) bytes. Fewer arguments will be used if:

xargs(1)

- The total number of arguments exceeds that specified by the `-n` option, or
- The total number of lines exceeds that specified by the `-L` option, or
- End of file is encountered on standard input before *size* bytes are accumulated.

Values of *size* up to at least `{LINE_MAX}` bytes are supported, provided that the constraints specified in DESCRIPTION are met. It is not considered an error if a value larger than that supported by the implementation or exceeding the constraints specified in DESCRIPTION is given. `xargs` will use the largest value it supports within the constraints.

- `-t` Enables trace mode. Each generated command line will be written to standard error just prior to invocation.
- `-x` Terminates if a command line containing *number* arguments (see the `-n` option above) or *number* lines (see the `-L` option above) will not fit in the implied or specified size (see the `-s` option above).

**OPERANDS** The following operands are supported:

*utility* The name of the utility to be invoked, found by search path using the `PATH` environment variable. (see `environ(5)`.) If *utility* is omitted, the default is the `echo(1)` utility. If the *utility* operand names any of the special built-in utilities in `shell_builtins(1)`, the results are undefined.

*argument* An initial option or operand for the invocation of *utility*.

**USAGE** The 255 exit status allows a utility being used by `xargs` to tell `xargs` to terminate if it knows no further invocations using the current data stream will succeed. Thus, *utility* should explicitly `exit` with an appropriate value to avoid accidentally returning with 255.

Notice that input is parsed as lines. Blank characters separate arguments. If `xargs` is used to bundle output of commands like `find dir -print` or `ls` into commands to be executed, unexpected results are likely if any filenames contain any blank characters or newline characters. This can be fixed by using `find` to call a script that converts each file found into a quoted string that is then piped to `xargs`. Notice that the quoting rules used by `xargs` are not the same as in the shell. They were not made consistent here because existing applications depend on the current rules and the shell syntax is not fully compatible with it. An easy rule that can be used to transform any string into a quoted form that `xargs` will interpret correctly is to precede each character in the string with a backslash (`\`).

## xargs(1)

On implementations with a large value for `{ARG_MAX}`, `xargs` may produce command lines longer than `{LINE_MAX}`. For invocation of utilities, this is not a problem. If `xargs` is being used to create a text file, users should explicitly set the maximum command line length with the `-s` option.

The `xargs` utility returns exit status 127 if an error occurs so that applications can distinguish “failure to find a utility” from “invoked utility exited with an error indication.” The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for “normal error conditions” and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked.

### EXAMPLES

**EXAMPLE 1** Using the `xargs` command

The following will move all files from directory `$1` to directory `$2`, and echo each move command just before doing it:

```
example% ls $1 | xargs -I {} -t mv $1/{} $2/{}>
```

The following command will combine the output of the parenthesised commands onto one line, which is then written to the end of file `log`:

```
example% (logname; date; printf "%s\n" "$0 $*") | xargs >>log>
```

The following command will invoke `diff` with successive pairs of arguments originally typed as command line arguments (assuming there are no embedded blank characters in the elements of the original argument list):

```
example% printf "%s\n" "$*" | xargs -n 2 -x diff>
```

The user is asked which files in the current directory are to be archived. The files are archived into `arch`; `a`, one at a time, or `b`, many at a time:

```
example% ls | xargs -p -L 1 ar -r arch>
ls | xargs -p -L 1 | xargs ar -r arch>
```

The following will execute with successive pairs of arguments originally typed as command line arguments:

```
example% echo $* | xargs -n 2 diff>
```

### ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `xargs`: `LANG`, `LC_ALL`, `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

`PATH` Determine the location of *utility*.

### EXIT STATUS

The following exit values are returned:

0 All invocations of *utility* returned exit status 0.

xargs(1)

- 1-125            A command line meeting the specified requirements could not be assembled, one or more of the invocations of *utility* returned a non-zero exit status, or some other error occurred.
- 126             The utility specified by *utility* was found but could not be invoked.
- 127             The utility specified by *utility* could not be found.

If a command line meeting the specified requirements cannot be assembled, the utility cannot be invoked, an invocation of the utility is terminated by a signal, or an invocation of the utility exits with exit status 255, the *xargs* utility will write a diagnostic message and exit without processing any remaining input.

**ATTRIBUTES**    See *attributes*(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

CSI	Enabled
Interface Stability	Standard

**SEE ALSO**    *echo*(1), *shell\_builtins*(1), *attributes*(5), *environ*(5), *standards*(5)

## xgettext(1)

<b>NAME</b>	xgettext – extract gettext call strings from C programs
<b>SYNOPSIS</b>	<b>xgettext</b> [-ns] [-a [-x <i>exclude-file</i> ]] [-c <i>comment-tag</i> ] [-d <i>default-domain</i> ] [-j] [-m <i>prefix</i> ] [-M <i>suffix</i> ] [-p <i>pathname</i> ] -  <i>filename...</i> <b>xgettext</b> -h
<b>DESCRIPTION</b>	<p>The <code>xgettext</code> utility is used to automate the creation of portable message files (<code>.po</code>). A <code>.po</code> file contains copies of “C” strings that are found in ANSI C source code in <i>filename</i> or the standard input if “-” is specified on the command line. The <code>.po</code> file can be used as input to the <code>msgfmt(1)</code> utility, which produces a binary form of the message file that can be used by application during run-time.</p> <p><code>xgettext</code> writes <i>msgid</i> strings from <code>gettext(3C)</code> calls in <i>filename</i> to the default output file <code>messages.po</code>. The default output file name can be changed by <code>-d</code> option. <i>msgid</i> strings in <code>dgettext()</code> calls are written to the output file <code>domainname.po</code> where <code>domainname</code> is the first parameter to the <code>dgettext()</code> call.</p> <p>By default, <code>xgettext</code> creates a <code>.po</code> file in the current working directory, and each entry is in the same order that the strings are extracted from <i>filenames</i>. When the <code>-p</code> option is specified, the <code>.po</code> file is created in the <i>pathname</i> directory. An existing <code>.po</code> file is overwritten.</p> <p>Duplicate <i>msgid</i>s are written to the <code>.po</code> file as comment lines. When the <code>-s</code> option is specified, the <code>.po</code> is sorted by the <i>msgid</i> string, and all duplicated <i>msgid</i>s are removed. All <i>msgstr</i> directives in the <code>.po</code> file are empty unless the <code>-m</code> option is used.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"><li>-n                    Add comment lines to the output file indicating file name and line number in the source file where each extracted string is encountered. These lines appear before each <i>msgid</i> in the following format:  # # File: <i>filename</i>, line: <i>line-number</i></li><li>-s                    Generate output sorted by <i>msgid</i>s with all duplicate <i>msgid</i>s removed.</li><li>-a                    Extract all strings, not just those found in <code>gettext(3C)</code>, and <code>dgettext()</code> calls. Only one <code>.po</code> file is created.</li><li>-c <i>comment-tag</i>    The comment block beginning with <i>comment-tag</i> as the first token of the comment block is added to the output <code>.po</code> file as # delimited comments. For multiple domains, <code>xgettext</code> directs comments and messages to the prevailing text domain.</li><li>-d <i>default-domain</i>    Rename default output file from <code>messages.po</code> to <i>default-domain.po</i>.</li></ul>

-j	Join messages with existing message files. If a .po file does not exist, it is created. If a .po file does exist, new messages are appended. Any duplicate <code>msgid</code> s are commented out in the resulting .po file. Domain directives in the existing .po file are ignored. Results not guaranteed if the existing message file has been edited.
-m <i>prefix</i>	Fill in the <i>msgstr</i> with <i>prefix</i> . This is useful for debugging purposes. To make <i>msgstr</i> identical to <i>msgid</i> , use an empty string (" ") for <i>prefix</i> .
-M <i>suffix</i>	Fill in the <i>msgstr</i> with <i>suffix</i> . This is useful for debugging purposes.
-p <i>pathname</i>	Specify the directory where the output files will be placed. This option overrides the current working directory.
-x <i>exclude-file</i>	Specify a .po file that contains a list of <i>msgid</i> s that are not to be extracted from the input files. The format of <i>exclude-file</i> is identical to the .po file. However, only the <i>msgid</i> directive line in <i>exclude-file</i> is used. All other lines are simply ignored. The -x option can only be used with the -a option.
-h	Print a help message on the standard output.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWloc

**SEE ALSO** `msgfmt(1)`, `gettext(3C)`, `attributes(5)`

**NOTES** `xgettext` is not able to extract cast strings, for example ANSI C casts of literal strings to `(const char *)`. This is unnecessary anyway, since the prototypes in `<libintl.h>` already specify this type.

In messages and translation notes, lines greater than 2048 characters are truncated to 2048 characters and a warning message is printed to `stderr`.

xstr(1)

<b>NAME</b>	xstr – extract strings from C programs to implement shared strings
<b>SYNOPSIS</b>	<b>xstr</b> -c <i>filename</i> [-v] [-l <i>array</i> ] <b>xstr</b> [-l <i>array</i> ] <b>xstr</b> <i>filename</i> [-v] [-l <i>array</i> ]
<b>DESCRIPTION</b>	<p>xstr maintains a file called <code>strings</code> into which strings in component parts of a large program are hashed. These strings are replaced with references to this common area. This serves to implement shared constant strings, which are most useful if they are also read-only.</p> <p>The command:</p> <pre>example% xstr -c <i>filename</i></pre> <p>extracts the strings from the C source in <code>name</code>, replacing string references by expressions of the form <code>&amp;xstr[<i>number</i>]</code> for some number. An appropriate declaration of <code>xstr</code> is prepended to the file. The resulting C text is placed in the file <code>x.c</code>, to then be compiled. The strings from this file are placed in the <code>strings</code> data base if they are not there already. Repeated strings and strings which are suffixes of existing strings do not cause changes to the data base.</p> <p>After all components of a large program have been compiled, a file declaring the common <code>xstr</code> space called <code>xs.c</code> can be created by a command of the form:</p> <pre>example% xstr</pre> <p>This <code>xs.c</code> file should then be compiled and loaded with the rest of the program. If possible, the array can be made read-only (shared) saving space and swap overhead.</p> <p>xstr can also be used on a single file. A command:</p> <pre>example% xstr <i>filename</i></pre> <p>creates files <code>x.c</code> and <code>xs.c</code> as before, without using or affecting any <code>strings</code> file in the same directory.</p> <p>It may be useful to run <code>xstr</code> after the C preprocessor if any macro definitions yield strings or if there is conditional code which contains strings which may not, in fact, be needed. <code>xstr</code> reads from the standard input when the argument <code>'-'</code> is given. An appropriate command sequence for running <code>xstr</code> after the C preprocessor is:</p> <pre>example% cc -E name.c   xstr -c - example% cc -c x.c example% mv x.o name.o</pre> <p><code>xstr</code> does not touch the file <code>strings</code> unless new items are added; thus <code>make(1S)</code> can avoid remaking <code>xs.o</code> unless truly necessary.</p>
<b>OPTIONS</b>	<code>-c <i>filename</i></code> Take C source text from <i>filename</i> .

`-v` Verbose: display a progress report indicating where new or duplicate strings were found.

`-l array` Specify the named *array* in program references to abstracted strings. The default array name is `xstr`.

**FILES**

`strings` data base of strings

`x.c` massaged C source

`xs.c` C source for definition of array "`xstr*(rq`

`/tmp/xs*` temp file when `xstr filename` doesn't touch `strings`

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**SEE ALSO** `make(1S)`, `attributes(5)`

**BUGS** If a string is a suffix of another string in the data base, but the shorter string is seen first by `xstr` both strings will be placed in the data base, when just placing the longer one there would do.

**NOTES** Be aware that `xstr` indiscriminately replaces all strings with expressions of the form `&xstr[number]` regardless of the way the original C code might have used the string. For example, you will encounter a problem with code that uses `sizeof()` to determine the length of a literal string because `xstr` will replace the literal string with a pointer that most likely will have a different size than the string's. To circumvent this problem:

- use `strlen()` instead of `sizeof()`; note that `sizeof()` returns the size of the array (including the null byte at the end), whereas `strlen()` doesn't count the null byte. The equivalent of `sizeof("xxx")` really is `(strlen("xxx")+1)`.
- use `#define` for operands of `sizeof()` and use the define'd version. `xstr` ignores `#define` statements. Make sure you run `xstr` on *filename* before you run it on the preprocessor.

You will also encounter a problem when declaring an initialized character array of the form

```
char x[] = "xxx";
```

`xstr` will replace `xxx` with an expression of the form `&xstr[number]` which will not compile. To circumvent this problem, use `static char *x = "xxx"` instead of `static char x[] = "xxx"`.

## yacc(1)

<b>NAME</b>	yacc – yet another compiler-compiler
<b>SYNOPSIS</b>	<code>/usr/ccs/bin/yacc [-dltVv] [-b <i>file_prefix</i>] [ -Q [y   n]] [-P <i>parser</i>] [-p <i>sym_prefix</i>] <i>file</i></code>
<b>DESCRIPTION</b>	<p>The <code>yacc</code> command converts a context-free grammar into a set of tables for a simple automaton that executes an LALR(1) parsing algorithm. The grammar may be ambiguous. Specified precedence rules are used to break ambiguities.</p> <p>The output file, <code>y.tab.c</code>, must be compiled by the C compiler to produce a function <code>yyparse()</code>. This program must be loaded with the lexical analyzer program, <code>yylex()</code>, as well as <code>main()</code> and <code>yyerror()</code>, an error handling routine. These routines must be supplied by the user. The <code>lex(1)</code> command is useful for creating lexical analyzers usable by <code>yacc</code>.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"><li><code>-b <i>file_prefix</i></code> Uses <i>file_prefix</i> instead of <code>y</code> as the prefix for all output files. The code file <code>y.tab.c</code>, the header file <code>y.tab.h</code> (created when <code>-d</code> is specified), and the description file <code>y.output</code> (created when <code>-v</code> is specified), will be changed to <code>file_prefix.tab.c</code>, <code>file_prefix.tab.h</code>, and <code>file_prefix.output</code>, respectively.</li><li><code>-d</code> Generates the file <code>y.tab.h</code> with the <code>#define</code> statements that associate the <code>yacc</code> user-assigned “token codes” with the user-declared “token names”. This association allows source files other than <code>y.tab.c</code> to access the token codes.</li><li><code>-l</code> Specifies that the code produced in <code>y.tab.c</code> will not contain any <code>#line</code> constructs. This option should only be used after the grammar and the associated actions are fully debugged.</li><li><code>-p <i>sym_prefix</i></code> Uses <i>sym_prefix</i> instead of <code>yy</code> as the prefix for all external names produced by <code>yacc</code>. The names affected include the functions <code>yyparse()</code>, <code>yylex()</code> and <code>yyerror()</code>, and the variables <code>yytval</code>, <code>yychar</code> and <code>yydebug</code>. (In the remainder of this section, the six symbols cited are referenced using their default names only as a notational convenience.) Local names may also be affected by the <code>-p</code> option. However, the <code>-p</code> option does not affect <code>#define</code> symbols generated by <code>yacc</code>.</li><li><code>-P <i>parser</i></code> Allows you to specify the parser of your choice instead of <code>/usr/ccs/bin/yaccpar</code>. For example, you can specify: <pre>example% yacc -P ~/myparser parser.y</pre></li><li><code>-Q[y   n]</code> The <code>-Qy</code> option puts the version stamping information in <code>y.tab.c</code>. This allows you to know what version of <code>yacc</code> built the file. The <code>-Qn</code> option (the default) writes no version information.</li></ul>

**-t** Compiles runtime debugging code by default. Runtime debugging code is always generated in `y.tab.c` under conditional compilation control. By default, this code is not included when `y.tab.c` is compiled. Whether or not the `-t` option is used, the runtime debugging code is under the control of `YYDEBUG`, a preprocessor symbol. If `YYDEBUG` has a non-zero value, then the debugging code is included. If its value is 0, then the code will not be included. The size and execution time of a program produced without the runtime debugging code will be smaller and slightly faster.

**-v** Prepares the file `y.output`, which contains a description of the parsing tables and a report on conflicts generated by ambiguities in the grammar.

**-V** Prints on the standard error output the version information for yacc.

**OPERANDS** The following operand is required:

*file* A path name of a file containing instructions for which a parser is to be created.

**EXAMPLES** **EXAMPLE 1** Accessing the yacc library

Access to the yacc library is obtained with library search operands to `cc`. To use the yacc library main:

```
example% cc y.tab.c -ly
```

Both the `lex` library and the yacc library contain `main`. To access the yacc main:

```
example% cc y.tab.c lex.yy.c -ly -ll
```

This ensures that the yacc library is searched first, so that its `main` is used.

The historical yacc libraries have contained two simple functions that are normally coded by the application programmer. These library functions are similar to the following code:

```
#include <locale.h>
int main(void)
{
    extern int yyparse();

    setlocale(LC_ALL, "");

    /* If the following parser is one created by lex, the
       application must be careful to ensure that LC_CTYPE
       and LC_COLLATE are set to the POSIX locale. */
    (void) yyparse();
    return (0);
}
```

## yacc(1)

### EXAMPLE 1 Accessing the yacc library (Continued)

```
#include <stdio.h>

int yyerror(const char *msg)
{
    (void) fprintf(stderr, "%s\n", msg);
    return (0);
}
```

### ENVIRONMENT VARIABLES

See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of yacc: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

yacc can handle characters from EUC primary and supplementary codesets as one-token symbols. EUC codes may only be single character quoted terminal symbols. yacc expects `yylex()` to return a wide character (`wchar_t`) value for these one-token symbols.

### EXIT STATUS

The following exit values are returned:

0 Successful completion.  
>0 An error occurred.

### FILES

`y.output` state transitions of the generated parser  
`y.tab.c` source code of the generated parser  
`y.tab.h` header file for the generated parser  
`yacc.acts` temporary file  
`yacc.debug` temporary file  
`yacc.tmp` temporary file  
`yaccpar` parser prototype for C programs

### ATTRIBUTES

See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbtool
Interface Stability	Standard

### SEE ALSO

[cc\(1B\)](#), [lex\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

### DIAGNOSTICS

The number of reduce-reduce and shift-reduce conflicts is reported on the standard error output. A more detailed report is found in the `y.output` file. Similarly, if some rules are not reachable from the start symbol, this instance is also reported.

**NOTES** | Because file names are fixed, at most one yacc process can be active in a given directory at a given time.

Users are encouraged to avoid using '\$' as part of any identifier name.

yes(1)

**NAME** | yes – generate repetitive affirmative output

**SYNOPSIS** | **yes** [*expletive*...]

**DESCRIPTION** | The *yes* utility repeatedly outputs *y*, or if *expletive* is given, it is output repeatedly, followed by a newline. Multiple arguments are output separated by spaces and followed by a newline. To terminate, type an interrupt character.

| *yes* can be used to respond programatically to programs that require an interactive response.

**ATTRIBUTES** | See *attributes*(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

**SEE ALSO** | *attributes*(5)

**NAME** ypcat – print values in a NIS database

**SYNOPSIS** **ypcat** [-kx] [-d *ypdomain*] *mname*

**DESCRIPTION** The *ypcat* command prints out values in the NIS name service map specified by *mname*, which may be either a map name or a map nickname. Since *ypcat* uses the NIS network services, no NIS server is specified.

Refer to *ypfiles*(4) for an overview of the NIS name service.

**OPTIONS**

- k Display the keys for those maps in which the values are null or the key is not part of the value. None of the maps derived from files that have an ASCII version in */etc* fall into this class.
- d *ypdomain* Specify a domain other than the default domain.
- x Display map nicknames.

**ATTRIBUTES** See *attributes*(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

**SEE ALSO** *ypmatch*(1), *ypfiles*(4), *attributes*(5)

## ypmatch(1)

<b>NAME</b>	ypmatch – print the value of one or more keys from a NIS map				
<b>SYNOPSIS</b>	<b>ypmatch</b> [-k] [-t] [-d <i>domain</i> ] <i>key</i> [ <i>key...</i> ] <i>mname</i> <b>ypmatch</b> -x				
<b>DESCRIPTION</b>	<p>ypmatch prints the values associated with one or more keys from the NIS's name services map specified by <i>mname</i>, which may be either a map name or a map nickname.</p> <p>Multiple keys can be specified; all keys will be searched for in the same map. The keys must be the same case and length. No pattern matching is available. If a key is not matched, a diagnostic message is produced.</p>				
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"><li>-k                    Before printing the value of a key, print the key itself, followed by a colon (:).</li><li>-t                    Inhibit map nickname translation.</li><li>-d <i>domain</i>        Specify a domain other than the default domain.</li><li>-x                    Display the map nickname table. This lists the nicknames the command knows of, and indicates the map name associated with each nickname.</li></ul>				
<b>OPERANDS</b>	<p>The following operand is supported:</p> <p><i>mname</i>     The NIS's name services map</p>				
<b>EXIT STATUS</b>	<p>The following exit values are returned:</p> <ul style="list-style-type: none"><li>0                    Successful operation.</li><li>1                    An error occurred.</li></ul>				
<b>ATTRIBUTES</b>	<p>See <a href="#">attributes(5)</a> for descriptions of the following attributes:</p> <table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWnisu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWnisu

<b>NOTES</b>	<p>ypmatch will fail with an RPC error message on yp operation if enough file descriptors are not available. The number of file descriptors should be increased if this occurs.</p>				

<b>NAME</b>	yppasswd – change your network password in the NIS database				
<b>SYNOPSIS</b>	<b>yppasswd</b> [ <i>username</i> ]				
<b>DESCRIPTION</b>	<p>The <code>yppasswd</code> utility changes the network password associated with the user <i>username</i> in the Network Information Service (NIS) database. If the user has done a <code>keylogin(1)</code>, and a <code>publickey/secretkey</code> pair exists for the user in the NIS <code>publickey.byname</code> map, <code>yppasswd</code> also re-encrypts the <code>secretkey</code> with the new password. The NIS password may be different from the local one on your own machine.</p> <p><code>yppasswd</code> prompts for the old NIS password, and then for the new one. You must type in the old password correctly for the change to take effect. The new password must be typed twice, to forestall mistakes.</p> <p>New passwords must be at least four characters long, if they use a sufficiently rich alphabet, and at least six characters long if monospace. These rules are relaxed if you are insistent enough. Only the owner of the name or the super-user may change a password; superuser on the root master will not be prompted for the old password, and does not need to follow password construction requirements.</p> <p>The NIS password daemon, <code>rpc.yppasswdd</code> must be running on your NIS server in order for the new password to take effect.</p>				
<b>ATTRIBUTES</b>	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWnisu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWnisu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWnisu				
<b>SEE ALSO</b>	<code>keylogin(1)</code> , <code>login(1)</code> , <code>nis+(1)</code> , <code>nispasswd(1)</code> , <code>passwd(1)</code> , <code>getpwnam(3C)</code> , <code>getspnam(3C)</code> , <code>secure_rpc(3NSL)</code> , <code>nsswitch.conf(4)</code> , <code>attributes(5)</code>				
<b>WARNINGS</b>	Even after the user has successfully changed his or her password using this command, the subsequent <code>login(1)</code> using the new password will be successful only if the user's password and shadow information is obtained from NIS. See <code>getpwnam(3C)</code> , <code>getspnam(3C)</code> , and <code>nsswitch.conf(4)</code> .				
<b>NOTES</b>	The use of <code>yppasswd</code> is discouraged, as it is now only a wrapper around the <code>passwd(1)</code> command, which should be used instead. Using <code>passwd(1)</code> with the <code>-r nis</code> option (see <code>nis+(1)</code> ) will achieve the same results, and will be consistent across all the different name services available.				
<b>BUGS</b>	The update protocol passes all the information to the server in one RPC call, without ever looking at it. Thus, if you type your old password incorrectly, you will not be notified until after you have entered your new password.				

## ypwhich(1)

- NAME** ypwhich – return name of NIS server or map master
- SYNOPSIS** **ypwhich** [-d *domain*] [ [-t] -m [*mname*] | [-Vn] *hostname*]  
**ypwhich** -x
- DESCRIPTION** ypwhich returns the name of the NIS server that supplies the NIS name services to a NIS client, or which is the master for a map. If invoked without arguments, it gives the NIS server for the local machine. If *hostname* is specified, that machine is queried to find out which NIS master it is using.
- Refer to ypfiles(4) for an overview of the NIS name services.
- OPTIONS**
- d *domain* Use *domain* instead of the default domain.
  - t This option inhibits map nickname translation.
  - m *mname* Find the master NIS server for a map. No *hostname* can be specified with -m. *mname* can be a mapname, or a nickname for a map. When *mname* is omitted, produce a list of available maps.
  - x Display the map nickname translation table.
  - Vn Version of ypbind, V3 is default.
- ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

<b>NAME</b>	zlogin – enter a zone
<b>SYNOPSIS</b>	<p><b>zlogin</b> [-CE] [-e <i>c</i>] [-l <i>username</i>] <i>zonename</i></p> <p><b>zlogin</b> [-ES] [-e <i>c</i>] [-l <i>username</i>] <i>zonename utility</i> [<i>argument...</i>]</p>
<b>DESCRIPTION</b>	<p>The <b>zlogin</b> utility is used by the administrator to enter an operating system zone. Only a superuser operating in the global system zone can use this utility.</p> <p><b>zlogin</b> operates in one of three modes:</p> <p><b>Interactive Mode</b></p> <p>If no utility argument is given and the stdin file descriptor for the <b>zlogin</b> process is a tty device, <b>zlogin</b> operates in <i>interactive mode</i>. In this mode, <b>zlogin</b> creates a new pseudo terminal for use within the login session. Programs requiring a tty device, for example, <b>vi(1)</b>, work properly in this mode. In this mode, <b>zlogin</b> invokes <b>login(1)</b> to provide a suitable login session.</p> <p><b>Non-Interactive Mode</b></p> <p>If a utility is specified, <b>zlogin</b> operates in <i>non-interactive mode</i>. This mode can be useful for script authors since stdin, stdout, and stderr are preserved and the exit status of <i>utility</i> is returned upon termination. In this mode, <b>zlogin</b> invokes <b>su(1M)</b> in order to set up the user's environment and to provide a login environment.</p> <p><b>Console Mode</b></p> <p>If the <b>-C</b> option is specified, the user is connected to the zone console device and <b>zlogin</b> operates in <i>console mode</i>. The zone console is available once the zone is in the installed state. Connections to the console are persistent across reboot of the zone.</p>
<b>OPTIONS</b>	<p>The following options are supported:</p> <ul style="list-style-type: none"> <li><b>-C</b> Connects to the zone console.</li> <li><b>-e <i>c</i></b> Specifies a different escape character, <i>c</i>, for the key sequence used to access extended functions and to disconnect from the login. The default escape character is the tilde (~).</li> <li><b>-E</b> Disables the ability to access extended functions or to disconnect from the login by using the escape sequence character.</li> <li><b>-l <i>username</i></b> Specifies a different <i>username</i> for the zone login. If you do not use this option, the zone username used is "root". This option is invalid if the <b>-C</b> option is specified.</li> <li><b>-S</b> "Safe" login mode. <b>zlogin</b> does minimal processing and does not invoke <b>login(1)</b> or <b>su(1M)</b>. The <b>-S</b> option can not be used if a username is specified through the <b>-l</b> option, and cannot be used with console logins. This mode should only be used to recover a damaged zone when other forms of login have become impossible.</li> </ul>
<b>Escape Sequences</b>	<p>Lines that you type that start with the tilde character (~) are "escape sequences". The escape character can be changed using the <b>-e</b> option.</p>

## zlogin(1)

`~ .` Disconnects from the zone. This is not the same as a `logout`, because the local host breaks the connection with no warning to the zone's end.

**SECURITY** Once a process has been placed in a zone other than the global zone, the process cannot change zone again, nor can any of its children.

**OPERANDS** The following operands are supported:

*zonename* The name of the zone to be entered.

*utility* The utility to be run in the specified zone.

*argument...* Arguments passed to the utility.

**EXIT STATUS** In interactive and non-interactive modes, the `zlogin` utility exits when the command or shell in the non-global zone exits. In non-interactive mode, the exit status of the remote program is returned as the exit status of `zlogin`. In interactive mode and console login mode, the exit status is not returned. `zlogin` returns a 0 exit status as long as no connection-related error occurred.

In all modes, in the event that a connection to the zone cannot be established, the connection fails unexpectedly, or the user is lacking sufficient privilege to perform the requested operation, `zlogin` exits with status 1.

To summarize, the following exit values are returned:

0 Successful entry.

1 Permission denied, or failure to enter the zone.

Any Return code from utility, or from `su(1M)` if operating in non-interactive mode.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWzoneu
Interface Stability	Evolving

**SEE ALSO** `login(1)`, `vi(1)`, `su(1M)`, `zoneadm(1M)`, `zoncfg(1M)`, `attributes(5)`, `zones(5)`

**NOTES** `zlogin` fails if its open files or any portion of its address space corresponds to an NFS file. This includes the executable itself or the shared libraries.

**NAME** zonename – print name of current zone

**SYNOPSIS** **zonename**

**DESCRIPTION** The zonename utility prints the name of the current zone.

**EXIT STATUS** The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWzoneu
Interface Stability	Evolving

**SEE ALSO** `zlogin(1)`, `zoneadm(1M)`, `zonectfg(1M)`, `attributes(5)`, `zones(5)`

## A

a new version of the network information name service — nis+, 1048  
a new version of the network information name service — NIS+, 1048  
a new version of the network information name service — nis, 1048  
accounting, search and print files —  
  acctcom, 32  
acctcom — search and print process accounting files, 32  
adb — debugger, 35  
addbib — create or extend bibliography, 36  
adds /dev entries to give SunOS 4.x compatible names to SunOS 5.x devices —  
  ucblinks, 1709  
alias — shell built-in functions to create your own pseudonym or shorthand for a command or series of commands, 38  
aliases, collected by sendmail — praliases, 1254  
allocate — allocate devices, 41  
answerbook2 — online documentation system, 44  
appcert — examine application-level products for unstable use of Solaris interfaces, 45  
apply changes to files — patch, 1154  
apptrace — trace application function calls to Solaris shared libraries, 52  
apropos — locate commands by keyword, 56  
ar — maintain portable archive or library, 57  
arch — display architecture of current host, 61  
archive, maintain a portable one across all machines — ar, 57

archives, create tape archives, and add or extract files — tar, 1606  
as — assembler, 62  
asa — convert FORTRAN carriage-control output to printable form, 66  
assembler, — as, 62  
at — execute commands at a later time, 68, 256  
atq — display the jobs queued to run at specified times, 75  
atrm — remove jobs spooled by at or batch, 76  
audio file formats, convert — audioconvert, 77  
audio files  
  play — audioplay, 81  
  record — audiorecord, 83  
audioconvert — convert audio file formats, 77  
audioplay — play audio files, 81  
audiorecord — record an audio file, 83  
authentication agent — ssh-agent, 1542  
authentication key generation —  
  ssh-keygen, 1546  
auths — print authorizations granted to a user, 86  
auto\_ef — auto encoding finder, 88  
auto encoding finder — auto\_ef, 88  
awk — pattern scanning and processing language, 91

## B

banner — make posters, 96  
basename — display portions of pathnames, 99  
basename — strips affixes from path names, 97

batch — execute commands at a later time, 68, 256

bc — arbitrary precision arithmetic language, 100

bdiff — display line-by-line differences between pairs of large text files, 104

bfs — big file scanner, 105  
bfs Commands, 105

bg — shell built-in functions to control process execution, 576

bibliography  
create an inverted index to a bibliographic database — indexbib, 563  
create or extend — addbib, 36  
expand and insert references from a bibliographic database — refer, 1341  
find references in a bibliographic database — lookbib, 795  
format and print a bibliographic database — roffbib, 1368  
sort a bibliographic database — sortbib, 1517

biff — mail notifier, 109

big file scanner — bfs, 105

binary file transmission  
decode binary file — uudecode, 1733  
encode binary file — uuencode, 1733

binary files  
find printable strings — strings, 1557  
locate — whereis, 1787

block count, for a file — sum, 1577

blocks, count a in file — sum, 1578

Bourne shell, — sh, 1478

Bourne shell commands, login command, 1488

Bourne shell variables, 1481  
— CDPATH, 1481  
— HOME, 1481  
— IFS, 1482  
— MAIL, 1481  
— MAILCHECK, 1481  
— MAILPATH, 1481  
— PATH, 1481  
— PS1, 1482  
— PS2, 1482  
— SHACCT, 1482  
— SHELL, 1482

break — shell built-in functions to escape from or advance within a controlling while, for, foreach, or until loop, 110

build programs — make, 881

## C

C compiler, 119

C language, C preprocessor — cpp, 205

C language program, resolve and remove ifdef'ed lines from C program source — undef, 1718

C program verifier — lint, 751

C programming language  
create C error messages — mkstr, 975  
extract strings from C code — xstr, 1806  
formats program in nice style using troff — vgrind, 1756

C shell  
aliases — csh, 235  
built-in commands — csh, 242  
command and filename substitution — csh, 238  
command execution — csh, 241  
command line parsing — csh, 233  
command substitution — csh, 238  
control flow — csh, 240  
environment variables and shell variables — csh, 250  
event designators — csh, 233  
expressions and operators — csh, 239  
filename completion — csh, 232  
filename substitution — csh, 238  
history substitution — csh, 233  
I/O redirection — csh, 236  
initialization and termination — csh, 231  
interactive operation — csh, 231  
job control — csh, 242  
lexical structure — csh, 232  
modifiers — csh, 235  
noninteractive operation — csh, 231  
quick substitution — csh, 235  
signal handling — csh, 241  
status reporting — csh, 242  
variable substitution — csh, 236  
word designators — csh, 234

## C shell commands

- %, 250
- :, 242
- @, 250
- alias, 242
- bg, 243
- break, 243
- breaksw, 243

- chdir, 243
- continue, 243
- default, 243
- dirs, 243
- echo, 243
- else, 245
- end, 244
- endif, 245
- eval, 243
- exec, 243
- exit, 244
- fg, 244
- foreach, 244
- glob, 244
- goto, 244
- hashstat, 244
- history, 244
- if, 244
- jobs, 245
- kill, 245
- limit, 245
- login, 246
- logout, 246
- nice, 246
- nohup, 246
- notify, 247
- onintr, 247
- popd, 247
- pushd, 247
- rehash, 247
- repeat, 247
- set, 247
- setenv, 247
- shift, 248
- source, 248
- stop, 248
- suspend, 249
- switch, 249

## C shell commands (Continued)

- time, 249
- umask, 249
- unalias, 249
- unhash, 249
- unlimit, 249
- unset, 250
- unsetenv, 250
- wait, 250
- while, 250
- cal — display a calendar, 112
- calculate message authentication codes of the input — mac, 837
- calculate a message digest — digest, 303
- calculator, desk, — dc, 286
- calendar — reminder service, 113
- calendar, display — cal, 112
- call-graph, display profile data — gprof, 524
- call rmmount to mount or unmount media — volrmmount, 1774
- cancel — cancel print requests, 115
- cancel user's request for removable media that is not currently in drive — volcancel, 1770
- cat — concatenate and display files, 117
- cc — C compiler, 119
- cd — shell built-in functions to change the current working directory, 121
- CD read and write — cdrw, 125
- CDPATH variable — sh, 1481
- cdrw — CD read and write, 125
- change a user's Kerberos password — kpasswd, 613
- change file access and modification times — touch, 1706
- change file access and modification times — settime, 1669
- touch, 1669
- character translation — tr, 1679, 1684
- chdir — shell built-in functions to change the current working directory, 121
- check spelling — spell, 1521
- check for media in a drive — volcheck, 1771
- check path names — pathchk, 1159
- checkeq — check eqn constructs, 368
- checknr — check nroff/troff files, 131
- chgrp — change the group ownership of a file, 132

chmod — change the permissions mode of a file, 137  
 chown — change owner of file, 143, 146  
 cksum — write file checksums and sizes, 167  
 clear — clear terminal screen, 175  
 cmp — compare two files, 176  
 cocheck — (FMLI utility) communicate with a process, 188  
 cocreate — (FMLI utility) communicate with a process, 188  
 code formatter, formats program in nice style using troff — vgrind, 1756  
 code set, conversion utility — iconv, 554  
 codestroy — (FMLI utility) communicate with a process, 188  
 col — filters reverse line-feeds from two-column nroff text, 178  
 comm — select or reject lines common to two files, 180  
 command — execute a simple command, 182  
 command, describe — whatis, 1786  
 command options  
   parse — getopt, 508  
   parse — getoptcv, 510  
 commands  
   display the last commands executed, in reverse order — lastcomm, 676  
   locate a command; display its pathname or alias — which, 1789  
   locate by keyword — apropos, 56  
 communications  
   connect to remote system — cu, 272  
   connect to remote system — tip, 1653  
   decode binary files — uuencode, 1733  
   encode binary files — uuencode, 1733  
   system to system command execution — uux, 1745  
   talk to another user — talk, 1604  
   UNIX-to-UNIX copy — uucp, 1729  
   user interface to a remote system using the TELNET protocol — telnet, 1621  
   UUCP list of names — uuname, 1729  
   UUCP log — uulog, 1729  
   write to another user — write, 1796  
 compare two files — diff, 296  
 compilers  
   C compiler — cc, 119  
   C program verifier — lint, 751  
   compilers (Continued)  
     regular expression compile — regcmp, 1343  
     RPC protocol compiler — rpcgen, 1372  
 compress — compress files, 185  
 concatenate, files and display them — cat, 117  
 configure LLC2 interface parameters — llc2\_config, 757  
 configure runtime linking environment — crle, 216  
 connect to remote system, — cu, 272  
 construct argument lists and invoke utility — xargs, 1799  
 continue — shell built-in functions to escape from or advance within a controlling while, for, foreach, or until loop, 110  
 control, audio mixer control — mixerctl, 969  
 control line printer — lpc, 804  
 control tracing and manipulate probe points in a process or the kernel — prex, 1262  
 convert binary log file to Common Log File format — ncab2clf, 1035  
 convert binary TNF file to ASCII — tnfdump, 1662  
 convert FORTRAN carriage-control output to printable form — asa, 66  
 convert Red Hat Package (RPM) to cpio archive — rpm2cpio, 1377  
 convert units — units, 1723  
 coproc — (FMLI utility) communicate with a process, 188  
 copy  
   archives — cpio, 196  
   files — cp, 192  
 core image, of running processes — gcore, 466  
 coreceive — (FMLI utility) communicate with a process, 188  
 cosend — (FMLI utility) communicate with a process, 188  
 count blocks in file — sum, 1578  
 count lines, words, characters in file — wc, 1782  
 cp — copy files, 192  
 cpio — copy archives, 196  
 cpp — C preprocessor, 205  
 cputrack — monitor process and LWP behavior using CPU performance counters, 211  
 create, bibliography — addbib, 36

create new task and optionally change project  
 — newtask, 1044  
 crle — configure runtime linking  
 environment, 216  
 crontab — user crontab file, 226  
 crypt — encrypt, 230  
 csh — shell command interpreter with a C-like  
 syntax, 231  
 csplit — split files based on context, 256  
 ct — spawn login to a remote terminal, 259  
 ctags — create a tags file for use with ex and  
 vi, 261  
 ctrun — execute command in a process  
 contract, 264  
 ctstat — display active system contracts, 267  
 ctwatch — watch events in a contract or group  
 of contracts, 270  
 cu — connect to remote system, 272  
 curve, smooth, interpolate — spline, 1523  
 cut — cut out selected fields of each line of a  
 file, 279

## D

date — display date and/or set date, 282  
 date  
 prompts for a date — ckdate, 147  
 provides error message for date —  
 errdate, 147  
 provides help message for date —  
 helpdate, 147  
 validates a date — valdate, 147  
 dead.letter, mail interrupted during input —  
 mail, 846  
 deallocate — deallocate devices, 290  
 debug tools, debugger — adb, 35  
 decode binary file — uudecode, 1733  
 decode files, — crypt, 230  
 decrypt — crypt, 230  
 decrypt — encrypt or decrypt files, 362  
 define locale environment — localedef, 777  
 dependencies, dynamic, of executable files or  
 shared objects — ldd, 720  
 deroff — remove nroff, troff, tbl and eqn  
 constructs, 292  
 describe command — whatis, 1786

describe instruction set architectures —  
 isainfo, 573  
 desk calculator, — dc, 286  
 determine which variant instruction set is  
 optimal to use — optisa, 1136  
 devices  
 allocation — allocate, 41  
 deallocation — deallocate, 290  
 eject media device from drive — eject, 352  
 list\_devices — list\_devices, 753  
 df — display status of disk space on file  
 systems, 293  
 dhcpinfo — display value of parameters  
 received through DHCP, 294  
 dictionary, system, find words — look, 794  
 diff — compare two files, 296  
 diff  
 3-way — diff3, 300  
 big — bdiff, 104  
 diff command, side-by-side — sdiff, 1445  
 diff3 — display line-by-line differences between  
 three text files, 300  
 diffmk — mark differences between versions of  
 a troff input file, 302  
 digest — calculate a message digest, 303  
 digestp — frontends to the mp Text to PDL  
 (Printer Description Language) pretty print  
 filter, 854  
 dircmp — compares contents of directories, 305  
 directories  
 compare contents — dircmp, 305  
 list contents — ls, 821  
 list contents of — ls, 828  
 make — mkdir, 971  
 make link to — ln, 770  
 print working directory name — pwd, 1319  
 remove — rmdir, 1356  
 dirname — delivers all but last level of path  
 name, 97  
 dirs — shell built-in functions to change the  
 current working directory, 121  
 dis — object code disassembler, 306  
 disable — disable LP printers, 360  
 disassembler, object code — dis, 306  
 disk usage, summary — du, 317  
 display editor — vi, 1759  
 display  
 a list of all valid user names — dispuid, 309

display (Continued)

- architecture of current host — arch, 61
- call-graph profile data — gprof, 524
- contents of directory — ls, 821
- current news — news, 1043
- date, 282
- disk usage — du, 320
- dynamic dependencies of executable files or shared objects — ldd, 720
- effective user name — whoami, 1793
- file names — ls, 828
- first few lines of files — head, 541
- group membership of user — groups, 536, 537
- how long the system has been up — uptime, 1727
- identifier of current host — hostid, 552
- last commands executed, in reverse order — lastcomm, 676
- list of all valid group names — dispgid, 308
- login and logout information about users and terminals — last, 674
- name of current host — hostname, 553
- name of the user running the process — logname, 792
- printer queue — lpq, 808
- process status — ps, 1313
- processor type of current host — mach, 839
- selected lines from file — sed, 1454
- size or sizes of a page of memory — pagesize, 1140
- status of disk space on file system — df, 293
- status of local hosts — ruptime, 1389
- status of network hosts — rup, 1387
- users on system — users, 1728
- working directory name — pwd, 1319
- display active system contracts — ctstat, 267
- display discretionary file information — getfacl, 502
- display information about currently logged-in users — w, 1777
- display information about the address space of a process — pmap, 1217
- manifest the optimal expansion of a pathname — moe, 980
- display package parameter values — pkgparam, 1205
- display profile data — prof, 1296
- display the internal versioning information of dynamic objects — pvs, 1316
- display the native instruction sets executable on this platform — isalist, 575
- display value of parameters received through DHCP — dhcpcinfo, 294
- document production
  - check spelling — spell, 1521
  - check nroff/troff files — checknr, 131
  - create an inverted index to a bibliographic database — indexbib, 563
  - create or extend bibliography — addbib, 36
  - eliminate .so's from nroff input — soelim, 1509
  - expand and insert references from a bibliographic database — refer, 1341
  - filters reverse line-feeds from two-column nroff text — col, 178
  - find references in a bibliographic database — lookbib, 795
  - format and print a bibliographic database — roffbib, 1368
  - format documents for display or line-printer — nroff, 1124
  - format tables for nroff or troff — tbl, 1617
  - mark differences between versions of a troff input file — diffmk, 302
  - remove nroff, troff, tbl and eqn constructs — deroff, 292
  - simple text formatters — fmt, 444
  - sort a bibliographic database — sortbib, 1517
  - troff postprocessor for PostScript printers — dpost, 314
  - typeset mathematics — eqn, 368
  - typeset or format documents — troff, 1687
- lari — link analysis of runtime interfaces, 667
- DOS
  - convert text file from DOS format to ISO format — dos2unix, 310
  - convert text file from ISO format to DOS format — unix2dos, 1725
- dos2unix — convert text file from DOS format to ISO format, 310
- download — host resident PostScript font downloader, 312
- download — prepends host resident PostScript fonts to files, 312

dpost — troff postprocessor for PostScript printers, 314  
 draw graph — graph, 529  
 du — summarize disk usage, 317  
 du — display disk usage per directory or file, 320  
 dump — dump selected parts of an object file, 322  
 dump selected parts of an object file — dump, 322  
 dump selected parts of an object file — elfdump, 355  
 dumpcs — show codeset table for the current locale, 325  
 dumpkeys — dump keyboard translation tables, 773  
 link analysis of runtime interfaces — lari, 667

## E

echo — (FMLI utility) put string on virtual output, 331  
 echo — echo arguments, 326  
 echo — echo arguments to standard output, 330  
 ed — text editor, 332  
 edit — text editor, 344  
 editing text, sed — stream editor, 1454  
 egrep — search a file for a pattern using full regular expressions, 349  
 eject — eject media device from drive, 352  
 elfdump — dump selected parts of an object file, 355  
 elfsign — sign binaries for the Solaris Cryptographic Framework, 357  
 enable — enable LP printers, 360  
 encode binary file — uuencode, 1733  
 encode files, — crypt, 230  
 encrypt — encrypt or decrypt files, 362  
 encrypt or decrypt files — decrypt, 362  
 encrypt or decrypt files — encrypt, 362  
 encryption key, user, change — chkey, 135  
 enhance — enhanced command-line editing facilities, 365  
 enhanced command-line editing facilities — enhance, 365  
 enter a zone — zlogin, 1817

env — set environment for command invocation, 366  
 environment  
   display variables — printenv, 1275  
   set terminal characteristics — tset, 1698  
 environment variables, global, FMLI, 1466  
 eqn — mathematical typesetting, 368  
 eqn, remove nroff, troff, tbl and eqn constructs — deroff, 292  
 equations, typeset mathematics — eqn, 368  
 error — analyze error messages, 373  
 eval — shell built-in functions to execute other commands, 387  
 evaluate condition(s) — test, 1633  
 ex — text editor, 376  
 examine application-level products for unstable use of Solaris interfaces — appcert, 45  
 exec — shell built-in functions to execute other commands, 387  
 execute a command in a profile — pfcsh, 1189  
 execute a command in a profile — pfexec, 1189  
 execute a command in a profile — pfksh, 1189  
 execute a command in a profile — pfsh, 1189  
 execute commands at a later time — at, 68, 256  
 execute commands at a later time — batch batch, 68, 256  
 execute a simple command — command, 182  
 execute command in a process contract — ctrun, 264  
 execute command in extended attribute name space — runat, 1384  
 exit — shell built-in functions to enable the execution of the shell to advance beyond its sequence of steps, 389  
 expand — expand TAB characters to SPACE characters, 391  
 export — shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents, 1460  
 exportfs — translates exportfs options to share/unshare commands, 393  
 expr — evaluate arguments as an expression, 394  
 expr — evaluate expressions, 397  
 expression evaluation — expr, 397  
 exstr — extract strings from source files, 400

extract kernel probes output into a trace file —  
tfxtract, 1667  
extract strings from C code — xstr, 1806

## F

face — executable for the Framed Access  
Command Environment Interface, 404  
factor — obtain the prime factors of a  
number, 405  
false — provide truth values, 1690  
fastboot — reboot system without checking  
disks, 406  
fasthalt — halt system without checking  
disks, 406  
fc — shell built-in functions to re-use previous  
command-lines from the current shell, 543  
fdformat — format floppy diskette or PCMCIA  
memory card, 407  
fg — shell built-in functions to control process  
execution, 576  
fgrep — search file for fixed-character  
string, 411  
file — determine file type, 413  
file  
change ownership — chown, 146  
determine type of — file, 416  
display names — ls, 828  
files perusal filter for CRTs — pg, 1191  
make link to — ln, 770  
print — lpr, 810  
strip affixes — basename, 99  
sum — sum and count blocks in file, 1578  
update last modified date of — touch, 1672  
file — get file type, 416  
file system  
display status of disk space — df, 293  
make hard or symbolic links to files —  
ln, 767  
where am I — pwd, 1319  
file transfer program, — ftp, 452  
filep — frontends to the mp Text to PDL (Printer  
Description Language) pretty print filter, 854  
files  
change owner of file — chown, 143  
change the permissions mode of a file —  
chmod, 137

## files (Continued)

compare two files — cmp, 176  
compress — compress, 185  
compress files — pack, 1137  
compress files — pcat, 1137  
concatenate and display — cat, 117  
copy — cp, 192  
copy archives — cpio, 196  
crypt — encrypt/decrypt, 230  
cut out selected fields of each line of a file —  
cut, 279  
display uncompressed files but leaves  
compressed files intact — zcat, 185  
display a count of lines, words and  
characters in a file — wc, 1782  
display first few lines — head, 541  
display last part — tail, 1601  
display line-by-line differences between pairs  
of large text files — bdiff, 104  
display line-by-line differences between three  
text files — diff3, 300  
expand compressed files — unpack, 1137  
extract SCCS version information from a file  
— what, 1784  
— find, 425  
mark differences between versions of a troff  
input file — diffmk, 302  
merge same lines of several files or  
subsequent lines of one file — paste, 1151  
move — mv, 1009  
print checksum and block count for a file —  
sum, 1577  
print differences between two files  
side-by-side — sdiff, 1445  
remove — rm, 1356  
search a file for a pattern — grep, 531  
search file for fixed-character string —  
fgrep, 411  
search for a pattern using full regular  
expressions — egrep, 349  
sort or merge — sort, 1510  
split a file into pieces — split, 1524  
strip affixes from path names —  
basename, 97  
transfer to and from a remote machine —  
tftp, 1645  
uncompress — uncompress, 185

filesync — synchronize files and directories, 418  
 Multiple Nomadic Machines, 420  
 Rules File, 419

filofaxp — frontends to the mp Text to PDL (Printer Description Language) pretty print filter, 854

find — find files, 425

find or signal processes by name and other attributes  
 — pgrep, 1196  
 — pkill, 1196

fmlcut — (FMLI utility) cut out columns from a table or fields from each line of a file, 435

fmlexpr — (FMLI utility) evaluate arguments as an expression, 437

fmlgrep — (FMLI utility) search afile for a pattern, 439

FMLI

- cocheck — communicate with a process, 188
- cocreate — communicate with a process, 188
- codestroy — communicate with a process, 188
- coproc — communicate with a process, 188
- coreceive — communicate with a process, 188
- cosend — communicate with a process, 188
- echo — put string on virtual output, 331
- fmlcut — cut out columns from a table or fields from each line of a file, 435
- fmlexpr — evaluate arguments as an expression, 437
- fmlgrep — search afile for a pattern, 439
- fmli — invoke fmli, 441
- getfrm — returns the current frameID number, 506
- getitems — returns a list of currently marked menu items, 507
- indicator — displays application specific alarms or working indicator, or both, on FMLI banner line, 562
- message — puts arguments on FMLI message line, 967
- pathconv — converts an alias to its pathname, 1162
- readfile, longline — reads file, gets longest line, 1338

FMLI (Continued)

- regex — match patterns against a string, 1345
- reinit — changes the descriptors in the initialization file, 1347
- reset — (FMLI utility) changes the entry in a field of a form to its default value, 1351
- run — runs a program, 1383
- set, unset — set and unset local or global environment variables, 1466
- setcolor — redefine or create a color, 1468
- shell — run a command using shell, 1496
- test — evaluates the expression expression, 1643
- vsig — synchronize a co-process with the controlling FMLI application, 1776

fmt — simple text formatters, 444

fold — fold long lines, 449

fonts, prepends host resident PostScript fonts to files — download, 312

force a defunct process to be reaped by its parent — preap, 1260

format floppy diskette or PCMCIA memory card — fdformat, 407

formatters, text, — fmt, 444

Forms and Menu Language Interpreter, *See* FMLI

FORTTRAN, create a tags file for use with ex and vi — ctags, 261

Framed Access Command Environment, *See* face

frameID number (FMLI utility) — getfrm, 506

franklinp — frontends to the mp Text to PDL (Printer Description Language) pretty print filter, 854

from — sender of mail messages, 451

frontends to the mp Text to PDL (Printer Description Language) pretty print filter — digestp, 854

frontends to the mp Text to PDL (Printer Description Language) pretty print filter — filep, 854

frontends to the mp Text to PDL (Printer Description Language) pretty print filter — filofaxp, 854

frontends to the mp Text to PDL (Printer Description Language) pretty print filter — franklinp, 854

frontends to the mp Text to PDL (Printer Description Language) pretty print filter — mailp, 854

frontends to the mp Text to PDL (Printer Description Language) pretty print filter — newsp, 854

frontends to the mp Text to PDL (Printer Description Language) pretty print filter — timemanp, 854

frontends to the mp Text to PDL (Printer Description Language) pretty print filter — timesysp, 854

ftp — file transfer program, 452

ftpcount — show current number of users in each FTP Server class, 464

ftpwho — show current process information for each FTP Server user, 465

function calls, trace application function calls to Solaris shared libraries — apptrace, 52

## G

gather public ssh host keys of a number of hosts — ssh-keyscan, 1550

gcore — get core images of running processes, 466

gencat — generate a formatted message catalog, 468

generate iconv code conversion tables — geniconvtbl, 471

generate LLC2 configuration files — llc2\_autoconfig, 756

generate message source file from source files — genmsg, 489

generate programs for lexical tasks — lex, 733

generate repetitive affirmative output — yes, 1812

geniconvtbl — generate iconv code conversion tables, 471

genmsg — generate message source file from source files, 489

- Auto Message Numbering, 489
- Comment Extraction, 489
- Invocation, 489
- Testing, 489

get configuration values — getconf, 495

get locale-specific information — locale, 774

get or set the resource controls of running processes, tasks, and projects — prctl, 1255

get or set the resource limits of running processes, — plimit, 1213

getconf — get configuration values, 495

getfacl — display discretionary file information, 502

getfrm — (FMLI utility) returns the current frameID number, 506

getitems — (FMLI utility) returns a list of currently marked menu items, 507

getopt — parse command options, 508

getoptcvl — parse command options, 510

getopts — shell built-in function to parse command-line options, 513

gettext — retrieve text string from message database, 519

gettxt — retrieve text string from message database, 521

glob — shell built-in function to expand a word list, 523

goto — shell built-in functions to enable the execution of the shell to advance beyond its sequence of steps, 389

gprof — call-graph profile, 524

graph — draw graph, 529

graphics filters for plotters — plot, 1215

graphics filters for plotters — tplot, 1673

graphics, interpolate smooth curve — spline, 1523

grep

- search a file for a pattern — grep, 531
- search a file for a pattern using full regular expressions — egrep, 349
- search file for fixed-character string — fgrep, 411

group IDs

- change real and effective — newgrp, 1041
- change the group ownership of a file — chgrp, 132
- display a list of all valid group names — dispgid, 308
- prompts for group ID — ckgid, 149
- provides error message for group ID — errgid, 149
- provides help message for group ID — helpgid, 149
- validates group ID — valgid, 149

groups — display group membership, 537  
groups — print group membership of user, 536  
grpck — check group database entries, 538

## H

halt system without checking disks —  
  fasthalt, 406  
hash — shell built-in functions to evaluate the  
  internal hash table of the contents of  
  directories, 539  
hashstat — shell built-in functions to evaluate  
  the internal hash table of the contents of  
  directories, 539  
head — display first few lines of files, 541  
Header, SYNOPSIS, 1182  
history — shell built-in functions to re-use  
  previous command-lines from the current  
  shell, 543  
HOME variable — sh, 1481  
host machines, local  
  show status — ruptime, 1389  
  who is logged in — rwho, 1393  
host machines, remote  
  display status of network hosts (RPC  
  version) — rup, 1387  
  who is logged in — rusers, 1392  
host resident PostScript font downloader —  
  download, 312  
hostid — display host ID, 552  
hostname — display host name, 553

## I

i386 — get processor type truth value, 840  
iAPX286 — get processor type truth value, 840  
idnconv — Internationalized Domain Name  
  (IDN) encoding conversion utility, 557  
IFS variable — sh, 1482  
in situ kernel debugger — kmdb, 607  
indicator — (FMLI utility) displays application  
  specific alarms or working indicator, or both,  
  on FMLI banner line, 562  
indxbib — create an inverted index to a  
  bibliographic database, 563  
install — install files, 564

instruction set, determining which variant is  
  optimal to use — optisa, 1136  
integer  
  prompts for an integer — ckint, 151  
  provides error message for integer —  
  errint, 151  
  provides help message for integer —  
  helpint, 151  
  validates an integer — valint, 151  
integer, range  
  prompts for an integer within a specified  
  range — ckrange, 161  
  provides error message for integer within a  
  specified range — errrange, 161  
  provides help message for integer within a  
  specified range — helprange, 161  
  validate an integer within a specified range  
  — valrange, 161  
interactive message processing system —  
  mail, 852  
interactive message processing system —  
  Mail, 852  
Internationalized Domain Name (IDN)  
  encoding conversion utility — idnconv, 557  
Internet  
  transfer files to and from a remote machine  
  — tftp, 1645  
  transfer of files to and from remote network  
  sites — ftp, 452  
  user name directory service — whois, 1795  
interprocess communication  
  remove a message queue, semaphore set, or  
  shared memory ID — ipcrm, 566  
  report status — ipcs, 568  
invoke a command with an altered scheduling  
  priority — nice, 1046  
ipcrm — remove a message queue, semaphore  
  set, or shared memory ID, 566  
ipcs — report inter-process communication  
  facilities status, 568  
isainfo — describe instruction set  
  architectures, 573  
isalist — display the native instruction sets  
  executable on this platform, 575

## J

- jobs — shell built-in functions to control process execution, 576
- join — relational database operator, 583
- jsh — the job control shell command interpreter, 1478

## K

- kbd — manipulate the state of keyboard or display the type of keyboard or change the default keyboard abort sequence effect, 586
- Kerberos keytab maintenance utility — ktutil, 665
- Kerberos login utility, — kinit, 600
- Kerberos tickets
  - destroy — kdestroy, 591
  - list currently held — klist, 605
- keyboard
  - load and dump keyboard translation tables — loadkeys, dumpkeys, 773
  - manipulate the state of keyboard or display the type of keyboard or change the default keyboard abort sequence effect — kbd, 586
- keylogin — decrypt and store secret key with keyserv, 593
- keylogout — delete stored secret key with keyserv, 595
- keywords, prompts for and validates a keyword — ckkeywd, 156
- kill — terminate a process by default, 596
- kmdb — in situ kernel debugger, 607
- Korn shell commands, login command, 652
- KornShell
  - aliasing — ksh, 616
  - arithmetic evaluation — ksh, 632
  - blank interpretation — ksh, 631
  - command execution — ksh, 640
  - command re-entry — ksh, 640
  - command substitution — ksh, 619
  - commands — ksh, 614
  - comments — ksh, 616
  - conditional expressions — ksh, 632
  - definitions — ksh, 614
  - emacs editing mode — ksh, 641
  - environment — ksh, 636

## KornShell (Continued)

- file name generation — ksh, 631
- functions — ksh, 637
- I/O — ksh, 634
- in-line editing options — ksh, 640
- invocation — ksh, 661
- jobs — ksh, 638
- jobs — shell\_builtins, 578
- parameter substitution — ksh, 622
- process substitution — ksh, 622
- prompting — ksh, 632
- quoting — ksh, 632
- restricted command and programming
  - language — rksh, 614
- signals — ksh, 639
- special commands — ksh, 648
- tilde substitution — ksh, 618
- vi editing mode — ksh, 644
- kpasswd — change a user's Kerberos password, 613
- ksh — KornShell, a standard command and programming language, 614
- ktutil — Kerberos keytab maintenance utility, 665

## L

- languages
  - C compiler — cc, 119
  - C preprocessor — cpp, 205
  - C program verifier — lint, 751
  - create C error messages — mkstr, 975
  - extract strings from C code — xstr, 1806
- last — display login and logout information about users and terminals, 674
- lastcomm — display the last commands executed, in reverse order, 676
- ld — link-editor for object files, 678
- ld — link editor, 691
- ld.so.1 — runtime linker for dynamic objects, 725
- ldap — LDAP as a naming repository, 692
- LDAP as a naming repository — ldap, 692
- ldap delete entry tool — ldapdelete, 696
- ldap entry addition and modification tools
  - ldapadd, 703
  - ldapmodify, 703

- ldap modify entry RDN tool —
  - ldapmodrdn, 709
- ldap search tool — ldapsearch, 713
- ldapadd — ldap entry addition and modification tools, 703
- ldapdelete — ldap delete entry tool, 696
- ldapmodify — ldap entry addition and modification tools, 703
- ldapmodrdn — ldap modify entry RDN tool, 709
  - Input Format, 712
- ldapsearch — ldap search tool, 713
  - Output Format, 713
- ldd — list dynamic dependencies of executable files or shared objects, 720
- let — shell built-in function to evaluate one or more arithmetic expressions, 732
- lex — generate programs for lexical tasks, 733
  - Actions in lex, 740
- lex, create a tags file for use with ex and vi — ctags, 261
- lex — generate programs for lexical tasks
  - Definitions in lex, 735
  - Output Files, 734
  - Regular Expressions in lex, 737
  - Rules in lex, 737
  - Stderr, 734
  - Stdout, 733
  - User Subroutines in lex, 737
- library archive, find ordering relation for an object or library archive — lorder, 796
- limit — set or get limitations on the system resources available to the current shell and its descendents, 745
  - csh, 745
  - ksh, 745
  - sh, 745
  - sh/ksh, 748
  - /usr/bin/ulimit, 745
- line — read one line from standard input and write to standard output, 750
- line numbering filter — nl, 1112
- line printer control — lpc, 804
- link, make hard or symbolic links to files — ln, 767
- link editor — ld, 691
- link-editor — ld, 678
- lint — C program verifier, 751
- list
  - contents of directory — ls, 821
  - file names — ls, 828
  - list, sorted, find lines — look, 794
  - list\_devices — list\_devices, 753
  - list of service grades, print — uuglist, 1737
  - listusers — list user login information, 755
  - llc2\_autoconfig — generate LLC2 configuration files, 756
  - llc2\_config — configure LLC2 interface parameters, 757
  - LLC2 Station, SAP, and Connection Statistics — llc2\_stats, 759
  - llc2\_stats — LLC2 Station, SAP, and Connection Statistics, 759
  - ln — make hard or symbolic links to files, 767
  - loadkeys — load keyboard translation tables, 773
  - locale — get locale-specific information, 774
  - localedef — define locale environment, 777
  - log, system, add entries — logger, 782
  - logger — add entries to the system log, 782
  - logger — make system log entry, 784
  - login — sign on to the system, 785
  - login command, 652, 1488
  - login
    - change login password and password attributes — passwd, 1143
    - display effective user name — whoami, 1793
    - display login and logout information about users and terminals — last, 674
    - get the name of the user running the process — logname, 792
    - list user login information — listusers, 755
    - remote — rlogin, 1352
    - spawn login to a remote terminal — ct, 259
    - who is logged in, and what are they doing — w, 1777
  - login environment
    - display variables — printenv, 1275
    - set terminal characteristics — tset, 1698
  - login password, change in NIS — yppasswd, 1815
  - logname — get the name of the user running the process, 792
  - logout — shell built-in function to exit from a login session, 793

logout, display login and logout information  
 about users and terminals — last, 674  
 look — find words in the system dictionary or  
 lines in a sorted list, 794  
 lookbib — find references in a bibliographic  
 database, 795  
 lorder — find ordering relation for an object or  
 library archive, 796  
 lp — send requests to a print service, 797  
 LP print services  
 cancel requests — cancel, 115  
 control line printer — lpc, 804  
 display printer queue — lpq, 808  
 generate printer test pattern — lptest, 820  
 print files — lp, 797  
 print files (BSD) — lpr, 810  
 remove print jobs — lprm, 814  
 lpc — line printer control, 804  
 lpq — display printer queue, 808  
 lpr — print files, 810  
 lprm — remove print jobs, 814  
 lpstat — print information about the status of  
 the print service, 816  
 lptest — generate printer test pattern, 820  
 ls — list contents of directory, 821  
 ls — list files, 828

## M

m4 — macro processor, 831  
 mac — calculate message authentication codes  
 of the input, 837  
 mach — display processor type of current  
 host, 839  
 machid — get processor type truth value, 840  
 machine IDs, get processor type truth value —  
 machid, 840  
 macro processor — m4, 831  
 madv library — madv.so.1, 842  
 madv.so.1 — madv library, 842  
 magnetic tape  
 backspace files — mt, 1006  
 backspace records — mt, 1006  
 copy — tcopy, 1619  
 erase — mt, 1006  
 forward space files — mt, 1006  
 forward space records — mt, 1006

magnetic tape (Continued)  
 get unit status — mt, 1006  
 manipulate — mt, 1006  
 place unit off-line — mt, 1006  
 retention — mt, 1006  
 rewind — mt, 1006  
 skip backward files — mt, 1006  
 skip backward records — mt, 1006  
 skip forward files — mt, 1006  
 skip forward records — mt, 1006  
 write EOF mark on — mt, 1006  
 mail — interactive message processing  
 system, 852  
 Mail — interactive message processing  
 system, 852  
 mail — read mail or send mail to users, 846  
 MAIL variable — sh, 1481  
 mail, automatic replies — vacation, 1749  
 mail aliases, aliases— system mail, 1254  
 mail services  
 mail notifier — biff, 109  
 sender of mail messages — from, 451  
 mail utilities, statistics — mailstats, 858  
 mailbox, storage for incoming mail —  
 mailx, 860  
 MAILCHECK variable — sh, 1481  
 mailcompat — provide SunOS compatibility for  
 Solaris mailbox format, 853  
 mailp — frontends to the mp Text to PDL  
 (Printer Description Language) pretty print  
 filter, 854  
 mailstats — mail delivery statistics, 858  
 mailx — interactive message processing  
 system, 860, 880  
 mailx commands  
 — !, 864  
 — #, 864  
 — =, 864  
 — ?, 864  
 — |, 868  
 — z, 871  
 — alias, 864  
 — alternates, 864  
 — cd, 864  
 — chdir, 864  
 — Copy, 864  
 — copy, 864  
 — delete, 865

mailx commands (Continued)

- discard, 865
- dp, 865
- dt, 865
- echo, 865
- edit, 865
- else, 866
- endif, 866
- exit, 865
- field, 865
- file, 865
- folder, 865
- Followup, 866
- followup, 866
- from, 866
- group, 864
- headers, 866
- help, 866
- hold, 866, 868
- if, 866
- ignore, 865
- inc, 866
- list, 867
- load, 867
- mail, 867
- mbox, 867
- More, 867
- New, 867
- new, 867
- next, 868
- Page, 867
- pipe, 868
- preserve, 866, 868
- Print, 868, 870
- print, 868, 870
- Put, 868
- put, 868
- quit, 868
- Reply, 869
- reply, 868
- replyall, 869
- replysender, 868
- Respond, 869
- respond, 868
- retain, 869
- Save, 869
- save, 869
- set, 869

mailx commands (Continued)

- shell, 869
  - size, 870
  - source, 870
  - top, 870
  - touch, 870
  - Type, 868, 870
  - type, 868, 870
  - unalias, 870
  - undelete, 870
  - undiscard, 870
  - ungroup, 870
  - unignore, 870
  - Unread, 867, 870
  - unread, 867, 870
  - unretain, 870
  - unset, 870
  - version, 870
  - visual, 871
  - write, 871
  - xit, 871
- maintain groups of programs —  
  sysV-make, 1590
- make — maintain, update, and regenerate  
  related programs and files  
    Appending to a Macro, 890  
    Bourne Shell Constructs, 910  
    Clearing Special Targets, 889  
    Command Dependencies, 889  
    Command Execution, 909  
    Command Substitutions, 910  
    Conditional Macro Definitions, 892  
    Dynamic Macros, 892  
    Global, 885  
    Hidden Dependencies, 889  
    Implicit Rules, 896  
    implicit rules, list of make/make.rules, 909  
    Library Maintenance, 909  
    Macros, 886, 889  
    Makefile Target Entries, 884  
    Pattern Matching Rules, 896  
    Pattern Replacement Macro References, 890  
    Predefined Macros, 893  
    Reading Makefiles and the  
      Environment, 884  
    Rules, 887  
    Signals, 911  
    Special Characters, 885

make — maintain, update, and regenerate related programs and files (Continued)  
 Special-Function Targets, 887  
 Special-Purpose Macros, 890  
 Suffix Replacement Macro References, 890  
 Suffix Rules, 896

make, System V version of make —  
 sysV-make, 1590

make — maintain, update, and regenerate related programs and files  
 Targets and Dependencies, 885  
 The Suffixes List, 909

make temporary filename — mktemp, 977

man — online display of reference pages, 916

manage softtoken object storage —  
 pktool, 1212

manual pages  
 accessing — man, 916  
 describe command — whatis, 1786  
 locate — whereis, 1787

matrix display program for PostScript printers —  
 postmd, 1232

mbox, storage file for read mail — mailx, 860

mconnect — open connection to remote mail server, 922

mcs — manipulate the comment section of an object file, 923

mdb — modular debugger, 925

menu item  
 builds a menu and prompts user to choose one item from menu — ckitem, 153  
 provides error message for menu item — erritem, 153  
 provides help message for menu item — helpitem, 153

menu items, FMLI, returns a list of —  
 getitems, 507

mesg — permit or deny messages via write, 966

message — puts arguments on FMLI message line, 967

messages  
 create message object file — msgfmt, 1000  
 display contents of, or search for a text string in, message data bases — srchtxt, 1526  
 display on stderr or system console — fmtmsg, 445  
 extract gettext call strings — xgettext, 1804

messages (Continued)  
 generate a formatted message catalog — gencat, 468  
 permit or deny messages via write — mesg, 966  
 retrieve text string from message database — gettext, 519

mixerctl — audio mixer control, 969

mkdir — make directories, 971

mkmsgs — create message files for use by  
 gettxt, 973

mkstr — create C error messages, 975

mktemp — make temporary filename, 977

modify the Access Control List (ACL) for a file or files — setfacl, 1469

modular debugger — mdb, 925

moe — manifest the optimal expansion of a pathname, 980

monitor process and LWP behavior using CPU performance counters — cputrack, 211

more — browse through a text file, 982

mp — text to PDL (Page Description Language) pretty print filter, 989

mpss.so.1 — shared object for setting preferred page size, 997

msgfmt — create message object file, 1000

mt — manipulate magnetic tape, 1006

mv — move files, 1009

## N

nawk — pattern scanning and processing language, 1012  
 Actions, 1012  
 Arithmetic Functions, 1012  
 Expression Patterns, 1012  
 Expressions in nawk, 1012  
 Functions, 1012  
 Input/Output and General Functions, 1012  
 Output Statements, 1012  
 Pattern Ranges, 1012  
 Patterns, 1012  
 Regular Expressions, 1012  
 Special Patterns, 1012  
 String Functions, 1012  
 User-defined Functions, 1012  
 /usr/bin/nawk, 1012

nawk — pattern scanning and processing language (Continued)  
 /usr/xcu4/bin/awk, 1012  
 /usr/xpg4/bin/awk, 1012  
 Variables and Special Variables, 1012

NCA — the Network Cache and Accelerator (NCA), 1033

nca — the Network Cache and Accelerator (NCA), 1033

ncab2clf — convert binary log file to Common Log File format, 1035

ncakmod — start or stop the NCA kernel module, 1037

neqn — mathematical typesetting, 368

newform — change the format of a text file, 1038

newgrp — changes a user's group ID, 1041

newgrp — shell built-in function to allow new group permissions to the user, 1041

news — print news items, 1043

newsp — frontends to the mp Text to PDL (Printer Description Language) pretty print filter, 854

newtask — create new task and optionally change project, 1044

NFS, secure  
 decrypt and store secret key with keyserv — keylogin, 593  
 delete stored secret key with keyserv—keylogout, 595

nice — invoke a command with an altered scheduling priority, 1046

nice, change process nice value — renice, 1348

nice — invoke a command with an altered scheduling priority, csh Builtin, 1046

nis — a new version of the network information name service, 1048

NIS  
 change login password in — yppasswd, 1815  
 print the value of one or more keys from a NIS map — ypmatch, 1814  
 print values in a NIS database — ypcat, 1813  
 return name of NIS server or map master — ypwhich, 1816

nis+ — a new version of the network information name service, 1048

NIS+ — a new version of the network information name service, 1048

NIS+  
 Authentication — nis+, 1055  
 Authorization — nis+, 1055  
 change access rights on a NIS+ object — nischmod, 1068  
 change password information — nispasswd, 1096  
 change the group owner of a NIS+ object — nischgrp, 1066  
 change the owner of a NIS+ object — nischown, 1071  
 change the time to live of a NIS+ object — nischttl, 1073  
 Concatenation Path — nis+, 1051  
 create NIS+ directories — nismkdir, 1090  
 Directories and Domains — nis+, 1054  
 Directory Authorization — nis+, 1056  
 display NIS+ defaults — nisdefaults, 1075  
 display NIS+ error messages — niserror, 1078  
 display tables — niscat, 1063  
 Grammar — nis+, 1050  
 Group Names — nis+, 1054  
 group administration — nisgrpadm, 1079  
 Indexed Names — nis+, 1049  
 list the contents of a NIS+ directory — nisl, 1085  
 Name Expansion — nis+, 1050  
 Namespaces — nis+, 1052  
 NIS+ Administrative Commands — nis+, 1059  
 NIS+ Directory Object — nis+, 1048  
 NIS+ Files and Directories — nis+, 1061  
 NIS+ Group Object — nis+, 1048  
 NIS+ Link Object — nis+, 1049  
 NIS+ Programming API — nis+, 1060  
 NIS+ Table Object — nis+, 1048  
 NIS+ User Commands — nis+, 1058  
 Principal Names — nis+, 1052  
 remove directories — nisrmdir, 1102  
 remove objects — nisrm, 1100  
 return the state of the NIS+ namespace using a conditional expression — nistest, 1110  
 Simple Names — nis+, 1049  
 symbolically link NIS+ objects — nisln, 1083  
 Table Authorization — nis+, 1057

NIS+ (Continued)

- table administration tool — nistbladm, 1104
- utilities for searching NIS+ tables —
  - nismatch, nisgrep, 1087
- niscat — display NIS+ tables, 1063
- nischgrp — change the group owner of a NIS+ object, 1066
- nischmod — change access rights on a NIS+ object, 1068
- nischown — change the owner of a NIS+ object, 1071
- nischttl — change the time to live of a NIS+ object, 1073
- nisdefaults — display NIS+ defaults, 1075
- niserror — display NIS+ error messages, 1078
- nisgrep — utility for searching NIS+ tables, 1087
- nisgrpadm — NIS+ group administration command, 1079
- nisl — symbolically link NIS+ objects, 1083
- nisl — list the contents of a NIS+ directory, 1085
- nismatch — utility for searching NIS+ tables, 1087
- nismkdir — create a NIS+ directory, 1090
- nism — remove NIS+ objects, 1100
- nismrmdir — remove a NIS+ directory, 1102
- nistbladm — administer NIS+ tables, 1104
- nistest — return the state of the NIS+ namespace using a conditional expression, 1110
- nl — number lines, 1112
- nm — print name list of an object file, 1115
- nohup — run a command immune to hangups, 1120
- notify — shell built-in functions to control process execution, 576
- notify user that volume requested is not in the CD-ROM or floppy drive —
  - volmissing, 1773
- nroff — format documents for display or line-printer, 1124
- nroff utilities
  - check nroff and troff files — checknr, 131
  - eliminate .so's from nroff input — soelim, 1509
  - filters reverse line-feeds from two-column nroff text — col, 178

nroff utilities (Continued)

- format tables — tbl, 1617
- remove nroff, troff, tbl and eqn constructs —
  - deroff, 292

## O

- object archive, find ordering relation for an object or library archive — lorder, 796
- object files
  - find printable strings — strings, 1557
  - manipulate the comment section — mcs, 923
  - print section sizes in bytes — size, 1503
  - strip symbol table, debugging and line number information — strip, 1559
- octal dump, — od, 1127
- od — octal dump, 1127
- on — execute a command on a remote system with the local environment, 1134
- onintr — shell built-in functions to respond to (hardware) signals, 1685
- online documentation system, —
  - answerbook2, 44
- online reference pages — man, 916
- optisa — determine which variant instruction set is optimal to use, 1136

## P

- pack — compress files, 1137
- page — page through a text file, 982
- pagesize — display size or sizes of a page of memory, 1140
- pargs — print process arguments, environment variables, or auxiliary vector, 1141
- Pascal, create a tags file for use with ex and vi —
  - ctags, 261
- passwd — change login password and password attributes, 1143
- password, change in NIS — yppasswd, 1815
- password file, edit — vipw, 1769
- passwords, change login password and password attributes — passwd, 1143
- paste — merge same lines of several files or subsequent lines of one file, 1151
- patch — apply changes to files, 1154

patch — apply changes to files (Continued)  
     File Name Determination, 1157  
     Patch Application, 1157  
     Patch File Format, 1156  
 PATH variable — sh, 1481  
 pathchk — check path names, 1159  
 pathconv — search FMLI criteria for  
     filename, 1162  
 pathname  
     prompts for a pathname — ckpath, 158  
     provides error message for pathname —  
         errpath, 158  
     provides help message for pathname —  
         helppath, 158  
     validates pathname — valpath, 158  
 pattern scanning and processing language —  
     nawk, 1012  
 pax — portable archive interchange, 1164  
     Modes of Operations, 1164  
     Output Files, 1178  
     Standard Error, 1177  
     Standard Output, 1177  
 pcat — compress files, 1137  
 pcred — proc tools, 1292  
 pdp11 — get processor type truth value, 840  
 performance monitoring  
     display call-graph profile data — gprof, 524  
     resource usage for a command —  
         rusage, 1390  
     time a command; report process data and  
         system activity — timex, 1651  
 pfcsh — execute a command in a profile, 1189  
 pfexec — execute a command in a profile, 1189  
 pfiles — proc tools, 1292  
 pfksh — execute a command in a profile, 1189  
 pflags — proc tools, 1292  
 pfsh — execute a command in a profile, 1189  
 pg — files perusal filter for CRTs, 1191  
 pgrep — find processes by name and other  
     attributes, 1196  
 pkginfo — display software package  
     information, 1200  
 pkgmk — produce an installable package, 1202  
 pkgparam — display package parameter  
     values, 1205  
 pkgproto — generate prototype file entries for  
     input to pkgmk command, 1207  
 pkgtrans — translate package format, 1209  
 pkill — signal processes by name and other  
     attributes, 1196  
 pktool — manage softtoken object  
     storage, 1212  
 pldd — proc tools, 1292  
 plimit — get or set the resource limits of  
     running processes, 1213  
 plot — graphics filters for plotters, 1215  
 plotters, graphics filters — plot, 1215  
 graphics filters — tplot, graphics filters, 1673  
 pmap — display information about the address  
     space of a process, 1217  
 popd — shell built-in functions to change the  
     current working directory, 121  
 portable archive interchange — pax, 1164  
 postplot — PostScript translator for plot(4B)  
     graphics files, 1235  
 postdaisy — PostScript translator for Diablo 630  
     daisy-wheel files, 1225  
 postdmd — PostScript translator for DMD  
     bitmap files, 1227  
 postio — serial interface for PostScript  
     printers, 1229  
 postmd — matrix display program for  
     PostScript printers, 1232  
 postprint — PostScript translator for text  
     files, 1237  
 postprocessors, troff for PostScript printers —  
     dpost, 314  
 postreverse — reverse the page order in a  
     PostScript file, 1239  
 PostScript  
     matrix display program — postmd, 1232  
     prepends host resident PostScript fonts to  
         files — download, 312  
     reverse the page order in a PostScript file —  
         postreverse, 1239  
     serial interface — postio, 1229  
     translator for Diablo 630 daisy-wheel files —  
         postdaisy, 1225  
     translator for DMD bitmap files —  
         postdmd, 1227  
     translator for plot(4B) graphics files —  
         postplot, 1235  
     translator for Tektronix 4014 files —  
         posttek, 1241  
     translator for text files — postprint, 1237

## PostScript (Continued)

- troff postprocessor for PostScript printers —  
dpost, 314
- PostScript translator for Diablo 630 daisy-wheel  
files — postdaisy, 1225
- PostScript translator for MD bitmap files —  
postdmd, 1227
- PostScript translator for Tektronix 4014 files —  
posttek, 1241
- PostScript translator for text files —  
postprint, 1237
- posttek — PostScript translator for Tektronix  
4014 files, 1241
- pr — print files, 1249
- praliases — display system mail aliases, 1254
- prctl — get or set the resource controls of  
running processes, tasks, and projects, 1255
- preap — force a defunct process to be reaped by  
its parent, 1260
- prex — control tracing and manipulate probe  
points in a process or the kernel, 1262
- prime factors, obtain for a number —  
factor, 405
- print — shell built-in function to output  
characters to the screen or window, 1274
- print
  - formatted output — printf, 1276
  - print files — pr, 1249
- print process arguments, environment variables,  
or auxiliary vector — pargs, 1141
- print authorizations granted to a user —  
auths, 86
- print execution profiles for a user —  
profiles, 1300
- print files — lpr, 810
- print files, prepends host resident PostScript  
fonts to files — download, 312
- print name of current zone — zonename, 1819
- print project membership of user —  
projects, 1302
- print roles granted to a user — roles, 1370
- print services, print information about the  
status — lpstat, 816
- printenv — display environment  
variables, 1275
- printers
  - cancel requests — cancel, 115
  - control — lpc, 804

## printers (Continued)

- display queue — lpq, 808
  - print information about the status —  
lpstat, 816
  - remove jobs from queue — lprm, 814
  - send requests — lp, 797
  - test — lptest, 820
- ## printers, LP
- disable, 360
  - enable, 360
- ## printf — print formatted output, 1276
- ## proc tools
- pcred, 1292
  - pfiles, 1292
  - pflags, 1292
  - pldd, 1292
  - prun, 1292
  - psig, 1292
  - pstack, 1292
  - pstop, 1292
  - ptime, 1292
  - ptree, 1292
  - pwait, 1292
  - pwdx, 1292
- ## process, running, change priority — renice, 1348
- ## process accounting
- search and print files — acctcom, 32
  - time a command; report process data and  
system activity — timex, 1651
- ## process scheduler, display or set scheduling parameters of specified process(es) — priosctl, 1281
- ## process status, report — ps, 1304
- ## processes
- display status — ps, 1313
  - get core images of running processes —  
gcore, 466
  - terminate a process by default — kill, 596
- ## processors, display type — mach, 839
- ## prof — display profile data, 1296
- ## profile, display call-graph — gprof, 524
- ## profiles — print execution profiles for a user, 1300
- ## programming languages
- analyze and disperse compiler error  
messages — error, 373
  - C compiler — cc, 119

programming languages (Continued)  
 C preprocessor — `cpp`, 205  
 C program verifier — `lint`, 751  
 extract strings from C code — `xstr`, 1806  
 formats program in nice style using `troff` —  
   `vgrind`, 1756  
 programming tools  
 arbitrary precision arithmetic language —  
   `bc`, 100  
 assembler — `as`, 62  
 create a tags file for use with `ex` and `vi` —  
   `ctags`, 261  
 create C error messages — `mkstr`, 975  
 debugger — `adb`, 35  
 display call-graph profile data — `gprof`, 524  
 dump selected parts of an object file —  
   `dump`, 322  
 find printable strings in an object or binary  
   file — `strings`, 1557  
 — `install`, 564  
 link editor — `ld`, 691  
 link-editor for object files — `ld`, 678  
 macro processor — `m4`, 831  
 make — build programs, 881  
 object code disassembler — `dis`, 306  
 print name list of an object file — `nm`, 1115  
 print section sizes in bytes of object files —  
   size, 1503  
 regular expression compile — `regcmp`, 1343  
 resolve and remove `ifdef`'ed lines from C  
   program source — `unifdef`, 1718  
 resource usage for a command —  
   `rusage`, 1390  
 RPC protocol compiler — `rpcgen`, 1372  
 Source Code Control System — `sccs`, 1401  
 strip symbol table, debugging and line  
   number information from an object file —  
   `strip`, 1559  
 touch — update last modified date of  
   file, 1672  
 projects — print project membership of  
   user, 1302  
 prun — proc tools, 1292  
 ps — display process status, 1313  
 PS1 variable — `sh`, 1482  
 PS2 variable — `sh`, 1482  
 psig — proc tools, 1292  
 pstack — proc tools, 1292

`pstop` — proc tools, 1292  
`ptime` — proc tools, 1292  
`ptree` — proc tools, 1292  
`pushd` — shell built-in functions to change the  
   current working directory, 121  
`pvs` — display the internal versioning  
   information of dynamic objects, 1316  
`pwait` — proc tools, 1292  
`pwd` — print working directory name, 1319  
`pwdx` — proc tools, 1292

## Q

`queue`, printer, display — `lpq`, 808  
 queues  
   display the jobs queued to run at specified  
     times — `atq`, 75  
   remove jobs spooled by at or batch —  
     `atrm`, 76

## R

`true` — convert archives to random  
   libraries, 1320  
`rcp` — remote file copy, 1325  
`rdist` — remote file distribution, 1329  
`read` — shell built-in function to receive from  
   standard input (keyboard), 1335  
`readfile`, longline — (FMLI utility) reads file,  
   gets longest line, 1338  
`readonly` — shell built-in function to protect the  
   value of the given variable from  
   reassignment, 1339  
 reboot system without checking disks —  
   `fastboot`, 406  
`red` — text editor, 332  
`refer` — expand and insert references from a  
   bibliographic database, 1341  
`regcmp` — regular expression compile, 1343  
 regenerate groups of programs —  
   `sysV-make`, 1590  
 regenerate programs — `make`, 881  
`regex` — (FMLI utility) match patterns against a  
   string, 1345

rehash — shell built-in functions to evaluate the internal hash table of the contents of directories, 539  
 reinit — (FMLI utility) changes the descriptors in the initialization file, 1347  
 relational database, — join, 583  
 reminder services  
   — calendar, 113  
   mail notifier — biff, 109  
 remote shell — rsh, 1378  
 remote system  
   connect — tip, 1653  
   connect to — cu, 272  
   execute a command on a remote system with the local environment — on, 1134  
   file copy — rcp, 1325  
   file distribution — rdist, 1329  
   remote login — rlogin, 1352  
   shell — rsh, 1378  
   show status — rup, 1387, 1388  
   spawn login — ct, 259  
   system to system command execution — uux, 1745  
   transfer files to and from — tftp, 1645  
   who is logged in on remote machines — rusers, 1392  
 removable rewritable media format utility — rmformat, 1360  
 renice — alter priority of running processes, 1348  
 report on the calls to a specific procedure — whocalls, 1794  
 report or filter out repeated lines in a file — uniq, 1720  
 report service status — svcs, 1584  
 reset — (FLMI utility) changes the entry in a field of a form to its default value, 1351  
 reset — reset terminal bits, 1698  
 reset terminal bits — reset, 1698  
 retrieve important information from a network entity — snmpstatus, 1507  
 retrieve service configuration properties — svcprop, 1580  
 return — shell built-in functions to enable the execution of the shell to advance beyond its sequence of steps, 389  
 reverse page order, PostScript file — postreverse, 1239  
 reverse the page order in a PostScript file — postreverse, 1239  
 rksh — KornShell, restricted command and programming language, 614  
 rlogin — remote login, 1352  
 rm — remove files, 1356  
 rmail — only permits sending of mail, 847  
 rmdir — remove directories, 1356  
 rmformat — removable rewritable media format utility, 1360  
 roffbib — format and print bibliographic database, 1368  
 roles — print roles granted to a user, 1370  
 RPC  
   display host status of remote machines — rup, 1388  
   display status of network hosts — rup, 1387  
   protocol compiler — rpcgen, 1372  
 RPC, secure  
   decrypt and store secret key with keysevr — keylogin, 593  
   delete stored secret key with keysevr — keylogout, 595  
 RPC Language, RPC protocol compiler — rpcgen, 1372  
 rpcgen — RPC protocol compiler, 1372  
 rpm2cpio — convert Red Hat Package (RPM) to cpio archive, 1377  
 rsh — remote shell, 1378  
 run — (FMLI utility) runs a program, 1383  
 run a command immune to hangups — nohup, 1120  
 runat — execute command in extended attribute name space, 1384  
 runtime linker for dynamic objects — ld.so.1, 725  
 rup — display status of network hosts (RPC version), 1387  
 rup — display status of network hosts, 1388  
 runtime — display status of local hosts, 1389  
 rusage — resource usage for a command, 1390  
 rusers — who is logged in on remote machines, 1392  
 rwho — who is logged in on local machines, 1393

## S

- sag — system activity graph, 1394
- sar — system activity reporter, 1396
- SCCS, extract SCCS version information from a file — what, 1784
- sccs-admin — create and administer SCCS history files, 1411
- sccs-cdc — change the delta commentary of an SCCS delta, 1415
- sccs-comb — combine deltas, 1417
- sccs — Source Code Control System, 1401
- SCCS commands
  - admin — create and administer SCCS history files, 1411
  - cdc — change the delta commentary of an SCCS delta, 1415
  - comb — combine deltas, 1417
  - delta — change the delta commentary of an SCCS delta, 1419
  - get — retrieve a version of an SCCS file, 1422
  - help — help regarding SCCS error or warning messages, 1428
  - prt — display delta table information from an SCCS file, 1433
  - rmdel — remove a delta from an SCCS file, 1436
  - sact — show editing activity status of an SCCS file, 1437
  - sccs-prs — display selected portions of an SCCS history, 1429
  - sccsdiff — compare versions of SCCS file, 1438
  - unget — unget SCCS file, 1439
  - val — validate SCCS file, 1440
- sccs-delta — change the delta commentary of an SCCS delta, 1419
- SCCS delta
  - change commentary — sccs-cdc, 1415
  - combine — sccs-comb, 1417
  - create — delta, 1419
  - remove — rmdel, 1436
- SCCS delta table, print form an SCCS file — sccs-prt, 1433
- SCCS files
  - compare versions — sccs-scsdiff, 1438
  - retrieve a version of a file — sccs-get, 1422
  - SCCS files (Continued)
    - show editing activity status — sccs-sact, 1437
    - undo a previous get of an SCCS file — sccs-unget, 1439
    - validate — sccs-val, 1440
  - sccs-get — retrieve a version of an SCCS file, 1422
  - sccs-help — help regarding SCCS error or warning messages, 1428
  - SCCS help, regarding SCCS error or warning messages — sccs-help, 1428
  - SCCS history, display selected portions — sccs-prs, 1429
  - SCCS history files, create and administer — sccs-admin, 1411
  - sccs-prs — display selected portions of an SCCS history, 1429
  - sccs-prt — display delta table information from an SCCS file, 1433
  - sccs-rmdel — remove delta from SCCS file, 1436
  - sccs-sact — show editing activity status of an SCCS file, 1437
  - sccs-scsdiff — compare versions of SCCS file, 1438
  - sccs-unget — unget SCCS file, 1439
  - sccs-val — validate SCCS file, 1440
  - scp — secure copy (remote file copy program), 1442
  - screen-oriented editor — vi, 1759
  - script — make script of terminal session, 1444
  - sdiff — print differences between two files side-by-side, 1445
  - secure copy (remote file copy program) — scp, 1442
  - secure file transfer program — sftp, 1474
  - Secure Shell proxy for HTTP — ssh-http-proxy-connect, 1544
  - Secure Shell proxy for SOCKS5 — ssh-socks5-proxy-connect, 1552
  - sed — stream editor, 1447, 1454
    - Functions, 1455
    - sed Addresses, 1448
    - sed Editing Commands, 1448
    - sed Regular Expressions, 1448
    - sed Scripts, 1454

- select or reject lines common to two files —
  - comm, 180
- serial interface for PostScript printers —
  - postio, 1229
- set — shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents, 1460
- set, unset — (FLMI utility) set and unset local or global environment variables, 1466
- set environment for command invocation —
  - env, 366
- set or get limitations on the system resources available to the current shell and its descendents
  - limit, 745
  - ulimit, 745
  - unlimited, 745
- set process group ID — setpgrp, 1473
- setcolor — (FMLI utility) redefine or create a color, 1468
- setenv — shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents, 1460
- setfacl — modify the Access Control List (ACL) for a file or files, 1469
  - acl\_entries Syntax, 1469
- setpgrp — set process group ID, 1473
- settime — change file access and modification times, 1669
- sftp — secure file transfer program, 1474
- sh — the standard shell command interpreter, 1478
- SHACCT variable — sh, 1482
- shared object for setting preferred page size — mpss.so.1, 997
- shell — (FMLI utility) run a command using shell, 1496
- SHELL variable — sh, 1482
- shell
  - Korn shell — ksh, 614
  - restricted Korn shell — rksh, 614
- shell command interpreter builtin-functions
  - alias, 38
  - bg, 576
  - break, 110
  - cd, 121
  - chdir, 121
- shell command interpreter builtin-functions (Continued)
  - continue, 110
  - dirs, 121
  - eval, 387
  - exit, 389
  - fc, 543
  - fg, 576
  - getopts, 513
  - glob, 523
  - hash, 539
  - hashstat, 539
  - history, 543
  - jobs, 576
  - kill, 596
  - let, 732
  - logout, 793
  - newgrp, 1041
  - notify, 576
  - onintr, 1685
  - popd, 121
  - print, 1274
  - pushd, 121
  - read, 1335
  - readonly, 1339
  - rehash, 539
  - return, 389
  - set, 1460
  - setenv, 1460
  - shift, 1501
  - source, 387
  - stop, 576
  - suspend, 1579
  - times, 1650
  - trap, 1685
  - typeset, 1707
  - umask, 1711
  - unalias, 38
  - unhash, 539
  - unset, 1460
  - unsetenv, 1460
  - wait, 1779
  - whence, 1707
- shell programming
  - echo arguments — echo, 326
  - read one line from standard input and write to standard output — line, 750

shell scripts
 

- display size or sizes of a page of memory —
  - pagesize, 1140
  - provide truth values — true, false, 1690

 shell variables, in Bourne shell, 1481

shells

- C shell — csh, 231
- remote — rsh, 1378
- the job control shell command interpreter —
  - jsh, 1478
- the standard shell command interpreter —
  - sh, 1478

shift — shell built-in function to traverse either a shell's argument list or a list of field-separated words, 1501

show codeset table for the current locale —
 

- dumpcs, 325

show current number of users in each FTP Server class —
 

- ftpcount, 464

show current process information for each FTP Server user —
 

- ftpwho, 465

shutdown — shut down multiuser operation, 1502

sign binaries for the Solaris Cryptographic Framework —
 

- elfsign, 357

sign on to the system —
 

- login, 785

Simple Mail Transfer Protocol, connection to remote mailserver —
 

- mconnect, 922

size — print section sizes in bytes of object files, 1503

sleep — suspend execution for an interval, 1505

SMTP, *See* Simple Mail Transfer Protocol

snmpstatus — retrieve important information from a network entity, 1507

soelim — eliminate .so's from nroff input, 1509

software package
 

- display information —
  - pkginfo, 1200
- display parameter values —
  - pkgparam, 1205
- generate prototype file entries for input to pkgmk command —
  - pkgproto, 1207
- produce an installable package —
  - pkgmk, 1202
- translate package format —
  - pkgtrans, 1209

sort, topological, items mentioned in input —
 

- tsort, 1703

sort — sort and/or merge files, 1510

sortbib — sort bibliographic database, 1517

sotruss — trace shared library procedure calls, 1519

source — shell built-in functions to execute other commands, 387

Source Code Control System, *See* SCCS

source files, locate —
 

- whereis, 1787

sparc — get processor type truth value, 840

spell — check spelling, 1521

spline — interpolate smooth curve, 1523

split files based on context —
 

- csplit, 256

split — split a file into pieces, 1524

srchtxt — display contents of, or search for a text string in, message data bases, 1526

ssh-agent — authentication agent, 1542

ssh-http-proxy-connect — Secure Shell proxy for HTTP, 1544

ssh-keygen — authentication key generation, 1546

ssh-keyscan — gather public ssh host keys of a number of hosts, 1550

ssh-socks5-proxy-connect — Secure Shell proxy for SOCKS5, 1552

standard output, replicate —
 

- tee, 1620

start or stop the NCA kernel module —
 

- ncakmod, 1037

statistics, collected by sendmail —
 

- mailstats, 858

stop — shell built-in functions to control process execution, 576

strchg — change stream configuration, 1554

strconf — query stream configuration, 1554

stream editor —
 

- sed, 1447, 1454

STREAMS, change or query stream configuration —
 

- strchg, strconf, 1554

string
 

- prompt for defined string answer —
  - ckstr, 164
- provide an error message for defined string answer —
  - errstr, 164
- provide an help message for defined string answer —
  - helpstr, 164
- validate a defined string answer —
  - valstr, 164

strings — find printable strings in object or binary file, 1557

strip — strip symbol table, debugging and line number information from an object file, 1559

stty — set the options for a terminal, 1561  
 stty command, 1570  
 sum — print checksum and block count for a file, 1577  
 sum — sum and count blocks in file, 1578  
 sun — get processor type truth value, 840  
 SunOS/BSD Source Compatibility Package, —  
 stty, 1570  
 SunOS/BSD Source Compatibility Package  
 commands  
 — arch, 61  
 — basename, 99  
 — biff, 109  
 — cc, 119  
 — chown, 146  
 — df, 293  
 — du, 320  
 — echo, 330  
 — expr, 397  
 — fastboot, 406  
 — file, 416  
 — from, 451  
 — groups, 537  
 — grpck, 538  
 — hostid, 552  
 — hostname, 553  
 — install, 564  
 — ld, 691  
 — lint, 751  
 — ln, 770  
 — logger, 784  
 — lpc, 804  
 — lpq, 808  
 — lpr, 810  
 — lprm, 814  
 — lptest, 820  
 — ls, 828  
 — mach, 839  
 — mkstr, 975  
 — pagesize, 1140  
 — plot, 1215  
 — printenv, 1275  
 — ps, 1313  
 — rusage, 1390  
 — shutdown, 1502  
 — sum, 1578  
 — test, 1641  
 — tr, 1684

SunOS/BSD Source Compatibility Package  
 commands (Continued)  
 — tset, 1698  
 — users, 1728  
 — vipw, 1769  
 — whereis, 1787  
 — whoami, 1793  
 provide SunOS compatibility for Solaris  
 mailbox format — mailcompat, 853  
 suspend — shell built-in function to halt the  
 current shell, 1579  
 suspend execution of command, — sleep, 1505  
 svcprop — retrieve service configuration  
 properties, 1580  
 svcs — report service status, 1584  
 symorder — update symbol table  
 ordering, 1589  
 synchronize files and directories —  
 filesync, 418  
 system to system copy — uucp, 1729  
 system activity  
 graphical representation — sag, 1394  
 reporter — sar, 1396  
 time a command; report process data and  
 system activity — timex, 1651  
 system administration, — install, 564  
 system call and signals, trace — truss, 1691  
 system log, add entries — logger, 782  
 system name, print — uname, 1715  
 system to system command execution —  
 uux, 1745  
 system uptime, display — uptime, 1727  
 sysV-make — maintain, update, and regenerate  
 groups of programs, 1590

## T

TAB characters, expand to SPACE characters,  
 and vice versa — expand, unexpand, 391  
 tables, format for nroff or troff — tbl, 1617  
 tabs — set tabs on a terminal, 1597  
 tail — display last part of file, 1601  
 talk — talk to another user, 1604  
 tape  
 backspace files — mt, 1006  
 backspace records — mt, 1006  
 erase — mt, 1006

tape (Continued)

- forward space files — mt, 1006
- forward space records — mt, 1006
- get unit status — mt, 1006
- place unit off-line — mt, 1006
- retension — mt, 1006
- rewind — mt, 1006
- skip backward files — mt, 1006
- skip backward records — mt, 1006
- skip forward files — mt, 1006
- skip forward records — mt, 1006
- write EOF mark on — mt, 1006

tape, magnetic

- copy, blocking preserved — tcopy, 1619
- manipulate — mt, 1006
- scan — tcopy, 1619

tape archives, create — tar, 1606

tar — create tape archives, and add or extract files, 1606

tbl — format tables for nroff or troff, 1617

tbl, remove nroff, troff, tbl and eqn constructs — deroff, 292

tcopy — copy a magnetic tape, 1619

tee — replicate the standard output, 1620

telnet — user interface to a remote system using the TELNET protocol, 1621

TELNET protocol, user interface to a remote system using the TELNET protocol — telnet, 1621

terminal

- set options — stty, 1561
- set tabs — tabs, 1597

terminal screen, — clear, 175

terminal session, make script— script, 1444

terminals

- get name — tty, 1705
- initialize a terminal or query terminfo database — tput, 1674
- reset bits — reset, 1698
- set characteristics — tset, 1698
- set characteristics — stty, 1570

terminate a process by default — kill, 596

terminfo database, initialize a terminal or query terminfo database — tput, 1674

test — (FMLI utility) evaluates the expression expression, 1643

test — evaluate condition(s), 1633

test — condition evaluation, 1641

text editing

- screen-oriented (visual) display editor based on ex — vi, 1759
- sed — stream editor, 1454
- stream editor — sed, 1447

text editor

- ed, 332
- edit, 344
- ex, 376

text files

- browse or page through a text file — more, page, 982
- change format — newform, 1038

text formatter, format documents for display or line-printer — nroff, 1124

text processing utilities

- check spelling — spell, 1521
- concatenate and display files — cat, 117
- display last part of file — tail, 1601
- pattern scanning and processing language — awk, 91
- search a file for a pattern — grep, 531
- search a file for a pattern using full regular expressions — egrep, 349
- search file for fixed-character string — fgrep, 411
- sort and/or merge files — sort, 1510
- split a file into pieces — split, 1524
- translate characters — tr, 1679, 1684
- underline text — ul, 1710

text retrieval tools

- create message files for use by gettxt — mkmsgs, 973
- retrieve text string from message database — gettxt, 521

text to PDL (Page Description Language) pretty print filter — mp, 989

tftp — trivial file transfer program, 1645

the Network Cache and Accelerator (NCA) — NCA, 1033

the Network Cache and Accelerator (NCA) — nca, 1033

tilde escape commands for mail, — mailx, 871

time — time a simple command, 1648

time

- prompts for time — cktime, 169
- provides error message for time — errtime, 169

time (Continued)  
 provides help message for time —  
 helptime, 169  
 validates time — valtime, 169

time a simple command — time, 1648

timed event services  
 display the jobs queued to run at specified  
 times — atq, 75  
 reminder service — calendar, 113  
 remove jobs spooled by at or batch —  
 atrm, 76  
 user crontab file — crontab, 226

timemanp — frontends to the mp Text to PDL  
 (Printer Description Language) pretty print  
 filter, 854

times — shell built-in function to report time  
 usages of the current shell, 1650

timesysp — frontends to the mp Text to PDL  
 (Printer Description Language) pretty print  
 filter, 854

timex — time a command; report process data  
 and system activity, 1651

tip — connect to remote system, 1653

tnfdump — convert binary TNF file to  
 ASCII, 1662

tnfextract — extract kernel probes output into a  
 trace file, 1667

touch — change file access and modification  
 times, 1669, 1706  
 settime, 1670  
 touch, 1669

touch — update last modified date of file, 1672

tplot — graphics filters for plotters, 1673

tput — initialize a terminal or query terminfo  
 database, 1674

tr — translate characters, 1679, 1684

trace function calls, trace application function  
 calls to Solaris shared libraries —  
 apptrace, 52

trace shared library procedure calls —  
 sotruss, 1519

translate characters — tr, 1679, 1684

translates exportfs options to share/unshare  
 commands — exportfs, 393

trap — shell built-in functions to respond to  
 (hardware) signals, 1685

Trivial File Transfer Protocol, *See* TFTP

troff — typeset or format documents, 1687

troff utilities  
 check nroff and troff files — checknr, 131  
 eliminate .so's from nroff input —  
 soelim, 1509  
 filters reverse line-feeds from two-column  
 nroff text — col, 178  
 format tables — tbl, 1617  
 formats program code — vgrind, 1756  
 postprocessor for PostScript printers —  
 dpost, 314  
 remove nroff, troff, tbl and eqn constructs —  
 deroff, 292

true — provide truth values, 1690

truss — trace system calls and signals, 1691

tset — set terminal characteristics, 1698

tsort — topological sort of items mentioned in  
 input, 1703

ttl — time to live value, nischtll, 1073

tty, set characteristics — stty, 1570

tty, set characteristics — tset, 1698

tty, set options — stty, 1561

tty — get the name of the terminal, 1705

typeset — shell built-in functions to set/get  
 attributes and values for shell variables and  
 functions, 1707

typeset documents — troff, 1687

## U

u370 — get processor type truth value, 840

u3b — get processor type truth value, 840

u3b15 — get processor type truth value, 840

u3b2 — get processor type truth value, 840

u3b5 — get processor type truth value, 840

ucblinks — adds /dev entries to give SunOS 4.x  
 compatible names to SunOS 5.x  
 devices, 1709

ul — underline text, 1710

ulimit — set or get limitations on the system  
 resources available to the current shell and  
 its descendents, 745

umask — shell built-in function to restrict  
 read/write/execute permissions, 1711

unalias — shell built-in functions to create your  
 own pseudonym or shorthand for a  
 command or series of commands, 38

uname — print name of current system, 1715

uncompress — uncompress files, 185  
 underline text — ul, 1710  
 unexpand — unexpand SPACE characters to TAB characters, 391  
 unhash — shell built-in functions to evaluate the internal hash table of the contents of directories, 539  
 undef — resolve and remove ifdef'ed lines from C program source, 1718  
 uniq — report or filter out repeated lines in a file, 1720  
 units — converts quantities expressed in standard scales to other scales, 1723  
 UNIX, convert text file from DOS format to ISO format — dos2unix, 310  
 UNIX-to-UNIX commands  
   uucp — uucp, 1729  
   uulog — uucp, 1729  
   uuname — uucp, 1729  
 unix2dos — convert text file from ISO format to DOS format, 1725  
 unlimit — set or get limitations on the system resources available to the current shell and its descendents, 745  
 unpack — expand compressed files, 1137  
 unset — shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents, 1460  
 unsetenv — shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents, 1460  
 update groups of programs — sysV-make, 1590  
 update last modified date of file — touch, 1672  
 update programs — make, 881  
 uptime — show how long the system has been up, 1727  
 user ID, change user IDs of files — chown, 146  
 user IDs  
   display a list of all valid user names — dispuid, 309  
   prompts for user ID — ckuid, 171  
   provides error message for user ID — erruid, 171  
   provides help message for user ID — helpuid, 171  
   validates user ID — valuid, 171  
 users  
   display effective name — whoami, 1793  
   display group membership — groups, 536  
   display information about local and remote users — finger, 432  
   get the name of the user running the process — logname, 792  
   list user login information — listusers, 755  
   talk to another user — talk, 1604  
   who is logged in, and what are they doing — w, 1777  
   who is logged in on local machines — rwho, 1393  
   who is logged in on remote machines — rusers, 1392  
   who is on the system — who, 1790  
   write to another user — write, 1796  
 users, network, Internet user name directory service — whois, 1795  
 users — display users on system, 1728  
 uucp — UNIX-to-UNIX copy, 1729  
 uucp  
   log — uulog, 1729  
   uucp status inquiry — uustat, 1738  
 uuencode — decode binary file, 1733  
 uuencode — encode binary file, 1733  
 uuglist — print list of service grades available, 1737  
 uulog — UUCP log, 1729  
 uuname — UUCP list of names, 1729  
 uustat — uucp status inquiry, 1738  
 uux — system to system command execution, 1745  
**V**  
 vacation — automatic mail replies, 1749  
 vax — get processor type truth value, 840  
 version control, — vc, 1752  
 vgrind — formats program in nice style using troff, 1756  
 vi — screen-oriented (visual) display editor based on ex, 1759  
 vipw — edit password file, 1769  
 volcancel — cancel user's request for removable media that is not currently in drive, 1770  
 volcheck — check for media in a drive, 1771

volmissing — notify user that volume requested is not in the CD-ROM or floppy drive, 1773  
volrmmount — call rmmount to mount or unmount media, 1774  
Volume Management  
cancel user's request for removable media that is not currently in drive — volcancel, 1770  
check for media in a drive — volcheck, 1771  
missing volume notification — volmissing, 1773  
vsig — synchronize a co-process with the controlling FMLI application, 1776

## W

w — display information about currently logged-in users, 1777  
w — who is logged in, and what are they doing, 1777  
wait — shell built-in function to wait for other jobs or processes, 1779  
watch events in a contract or group of contracts — ctwatch, 270  
wc — display a count of lines, words and characters in a file, 1782  
what — extract SCCS version information from a file, 1784  
whatis — describe command, 1786  
whence — shell built-in functions to set/get attributes and values for shell variables and functions, 1707  
whereis — locate the binary, source and manual page files for a command, 1787  
which — locate a command; display its pathname or alias, 1789  
who is logged in — w, 1777  
who — who is on the system, 1790  
whoami — display effective user name, 1793  
whocalls — report on the calls to a specific procedure, 1794  
whois — Internet user name directory service, 1795  
write — write to another user, 1796  
write file checksums and sizes — cksum, 167

## X

xargs — construct argument lists and invoke utility, 1799  
xgettext — extract gettext call strings, 1804  
xstr — extract strings from C code, 1806

## Y

yacc — yet another compiler-compiler, 1808  
yacc, create a tags file for use with ex and vi — ctags, 261  
yes — generate repetitive affirmative output, 1812  
yes/no answer  
prompts for yes/no answer — ckyorn, 173  
provides error message for yes/no answer — erryorn, 173  
provides help message for yes/no answer — helpyorn, 173  
validates yes/no answer — valyorn, 173  
yet another compiler-compiler — yacc, 1808  
ypcat — print values in a NIS database, 1813  
ypmatch — print the value of one or more keys from a NIS map, 1814  
yppasswd — change your network password in the NIS database, 1815  
ypwhich — return name of NIS server or map master, 1816

## Z

zcat — displays uncompressed files but leaves compressed files intact, 185  
zlogin — enter a zone, 1817  
zonename — print name of current zone, 1819
